5. Copy the app.xml file to the TECHMOBILE/src folder of your local workspace. If your configuration introduced new XML files, they can be copied from the version 8.8 workspace folder. If you created JavaScript code, the AppCustomizations.js file can be copied to the version 8.9 TECHMOBILE/src folder.

## Upgrading duplicated applications

There are deviations and additional steps to the upgrade process if you are upgrading a duplicated application.

### Procedure

1. After you create the delta file, open the version 8.9 TECHMOBILE and the TECHDUP applications to download their files to your local workspace.
2. Copy the contents of the TECHMOBILE/src folder and overwrite the contents of the TECHDUP/src folder.
3. Open the app.xml file of the TECHDUP application in a text editor. Change the ID attribute of the maximo-application element from techmobile to techdup.

```

<maximo-application navigator-tile-order="100" controller="AppController" theme="touch" product-name="Maximo"
product-name-adaptive="Maximo" title="Maximo"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_upgrading_duplicated_applicatio
ns_techdup" version="8.9.0.0" default-log-level="error"
user-menu-enabled="true" nav-initial-open-state="false" mas-enabled="false">

```

4. Copy the TECHDUP app.xml file to the 89ORIG folder.
5. Run the apply command.

## Anatomy of an application XML file

The app.xml file contains global elements and attributes that are defined at the beginning of the file.

Individual pages and elements of those pages are defined later in the file.

### Maximo-application

- Application navigation menu
  - Application navigation tiles for mobile navigation
- Application state that defines variables for all application pages
- Application data sources that defines data sources for all pages
- Pages container that includes all application pages.
  - Individual page
    - Page state variables
    - Page level data sources
    - Page header
    - Page body
    - Dialogs used in the page

At the beginning of the Technician application XML file, a section is used to define global elements and properties. The datasources that are defined at the beginning of the file can be referenced and used by elements that are defined throughout the file.

Figure 1. Technician global datasource definition

```

1 <maximo-application controller="AppController" theme="touch" product-name="Max
2 > <properties id="nba7e"> ...
6 </properties>
7 > <menu slot="navigation-items" id="k9p4v"> ...
11 </menu>
12 > <maximo-datasource id="synonymdomainData" lookup-data="true" object-structur
23 </maximo-datasource>
24 > <maximo-datasource id="dsFailureList" lookup-data="true" default="true" page-
34 </maximo-datasource>
35 > <pages id="pages"> ...

2002 > <messages id="n5_2r"> ...
2025 </messages>
2026 </maximo-application>

```

Table 1. Application XML elements

XML element	Description
<maximo-application>	The root element of the Maximo application XML file.
<properties>	The property definitions used across the application.
<menu>	The navigational side bar appearing on the left side of the application.
<maximo-datasource>	<p>The definition of a Maximo datasource. It can be defined at a global level or more targeted if nested within a component structure. Data sources provide data to a component that is defined in application XML. The &lt;maximo-datasource&gt; element identifies a Maximo Object Structure (API) that is used to retrieve data for that data source.</p> <p>If you add a data source, include only the attributes that you need. Including all attributes of the datasource can lead to performance issues.</p>
<pages>	This element contains the details of each page that is displayed in the application. Most configuration work involves page structures.
<messages>	This element contains information about messages that are used by the application.

Datasources that are defined in the page structure portion of the application XML file are referenced and used by elements that are defined within the local page definition.

Figure 2. Technician local datasource definition

```

35 <pages id="pages">
36 <page padding="true" id="schedule" path="/schedule" title="My Schedule" icon="maximo:schedule" contr
37 <states id="nmvrw">...
51 </states>
52 <maximo-datasource id="dswolist" object-structure="mxapiwodetail" saved-query="uxtechnicianownerfi
53 <schema id="gjjw7p">...
118 </schema>
119 <maximo-datasource-override id="todaywoassignedDS" pre-load="true" saved-query="ASSIGNEDWOLIST"/>
120 <maximo-datasource-override id="pmduewolistDS" saved-query="PMWOLIST" where="schedfinish=>="{
121 </maximo-datasource>
122 <maximo-datasource id="wodetails" object-structure="mxapiwodetail" item-url="{page.params.href}">...
147 </maximo-datasource>
148 <maximo-datasource id="dsnewreading" lookup-data="true" object-structure="mxapiindomain" page-size
157 </maximo-datasource>
158 <json-datasource id="dsstatusDomainList" src="{}" items="statusItems" selection-mode="single" id
163 </json-datasource>
164 <header-template hide-breadcrumb="true" title-column-width="{app.state.screen.size === 'md' ? 48 :
173 </header-template>
174 <stacked-panel selected-index="{page.state.selectedSwitch}" id="qzfnm">...
183 </stacked-panel>
184 <dialogs id="wnynq">...
194 </dialogs>
195 </page>

```

Table 2. Application XML elements

XML element	Description
<states>	Properties that are used across the application.
<maximo-datasource>	The definition of a Maximo data source. In this example, it is embedded within a <page> element. This data source is defined for only that page.  If you add a data source, include only the attributes that you need. Including all attributes of the data source can lead to performance issues.
<json-datasource>	A JSON data source that provides static data to a component that is defined in application XML. In this example, it is embedded within a <page> element. This data source is defined for only that page.
<header-template>	A layout for a header section of a page.
<stacked-panel>	This element defines the panels that are used in the page.
<dialogs>	This element defines the dialog boxes that open in the page.
<id>	A unique identifier for an element. When you add an element, you do not need to assign a value to this attribute. The application build process assigns the element a unique ID. If you plan to reference this element in another part of the XML, you can create a unique ID value. Do not change an ID value after it is assigned.

## Referencing other application XML files

Splitting application XML components across several files can help with maintenance and modularization efforts. You can reference an application XML file by using the <include> element.

In the following example for the Technician application, an XML file that contains work order card components is included in the main app.xml file.

```

<include src="/home/markdown/jenkins/workspace/Transform/in/SSLPL8_cd/com.ibm.mam.doc/mobile/wo-card-group.xml"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_anatomy_of_an_application_xml_file_j
wq72"/>

```

## Comments

You can add comments to any application XML file by using the code-comment component.

The XML parser ignores any text that appears in the text attribute of the code-comment tags.

```

<maximo-application
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_anatomy_of_an_application_xml_file_a
ttributeAppAppWithComments2">
 <code-comment text="This datasource is used to get a list of inspections" />
 <maximo-datasource
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_anatomy_of_an_application_xml_file_i
nspectionsDsAppWithComments2">

```

- [Datasources](#)

Datasources provide data to a component that is defined in application XML. A JSON data source provides static data. A Maximo datasource identifies a Maximo Object Structure (API) that is used to retrieve data from the Maximo application server for that datasource.

## Related information

- [IBM Maximo Application Framework Component Reference](#)

## Datasources

Datasources provide data to a component that is defined in application XML. A JSON data source provides static data. A Maximo datasource identifies a Maximo Object Structure (API) that is used to retrieve data from the Maximo application server for that datasource.

The following screen shows a JSON datasource:

Figure 1. JSON datasource

```
766 <json-datasource id="jtoolsds" src="{[]}" items="wptool" schema="schema" id-attribute="wpitemid">
767 <schema id="a8vqr">
768 <attribute name="itemnum" id="dgy62"/>
769 <attribute name="description" id="y2wmq"/>
770 <attribute name="itemqty" id="e8xk5"/>
771 <attribute name="location" id="qz7dd"/>
772 <attribute name="locationDesc" id="qzdwy"/>
773 <attribute name="wonumDesc" id="z8_nm"/>
774 <attribute name="locHours" id="vpgxp"/>
775 <attribute name="itemnumDesc" id="n9r2v"/>
776 <attribute name="wpitemid" id="grz5a"/>
777 </schema>
778 </json-datasource>
```

The following two screens show snippets of Maximo datasource definitions:

Figure 2. Maximo datasource 1

```
52 <maximo-datasource id="dswolist" object-structure="mxapiwodetail" saved-query="uxtechnicianownerfilter" order-by="wopriority"
53 pre-load="false" controller="ScheduleDataController" selection-mode="none">
54 <schema id="gjw7p">
55 <attribute name="plussgeojson" id="wymyz"/>
56 <attribute name="wonum" unique-id="true" searchable="true" id="g4dk9"/>
57 <attribute name="description" searchable="true" id="ej423"/>
58 <attribute name="location.description" searchable="true" id="d_m_3"/>
59 <attribute name="location.location" searchable="true" id="gy6zb"/>
60 <attribute name="wopriority" searchable="true" id="x3nyj"/>
```

Figure 3. Maximo datasource 2

```
849 <maximo-datasource id="woDetailResource" default="true" object-structure="mxapiwodetail"
850 where="wonum="{page.params.wonum}" and siteid="{page.params.siteid}";" controller="WorkOrderDataController"
851 item-url="{page.params.href}">
852 <schema id="qmvzy">
853 <attribute name="plussgeojson" id="yn258"/>
854 <attribute name="workorderid" unique-id="true" id="p6d4b"/>
855 <attribute name="wonum" id="q9qmr"/>
856 <attribute name="title" id="gmp_2"/>
857 <attribute name="description" id="kq9yq"/>
```

Each data source has an *id* attribute, which is used when a UI component references the datasource.

The *saved-query* attribute references an object structure query that is associated to the object structure that is defined in the object-structure attribute. The *where* clause identifies the filtering of the data in the datasource. The schema consists of a list of attributes. These attributes identify the API fields that are available to

the UI component using this datasource.

A Maximo datasource can include child datasources which show data that is related to the parent or outer datasource. For example, the outer datasource might be work order data. A child datasource might be tasks that are related to an instance of the outer work order datasource.

A field can be identified as `{item.wonum}`, where `item` represents the current record of the datasource. The term `item` is a reserved variable. Do not confuse it with the use of `item`, as a Maximo dot notation that refers to a Maximo relationship name that called `item`. The following Maximo datasource snippet shows an example of how to override the `saved-query` and where properties of the `pmduewolistDS` datasource:

Figure 4. Saved-query override in a datasource

```
121 <maximo-datasource-override id="pmduewolistDS" saved-query="PMWOLIST"
122 where="schedfinish>="&SYSDAY&" and schedfinish<="&SYSDAY&+7D""/>
```

A Maximo data source can be overridden where any property of the data can be replaced by a property value in the override. Do not override the object-structure property.

In this next series of examples, a `wo` datasource is used in several contexts.

```
<maximo-datasource id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_datasources_wo"
object-structure="mxapiwodetail"
where="location="SHIPPING"" pre-load="false" page-size="10"
include-counts="false" order-by="wonum ascending"
controller="WODetailController">
 <maximo-datasource
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_datasources_taskWO"
relationship="showtasks">
 </maximo-datasource>
</maximo-datasource>
```

In the following table example, `wo` is a detail data source for work order details and `taskWO` includes the work order tasks for that datasource. It is updated at the current `Item` of the parent whenever it is updated.

```
<table datasource="wo"
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_datasources_gexqa">
 <table-column name="wonum" sigoption="workview.read">
 id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_datasources_jw2jb">
 <link label="{item.wonum}" page="woDetailPage">
 </table-column>
 </table-column>
 <table-column name="estlabcost" license="tpaebase">
 id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_datasources_sadsd">
 </table-column>
</table>
```

In this case, the table is using the `wo` data source. The table column `wonum` uses a custom cell render to render a `link` and the value of the link is `item.wonum`. The `item` variable always points to the current item or record in a datasource as it is being rendered.

Consider the following data sources:

```
<maximo-datasource id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_datasources_wo"
object-structure="mxapiwodetail"
where="location="SHIPPING"" pre-load="false" page-size="10"
include-counts="false" order-by="wonum ascending"
controller="WODetailController">
</maximo-datasource>

<maximo-datasource
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_datasources_woview" object-
structure="mxapiwodetail"
where="location="SHIPPING"" pre-load="false" page-size="10"
include-counts="false" order-by="wonum ascending"
controller="WODetailController">
</maximo-datasource>
```

These two datasources have no relationship to each other. A typical application can have several datasources. Some datasources are related while others are not.

Consider the following fields:

```
<field value="{wo.item.description}" />
<field value="{woview.item.description}" />
```

The `wo` and `wodescription` values are datasources. The `item` value is the current record. The `description` value is the value that is specified for the field. If the datasource moves to a new item or record, then this field is updated.

## Maximo Mobile Queries

Maximo® Mobile uses queries to retrieve record data from the Maximo Manage server.

Queries that are used in Maximo Mobile and Maximo Manage role-based apps are defined through a Maximo datasource. Datasources are defined in the application XML file. The datasource references the Maximo object structure that provides the data to the datasource.

As an example, the `dsworktype` datasource that is defined in the Technician application references the `mxapiworktype` object structure.

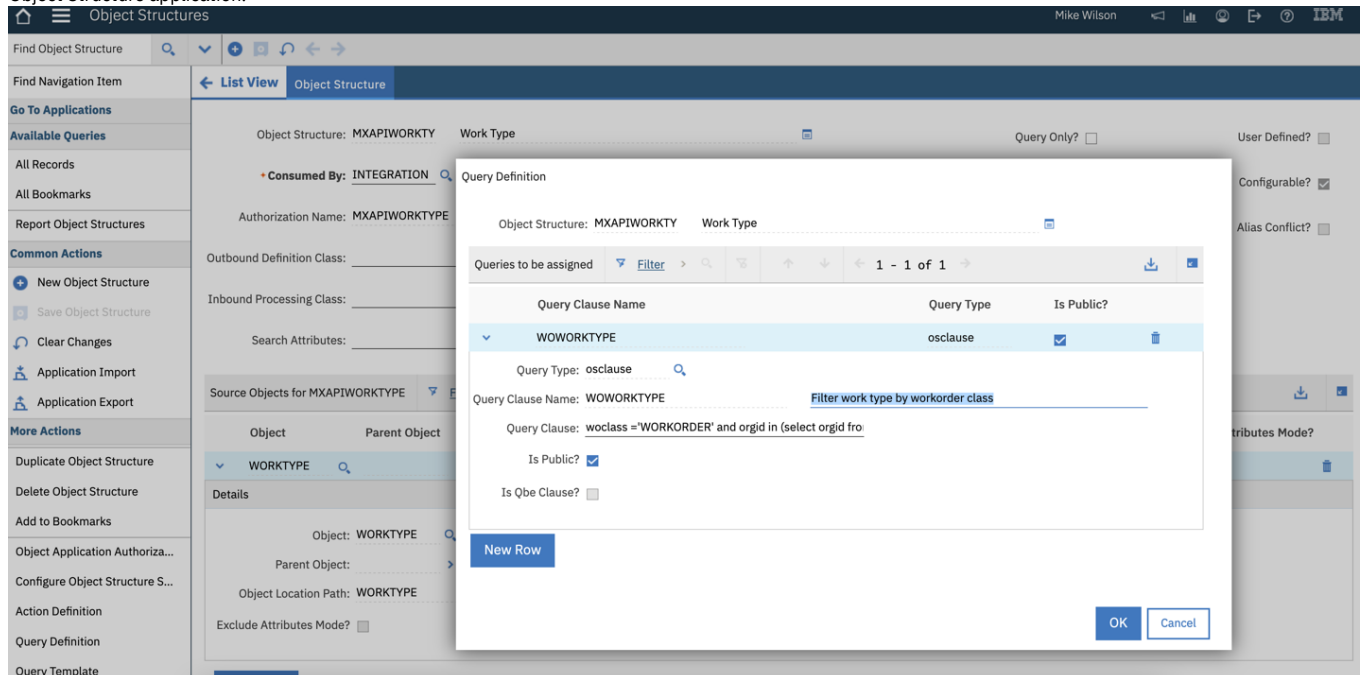

```
<maximo-datasource
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_dsworktype"
```

```

offline-immediate-download="true" selection-mode="single" saved-query="WOWORKTYPE" lookup-data="true" pre-load="true"
object-structure="mxapiworktype" page-size="100">
 <schema
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_b2rkz">
 <attribute name="worktype" searchable="true" unique-
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_true"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_rrpez"/>
 <attribute name="wtypedesc" searchable="true"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_w5_zm"/>
 <attribute name="woclass" searchable="true"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_b8w9r"/>
 <attribute name="orgid" searchable="true"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_b_jdj"/>
 <attribute name="promptdown"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_n_5q4"/>
 <attribute name="startstatus"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_vm3ke"/>
 <attribute name="completestatus"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_a5yen"/>
 </schema>
</maximo-datasource>

```

The **dsworktype** datasource identifies a saved query that is associated with the **WOWORKTYPE** object structure. You can manage this query in the Maximo Manage Object Structure application.

If you modify the Query Clause value, you change the work type data that is used by the Technician application and any other application or API client that references that saved query.

You can also extend a saved query by adding a WHERE clause in the datasource. Do this instead of changing the query itself, which could be used by many applications. Extending a saved query in this way appends it to the saved query.

```

<maximo-datasource-override
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_pmduewolistDS"
saved-query="PMWOLIST"
where="schedfinish=<="&SYSDAY&";
and schedfinish=<="&SYSDAY&+7D";" mobile-qbe-filter="{ 'status_maxvalue':
'!=COMP,CAN,CLOSE,WAPPR' }" offline-immediate-download="true"/>

```

To find the default Technician application queries, you can search for the **dropdown-item** component in the application XML file.. You could also search for the value that is displayed in the drop-down query menu when you are using the Technician application.

```

<header-template hide-breadcrumb="true" title-column-width="{page.state.breadcrumbWidth ? page.state.breadcrumbWidth :
app.state.screen.size === 'md' ? 50 : app.state.screen.size === 'lg' ? 30 : app.state.screen.size === 'xlg' ? 21 : 65}"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_zewd">
 <dropdown slot="dropdown" background-color="white" selected-item="{page.state.selectedDS}"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_rzvz4" on-
change="loadWOListData" hide-unselected-placeholder="true">
 <dropdown-item value="todaywoassignedDS" text="Assigned work"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_njkmd"/>
 <dropdown-item value="pmduewolistDS" text="PMS due this week"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_jxr9k"/>
 <dropdown-item value="myworkDS" text="Work created by me" hidden="{app.device.isMaximoMobile}"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_wgadv"/>
 <dropdown-item value="myworkCreatedLocally" text="Work created on device" hidden="{!app.device.isMaximoMobile}"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_wgbb8"/>
 <dropdown-item value="myWorkOrder" sigoption="MXAPIWODETAIL.uxtechlist" text="My work order"
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_mobile_t_maximo_mobile_queries_d3v_7"/>
 </dropdown>

```

- [Filtering records returned from a query.](#)

The number of records returned from a query can sometimes be unmanageable on mobile devices. In some cases, you might want to limit the number of records received. For example, you might want to limit the number of records displayed in a work list.

- [Changing a query](#)

Queries can be extended to return different sets of records.

---

## Filtering records returned from a query

The number of records returned from a query can sometimes be unmanageable on mobile devices. In some cases, you might want to limit the number of records received. For example, you might want to limit the number of records displayed in a work list.

You can modify the query located on the Maximo application server using the Object Structure application. For example, if you want to use the work order owner value instead of assignments, you can change the ASSIGNEDWOLIST query located within the MXAPIWODETAIL object structure. The new WHERE clause would be:

```
(siteid = (select defsitem from maxuser where userid=:USER) and status in
(select value from synonymdomain where domainid='WOSTATUS' and maxvalue not
in ('CAN','CLOSE','COMP','WAPPR')) and istask=0 and owner= (select laborcode
from labor, maxuser where labor.personid = maxuser.personid and
maxuser.userid=:USER)
```

Then, in the XML file that you are configuring, change the uxtechnicianownerfilter value to ASSIGNEDWOLIST.

```
<maximo-datasource controller="ScheduleDataController"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_filtering_record_returned_from_a_query_dswolist" object-
structure="mxapiwodetail" order-by="wopriority" pre-load="false" saved-
query="ASSIGNEDWOLIST" selection-mode="single" where=wopriority
```

---

## Changing a query

Queries can be extended to return different sets of records.

The Assigned Work query is the default query in the Technician application. The Assigned Work query references the **dswolist** datasource, which is configured to use the **mxapiwodetail** object structure or API, and the **assignedwolist** saved query. The **dswolist** datasource has an override that is called **todaywoassignedDS**.

```
(siteid = (select defsitem from maxuser where userid=:USER) and status in
(select value from synonymdomain where domainid='WOSTATUS' and maxvalue not in
('CAN','CLOSE','COMP','WAPPR')) and wonum in (select wonum from assignment where
laborcode = (select laborcode from labor, maxuser where labor.personid = maxuser.personid
and maxuser.userid=:USER and labor.orgid = (select orgid from site where siteid = (select
defsitem from maxuser where userid=:USER))) and (siteid = (select defsitem from maxuser
where userid=:USER))))
```

In the Object Structure application, you can select the **mxapiwodetail** object structure and then select the Query Definition action. To change the default query, copy the WHERE clause, create a new row, and create a new **OSCLAUSE** query called **NEWASSIGNEDWOLIST**. If you wanted the query to include unapproved Work Orders, you can remove the **WAPPR** entry from the status list:

```
(siteid = (select defsitem from maxuser where userid=:USER) and status in
(select value from synonymdomain where domainid='WOSTATUS' and maxvalue not in
('CAN','CLOSE','COMP')) and wonum in (select wonum from assignment where laborcode =
(select laborcode from labor, maxuser where labor.personid = maxuser.personid and
maxuser.userid=:USER and labor.orgid = (select orgid from site where siteid =
(select defsitem from maxuser where userid=:USER))) and (siteid =
(select defsitem from maxuser where userid=:USER))))
```

Once saved, you can change the saved query on the datasource override in the app.xml file:

```
<maximo-datasource-override
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_c_changing_a_query_todaywoassignedDS"
mobile-qbe-filter="{('status_maxvalue': '!=COMP,CAN,CLOSE,WAPPR')}"
offline-immediate-download="true" saved-query="NEWASSIGNEDWOLIST"/>
```

When you test the application, the Assigned Work query now includes Waiting on Approval work orders.

---

## Adding an owner group reference on a work order

In the Maximo® Mobile Technician application, a Create Work Order page is used by a technician to create a new work order. In some organizations, the technician might be responsible for assigning the ownership of the work order.

---

### About this task

Add the Owner Group field and its associated look-up capability on the Work Order Create page. by configuring the app.xml file of the Technician application for Maximo Mobile 8.8 or higher.

## Procedure

1. Use the Maximo Application Framework Configuration application to download the **TECHMOBILE** application and begin editing it in the XML editor.
2. Add the datasource at the beginning of the application XML code.  
The datasource must be added before the **pages** component.

```
<maximo-datasource
id=" _home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_add_owner_group_on_work_order_p
ersongroupLookupDS" lookup-data="true" object-structure="mxapipersongroup" offline-immediate-download="true"
selection-mode="single">
 <schema>
 <attribute name="persongroup" searchable="true" unique-
id=" _home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_add_owner_group_on_work_order_t
rue"/>
 <attribute name="description" searchable="true"/>
 </schema>
</maximo-datasource>
```

3. Before the **pages** component, add the **dialogs** component at the top of the application XML code.  
Placing the **dialogs** component at the beginning of the application XML code allows this look up action to be used on multiple pages.

```
<dialogs
id=" _home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_add_owner_group_on_work_order_d
emolookups">
 <lookup-with-filter datasource="persongroupLookupDS"
id=" _home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_add_owner_group_on_work_order_o
wnergroupLookup" lookup-attributes="{['persongroup','description']}" search-placeholder="Search Owner Group"/>
</dialogs>
```

4. Locate the **Create WO** page XML component and then add the **ownergroup** attribute to the **dsCreateWo** datasource.

```
<attribute name="ownergroup"/>
```

5. Define the Owner **lookup** action to display it and retrieve the attribute.

```
<box children-sizes="50" direction="row" fill-child="true" fill-parent="true" padding-bottom=".5"
padding-top=".5">
 <smart-input enable-lookup-buttongroup="true" label="Owner Group" lookup="ownergroupLookup" select-
lookup-attribute="persongroup" value="{dsCreateWo.item.ownergroup}"/>
</box>
```

6. Verify that the changes work as expected by previewing the **TECHMOBILE** application in the Maximo Application Framework Configuration application.
7. Republish the **TECHMOBILE** application to the Maximo Manage server.

## Maximo Mobile REST APIs

Maximo® Mobile uses REST APIs to download data from Maximo Manage to a user's device.

## Maximo Mobile endpoints

The Maximo Mobile APIs use the following endpoints:

- /maximo/oslc/ping.jsp
- /maximo/oslc/Login
- /maximo/oslc/whoami
- /maximo/oslc/systeminfo
- /maximo/oslc/permission/allowedappoptions
- /maximo/oslc/licenseinfo
- /maximo/oslc/service/system

## Data downloaded by Maximo Mobile APIs

The following table lists the data that is downloaded by the Maximo Mobile APIs for each Maximo Mobile app.

Table 1. Data downloaded by the c APIs

API	Technician app	Approvals app	Inspections app	Service Request app	Inventory Counting app
MXAPIDOMAIN	All data	All data	All data	All data	No data

## Maximo Mobile application object structures, query information, and security authorization

Object structures, query information, and related security authorizations that are used in the Technician, Approvals, Inspections, and Service Request applications are listed here. Security authorization listed for applications that are installed using the same security group.

### Technician and Approvals

Table 1. Technician and Approvals applications object structures, query information, and security authorizations

Object structure API	Saved query	Data source WHERE clause	Application page location	Object structure authorizations
mxapisynonymdomain	MOBILEDOMAIN	where="domainid=&quot;ISSUETYP&quot; and maxvalue in [&quot;ISSUE&quot;;,&quot;RETURN&quot;];"	Report work	Read
mxapiwodetail	uxtechnicianowner filter	where="wonum=&quot;{page.params.wonum}&quot; and siteid=&quot;{page.params.siteid}&quot;;" where="wonum=&quot;0&quot;";	<ul style="list-style-type: none"> <li>My Schedule</li> <li>Work Order</li> </ul>	<ul style="list-style-type: none"> <li>Read</li> <li>Save</li> <li>Insert</li> </ul>

## Security and user management

You use the applications in the Security module to implement and to manage security for users and groups. Users are added and authenticated in the administrative console of Maximo® Application Suite. Users that have an entitlement to Maximo Manage are synchronized to Maximo Manage by a process that continuously queries the user registry in Maximo Application Suite.

Authorization enables access to applications, application actions, and data in Maximo Manage. Authorization is provided by assigning users to one or more security groups in Maximo Manage.

- [User creation, authentication, and synchronization](#)  
You add and authenticate users in Maximo Application Suite. Then, if users have entitlement to Maximo Manage, their user data is synchronized to Maximo Manage. Data to be synchronized can be customized to include or exclude fields.
- [Security group synchronization and default assignments](#)  
Authorization to applications, actions, and data is provided by assigning users to one or more security groups in Maximo Manage.
- [User processing by the integration framework](#)  
User and user group data that is synchronized from Maximo Application Suite is processed by enterprise services of the integration framework in Maximo Manage.
- [License type updates](#)  
License type information updates can be sent to Maximo Application Suite when authorizations change or when the calculated license type has a different entitlement value in Maximo Manage.
- [Upgrade of users from Maximo Asset Management to Maximo Application Suite](#)  
Users are added in Maximo Application Suite and their profiles, login information, and application entitlements are managed in Maximo Application Suite. If you are upgrading from Maximo Asset Management to Maximo Application Suite with Maximo Manage, user data is upgraded.
- [Configuring security groups](#)  
You can configure many types of security groups to support different roles in your organization. You can configure standard security groups that include default start centers and applications, and you can configure Work Center security groups to manage authorization to the user interface components and data required for a role.
- [Managing users](#)  
User records contain identifying information and security profiles that determine the applications, options, and data that a user can access. Users are added in the administrative console of Maximo Application Suite. Certain aspects of user records are managed in Maximo Application Suite. You use Maximo Manage to manage their authorizations, or security privileges and some default settings.
- [Implementing additional security](#)  
You can implement additional security measures to protect your organization, including login tracking, setting encryption properties, and safeguarding against intrusion and malicious attacks.

## User creation, authentication, and synchronization

You add and authenticate users in Maximo® Application Suite. Then, if users have entitlement to Maximo Manage, their user data is synchronized to Maximo Manage. Data to be synchronized can be customized to include or exclude fields.

### User creation and authentication

Users are added and authenticated in the administrative console of Maximo Application Suite. Authentication validates the user by verifying the supplied credentials.

Users can be added and authenticated in the Maximo Application Suite in several ways. Refer to the related links for more information about adding and authenticating users.

## Synchronization to Maximo Manage

Users who have an entitlement to Maximo Manage are synchronized from Maximo Application Suite to Maximo Manage by an agent process that continuously queries the user registry in Maximo Application Suite. Users who have a PENDING or DELETE\_PENDING status are synchronized to Maximo Manage. The synchronization status for a user who is synchronized successfully is SUCCESS. The synchronization status for a user who fails to be synchronized is ERROR. You can view status information in the administrative console of Maximo Application Suite or in the output logs.

Synchronized user data is processed as a series of messages by an enterprise service of the integration framework in Maximo Manage.

Synchronized users are listed in the Users application. Users who are updated to be deleted or to have no access entitlement in Maximo Application Suite are made inactive in Maximo Manage, but they are not deleted.

When a user's data is synchronized from Maximo Application Suite to Maximo Manage, if the user has a phone type or an email type that does not exist in Maximo Manage, the phone type or email type is automatically added to the PHONETYPE or EMAILTYPE domain, respectively. If the phone type or email type already exists, the types are not added.

Because the length and type of the Maximo Application Suite user IDs do not match the length and type of user IDs in Maximo Manage, errors might occur when you create new users. Configuration of user lengths and types should be performed in Maximo Application Suite and then propagated to Maximo Manage. The following tables provide information about the length and type of Maximo Application Suite user ID fields.

Table 1. User Synchronization

Attributes	Manage object and attribute	Type	Length	Values that are allowed
_id	USER.LOGINID	ALN	100	
username	USER.USERID, PERSON.PERSONID	UPPER	100	
displayName	PERSON.DISPLAYNAME	ALN	82	
familyName	PERSON.LASTNAME	ALN	30	
givenName	PERSON.FIRSTNAME	ALN	50	
title	PERSON.TITLE	ALN	30	
issuer	PERSON.MASISSUER	ALN	20	local, ldap, saml
preferences.locale.language	PERSON.LOCALE	ALN	10	
preferences.timezone	PERSON.TIMEZONE	ALN	33	
email.value	EMAIL.EMAILADDRESS	ALN	100	
email.type	EMAIL.TYPE	UPPER	10	HOME,WORK
email.primary	EMAIL.ISPRIMARY	BOOLEAN	1	
phoneNumbers.value	PHONE.PHONENUM	ALN	20	
phoneNumbers.type	PHONE.TYPE	UPPER	10	HOME,MOBILE,WORK
phoneNumbers.primary	PHONE.ISPRIMARY	BOOLEAN	1	
address.streetAddress	PERSON.ADDRESSLINE1 + PERSON.ADDRESSLINE2 + PERSON.ADDRESSLINE3	ALN	169	
address.locality	PERSON.CITY	ALN	36	
address.region	PERSON.STATEPROVINCE	ALN	36	
address.country	PERSON.COUNTRY	ALN	36	
address.postalCode	PERSON.POSTALCODE	ALN	12	
entitlement.application	MAXDOMAIN	ALN	25	

Table 2. Group Synchronization

Attributes	Manage attribute and object	Type	Length
id	MAXGROUP.GROUPNAME	ALN	30
members	GROUPUSER.USERID	ALN	30
displayName	MAXGROUP.DESCRPTION	ALN	200

## Customization of inbound data

You can customize the data that is synchronized for users in several ways. For example, you can specify more user data, such as security group and information about employee ID and cost center. Synchronization of inbound user data is handled by an enterprise service of the integration framework in Maximo Manage. Sample inbound integration messages from Maximo Application Suite are shown in the [masuser.json](#) file and the [masgroup.json file](#).

You can customize messages by supplying extra values to the extensions attributes that are not part of the default mapping of a message. The sample file [masuser-mapped.json](#) shows the result in the Maximo Manage object structures after the masuser.json file is mapped by using the supplied user exit. You can use this file to understand how to further customize the mapping.

Experienced administrators whose expertise includes the integration framework and customization can customize mapping in the following ways:

- Create a Java™ user exit. Use the output of the default mapping, such as masuser-mapped.json, as the input.
- Create an automation script that acts on the user exit. Use the output of the default mapping, such as masuser-mapped.json, as the input.
- Create a JSON map. Use the output of the default mapping, such as masuser-mapped.json, as the input.
- Create a JSON map to replace the provided default mapping by replacing the psdi.iface.migexits.MASUserMapperExit user exit class with the com.ibm.tivoli.maximo.fdmbo.JSONMapperExit standard user exit. Input is the user object that is synchronized from Maximo Application Suite, for example, masuser.json.

## Security group synchronization and default assignments

Authorization to applications, actions, and data is provided by assigning users to one or more security groups in Maximo® Manage.

## Security group synchronization

---

Synchronized users are assigned to one or more default security groups. You can assign synchronized users to other security groups in any of the following ways. If you use an LDAP identity provider and manage user groups in the identity provider, you can synchronize group data to n and then to Maximo Manage. Your security group setup can depend on whether you maintain user groups in an LDAP provider.

- Synchronize locally added users from n and then assign users to security groups in Maximo Manage.
- Synchronize a user registry that does not include groups from n and assign those users to security groups in Maximo Manage.
- Synchronize a user registry that includes user groups after you determine the mapping of the user groups to Maximo Manage security groups. Configure the synchronization of that information in Maximo Application Suite. Groups are not visible in Maximo Application Suite. Information then is synchronized to Maximo Manage.

All existing users in a security group are replaced by synchronized users that map to that group. This means that users might be added or removed from a group. Users in security groups must be valid users of Maximo Manage.

Synchronized group data is processed as a series of messages by an enterprise service of the integration framework in Maximo Manage.

## Default group assignments

---

All new Maximo Manage users are added to the DEFAULTREG group and to the group that is specified by the value of the *NEWUSERGROUP* varname in the MAXVARS table. The default value of the *NEWUSERGROUP* varname is MAXEVERYONE.

Users that are upgraded from Maximo Asset Management are assigned to groups that are defined by the values of the *NEWUSERGROUP* and *ALLUSERGROUP* varnames in the MAXVARS table.

Users who are given one of the administrator entitlements in Maximo Application Suite and then synchronized to Maximo Manage are assigned to the security groups that are specified by values of the *ADMINGROUP* varname in the MAXVARS table. The default value for this varname is MAXADMIN. These users also can be assigned to other administrative security groups.

Users that are only in the DEFLTREG security group are limited to changing their passwords or accessing the Start Center until an administrator assigns them to other groups.

---

## User processing by the integration framework

User and user group data that is synchronized from Maximo® Application Suite is processed by enterprise services of the integration framework in Maximo Manage.

## Processing of user messages

---

To process messages about users, the following integration framework components are used:

- MASPERUSER enterprise service
- MASPERUSER object structure
- MASSYNC external system

Each synchronization processes one user and adds or updates the following objects in Maximo Manage:

- PERSON
- MAXUSER
- GROUPUSER
- EMAIL
- PHONE

A sample inbound integration message for users is shown in the [masuser.json](#) file.

## Processing of group messages

---

To process messages about groups, the following integration framework components are used:

- MASGROUP enterprise service
- MASGROUP object structure
- MASSYNC external system

Each synchronization adds or updates the following objects in Maximo Manage:

- MAXGROUP
- GROUPUSER

Synchronization details and a sample inbound integration message for groups is shown in the [masgroup.json](#) file.

---

## License type updates

License type information updates can be sent to Maximo® Application Suite when authorizations change or when the calculated license type has a different entitlement value in Maximo Manage.

License types are set in Maximo Application Suite and that data is synchronized to Maximo Manage with each new user. License type becomes part of the user profile.

In Maximo Manage, the MasUserAnalyzer cron task regularly reviews and calculates license types, according to the number or type of applications that users can access. License type is sent from Maximo Manage to Maximo Application Suite if one of the following conditions is met:

- A change to authorizations in Maximo Manage causes a change in the license type calculation.
- The calculated license type is higher than the entitlement value that was synchronized from Maximo Application Suite.

For example, a user is not given administrator entitlement in Maximo Application Suite. This user is synchronized to Manage and is added to a system administrator security group later. The new license type is sent to Maximo Application Suite.

---

## Upgrade of users from Maximo Asset Management to Maximo Application Suite

Users are added in Maximo® Application Suite and their profiles, login information, and application entitlements are managed in Maximo Application Suite. If you are upgrading from Maximo Asset Management to Maximo Application Suite with Maximo Manage, user data is upgraded.

If you are upgrading from Maximo Asset Management and use an integration to create or update users, you must send user data to Maximo Application Suite and not to Maximo Manage.

Note:

When you upgrade Maximo Asset Management to Maximo Application Suite, user and administrator records in the Maximo database are imported by Maximo Application Suite if they do not exist there or if they are not managed by an identity provider. Information includes language, time zone, and locale. Imported users are considered as already synchronized to Maximo Manage. User records also remain in the database that was upgraded.

If SMTP is enabled in Maximo Application Suite, a welcome email is sent to the email address that is associated with the user ID when the user or administrator account is created. If the SMTP email security is set to [email passwords to all users](#), a second email is sent with the user or administrator password. If SMTP is not set up, or if passwords are not emailed to users or administrators, a Maximo Application Suite administrator must supply the password.

---

## Configuring security groups

You can configure many types of security groups to support different roles in your organization. You can configure standard security groups that include default start centers and applications, and you can configure Work Center security groups to manage authorization to the user interface components and data required for a role.

- [Security groups overview](#)  
You use security groups to grant read, insert, save, or delete access to the applications, actions, and data that users can access. Predefined security groups are provided to enable basic functionality, but until you create security groups and add users to them, users cannot access sites, start centers, applications, and work centers.
- [Creating security groups](#)  
You create security groups to manage authorizations to start centers, applications, actions, and data.
- [Creating Work Center and Tool security groups](#)  
Security group templates are provided to authorize users to access Work Centers and Tools and Tasks. When you apply a security group template, members of the group are authorized to access the default applications for the Work Center or Tool. If you want to modify the default authorizations, you duplicate a security group template to create a user-defined template.
- [Granting administrative login authorization for database configuration](#)  
To configure the database in administration mode, you must have administrative login authorization. Authorization is granted by security group.
- [Authorizing standard services for security groups](#)  
When you assign a signature option (SIGOPTION) to a standard service, only users or groups that are authorized for that option can execute the standard service.
- [Authorizing security group reassignments for users](#)  
For security purposes, you can specify the users who are authorized to add or to remove users from a security group.
- [Setting user defaults](#)  
You use the Security Controls action to specify the defaults for user records. You can access the Security Controls action from either the Security Groups application or the Users application.
- [Deleting users from security groups](#)  
The security group to which a user belongs controls the level of access and privileges for the user within the system. To address changes in your security needs, you can remove a user from a security group.

---

## Security groups overview

You use security groups to grant read, insert, save, or delete access to the applications, actions, and data that users can access. Predefined security groups are provided to enable basic functionality, but until you create security groups and add users to them, users cannot access sites, start centers, applications, and work centers.

All users are added to the DEFLTREG group and to the group that is specified by the value of the *NEWUSERGROUP* varname in the MAXVARS table. The default value of the *NEWUSERGROUP* varname is MAXEVERYONE. Users that are upgraded from is assigned to groups that are defined by the values of the *NEWUSERGROUP* and *ALLUSERGROUP* varnames in the MAXVARS table.

Security groups can provide broad authorizations to many applications, or you can take a modular approach by adding users to multiple groups that grant fewer access privileges. You can specify different levels of authorization, which can be a combination of read, insert, save and delete, or all levels.

When you add users to multiple groups, authorizations are combined across the groups in most cases. However, if you specify that a security group is independent of other groups, the privileges do not combine with privileges from other groups.

In multisite implementations, the security architecture is designed to use sites as the first level of security. If your company has multiple sites, you can create a group for each site. You can then create functional groups such as administration or maintenance, to grant functional privileges. Combined membership of site groups and functional groups provides users with modular sets of security privileges. If you create an independent group, you must grant access to at least one site and one application because privileges cannot be combined with other groups.

To enable access to work centers, you must create a separate security group for each work center. A template is provided for each work center group that enables default privileges for the work center. You can apply the template, or you can duplicate it to create a user-defined group where you can modify the default privileges.

If you are using in authentication, you create security groups in the Security Groups application. If you manage users in an LDAP user registry, you create groups in the user registry and synchronize the data to Maximo® Application Suite so that it can be synchronized to in . Map your LDAP groups to in security groups before you synchronize them to the suite. You can configure more access privileges for the imported security groups in the Security Groups application.

You can configure the following authorizations and restrictions for security groups:

#### Sites

Grant access to all sites, individually-selected sites, or no site. If site access is not authorized for a group, members must be also members of a group that grants site access.

#### Applications

Grant access to applications, including work centers, and configure signature options for individual applications.

#### Object structures

Grant access to object structure APIs to enable users to exchange data with work centers and external applications.

#### Storerooms

Grant access to users to perform inventory transactions with all storerooms or in specific storerooms.

#### Labor

Grant access to all labor records, sets of labor records, or to individual labor records.

#### General Ledger Components

Grant access to all general ledger components or to individual records.

#### Limits and Tolerances

Specify approval limits on the value of purchase orders, purchase requests, material requisitions, invoices, and contracts. You can also specify the amount that invoices, taxes, and services can deviate from an initial agreement.

#### Data restrictions

Restrict access to data in applications and fields. You can also specify conditions when data restrictions apply. You define conditional expressions in the Expression Manager application.

- [Combination of security groups](#)

When you add users to multiple security groups, the authorization privileges of the security groups combine except for security groups that are set as independent.

- [Authorizations for security groups](#)

A security group grants access to members of the group to start centers, applications, Work Centers, and object structures. The access options can be read, insert, save, and delete. You can use conditions to hide fields, tabs, and menus from group members, and you can set data restrictions on objects and attributes.

- [Security profiles](#)

A security profile is the list of rights a user derives from the security groups to which the user belongs. The user rights define the ability of a user to access asset management system applications and to perform specific application functions. You can view a user security profile list in the Security Profile tab in the Users application.

---

## Combination of security groups

When you add users to multiple security groups, the authorization privileges of the security groups combine except for security groups that are set as independent.

When you combine security groups, the following rules apply:

- If you specify that a security group is independent, privileges do not combine with other security groups.
- The privileges of all other security groups are combined.
- When you combine privileges, the highest privileges prevail. If a user belongs to multiple security groups that define the same privilege at different levels, the user has the highest privilege. For example, security group A has a purchase order limit of \$5,000. Security group B has a purchase order limit of \$10,000. A user who is a member of both security groups has a purchasing limit of \$10,000.
- Using the Security Controls action in the Security Groups application or Users application, you can specify the group for all users, the MAXEVERYONE group. The MAXEVERYONE group always combines, even if the group is specified as independent.

---

## Combination rules in a multiple site environment

Combining privileges is useful when you have multiple sites. Typically, you set up security groups that only define site access. You set up other security groups to define application privileges, purchasing approval limits, and so on. For example, your organization has three sites, site 1, site 2, and site 3. You have a user for whom you created a security profile that includes site 1 and associated privileges. You want the user to have the same privileges at site 2, therefore, you add site 2 to the profile for the user.

You can also define some security groups as independent, so that when you combine security groups, a user has a set of privileges at one site and a different set of privileges at another site.

## Combination rules for data restrictions

---

The following combination rules apply when you set data restrictions on security groups:

- If a user is a member of multiple groups, and you specify data restrictions on one of those security groups, the user is granted the highest privileges across the security groups. For example, take two security groups: the Managers security group and the Maintenance security group. The user has access to pay rate information in the Managers security group, but does not have access to the information in the Maintenance security group. When the two security groups are combined, the user has access to pay rate information in the Maintenance group.
- When you add a user to a security group that has data restrictions, the restrictions are added to the security profile for the user. This action can reduce the access rights that were otherwise granted by the combined security groups. Data restrictions always combine across security groups by using the OR operator. For example, take two security groups: one security group contains a READONLY data restriction condition ":orgid [equals character] 'EAGLENA'". The second security group contains a READONLY data restriction condition ":orgid [equals character] 'EAGLEUK'". The restrictions combine to make the object or attribute read only if the ORGID is EAGLENA\_OR\_ EAGLEUK.

## Combination rules for approval limits and tolerances

---

The following rules apply to limits and tolerances when you add users to multiple security groups:

- The limits and tolerances that you authorize for a security group are at the organizational level. Users inherit authorizations for only those sites to which they have access.
- If there are two different values for the same approval limit, the higher value is applied to the security profile for the user.
- If there are two different values for the same tolerance type, the higher value is applied to the security profile for the user.
- If there are two different values for the same tolerance type, but the security groups that grant the tolerance amount have sites in different organizations, the higher value for sites within the same organization is applied to the security profile for the user.
- If a user has access to two different organizations with different limits and tolerances in each organization, the user inherits the limits and tolerances for each site to which the user has access in each organization.

## Combination rules for general ledger components

---

The following rules apply to general ledger components when you add users to multiple security groups:

- If any of the security groups to which a user belongs grants authorization to change all general ledger components or specific general ledger components, the security profile for the user reflects the maximum amount of general ledger component authorization.
- If you do not authorize a security group to change all general components, and you do not authorize individual components for the security group, a user cannot change general ledger components.
- The general ledger component authorizations specified for security groups apply to all of the applications, sites, and organizations for those security groups for the user.
- The general ledger component authorizations specified for an independent security group apply exclusively to the applications, sites, and the organizations associated with that security group.

## Combination rules for labor authorization

---

The following rules apply to labor authorization when you add users to multiple security groups:

- All labor in an organization.
- All labor in the same crew as the user.
- All labor in the same person group as the user.
- All labor that the user supervises.
- Only the labor records for the user.
- Individual labor records that are listed in the table window.

## Combination rules for site and storeroom authorization

---

The following rules apply to site and storeroom authorization when you add users to multiple security groups:

- A user must have access to both a storeroom and the site for the storeroom before the storeroom authorization is added to the security profile for the user.
- The storeroom authorizations specified for all security groups apply to all sites that are specified for the security groups.
- The storeroom authorizations that are specified for an independent security group apply exclusively to the sites associated with that security group.
- If any of the security groups to which a user belongs grants access to all or specific storerooms at a given site, then the security profile for the user reflects the maximum amount of storeroom access.
- You can give a user access to the Users application and Security Groups application, but not grant that user access to any storeroom records. In this scenario, the user can use these applications to authorize access to all storerooms, but cannot add specific storerooms records.

---

## Authorizations for security groups

A security group grants access to members of the group to start centers, applications, Work Centers, and object structures. The access options can be read, insert, save, and delete. You can use conditions to hide fields, tabs, and menus from group members, and you can set data restrictions on objects and attributes.

## Start center access

---

You can specify a default start center for a security group to provide quick access to the tools and key performance indicators that members need. When users log in, they see a start center based on a template for their security group. If users belong to more than one security group, they can see tabs representing a start center page for each security group. You can grant users authorization to configure their start centers. You control the portlets that users can view and can configure.

## Work Center access

Security group templates are provided for Work Centers and Tools and Tasks application types. You can duplicate a template to create a user-defined Work Center security group, or you can apply the template to use the default security options provided for the Work Center. When a user logs in, the Work Center landing page opens and contains the Work Centers and Tools and Tasks that the user is authorized to access.

The Work Center landing page includes a link to the landing page for Maximo® Manage. If you want Work Center users to have access to standard Maximo Manage applications, they must also be members of a security group that grants access to these applications.

## Application access levels

You can grant access for a security group to all options for an application or you can restrict access to only specific options. For example, in a security group for managers, you can grant access to read work order histories, costs, and warranties, but not to insert work orders or service requests. You must configure each application for read access so that users can select additional application access options.

When you specify an access option for an application, related options are set. Read access also grants the standard system options of clear, bookmark, next, previous, viewhist, and drilldown. Insert access for an application also grants save access. The following table describes the related options for each access option.

Table 1. Standard options for prerequisite, also grants, and also revokes access

Standard options	Relationships between options
Standard prerequisite <ul style="list-style-type: none"><li>• Duplicate</li><li>• Delete</li></ul>	Prerequisite <ul style="list-style-type: none"><li>• Insert</li><li>• Save</li></ul>
Standard also grants <ul style="list-style-type: none"><li>• Insert</li><li>• Read</li></ul>	Also grants <ul style="list-style-type: none"><li>• Save</li><li>• Clear, bookmark, next, previous, viewhist, drilldown</li></ul>
Standard also revokes <ul style="list-style-type: none"><li>• Read</li><li>• Save</li><li>• Insert</li></ul>	Also revokes <ul style="list-style-type: none"><li>• All options</li><li>• Insert, duplicate</li><li>• Duplicate</li></ul>

The relationships between options in individual applications can sometimes vary. Access options for applications are stored in the SIGOPTION table in the database. You can use an SQL editor to search the SIGOPTION table.

## Object structure access

Object structure access authorizes group members to access specified object structure APIs to support the integration of data with external applications.

## Conditional access

You can define conditions, either as expressions or as custom class files, and use them to control access to applications and to controls in applications. In the Security Groups application, you can use conditions, for example, to restrict access to application fields and tabs to certain users or to restrict a field to read-only access. Conditional access is granted in the security groups application. If a user is in multiple security groups, the highest level of access is granted when the security groups are combined.

## Data restrictions

Data restrictions on objects and attributes limit the data that is available to group members, to hide records, or to make records read-only. Because these restrictions exist at the data-level, the restrictions apply to any user interface element or application that uses an object or attribute.

Data restrictions provide the following ways to restrict access to data for groups of users:

- You can make an object hidden or read-only, conditionally or unconditionally, for all Maximo Manage users, or for members of a specific security group.
- You can associate an object with a condition to qualify the data that is returned by the database. This configuration differs from data that is fetched from the database but is hidden in a certain condition. Qualified data restrictions apply only to top-level objects in lookup menus and dialog windows that are configured to allow them.
- You can set data restrictions for attributes within objects, either with or without an application specified.
- Data restrictions for a security group supersede any restrictions that you set in the Application Designer application.
- Data restrictions that you set in the Security Groups application apply wherever an attribute is used, while Application Designer configurations do not.
- Application Designer configurations are always for one application. Configurations that use data restrictions can apply to all applications that use the object or attribute or to one specific application.
- If you create a data restriction on an object, the restriction does not apply to views of that object. For the restriction to apply to all views of the object, you create a separate restriction for each view.

---

## Security profiles

A security profile is the list of rights a user derives from the security groups to which the user belongs. The user rights define the ability of a user to access asset management system applications and to perform specific application functions. You can view a user security profile list in the Security Profile tab in the Users application.

Before you can view a user security profile list, you must first create a user in the Users application. You must then assign the user to a security group and allocate group rights in the Security Groups application. When you assign a user to more than one group, the user inherits the security rights from the assigned groups.

You can use the Security Groups application to define user rights according to the following asset management system security components:

- Site
- Application
- Storeroom
- Labor
- GL Component
- Limit and tolerance
- Data restriction

By default, the asset management system includes the following user rights:

- The ability to change a password at login, even when a password expires
- The ability to access the asset management system start center

If your implementation uses a Lightweight Directory Access Protocol (LDAP) directory server to authenticate an external directory, do not use the asset management system security settings to perform the following functions:

- Self registration
- Password and password hint changes

---

## Creating security groups

You create security groups to manage authorizations to start centers, applications, actions, and data.

---

### About this task

This task describes how to create a security group in the product. If you manage users in an LDAP user registry, you create groups in the user registry and synchronize the data to Maximo® Application Suite so that it can be synchronized to Manage. Map your LDAP groups to Manage security groups before you synchronize them to the suite.

---

### Procedure

1. In the Security Groups application, create a group, name it, specify a default start center, and set other optional values.
2. On the Sites tab, authorize group members to have access to all sites or specify individual sites.
3. On the Applications tab, select the applications that you want to authorize and grant the appropriate types of access to each.
4. Optional: If you want to enable group members to share data with external applications, on the Object Structures tab, authorize access to object structure APIs.
5. Authorize the storerooms, labor, general ledger components and limits and tolerances for members of the security group.
6. On the Data Restrictions tab, you can restrict access to objects, attributes, and collections.
7. On the Users tab, add users to the group.

---

## Creating Work Center and Tool security groups

Security group templates are provided to authorize users to access Work Centers and Tools and Tasks. When you apply a security group template, members of the group are authorized to access the default applications for the Work Center or Tool. If you want to modify the default authorizations, you duplicate a security group template to create a user-defined template.

---

### Procedure

1. In the Security Groups application, create a new group and name it.
2. On the Sites tab, select Authorize Group for All Sites? to enable the group to access all sites, or specify individual sites.
3. On the Applications tab, define a security group for a Work Center or Tool:
  - a. In the Application Type column, filter for Tools and Tasks.
  - b. Select a record.
  - c. Click Manage/Apply Template. In the Add/Modify Authorization Template window, click Apply Template to create a group based on the predefined authorization settings of the template.
  - d. Optional: Click Add/Modify Signature Options to set signature options at the level of the application.
  - e. Optional: Click Object Structure Authorizations to specify access to data at the level of the application.
  - f. Click OK.

4. On the Object Structures tab, specify access to data at the security group level:
    - a. Select the MXAPIPERUSER object structure and grant access to Read and Save authorizations.  
This authorization authenticates to the user interface for the Work Center or Tool.
    - b. Optional: Grant access to any other object structures that you want members of the security group to have access to.  
This authorization is necessary if you want to enable access to data from external applications.
  5. Authorize the storerooms, labor, general ledger components, and limits and tolerances for members of the security group.
  6. On the Data Restrictions tab, you can restrict access to objects, attributes, and collections.
  7. On the Users tab, add users to the group.
- **Example: Specifying security access for inventory clerks**  
You can create security groups that grant different types of security access to features in the Manage Inventory Work Center. Typically, inventory clerks are granted security access to several features on each page of the Work Center.
  - **Example: Specifying security access for technicians**  
When you apply a security group template to a Technician application users group, members of the group are authorized to access the Technican application.
  - **Application templates**  
Applications use the following security group templates to authorize application access to users.

---

## Example: Specifying security access for inventory clerks

You can create security groups that grant different types of security access to features in the Manage Inventory Work Center. Typically, inventory clerks are granted security access to several features on each page of the Work Center.

---

### Before you begin

Review information in the topic *Authorizations for security groups* that explains the security authorization levels more completely. It also provides information about more granular security permissions that you can configure.

---

### About this task

Security groups for Work Centers need to have authorizations to object structures and menu features that are used by the Work Centers. The Security Groups application includes templates for all Work Centers to help you create role-based security groups more easily. Typically, you provide an inventory clerk with fewer authorizations than you provide to a manager or planner, so you clear check boxes to remove authorizations that are granted by the template.

---

### Procedure

1. In the Security Groups application, add a group. Specify the Manage Inventory Work Center as the default application to open when the user logs in. Save the record.
2. On the Sites tab, specify the sites that the group can access or authorize access to all sites and save the record.
3. On the Applications tab, filter the list by selecting the Work Center application type, and then select Manage Inventory. In the Options for Manage Inventory section, grant access to the Inventory Management app and save the record.
4. Select Manage/Apply Template to access the Inventory security template.
5. Duplicate the template and select the new copy. Maximize the Security Template Authorizations section.  
You can review all authorizations that the template provides by maximizing the Security Template Authorizations section and selecting each tab.
6. On the Object Structures Authorizations tab, select an object structure name and modify authorizations that are granted by the original template.  
Tip: If you want to grant any access to an object structure, you must grant Read access. If you grant Edit access to an object, you must grant Save access. If you grant Insert access, users also have Save access.  
For this role, you clear all but the following authorizations:
  - Grant all of the accesses to the MXAPIITEM object structure.
  - Grant all of the accesses to the MXAPIINVENTORY object structure. With Delete access, users can set the status of an inventory item to Obsolete.
  - Grant all of the accesses to the MXAPIINVRES object structure. Ensure that you granted Insert and Save access to MXAPIINVENTORY and the required access in the application or Work Center where the reservation originates.
  - Grant the following accesses to the MXAPIINISSUE object structure:
    - Grant Insert and Save access to this object and ensure that you granted Insert and Save access to MXAPIINVENTORY.
    - Grant Return issued items access to this object.
7. Save the new template and apply the new template to this group.
8. Optional: If this security group needs access to object structures that are not contained in the template, select the Object Structures tab and grant access to other object structures.
9. Select the storerooms that the group can access and any GL segments that they can modify.  
You also can specify limits to spending and approvals, objects and attributes, and collections.
10. Add users to the group and save the record.

---

### What to do next

Open the Work Center as a member of the group and test that you can see and work with the correct features.

---

## Example: Specifying security access for technicians

When you apply a security group template to a Technician application users group, members of the group are authorized to access the Technican application.

## Before you begin

Review information in the topic [Authorizations for security groups](#) that explains the security authorization levels more completely. It also provides information about more granular security permissions that you can configure.

## About this task

Security groups for applications require authorizations to object structures and menu features that are used by the application. Complete these steps to authorize a new user for the Technician application. In this example, you create a new user and group to ensure that the security template is applied correctly to the Technician application.

Note: After you verify this process, you can repeat it and authorize existing users and groups for the application.

## Procedure

1. Create a new user.
2. In the Security Groups application, create a new group and name it `Technician_group`.
3. On the Sites tab, select Authorize Group for All Sites? to enable the group to access all sites, or specify individual sites.
4. On the Applications tab, configure the `Technician_group` as the security group for the Technician application:
  - a. In the Application Type column, filter for Tools and Tasks.
  - b. Select the Technician record.
  - c. Click Manage/Apply Template. In the Add/Modify Authorization Template window, click Apply Template to create a group based on the predefined authorization settings of the TECHMOBILE template.
  - d. Optional: Click Add/Modify Signature Options to set signature options at the level of the application.
  - e. Optional: Click Object Structure Authorizations to specify access to data at the level of the application.
  - f. Click OK.
5. On the Object Structures tab, specify access to data at the security group level:
  - a. Select the MXAPIPERUSER object structure and grant access to Read and Save authorizations.  
This authorization is required to authenticate to the user interface for the application.
  - b. Optional: Grant access to any other object structures that you want members of the `Technician_group` security group to have access to.  
This authorization is necessary if you want to enable access to data from external applications.
6. Authorize the storerooms, labor, general ledger components and limits and tolerances for members of the security group.
7. On the Data Restrictions tab, you can restrict access to objects, attributes, and collections.
8. On the Users tab, add your new user you created to the `Technician_group` group.

## Results

The user you created should now have access to the Technician application. You can verify access by logging in as the new user and opening the application.

## Application templates

Applications use the following security group templates to authorize application access to users.

Table 1. Application templates

Template	Description	Applications
SUPMOBILE	Full access to the Work Approvals application.	Work Approvals
TECHMOBILE	Full access to the Technician application.	Technician
SRMOBILE	Full access to the Service Requests application.	Service Requests
INSPECTION	Full access to the Inspection application.	Inspection
OPDASHBOARD	Full access to the Operational dashboard.	Operational dashboard
WOSUMMARY	Full access to the Work Orders application.	Work Orders
WFASSIGN	Full access to the Workflow Assignments application.	Workflow Assignments

## Granting administrative login authorization for database configuration

To configure the database in administration mode, you must have administrative login authorization. Authorization is granted by security group.

## Procedure

1. In the Security Groups application, select a security group and then click the Applications tab.
2. In the Applications section, search for Start Center.
3. In the Options for Start Center section, select Can Log In During Admin Mode and click Grant Listed Options for This Application.

## Authorizing standard services for security groups

When you assign a signature option (SIGOPTION) to a standard service, only users or groups that are authorized for that option can execute the standard service.

## About this task

---

Standard service authorization does not support the use of conditions that may be associated with the signature option. Any condition assigned will be ignored.

## Procedure

---

1. In the Security Groups application, select the Standard Service Authorization action.
2. In the Standard Service Authorization window, click New Row.
3. Specify values for service, method, and option.  
After you specify these values, the Application field is populated with a value.
4. Click OK.

## Results

---

The standard service is assigned a signature option. Any user that calls the standard service by means of the integration framework (HTTP, EJB, or SOAP) requires their authorization to the signature option to execute the standard service.

---

## Authorizing security group reassignments for users

For security purposes, you can specify the users who are authorized to add or to remove users from a security group.

## Procedure

---

1. In the Security Groups application, select the group for which you want to authorize group reassignment.
2. Select the Authorize Group Reassignment action.
3. In the Authorize Group Reassignment window, click New Row.
4. To authorize users, click Select Users.
5. Click OK.

---

## Setting user defaults

You use the Security Controls action to specify the defaults for user records. You can access the Security Controls action from either the Security Groups application or the Users application.

## About this task

---

You can specify the following defaults for user records:

- Default security group for new users - New users are automatically assigned to a security group. The default group defines their security permissions until they are assigned to additional groups. The default group is MAXDEFLTREG. The permissions for this group are limited to access to the Start Center. Users can change their own passwords.
- Default status for new user records - The default status is NEWREG. The NEWREG status allows you to search for new user records. You can also route records into a workflow process.
- Group for all users - The default security group for global permissions is MAXEVERYONE. When you select Group for All Users in Security Controls, the user is added to MAXEVERYONE.
- Electronic signature dialog - When you select Display User ID in the Electronic Signature Dialog in Security Controls, the system displays the user ID in the window, and prompts the user to enter a password.

Your implementation might use an application server to authenticate with an external directory by means of the Lightweight Directory Access Protocol (LDAP). In this case, you do not use the system to perform some functions. These functions might include:

- Self registration - This function is not supported in conjunction with an external directory.
- Setting or changing passwords and password hints - All password-related functions are managed by the directory.

By default, when you use an application server for authentication, the directory manages user and group creation. You can set properties to allow user and group creation to be performed directly in the system. The settings of these properties result in certain features being enabled or disabled in the system.

## Procedure

---

1. Select the Security Controls action.
2. In the User Defaults section, specify the following defaults:
  - a. In the Default Group for New Users field, type the name of the group, or click Detail Menu.
  - b. In the Initial Self-Registered User Status field, type a user status.
  - c. In the Group for All Users field, specify the group for global permissions. The default is MAXEVERYONE.
  - d. Select the Display User ID in the Electronic Signature Dialog check box to display the user ID in the window when the system prompts users to enter their passwords. If you implement electronic signatures, you must enable login tracking.

3. Click OK.

---

## Deleting users from security groups

The security group to which a user belongs controls the level of access and privileges for the user within the system. To address changes in your security needs, you can remove a user from a security group.

---

### Before you begin

You must delete a security group from the application server before you can remove users from a security group. To remove a user from a group, you must be authorized to reassign users to that group. Use the Authorize Group Reassignment action in the Security Groups application or the Users application to grant this authorization.

---

### About this task

If you delete a security group in the directory server, but you do not want to delete the group from the system, you can delete the users from that group. The users will then no longer have access to the applications to which the group previously had access. If your implementation uses an application server to authenticate with a directory, you can associate users with groups in the directory or in the system, depending on your settings. You cannot delete users from the MAXEVERYONE group.

---

### Procedure

1. In the directory server, delete the users from the security group that you want to delete.  
You must wait until the VMMSYNC cron task has fully synchronized the users and security groups in the directory server with the users and groups in the system.
2. Delete the security group in the directory server.
3. In the Security Groups application, select the group containing the relevant user.
4. Click the Users tab.
5. Delete the user.
6. Save your changes

- **Deleting security groups**

As your business needs change, you can delete security groups. You can delete security groups in the Security Groups application, set up an archiving process, or create a cron task to remove the groups.

---

## Deleting security groups

As your business needs change, you can delete security groups. You can delete security groups in the Security Groups application, set up an archiving process, or create a cron task to remove the groups.

---

### Before you begin

You must delete a security groups from the application server before you can delete the security group from the system.

---

### About this task

You can delete a security group in the directory server but the VMMSYNC cron task does not delete the group from the system tables. If there are users associated with a security group or if a security group is specified as the default security group for all users, that security group cannot be deleted. You cannot delete the MAXEVERYONE group.

---

### Procedure

1. In the directory server, delete the users from the security group that you want to delete.  
You must wait until the VMMSYNC cron task has fully synchronized the users and security groups in the directory server with the users and groups in the system.
2. Delete the security group in the directory server.
3. In the Security Groups application, select the group that you want to delete.
4. Select the Delete Group action.
5. Click Yes.

---

### What to do next

If implementation uses an application server to authenticate with an external directory (by means of LDAP), a user that is deleted in the directory is not automatically deleted in the system. You must manually delete it.

---

## Managing users

User records contain identifying information and security profiles that determine the applications, options, and data that a user can access. Users are added in the administrative console of Maximo® Application Suite. Certain aspects of user records are managed in Maximo Application Suite. You use Maximo Manage to manage their authorizations, or security privileges and some default settings.

### About this task

---

To manage user security privileges and some default settings, you can take the following actions:

- View user status.
- View user security profile.
- Add users to security groups.
- Specify various user defaults, such as default insert site, default storeroom, default language, and default general ledger accounts for purchasing. The default purchasing account is the general ledger account that is used for desktop requisitions, but not for all purchasing.
- Grant users the right to access inactive sites.
- Specify which users can access a screen reader to assist in interacting with the system.
- Set system-wide security controls and new user default groups.
- Create database users (if you are using an external identity provider, this feature is not available).
- [Users overview](#)  
Users are added or synchronized to Maximo Application Suite and synchronized to Maximo Manage if they have entitlement to Manage.
- [Working with users](#)  
You manage users by adding them, by assigning them to security groups, by changing general ledger accounts for users, and by performing other administrative tasks.
- [Setting signature key requirements](#)  
You can set requirements for electronic signature keys. Requirements include things like specifying minimum length, inclusion of character types, and disallowed words.
- [Configuring user authorizations](#)  
You must configure authorizations for users, such as specifying security groups and specifying security profiles.
- [Setting user defaults](#)  
You use the Security Controls action to specify the defaults for user records. You can access the Security Controls action from either the Security Groups application or the Users application.

---

## Users overview

Users are added or synchronized to Maximo® Application Suite and synchronized to Maximo Manage if they have entitlement to Manage.

Users need initial access privileges. To provide this access, you assign all new users to a security group that includes default privileges. When new users authenticate to the product or to their identity provider, they can change their password and have access to a default start center.

- [Administrative users](#)  
Administrative users have full or restricted access to the Security Groups application and to the Users application. Administrative users are responsible for implementing and maintaining security services, such as adding users, building profiles, or managing general site administration.
- [Database users](#)  
Database users are granted access to read, insert, update, and delete specific objects that define a set of fields and business rules. These objects can also update one or more database tables.
- [System users](#)  
There are certain user IDs, like MAXADMIN and MAXREG, that are required for the system to run properly. These user IDs are known as system users
- [Self service users](#)  
Self service users can add service requests and view their service requests.
- [Security controls](#)  
You can implement security controls for users, such as authorizations and security profiles.

---

## Administrative users

Administrative users have full or restricted access to the Security Groups application and to the Users application. Administrative users are responsible for implementing and maintaining security services, such as adding users, building profiles, or managing general site administration.

Administrative users might need access to the following applications to perform system administration"

- Actions
- Application Designer
- Calendars
- Chart of Accounts
- Classifications
- Communication Templates
- Cron Task Setup
- Database Configuration
- Currency Codes

- Domains
- E-mail Listeners
- Escalations
- Exchange Rates
- Integration
- Launch in Context
- Logging
- Object Structures
- Organizations
- Roles
- Security Groups
- Sets
- System Properties
- Users
- Web Services Library
- Workflow Administration
- Workflow Designer

Some users might assign management functions that are administrative in nature to supervisors or managers, especially in the areas of Information Technology Asset Management and Service Desk operations. These users are not considered administrative users.

---

## Database users

Database users are granted access to read, insert, update, and delete specific objects that define a set of fields and business rules. These objects can also update one or more database tables.

In the Users application, you use the Database Access action to create database users. If you implement databases that need operating system IDs, you must create the operating system ID.

The default database username is `maximo`.

The following commands detail the standard authorizations that are required:

- Create user *dbusername* identified by the system
- Alter user *dbusername* default table space quota as unlimited
- Alter user *dbusername* temporary table space temp
- Grant create trigger to *dbusername*
- Grant create session to *dbusername*
- Grant create sequence to *dbusername*
- Grant create synonym to *dbusername*
- Grant create table to *dbusername*
- Grant create view to *dbusername*
- Grant create procedure to *dbusername*
- Grant alter session to *dbusername*
- Grant execute on `ctxsys.ctx_ddl` to *dbusername*

To allow database access to users, the following commands detail the additional grants that are required to create database users:

- Grant create user to *dbusername*
- Grant drop user to *dbusername*
- Grant create session to *dbusername* with admin option
- Grant alter user to *dbusername*

---

## System users

There are certain user IDs, like MAXADMIN and MAXREG, that are required for the system to run properly. These user IDs are known as system users

The system users MAXADMIN and MAXREG are part of the database. To create system users, you use the system account option in the Users application. You cannot delete a system user.

---

## Self service users

Self service users can add service requests and view their service requests.

New self service users are added to the DEFAULTREG group and to the group that is specified by value of the *NEWUSERGROUP* varname in the MAXVARS table. The default value of the *NEWUSERGROUP* varname is MAXEVERYONE. Upgraded users are assigned to groups that are defined by the values of the *NEWUSERGROUP* and the *ALLUSERGROUP* varnames in the MAXVARS table.

In the Users application or Security Groups application, an administrator can replace the default security group with another security group, such as the SELFSERVICE group.

---

## Security controls

You can implement security controls for users, such as authorizations and security profiles.

- [Security profiles for users](#)

You can specify the security profile for a user. You can assign the user to groups and set other security attributes. These attributes include default insert sites, storeroom sites, and default storerooms.

- [Database access for users](#)

By default, users do not have authorization to access the database. However, in some instances, users need access to the database. For example, a user might need database authorization to view tables and columns to create reports.

- [Default insert sites for users](#)

In the Users application, you assign users to a default insert site to insert records. The records that users view pertain only to the default insert site. Without a default insert site, some applications cannot function. For example, without a default insert site, users cannot add purchase orders in a site-level application.

---

## Security profiles for users

You can specify the security profile for a user. You can assign the user to groups and set other security attributes. These attributes include default insert sites, storeroom sites, and default storerooms.

The following points are applicable to security profiles:

- The default insert site is the default value to use when a user creates a record. The value in the Organization field is the organization to which the default insert site belongs.
- By default, new users are assigned to the MAXDEFLTREG group. You cannot delete this group from a security profile.
- If the use default insert site as a display filter option is selected, the user views records for only the default insert site on the List tab of all applications.
- The value for default storeroom applies to when a user creates a material requisition. You can specify a value for the storeroom site only. However, if you specify a default storeroom, you must also specify the storeroom site. If you enter a default insert site or storeroom site, you must grant the user privileges to a group with that site.

- [Resending multiple users from Maximo Manage to Maximo Application Suite](#)

You can use a cron task parameter to resend multiple users from Maximo® Manage to Maximo Application Suite.

---

## Resending multiple users from Maximo Manage to Maximo Application Suite

You can use a cron task parameter to resend multiple users from Maximo® Manage to Maximo Application Suite.

In Maximo Manage 8.5 and earlier versions, users who are migrated from Maximo Manage Maximo Application Suite during upgrade, could not be resent without editing the database.

In Maximo Manage 8.5, you can reset the RESENDUSERSSEL cron task parameter to resend multiple users from Maximo Manage to Maximo Application Suite.

Cron task parameter	Description
RESENDUSERSSEL	Specifies a WHERE clause that selects all users that you want to resend from Maximo Manage to Maximo Application Suite.

---

## Database access for users

By default, users do not have authorization to access the database. However, in some instances, users need access to the database. For example, a user might need database authorization to view tables and columns to create reports.

You can grant a user authorization to read, insert, update, and delete specific objects that define a set of fields and business rules, and that update one or more database tables. Before you can grant database access, you must complete additional steps to grant authorization to database users. To provide a user complete database authorization, use the tools and procedures of your database platform.

---

## Database passwords

The database user ID and password do not have to be the same. However, the database password must meet the requirements of your database platform. For example, if you are using the Oracle database platform, you cannot create a password with certain special characters that Oracle does not support.

You use the Change Password action to change a password for database users. You can set a database user password to match a system password. However, the database user password must support the password requirements. Users cannot change their own database passwords.

---

## Default insert sites for users

In the Users application, you assign users to a default insert site to insert records. The records that users view pertain only to the default insert site. Without a default insert site, some applications cannot function. For example, without a default insert site, users cannot add purchase orders in a site-level application.

For site-level records, the site defaults to the value of the default insert site. For organization-level records, the organization defaults to the organization of the site that is specified as the default insert site. The Profile link in the navigation bar enables users to change their default insert site.

The Use Default Insert Site as a Display Filter setting is a filter that allows users to view only records from their default insert site. However, if the application is at the organizational level, this setting allows users to view all records from all sites within the organization. If you do not use this setting, users can view records for all the sites to which they have access.

---

## Working with users

You manage users by adding them, by assigning them to security groups, by changing general ledger accounts for users, and by performing other administrative tasks.

- [Assigning users to security groups](#)  
To manage security settings and to grant user privileges, you can assign users to security groups. New users are assigned to the default group (MAXDEFLTREG) and the group for all users (MAXEVERYONE). The default group is used to give newly registered users basic privileges, and the group for all users is used to specify global settings.
- [Authorizing users to assign other users to security groups](#)  
When you create a security group, you are authorized to assign users to that group. As an administrator, you can authorize a user to assign other users to security groups.
- [Changing persons associated with users](#)  
You can manage your work force information by associating user IDs with specific person records. Once an association is no longer being used, you can reuse the user ID with another person record.
- [Configuring user settings](#)  
You can configure user settings, such as the settings for storerooms, insert sites, GL accounts, locale, language, time zone, and screen reader access. Configure the settings for a single user or for a selected group of users.
- [Deleting security groups from user profiles](#)  
To manage the security privileges associated with user records, you can delete a security group from a user profile.

---

## Assigning users to security groups

To manage security settings and to grant user privileges, you can assign users to security groups. New users are assigned to the default group (MAXDEFLTREG) and the group for all users (MAXEVERYONE). The default group is used to give newly registered users basic privileges, and the group for all users is used to specify global settings.

---

### About this task

You can add only security groups that you are authorized to manage. You can delete a security group from a user profile when the user is assigned to another security group.

---

### Procedure

1. In the Users application, select the user to whom you would like to assign security groups and select the Groups tab.
2. In the Groups section, complete one of the following steps.

Option	Description
<b>Click New Row</b>	Specify a security group for a user
<b>Click Select Groups</b>	Specify multiple security groups

3. Click OK.

---

## Authorizing users to assign other users to security groups

When you create a security group, you are authorized to assign users to that group. As an administrator, you can authorize a user to assign other users to security groups.

---

### Procedure

1. In the Users application, access the user whom you want to authorize.
2. Select the Authorize Group Reassignment action.
3. To authorize assignments to security groups, select one of the following options:
  - To authorize one security group, in the Group field, specify a group.
  - To authorize several security groups, click Select Groups and select the check boxes next to the groups that you want to add.
4. Click OK.

---

## Changing persons associated with users

You can manage your work force information by associating user IDs with specific person records. Once an association is no longer being used, you can reuse the user ID with another person record.

### Procedure

---

1. In the Users application, access the user for whom you want to make an association.
2. Select the Change Person action.
3. In the New Person field in the Change Person window, specify a new person record.
4. Click OK.

### Example

---

For example, there is a user ID with the value of contractor 1 that is associated with Bob Smith from XYZ Consulting. The contract for Bob Smith expired. Therefore, you can associate the user ID, contractor 1, with another user ID.

---

## Configuring user settings

You can configure user settings, such as the settings for storerooms, insert sites, GL accounts, locale, language, time zone, and screen reader access. Configure the settings for a single user or for a selected group of users.

All of the configurations are optional.

### About this task

---

You can specify settings for multiple users by selecting them on the main tab of the Users application and then selecting the Set Security Profile action.

- Add, remove, or replace security groups for the users.
- Specify the default insert site and use the default insert site as a display filter.
- Specify the default storeroom and storeroom site for filling material requisitions for these users.

### Procedure

---

1. To configure settings for a single user, select the user in the Users application.
2. Specify settings about the default insert site to be used on records that the user creates.
  - a. Specify the default insert site.
  - b. Specify whether to use the default insert site as a display filter.
3. Specify storeroom information for material requisitions submitted by this user.
  - a. Specify the default storeroom.
  - b. Specify the site of the default storeroom.
4. Enable access to work with records that reference inactive sites.
5. Set display settings.
  - a. Specify settings for language, locale, or time zone.

If you change the setting for the language that was synchronized from Maximo® Application Suite, it is not overwritten by a future synchronization from Maximo Application Suite.
  - b. Enable use of a screen reader.
6. Specify purchasing information by adding the organization and default debit general ledger (GL) account.

This information can be overwritten by a GL account that defaults from some other relationship.
7. Save your changes.

---

## Deleting security groups from user profiles

To manage the security privileges associated with user records, you can delete a security group from a user profile.

### Before you begin

---

You can delete a security group from a user profile once the user is assigned to another security group.

### About this task

---

When you delete a security group from a user profile, the association between the security group and the user is removed. The group then remains in the database.

### Procedure

---

1. In the Users application, open the user record whose groups you want to change.
2. Click the Groups tab.
3. To delete a group, click Mark Row for Delete.
4. Save your changes.

---

## Setting signature key requirements

You can set requirements for electronic signature keys. Requirements include things like specifying minimum length, inclusion of character types, and disallowed words. Electronic signature keys that are created manually or that are generated automatically conform to the requirements that you specify.

### Procedure

---

1. In the Users application, select a user and then select the Security Controls action. In the Security Controls window, configure settings in the following sections:

Option	Description
<b>E-Signature Key Requirements</b>	Specify a minimum length, the number of allowed identical adjacent characters, and whether the key can contain the user login ID. These rules are enforced whether a user creates the key or whether a reset is done.
<b>Required E-Signature Key Characters</b>	Specify the allowed and required character types. These rules are enforced whether a user creates the key or whether a reset is done.
<b>Allowed Placement of E-Signature Key Characters</b>	Specify the allowed placement of characters. These rules are enforced whether a user creates the key or whether a reset is done.
<b>Excluded E-Signature Key List</b>	Add a row for each word that you want to exclude from use. These rules are enforced whether a user creates the key or whether a reset is done.

2. Save your changes.

---

## Configuring user authorizations

You must configure authorizations for users, such as specifying security groups and specifying security profiles.

- [Specifying security groups for users](#)  
To grant users the privileges that are associated with a security group, you can specify a security group for that user.
- [Specifying security profiles for users](#)  
When you specify a security profile for multiple users, you assign the users to groups and set other security attributes. The groups and security attributes include the default insert site, the use default insert site as a display filter, the storeroom site, and the default storeroom.
- [Specifying security profiles for multiple users](#)  
When you specify a security profile for multiple users, you assign the users to groups and set other security attributes. These groups and security attributes include the default insert site, the use default insert site as a display filter, the storeroom site, and the default storeroom.
- [Granting user access to Oracle and Structured Query Language server databases](#)  
You can grant a user authorization to read, insert, update, and delete specific objects that define a set of fields and business rules, and that update one or more database tables.
- [Changing user access to Oracle and Structured Query Language server databases](#)  
To manage database access for users, you can change their existing access. You can remove rights to objects, and add, delete, or change existing rights.
- [Removing user access to Oracle and Structured Query Language server databases](#)  
You can remove access for a user to read, insert, update, and delete specific objects. These objects define a set of fields and business rules, and update one or more database tables.

---

## Specifying security groups for users

To grant users the privileges that are associated with a security group, you can specify a security group for that user.

### Procedure

---

1. In the Users application, select the user to whom you would like to assign security groups and select the Groups tab.
2. In the Groups section, click Select Groups.
3. Complete one of the following steps:
  - Select the check box next to the security group that you want to select.
  - To select all of the groups, select the Group check box in the table heading row.
4. Click OK.

---

## Specifying security profiles for users

When you specify a security profile for multiple users, you assign the users to groups and set other security attributes. The groups and security attributes include the default insert site, the use default insert site as a display filter, the storeroom site, and the default storeroom.

## Procedure

---

1. In the Users application, select one or more users.
2. Select the Set Security Profile action.  
If you selected multiple users, the User Count field displays the number of users.
3. In the Set Security Profile window, select whether you want to add, remove, or replace groups.
4. Click New Row and specify a group.
5. In the Update User Defaults section, select the Edit check box for each default that you want to specify, and specify a value for each default.
6. Click OK.

## Results

---

The number of records that you updated is not always the same as the number in the User Count field. A record is not updated unless the change affects the current security profile. For example, if the security profile for a user contains groups A and B and you add group A, then the record for the user is not updated.

---

## Specifying security profiles for multiple users

When you specify a security profile for multiple users, you assign the users to groups and set other security attributes. These groups and security attributes include the default insert site, the use default insert site as a display filter, the storeroom site, and the default storeroom.

## Procedure

---

1. In the Users application on the List tab, select the user records for which you want to specify security profiles.
2. Select the Set Security Profile action.  
In the Set Security Profile window, the User Count field displays the number of users that you selected.
3. In the Set Security Profile window, select whether you want to add, remove, or replace groups.
4. Click New Row and specify a group.
5. In the Update User Defaults section, select the Edit check box for the default settings that you want to specify.
6. Specify settings for default insert site, use default insert site as a display filter, storeroom site for self-service requisitions, and default storeroom for self-service requisitions.
7. Click OK.

## Results

---

The number of records that you updated is not always the same as the number in the User Count field. A record is not updated unless the change affects the current security profile. For example, if the security profile for a user contains groups A and B and you add group A, then the record for the user is not updated.

---

## Granting user access to Oracle and Structured Query Language server databases

You can grant a user authorization to read, insert, update, and delete specific objects that define a set of fields and business rules, and that update one or more database tables.

## Before you begin

---

Before you can grant database access, you must perform additional steps to grant authorization to database users. To provide a user complete database authorization, use the tools and procedures of your database platform. If you use the IBM® Db2® database platform, you must use Db2 tools to provide database access rights. If you use an application server for authentication and user management, you cannot use change database access.

## Procedure

---

1. In the Users application, access the user who needs database access.
2. Select the Database Access action.
3. In the Database Access window, type an ID for the user. The ID must meet the requirements of the database platform and can be different from the user ID.
4. In the Database Password field and Confirm Password fields, type a database password. This password can be different than the user password.
5. To grant a user access to specific tables or objects in the database, complete the following steps:
  - a. Click New Row.
  - b. Specify the name of the object.  
The name of the entity populates the Entity Name field.
  - c. To define user rights to the tables associated with the object, select the Read, Insert, Update and Delete check boxes.
6. Click OK.

---

## Changing user access to Oracle and Structured Query Language server databases

To manage database access for users, you can change their existing access. You can remove rights to objects, and add, delete, or change existing rights.

## Before you begin

---

If you use the IBM® Db2® database platform, you must use IBM Db2 tools to provide database access rights. If you use an application server for authentication and user management, you cannot change database access.

## Procedure

---

1. In the Users application, open the user for whom you want to change database access.
2. Select the Database Access action.
3. In the Database Access window, remove specific object rights; and add, delete, or change the rows.
4. Click OK.

---

## Removing user access to Oracle and Structured Query Language server databases

You can remove access for a user to read, insert, update, and delete specific objects. These objects define a set of fields and business rules, and update one or more database tables.

## Before you begin

---

If you use the IBM® Db2® database platform, you must use Db2 tools to provide database access rights. If you use an application server for authentication and user management, you cannot use change database access.

## Procedure

---

1. In the Users application, access the user for whom you want to delete database access.
2. Select the Database Access action.
3. In the Database Access window, click Drop Database User.
4. Click OK.

---

## Setting user defaults

You use the Security Controls action to specify the defaults for user records. You can access the Security Controls action from either the Security Groups application or the Users application.

## About this task

---

You can specify the following defaults for user records:

- Default security group for new users - New users are automatically assigned to a security group. The default group defines their security permissions until they are assigned to additional groups. The default group is MAXDEFLTREG. The permissions for this group are limited to access to the Start Center. Users can change their own passwords.
- Default status for new user records - The default status is NEWREG. The NEWREG status allows you to search for new user records. You can also route records into a workflow process.
- Group for all users - The default security group for global permissions is MAXEVERYONE. When you select Group for All Users in Security Controls, the user is added to MAXEVERYONE.
- Electronic signature dialog - When you select Display User ID in the Electronic Signature Dialog in Security Controls, the system displays the user ID in the window, and prompts the user to enter a password.

Your implementation might use an application server to authenticate with an external directory by means of the Lightweight Directory Access Protocol (LDAP). In this case, you do not use the system to perform some functions. These functions might include:

- Self registration - This function is not supported in conjunction with an external directory.
- Setting or changing passwords and password hints - All password-related functions are managed by the directory.

By default, when you use an application server for authentication, the directory manages user and group creation. You can set properties to allow user and group creation to be performed directly in the system. The settings of these properties result in certain features being enabled or disabled in the system.

## Procedure

---

1. Select the Security Controls action.
2. In the User Defaults section, specify the following defaults:
  - a. In the Default Group for New Users field, type the name of the group, or click Detail Menu.
  - b. In the Initial Self-Registered User Status field, type a user status.
  - c. In the Group for All Users field, specify the group for global permissions. The default is MAXEVERYONE.
  - d. Select the Display User ID in the Electronic Signature Dialog check box to display the user ID in the window when the system prompts users to enter their passwords. If you implement electronic signatures, you must enable login tracking.
3. Click OK.

---

## Implementing additional security

You can implement additional security measures to protect your organization, including login tracking, setting encryption properties, and safeguarding against intrusion and malicious attacks.

- [Login tracking](#)

You use login tracking to track the number of login attempts and view the current login status for a user.

---

## Login tracking

You use login tracking to track the number of login attempts and view the current login status for a user.

By default, login tracking is enabled in Maximo® Manage. Login tracking enhances security, however, this tracking can sometimes impact system performance.

When login tracking is enabled, all successful and unsuccessful login attempts are tracked. Login tracking must be enabled if you use electronic signatures. You enable or disable login tracking by setting the *VARVALUE* variable values in the MAXVARS table.

- [Enabling and disabling login tracking](#)

By default, login tracking is enabled in Maximo Manage. Login tracking enhances security, however, this tracking can sometimes impact system performance.

---

## Enabling and disabling login tracking

By default, login tracking is enabled in Maximo® Manage. Login tracking enhances security, however, this tracking can sometimes impact system performance.

---

## About this task

When you enable login tracking, the product logs all sign in attempts, successful and unsuccessful. You enable or disable login tracking by setting variable values in the MAXVARS table.

---

## Procedure

1. Run one of the following SQL statements on the database to enable or disable login tracking:
  - Enable tracking with the following statement: `update MAXVARS set VARVALUE = '1' where VARNAME= 'LOGINTRACKING'`
  - Disable tracking with the following statement: `update MAXVARS set VARVALUE = '0' where VARNAME= 'LOGINTRACKING'`
2. Restart the server.

---

## Work Centers

Work Centers are role-based user interfaces where users can access and complete daily tasks. By using Work Centers, you can access system data and complete tasks without opening multiple applications. You can use tools to complete specific tasks such as creating a service request, designing data sets for business analysis, or creating inspection forms.

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, the following work centers are no longer available: Business Analysis, Design Data Sets, Conduct an Inspection, Work Execution, Work Supervisor, Service Request, Assets, and Administration. The documentation that is provided for those work centers applies only to Maximo Manage 8.4 and earlier versions.

If you have access to multiple Work Centers and tools, you can set one Work Center or tool as your default.

- [Introduction to Work Centers](#)

Work Centers offer you a simpler, task-based, and role-based interface that is responsive on desktops, notebooks, tablets, and smartphones. Because these Work Centers offer only the features that you need to complete your most critical work, your learning curve can be shortened, and you work more efficiently.

- [Administering Work Centers](#)

Work Centers are role-based user interfaces where users can access and complete daily tasks. After you have access to a Work Center, either you or your administrator can apply extra configurations.

- [Configuring service requests](#)

Administrators can use the Service Request Configuration page of the Administration Work Center to configure the options that users have when they create service requests.

- [Configuring integration](#)

As the system administrator, you can integrate your Manage system with other applications in your enterprise or with an external system or application. In the Administration Work Center, on the Integration tab, you can access some predefined integration components that enable integration with Manage business objects, and you can create and configure message templates and API keys. You use message templates and API keys as part of the Maximo® Integration Framework. You can create, edit, and review other integration components for the Maximo Integration Framework in Manage applications.

- [Analyzing data](#)

Business analysts can use the Business Analysis Work Center to analyze information and monitor and identify trends to improve operator performance.

- **[Managing inventory](#)**  
In the Manage Inventory Work Center, you manage your item catalog, inventory reservations, and inventory in storerooms. These activities help you maintain adequate item balances and manage carrying costs so that your teams have the items that they need to maintain your assets.
- **[Managing assets and locations](#)**  
In the Manage Assets Work Center, you manage corporate assets and locations.
- **[Work Supervision Work Center](#)**  
The Work Supervision Work Center facilitates the work management activities of supervisors. As a supervisor, you can manage the workload of technicians and assign owners to the work.
- **[Work Execution Work Center](#)**  
As a maintenance technician, you can use the Work Execution Work Center on a computer or mobile device to manage work orders that you own.
- **[Work Center Configuration](#)**  
Business analysts and administrators can evaluate business requirements and configure the top-level information for the Work Supervision and Work Execution Work Centers to make them more specific to certain user roles.
- **[Managing inspection forms](#)**  
In the Manage Inspection Forms tool, you create inspection forms by adding questions and defining responses. The inspection forms that you create are then available to inspectors in the Conduct an Inspection tool.
- **[Conducting inspections](#)**  
In the Conduct an Inspection tool, you conduct inspections that have been defined in the Manage Inspection Forms tool. You can also review the results of completed inspections, and create unscheduled inspections as necessary.
- **[Submitting service requests](#)**  
You use the Submit a Service Request tool to quickly create service requests by using your computer or mobile device. You can also monitor the status of existing service requests that you created or are affected by.

## Introduction to Work Centers

Work Centers offer you a simpler, task-based, and role-based interface that is responsive on desktops, notebooks, tablets, and smartphones. Because these Work Centers offer only the features that you need to complete your most critical work, your learning curve can be shortened, and you work more efficiently.

Several related tools are available for activities such as designing data sets for business analysis, creating inspection forms, and quickly entering service requests.

Business administrators can configure parts of the Work Centers for Work Supervision and Work Execution.

Several Work Centers provide short tours about Work Center features. Available tours are listed in your Profile menu in a Work Center.

Work Center or feature	Description
<a href="#">Administration</a>	Complete administrative tasks. Administrators can customize the selections that users make in the Service Requests tool by creating categories and adding issues as options for each category.
<a href="#">Configuring service requests</a>	
<a href="#">Manage Assets</a>	Manage corporate assets and locations.
<a href="#">Business Analysis Work Center</a>	Analyze information, and monitor and identify trends. Business analysts can use the data that is provided by the Work Center to improve operation and user performance.
<a href="#">Conduct an Inspection</a>	Conduct and review inspections.
<a href="#">Manage Inspection Forms</a>	Create inspection forms by adding questions and defining responses.
<a href="#">Manage Inventory</a>	Manage your item catalog, inventory reservations, and inventory in storerooms.
<a href="#">Service Requests</a>	Create service requests by using your desktop computer, notebook computer, or mobile device. You can also monitor the status of existing service requests that you created or are affected by.
<a href="#">Work Execution</a>	Manage work orders that you own. Maintenance technicians can use the Work Execution Work Center on a desktop computer or mobile device.
<a href="#">Work Supervision</a>	Manage the work of your team. As a supervisor, you can manage the workload of technicians and assign owners to the work.
<a href="#">Work Center Configuration</a>	Business administrators can configure parts of the Work Supervision and Work Execution Work Centers.

## Administering Work Centers

Work Centers are role-based user interfaces where users can access and complete daily tasks. After you have access to a Work Center, either you or your administrator can apply extra configurations.

- **[Enabling tasks as work orders](#)**  
For scheduling and tracking purposes, some businesses want to process work tasks as work orders. To view tasks as work orders in Work Supervision and Work Execution Work Centers, administrators must configure the object structure for work orders.
- **[Enabling technicians to create work orders](#)**  
By default, technicians cannot create work orders in the Work Execution Work Center. Administrators can give technicians permission to create work orders. Administrators must also configure the Work Center to display work orders that technicians create.
- **[Disabling access to Learn more links from Work Centers](#)**  
You can access information about Maximo® Manage, such as announcements about new products and releases, support information, and training from the Learn more link on the landing page for the Work Centers. To disable access to this information, you must deactivate the EXTLINK escalation and disable the Learn more link.

- [Managing notifications](#)

Notifications are used to communicate the status of your assets. In the Notifications application, you can create, update, or delete notifications. In the Work Center, you can manage notifications and your subscriptions to notifications.

## Enabling tasks as work orders

For scheduling and tracking purposes, some businesses want to process work tasks as work orders. To view tasks as work orders in Work Supervision and Work Execution Work Centers, administrators must configure the object structure for work orders.

### About this task

Businesses can choose to process work order tasks as separate work orders. For example, when a work order for an office renovation includes electrical work and painting, you might want to display the electrical task as a work order for the electrician and the painting task as a work order for the painter.

By default, tasks are not processed as work orders. The following procedures explain how to enable tasks as work orders for your Work Supervision and Work Execution Work Centers.

## Enabling tasks as work orders for technicians

To enable tasks as work orders for technicians, an administrator must configure the query clause for technicians.

### About this task

To configure tasks as work orders for technicians, an administrator must edit the `uxtechnicianownerfilter` query clause in the `MXAPIWODETAIL` object structure.

### Procedure

1. In the Object Structures application, filter to locate the `MXAPIWODETAIL` object structure and select that object.
2. From the More Actions menu, select Query Definition.
3. In the Query Definition window, filter for the `uxtechnicianownerfilter` query clause.
4. Expand the row for the query clause.
5. In the Query Clause field, specify the appropriate clause for your needs, as shown in the following table.

To enable tasks as work orders, the `istask` parameter must be set to `istask=1`.

Table 1. Sample code for technician query clauses

To display the following information...	Specify this query
Technician sees only regular work orders. This option is the default. To keep this option, no action is needed.	<code>owner = :&amp;personid&amp; or ownergroup in (select persongroup from persongroupteam where respparty=:&amp;personid&amp;) and istask=0</code>
Technician sees only task work orders.	<code>owner = :&amp;personid&amp; or ownergroup in (select persongroup from persongroupteam where respparty=:&amp;personid&amp;) and istask=1</code>
Technician sees both task and regular work orders.	<code>owner = :&amp;personid&amp; or ownergroup in (select persongroup from persongroupteam where respparty=:&amp;personid&amp;)</code>

6. Click OK.

### Results

After you complete the configuration, if you specify the value 1 for the `istask` parameter in the query, tasks are displayed as work orders.

## Enabling tasks as work orders for supervisors

To enable tasks as work orders for supervisors, an administrator must configure the query clauses for supervisors.

### About this task

To configure tasks as work orders for supervisors, an administrator must edit the following query clauses in the `MXAPIWODETAIL` object structure: `APPROVEWORK`, `CLOSEWORK`, `MONITORWORK`, `FINDOWNERWORK`, and `CLOSEDWORK`.

### Procedure

1. In the Object Structures application, filter to locate the `MXAPIWODETAIL` object structure and select that object.
2. From the More Actions menu, select Query Definition.
3. In the Query Definition window, filter for the query clause that you want to update.
4. Expand the row for the query clause.
5. In the Query Clause field, specify the appropriate clause for your needs, as shown in the following table:

Table 2. Sample code for supervisor query clauses

To display the following information...	Specify this query
Supervisor sees only regular work orders. This option is the default. To keep this option, no action is needed.	<code>(woclass =(select value from synonymdomain where domainid ='WOCLASS' and maxvalue = 'WORKORDER') and historyflag=0 and istask=0 and supervisor=:&amp;personid&amp;)</code>

To display the following information...	Specify this query
Supervisor sees only task work orders.	<code>(woclass =(select value from synonymdomain where domainid ='WOCLASS' and maxvalue = 'ACTIVITY') and historyflag=0 and istask=1 and supervisor=:&amp;personid&amp;)</code>
Supervisor sees both task and regular work orders.	<code>(woclass IN (select value from synonymdomain where domainid ='WOCLASS' and maxvalue IN ('ACTIVITY','WORKORDER')) and historyflag=0 and supervisor=:&amp;personid&amp;)</code>

6. Click OK.

## Enabling technicians to create work orders

By default, technicians cannot create work orders in the Work Execution Work Center. Administrators can give technicians permission to create work orders. Administrators must also configure the Work Center to display work orders that technicians create.

### About this task

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, this work center is no longer available. The information that is provided here applies only to Maximo Manage 8.4 and earlier versions.

## Granting technicians permission to create work orders

To grant technicians permission to create work orders, administrators must give the security group for technicians Insert permission for the MXAPIWODETAIL object structure.

### Procedure

1. In the Security Groups application, filter to locate the security group for technicians and select that security group.
2. On the Object Structures tab, filter to locate the MXAPIWODETAIL object structure and select that object structure.
3. Select the Grant Access check box for the Insert MAXAPIWODETIAL option.
4. Click Grant Listed Options for This Object Structure.
5. Click OK.
6. Save the record.  
Technicians now have permission to create work orders.
7. To complete the configuration, complete the following steps to clear the technician user sessions from the admin log:
  - a. Go to the Users application.
  - b. From the More Actions menu, select Manage Sessions.
  - c. In the Manage Sessions window, delete all sessions for the users who are logged in as technicians.
  - d. Click OK.
  - e. In response to the system message about errors that occurred, click OK.
  - f. To confirm that you want to log out the users, click Yes.
8. Log in to the system as a technician and verify that you can create work orders.

## Configuring tabs to display work orders that a technician creates

If administrators give technicians permission to create work orders, they must also configure one of the tabs in the Work Execution Work Center to display the work orders that a technician creates. To configure a tab to display work orders created by a technician, use the Design mode for the Work Execution Work Center.

### Procedure

1. Log in to the Work Execution Work Center as an administrator with design configuration rights.
2. Click Edit to enter Design mode.
3. Select the column that you want to edit.
4. In the Design work panel, enter a new name for the column, such as *Created by Me*.
5. Select the REST query option.
6. Replace the existing clause in the Where clause field with the following clause:

```
{ "qbewhere": { "siteid": { "operator": "=", "value": "-dfltsite-", "status":
{ "operator": "in", "valueset": { "APPR", "WPCOND", "HISTEDIT", "INPRG", "WAPPR",
"WMATL", "WSCH" } }, "reportedby": { "operator": "=", "value": "-personid-" } } }
```

7. Click Save.
8. To publish the changes, complete the following steps:
  - a. Click Manage.
  - b. Select the Publish as active workcenter action.
  - c. In the Publish your Work Center window, click Publish.

## Disabling access to Learn more links from Work Centers

You can access information about Maximo® Manage, such as announcements about new products and releases, support information, and training from the Learn more link on the landing page for the Work Centers. To disable access to this information, you must deactivate the EXTLINK escalation and disable the Learn more link.

## About this task

By default, the EXTLINK escalation verifies whether web portals or other resources on a specific server are available and the disableAllLinks attribute is set to false in the ext-link-config.json file.

## Procedure

1. In the Escalation application, select the EXTLINK escalation.
2. Deactivate the escalation from the More Actions menu.  
By default, the escalation is set to run every 12 hours.
3. Disable the Learn more link to hide the link on the landing page for the Work Centers.
  - a. In the *install\_home*\applications\maximo-x\script directory, open the ext-link-config.json file.
  - b. Change the value for the disableAllLinks attribute to `True`.
4. Build the Work Center WAR file, maximo-x.war, by running the **buildmaximo-xwar** command.  
The maximo-x.war file is created in the *install\_home*\deployment\default directory.
5. Deploy the Work Center WAR file, maximo-x.war.

## Managing notifications

Notifications are used to communicate the status of your assets. In the Notifications application, you can create, update, or delete notifications. In the Work Center, you can manage notifications and your subscriptions to notifications.

- [Creating notification message templates](#)  
You create notification message templates to define notifications.
- [Creating notification events](#)  
You create notification events to notify users of asset and work order information by way of email, SMS, or a Work Center notification.
- [Consuming notification events](#)  
Notifications can be silent or endpoint-based notifications.
- [Changing the deletion frequency of notifications](#)  
The NOTFDELETE cron task controls which notifications are deleted from the system. You can change the PURGETIME parameter for this cron task to change how old a notification is before it is deleted.

## Creating notification message templates

You create notification message templates to define notifications.

## Procedure

1. Start Maximo® Manage.
2. In the Notifications application, select the Notification Message Template.
3. Select New Row.
4. In the Notification Template field, enter a name and description for the notification template.
5. Select the Message Properties or Message Text notification message type, and specify the properties or text to include in the notification.  
The notification message type indicates the content of the messages to be sent as part of the notification.

Option	Description
Message Properties	Work Center notifications. For example, assetnum,description,status
Message Text	Email or SMS notifications For example, The following asset :assetnum has changed its status to :status.

6. Save your changes.

## Creating notification events

You create notification events to notify users of asset and work order information by way of email, SMS, or a Work Center notification.

## About this task

The Maximo® Manage Notifications application is used to configure notification events based on object structures. Events consist of a set of conditions for a specific Maximo business object which is the root object of the object structure. If event conditions are met, the event occurs. Event messages can be configured as a message template from the Notification Message Template dialog. Users can subscribe themselves to an event. Alternatively, a system administrator can subscribe a user to an event. Use the Notification User Subscription dialog in the Notifications application to manage subscriptions..

## Procedure

---

1. Start Maximo Manage.
2. In the Notifications application, click Create Notification.
3. In the Notification field, specify a value.
4. In the Object Structure field, specify an object structure.  
You can specify any object structure. For example, the MXAPIASSET object structure is typically used for assets.
5. In the Message Template field, specify a value.  
For more information, see [Creating notification message templates](#).
6. Optional: Specify when the event results in a notification by selecting the On Add, On Update, or On Delete check box.
7. Optional: In the Event Filter Condition field, specify any conditions that are required to send a notification.  
Conditions include attribute conditions and conditional operators such as OR, AND, or WHILE that are evaluated and dictate whether an attribute is modified.
8. Optional: Select Notification User Subscription under More Actions.
  - a. Click the New Row icon to add a user for the notification event.
  - b. Specify the person ID in the Event For User field and click OK.
  - c. Specify the person ID in the User field and click OK.
9. Save your changes.

---

## Consuming notification events

Notifications can be silent or endpoint-based notifications.

Silent notifications

This type of notifications does not use any queuing technology.

Endpoint-based notifications

This type of notifications uses a queuing technology.

In uid , you can use either JMS or Kafka queuing for endpoint-based notifications. You can set up the queuing method in the External Systems application, by using the NOTIFICATION external system. Set up only the outbound queue for this external system because all notifications in Maximo® Manage are outbound notifications.

Before Maximo Application Suite 8.8, Kafka outbound notification queues were consumed only sequentially. So, if one notification message got stuck in the Kafka queue, all subsequent notification messages were stuck in the queue behind it. This setup is not ideal for notifications and was changed to a continuous processing method in Maximo Application Suite 8.8.

JMS notification queues did not have this limitation because you can set up message-driven beans to proceed with the notification messages continuously.

---

## Changing the deletion frequency of notifications

The NOTFDELETE cron task controls which notifications are deleted from the system. You can change the PURGETIME parameter for this cron task to change how old a notification is before it is deleted.

### About this task

The default schedule of the NOTFDELETE cron task is set to once a day. The default value for the PURGETIME parameter is one day. By default, the cron task runs once a day and deletes any notification that is more than a day old.

---

## Procedure

1. In the Cron Task Setup application, select the NOTFDELETE cron task.
2. On the Parameters tab, enter a new value for the PURGETIME parameter. The value must be a whole number followed by D for day, M for month, or Y for year.

---

## Configuring service requests

Administrators can use the Service Request Configuration page of the Administration Work Center to configure the options that users have when they create service requests.

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, this work center is no longer available. The information that is provided here applies only to Maximo Manage 8.4 and earlier versions.

You can configure categories for users to select from when they create new requests and set default values for service requests that are created in Work Centers.

To configure service requests, you must have access to do so. In the Security Groups application, go to the Applications tab and select Administration Work Center. Select the Grant Access checkbox for the View Service Request Configuration option.

- [Configuring service request properties](#)  
Using the Service Request Configuration page, you can define certain values for service requests that are created in work centers.
- [Configuring categories for service requests](#)  
You customize the selections that users make in the Submit a Service Request tool by creating categories and adding issues as options for each category.

You configure this information by using the Service Request Configuration page.

---

## Configuring service request properties

Using the Service Request Configuration page, you can define certain values for service requests that are created in work centers.

---

### Procedure

1. In the Service Request Configuration page of the Administration Work Center, click the Properties tab.
2. Enter a value in the Reported priority field.  
This value is the priority for service requests that are created with the High priority check box cleared.
3. Enter a value in the High priority field.  
This value is the priority for service requests that are created with the High priority check box selected. If the SET\_PRIORITY signature option is turned off in the Security Groups application, users do not see the High priority check box when they enter service requests in the Submit a Service Request tool.
4. In the Source field, enter the value that you want to use for service requests that are entered by using Work Centers.  
All service requests that are created in work centers can be identified by using a specific source type. You can use this information to report on the volume of requests that were created in the work center versus service requests that were created from the Service Requests application. The default value for service requests created in the work centers is SRWC.
5. Enter a value in the "Describe the Issue" class structure ID field. You can select a value from the menu or start typing in the field to see a list of values. The value that you define must be a valid service request classification.  
When users create a service request and select a category, a class structure ID value is assigned to the service request. If users do not select a category and use the Describe the Issue option, the value defined in the "Describe the Issue" class structure ID field is used.
6. If you want users to have access to only site-specific information (like categories, people, locations, and assets) when they enter service requests, turn on the Filter on person site toggle.

---

### What to do next

Refresh the Submit a Service Request tool to show the changes.

---

## Configuring categories for service requests

You customize the selections that users make in the Submit a Service Request tool by creating categories and adding issues as options for each category. You configure this information by using the Service Request Configuration page.

---

### About this task

A category must have at least one issue that is assigned before the category is shown in the Submit a Service Request tool.

For example, you want to add a category that is called Heat and Air that has the following issues:

- It's too hot.
- It's too cold.
- The system is noisy.

You create a category and name it `Heat and Air`. Then, create the category issues, such as `It's too hot`.

---

### Procedure

1. In the Service Request Configuration page of the Administration Work Center, click the Categories tab. Specify who can create service requests. You can specify the domain name of a company, for example @companyxyz.com, to allow anyone who works there to create requests, or you can list the email addresses of specific users.
2. Click Add.
3. In the Service Requests Categories section, select a category for the type of issues that users can enter. You can enter categories in the following ways:
  - Choose from an existing category in the Category list.
  - To edit a category description, click the pencil icon for the category. Edit the category description, then click the Save icon.
  - Create a category by clicking the + sign next to the category header and typing in the Enter category field. Click the Save icon.
4. Select a subcategory. Choose from existing subcategories, modify a subcategory, or enter a new one.
5. Add common issues that are associated with that category. Choose from existing issues, modify an existing issue, or create a new one.  
A category must have at least one issue that is assigned before the category is shown in the Submit a Service Request tool.
6. Add categories and issues as needed. Your changes are automatically saved.

---

### What to do next

Refresh the Submit a Service Request tool to show the categories and associated category issues.

---

## Configuring integration

As the system administrator, you can integrate your Manage system with other applications in your enterprise or with an external system or application. In the Administration Work Center, on the Integration tab, you can access some predefined integration components that enable integration with Manage business objects, and you can create and configure message templates and API keys. You use message templates and API keys as part of the Maximo® Integration Framework. You can create, edit, and review other integration components for the Maximo Integration Framework in Manage applications.

---

## Analyzing data

Business analysts can use the Business Analysis Work Center to analyze information and monitor and identify trends to improve operator performance.

- [Business Analysis Work Center](#)  
As a business analyst, you can use the Business Analysis Work Center to analyze information, and monitor and identify trends. You can use the data that is provided by the Work Center to improve operation and user performance.
- [Data Set Designer](#)  
Business analysts can use the Data Set Designer to create data sets quickly and without the involvement of IT personnel.

---

## Business Analysis Work Center

As a business analyst, you can use the Business Analysis Work Center to analyze information, and monitor and identify trends. You can use the data that is provided by the Work Center to improve operation and user performance.

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, this work center is no longer available. The information that is provided here applies only to Maximo Manage 8.4 and earlier versions.

The Business Analysis Work Center converts Manage data to different formats for the various aspects of your organization. These areas include work efficiency, schedule compliance, supply rates, and inventory balances. Converted data is displayed in multiple chart types to ensure that information is easy to understand and analyze. You can download charts as images to share and present data, or you can change the chart type to meet your viewing needs.

Additionally, you can view your data in KPIs to monitor operational performance. New KPIs focus on data quality and allow you to collect, track, and measure the most important data for your organization.

You can use the Data Set Designer tool to create data sets. Data sets can be downloaded in a comma-separated value (CSV) format.

Before you can access the Business Analysis Work Center, an administrator must add you to the security group template for the Work Center. Security group templates are provided to enable access to work centers and tools and tasks.

---

## Data Set Designer

Business analysts can use the Data Set Designer to create data sets quickly and without the involvement of IT personnel.

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, this work center is no longer available. The information that is provided here applies only to Maximo Manage 8.4 and earlier versions.

Building a data set in the Data Set Designer involves selecting an object set and specifying the content or fields that you want to include. You can then configure the content by selecting fields and applying filters and sorting. While you are configuring the data set, you can use the preview feature.

You can apply either an existing application query to your data set or you can create a new one. After you save the data set, you can export its contents to comma-separated value (CSV) format.

Before you can access the Data Set Designer, an administrator must add you to the security group template. Security group templates are provided to enable access to Work Centers and tools and tasks.

---

## Update to report object structures (ROS)

To support Data Set Designer features, report object structures (ROS) are updated to enable the Support Flat Structure field. Report object structures are used in a variety of locations in Maximo® Manage, including QBR (Ad Hoc) Reporting, Result Set portlets, and Cognos® metadata package publishing.

All standard report object structures are updated and a script is provided to update any custom report object structures that you created.

Review your custom report object structures for alias conflicts. Alias conflicts occur when the same attribute name is used in multiple objects in the object structure. If you do not correct alias conflicts, problems might occur if you use them in the Data Set Designer features.

For more information about handling alias conflicts for object structures, see [Resolving alias conflicts](#).

---

## Managing inventory

In the Manage Inventory Work Center, you manage your item catalog, inventory reservations, and inventory in storerooms. These activities help you maintain adequate item balances and manage carrying costs so that your teams have the items that they need to maintain your assets.

In several areas of the Work Center, you can reduce manual data entry effort by scanning bar codes. For example, you can scan a code to select an existing bin or lot when you issue or transfer items.

The following pages help you to manage your inventory:

#### Reservations

View and manage reservations for storeroom inventory. Reservations are sometimes made automatically when materials are specified on approved work orders or tasks. You can issue or transfer reserved items individually or in batches.

#### Storerooms

When items are stocked in storerooms as inventory, they can be managed and made available for asset maintenance. You can manage details about balances, costs, bins and lots, and reordering. Issue and transfer items. Perform cycle counts and reconcile balances.

#### All Items

Add or import items and add details about items before they are added to storerooms. Details can include issue and order units, status, lot and bin information, indicator for rotating items, default vendor, commodity information, and attachments. Items automatically receive an identifier that can be edited.

Some activities are completed by an administrator in other applications. These activities include setting up security, financial processes, detailed item master information, detailed inventory information, and more complex inventory usage. Administrators can refer to the related links for more help.

- [Items](#)  
You can add or import items to your master item list on the All Items page. Items then can be added to storerooms and managed as inventory.
- [Storeroom management](#)  
Storeroom management activities involve balancing inventory availability with carrying costs.
- [Reservations](#)  
You can view and manage reservations for inventory. Reservations help prevent problems with insufficient balances in a storeroom.
- [Picking and staging inventory](#)  
To help maximize efficient movement of inventory out of storage locations, you can add inventory pick lists and issue inventory by line or by batch. Optionally, you can specify intermediate staging locations. You can monitor list status as all lines move forward through the process.

---

## Items

You can add or import items to your master item list on the All Items page. Items then can be added to storerooms and managed as inventory.

---

## Storage and uniqueness of item data

All items belong to an item set. Item sets are at a level above the level for organizations. This means that in an item set, multiple organizations can share item data. You do not see item set information unless your company uses more than one item set.

---

## Item numbering

When you add items, they are automatically numbered, but you can edit the identifiers. Identifiers must be unique at the item set level.

An administrator can specify the seeds and prefixes for automatically numbered items in the Organizations application.

---

## Specifying item details

After you add or import items, you can specify the following information:

- Units in which you issue and order items. Your administrator sets up conversion factors that convert order units to issue units.
- Status of the item. Items must be active before they can be moved to storerooms.
- Lot indicator. A lotted item has a shelf life and calculated expiration date.
- Bin identifier. The first bin that you specify becomes the default bin, but you can change it.
- Rotating item indicator. A rotating item represents a set of interchangeable assets that can be tracked as they change locations. These assets are repaired rather than replaced.
- Default vendor for restocking the item.
- Attachments, such as images, specifications, and safety data sheets.
- Commodity group and code. This information helps you to analyze product use and costs.

---

## Adding items to storerooms

Items can be added to a storeroom that you select. An administrator can limit this action so that it is available only if the storeroom is associated with control and debit GL accounts. You can add items to storerooms in the following ways:

- Add items to a storeroom on the Storerooms tab of the All Items page for a selected item.
- Add items to a storeroom that you select from the Storerooms page.
- [Importing item data](#)  
You can import data for many items by using an item import template.
- [Item statuses](#)  
An item record has various statuses during its lifecycle. You can apply a status change to an item or to the item in all storerooms in one or more organizations for the item set.
- [Condition-enabled items](#)  
To help you to track inventory costs and charges accurately, you can enable conditions on items, and then you can assign condition codes and their associated condition rates. A condition code describes the current physical condition of the item, and the rate specifies the value or cost of the item in that condition.

---

## Importing item data

You can import data for many items by using an item import template.

### About this task

---

Modify the provided template and then import your item data file. The item data file adds and replaces data. If an existing item is not included in the data file, its data is not changed. The data file must be uploaded as a .csv file.

### Procedure

---

1. On the All Items page of the Manage Inventory Work Center, select Add item > Import list.  
You can review the template help to understand the field requirements, field values, and allowed lengths.
2. In the Upload item file dialog box, select the option to download the template file.
3. Modify the file and upload it as a .csv file.
4. On the All Items page, review your imported items.

---

## Item statuses

An item record has various statuses during its lifecycle. You can apply a status change to an item or to the item in all storerooms in one or more organizations for the item set.

The default insert status of an item for all organizations in an item set is specified in the Organizations application.

### Changing the item status

---

You can change the item status on the Items page of the Manage Inventory Work Center. Then, you can apply that status to the stocked item in storerooms that belong to an organization that uses this item set.

You also can change the item status in the Item Master application. Then, you can apply that status to the stocked item in storerooms that belong to some organizations or to all organizations that use this item set. In the Item Master application, you can take one of the following actions:

Apply a change to storerooms in specified organizations

Select the Item/Organization Details action, specify the status for one or more organizations and then apply the new status to the item in inventory.

Apply a change to all storerooms in all organizations

Select the Change Status action and then apply the new status to the item in inventory.

The status of the master item record can be different from the status of an item in inventory. This difference occurs if a status change was made to the item but was not applied to the item in all inventory locations. It can also occur if the status of a stocked item was changed in the Inventory application.

---

## Item statuses

An item can have one of the following statuses:

Pending

Pending items are available only in the Manage Inventory Work Center and in the Item Master and Inventory applications. Financial transactions cannot be created for pending items, and they are not available in lookup lists.

Planning

Planning items can be referenced by work order plans, purchase orders, and purchase requisitions, but financial transactions cannot be created for them.

Active

Active items can be used in Work Centers and applications without any restrictions.

Pending Obsolescence

Pending Obsolescence items can be depleted from storerooms, but existing balances cannot be replenished.

Obsolete

Obsolete items cannot be used except to generate invoices and view for historical purposes. Items that have an obsolete status are not available in lookup lists. If you change an item to this status, the status change is also applied to the item wherever it is stocked in locations that belong to this item set. This status change cannot be reversed.

---

## Condition-enabled items

To help you to track inventory costs and charges accurately, you can enable conditions on items, and then you can assign condition codes and their associated condition rates. A condition code describes the current physical condition of the item, and the rate specifies the value or cost of the item in that condition.

As an item's physical condition changes, applying the appropriate code and rate helps you to charge or otherwise track accurate item costs. For example, a rotating item that is part of a motor assembly might cost \$5000.00 when new. That full amount is charged when the rotating item is placed into service. After several years, the item needs repair and is later reissued at a rebuilt, or 50%, cost.

Condition codes are defined at the item set level, so they are available to all items in organizations that belong to the item set. Lotted items cannot be condition-enabled.

After an item is condition-enabled, its condition is specified each time that the item is added or returned to inventory, or picked, staged, issued, or transferred. The first time that an item is added to a storeroom, its condition is specified at the 100% rate. Inventory cost transactions are recorded for each of these actions.

---

## Enabling conditions on items

Items are condition-enabled on the Detail page for an item. If you add a set of condition codes, you must add one code for the full, or 100%, rate. Other codes and values represent a percentage of the full rate or cost.

You also can add condition codes and rates in the Condition Codes application and associate them with items in the Master Item application.

When existing inventory is condition-enabled, the 100% rate is applied to that inventory.

---

## Disabling conditions on items

You can disable conditions on items unless they include codes that are being used. A code is being used if the item is in inventory with either costs or balances. If you disable conditions on an item, the codes are removed from the item, but they are available to other items in the item set. In the code list for the item, you also can remove individual codes that are not being used with the item.

---

## Purchasing condition-enabled items

Conditions can be specified in purchasing documents for condition-enabled items, so, for example, you can purchase a mix of new and rebuilt motors.

- [Adding condition codes and rates to items](#)

You can enable conditions on items and assign condition codes and the rates that describe different physical conditions of the items. An assigned code and rate help determine the item's value at that time. All conditions are measured against the value of the full, or 100%, rate.

---

## Adding condition codes and rates to items

You can enable conditions on items and assign condition codes and the rates that describe different physical conditions of the items. An assigned code and rate help determine the item's value at that time. All conditions are measured against the value of the full, or 100%, rate.

---

## About this task

Enable conditions and select or add condition codes for an item in the item Details page of the Manage Inventory Work Center. You also can add condition codes in the Condition Codes application and associate condition codes with items in the Master Item application.

Condition codes are added to an item set and are available to all items in the set.

Lotted items cannot be condition-enabled.

---

## Procedure

1. On the Items page of the Manage Inventory Work Center, select or add an item.
2. Edit the Condition-enabled tile and set the switch to Yes. Save your changes to open the Condition Codes list.
3. In the Condition Codes list, take one of the following actions:
  - Select one or more condition codes and rates for the item and save your changes. You must select one code for the 100% condition rate and you can select other codes as needed.
  - Select Add and add condition codes, then select the appropriate codes. At least one code for the 100% rate must be listed and selected for the item.For example, you select the following condition codes and rates for a tire:
  - New (condition rate is 100%)
  - Good (condition rate is 80%)
  - Fair (condition rate is 50%)
  - Poor (condition rate is 20%)

---

## Results

After an item is condition-enabled, its condition is specified each time that the item is added or returned to inventory, or staged, issued, or transferred. Referring to the example in Step 3, tires with a 100% condition rate are valued at \$300. Tires with a New condition are issued at a cost of 100% of \$300. Tires with a Good condition are issued at a cost of 80% of \$300, or \$240, and so on.

---

## Storeroom management

Storeroom management activities involve balancing inventory availability with carrying costs.

In the Storerooms page of the Inventory Management Work Center, you can add storerooms, monitor balances and availability of inventory items, record physical counts and reconcile them, and take other actions. Select a storeroom to work with its inventory.

You can manage inventory balances for a selected storeroom in the Balances tab. Add existing items and specify bin or lot, starting balance, cost type, costs, issue and order units, default bin, reorder information, and count frequency. Balances that are specified in the Reserved column include hard balances and back order balances only.

The following actions might be available to you from the Actions menu on an item row, depending on your security options:

- Edit most information for the item, including balances of non-rotating items and the default bin.
- Issue items to a work order, asset, location, or general ledger account.
- Transfer items to another storeroom or to another bin or lot in the same storeroom.
- Manage reordering. You can specify a default vendor, manufacturer, reorder point, lead time, and the order quantity that minimizes carrying costs. Your administrator can set up automated reordering processes that use this information to create purchasing records. You also can view past orders from various vendors and manufacturers.
- View information about the rotating assets that are associated with rotating items.

In the Counts tab, you can record physical counts of items that you select. You can sort the table by multiple column headers, including the due date for the count.

In the Reconcile tab, you can reconcile your most recent physical count with any transactions that have completed since that date and time. You can preview balance changes that occur from a reconcile action.

If you need to work with more storeroom features, on a storeroom card, select Open storeroom details to open the record in the Storerooms application.

## Adding items to storerooms

Items can be added to a storeroom that you select. An administrator can limit this action so that it is available only if the storeroom is associated with debit and credit GL accounts. You can add items to storerooms in the following ways:

- Add items to a storeroom that you select from the Storerooms page.
- Add items to a storeroom on the Storerooms tab of the All Items page for a selected item.
- [Issuing items](#)  
In the Inventory Work Center, you can issue items directly from a storeroom or from a list of items that are reserved in work order plans.
- [Transferring rotating items](#)  
You can transfer rotating items and their associated assets from one storeroom to another.
- [Managing reorder rules](#)  
You can specify reorder rules for items that are stocked in storerooms. Then, when the specified criteria for the rules are met, an automated reorder process can create purchasing records for the items.
- [Cycle counting your inventory](#)  
You can validate inventory balances by periodically counting a set of inventory in storerooms. Counting can help ensure that all inventory is validated at least annually and that your most valuable or most frequently used inventory is validated more often.
- [Reconciling inventory balances](#)  
In the Manage Inventory Work Center, you can help ensure accurate balances by reconciling your current inventory balances with your physical counts. This activity ensures that the final current balance includes transactions that occurred between the date and time that you saved the physical count data and the date and time that you reconcile the balances.

## Issuing items

In the Inventory Work Center, you can issue items directly from a storeroom or from a list of items that are reserved in work order plans.

## About this task

When you issue items, material use transactions are created and item costs are charged to one of several debit GL accounts. If items are issued from a reservation, the charged entity is already specified on the associated work order or task. If items are issued from a storeroom, you specify the entity to issue to, and the following rules are used to charge the associated GL account:

- When you issue items to a task or work order, the cost is charged to the GL account for the task or work order.
- When you issue items to an asset, the cost is charged to the GL account for the asset.
- When you issue items to a location that has a single asset, the cost is charged to the GL account for the asset. If more than one asset is in the location, the cost is charged to the location.
- If none of these situations apply, such as for a set of cleaning items, specify a debit GL account to be charged for the item cost.

## Procedure

Issue items in one of the following ways:

Task	Description
<b>Issue items from a storeroom</b>	<ol style="list-style-type: none"><li>1. In the Balances tab of a storeroom that is opened from the Storerooms page, select the row detail for the item and then select Issue.</li><li>2. Specify the charging entity to which the item is issued. A rotating item is always issued to a location. For a rotating item, you also need to specify identifiers for the rotating assets that this item quantity represents</li></ol>
<b>Issue reserved items</b>	<ul style="list-style-type: none"><li>• Issue a single reservation: in the Reservations tab of the Reservations page, select the row detail of the reserved item and then select Issue. A rotating item is always issued to a location. For a rotating item, you also need to specify identifiers for the rotating assets that this item quantity represents.</li><li>• Create a batch of reservations and issue the batch.</li></ul>

---

## Transferring rotating items

You can transfer rotating items and their associated assets from one storeroom to another.

### About this task

---

A rotating item that has a storeroom and balance represents the balance of a group of serialized, rotating assets. You can transfer the items to another storeroom.

### Procedure

---

1. On the Storerooms page, select the storeroom and then select the rotating item.
2. From the Actions menu on the row, select Transfer to open the Transfer to storeroom dialog box.
3. Enter information about the transfer. In the Rotating asset list, select one or more assets.  
The quantity of rotating assets that you select must match the quantity of items that you specify for the transfer.
4. Transfer the items.

---

## Managing reorder rules

You can specify reorder rules for items that are stocked in storerooms. Then, when the specified criteria for the rules are met, an automated reorder process can create purchasing records for the items.

### Before you begin

---

Reorder rules take effect after an administrator enables the automated reorder schedule in the Cron Task application and automated purchasing records in the Organizations application.

### About this task

---

You can enable automated reordering on existing storeroom items or when you add items to a storeroom. This task describes adding reorder information to an existing storeroom item, but the task is similar in both cases.

### Procedure

---

1. On the Storerooms page, select the storeroom to open the item list for the storeroom.
2. On an item row, select the Actions menu and then select Reorder rules.
3. Set the Enable reordering switch to Yes to display the reorder fields and the Vendor table.
4. Specify reorder information, including a primary vendor and the manufacturer for the vendor.  
You can view vendor and price data from past orders in the Vendor table. Listed vendors might not be primary vendors.
5. Save your changes to enable reordering.

## Cycle counting your inventory

You can validate inventory balances by periodically counting a set of inventory in storerooms. Counting can help ensure that all inventory is validated at least annually and that your most valuable or most frequently used inventory is validated more often.

### About this task

---

By default, inventory that has an overdue or nearly due count date is shown at the top of the Counts table. The count due date for an item is calculated based on the date of the last physical count in this storeroom and the count frequency.

Count frequencies often relate to the value of the items or how quickly certain items are consumed. The count frequencies can be specified manually for items in storerooms. They also can be assigned by associating an ABC type with the items in that storeroom and running the ABC analysis report in the Inventory application. The frequency values for the ABC types are specified in the Organizations application.

If an item is located in multiple bins, the Counts table shows a row for each bin. Obsolete items and items in staging bins are not included in the table.

### Procedure

---

1. On the Storerooms page, select the storeroom that has inventory that you want to count and then select the Counts tab.  
Storeroom inventory can be filtered or sorted by several criteria to help you identify which inventory to count.

2. Specify a new count value for the items that you selected and counted.  
Before you update the New count field, it shows a numerical value if the previous balance was counted but not reconciled. If the previous balance was counted and reconciled, the field shows two dashes.
3. Save your changes.

---

## Results

Saved counts are updated. Current® balances are not adjusted until balances are reconciled.

---

## What to do next

Reconcile the balances. Balances can be reconciled on the Reconcile tab of the Storerooms page. Balances also can be reconciled in the Inventory application by using the Inventory Adjustments > Reconcile Balances action. Reconciliation records any losses or gains to the GL accounts of the storeroom.

---

## Reconciling inventory balances

In the Manage Inventory Work Center, you can help ensure accurate balances by reconciling your current inventory balances with your physical counts. This activity ensures that the final current balance includes transactions that occurred between the date and time that you saved the physical count data and the date and time that you reconcile the balances.

---

## About this task

You typically reconcile inventory balances for a storeroom soon after a physical count. Sometimes a delay occurs between counting and reconciling, and during the delay, transactions, such as issues, returns, transfers, and receipts can change the current balances. You want to include these transactions with the physical count updates to get accurate current balances. You can preview balance changes that a reconcile action would cause.

Inventory items can be reconciled if they are associated with control and shrinkage GL accounts. Typically, these accounts are applied to the storeroom and all inventory added to the storeroom becomes associated with those GL accounts. If needed, you can associate inventory with the storeroom GL accounts during reconciliation.

Balances do not include staged, obsolete, or rotating items.

---

## Procedure

1. In the Manage Inventory Work Center, select a storeroom from the Storerooms page and then select the Reconcile tab.  
You can sort or filter the Reconcile table by multiple criteria, including sorting by the balance change.
2. Select a group of items to reconcile balances for or select all items.  
The Reconcile table includes a Preview section that shows the physical count balances and calculated new balances. The calculated new balances are from the physical count plus or minus transactions that occur between the date and time of the physical count and the date and time of the table refresh. You can refresh the table to see the latest changes.  
For example, yesterday, a physical count of item ITD357 was 17. Its current balance before the count was 15. Earlier today, 10 of the items were received and stocked in this storeroom. You refresh the table. The Calculated column shows a balance of 27, with an increase to the physical count of 10. When you reconcile the balance, the current balance is updated to 27.
3. Select Reconcile to accept the new balances as the current balances for the items.  
If one or more of the inventory records is not associated with the control and shrinkage GL account of the storeroom, the row has an alert indicator. Select an alert indicator to update the GL information for that row or for all rows with alert indicators. Rows that still have alert indicators when you reconcile are not updated with new current balances.

---

## Reservations

You can view and manage reservations for inventory. Reservations help prevent problems with insufficient balances in a storeroom.

Inventory can be automatically reserved when materials are specified on approved work orders or tasks. View details about inventory reservations on the Reservations page of the Manage Inventory Work Center. *Soft* reservations indicate that the reserved items are not needed at a specific time. Soft reservations do not affect available balances. *Hard* reservations indicate that material is needed by a specified date. Hard reservations affect current and available balances. *Backorder* reservations are created when a hard reservation causes the available balance in the bin to drop below zero and the option to disallow negative available balances is set in the Organizations application. Automatic reservations are specified as hard or soft based on the required date.

When you open the Reservations tab, the reservation list is filtered by time, site, and storeroom. Change the filters to show more or fewer records.

The following actions might be available to you from the Action menu on a reservation row, depending on your security options:

- Edit information such as the item type, date, and quantity.
- Issue inventory after you specify the quantity and the applicable bin or lot information. You can issue more or less than the reserved amount. If the full amount is issued, the reservation line is deleted.
- Issue rotating items after you specify the associated rotating assets in the data list. You can issue more or less than the reserved amount and you can issue from multiple bins. If the full amount is issued, the reservation line is deleted.
- Delete a reservation.

You can view information about issued items, including items that were issued from reservations, on the Issued Items tab of the Reservations page.

- [Issuing items](#)  
In the Inventory Work Center, you can issue items directly from a storeroom or from a list of items that are reserved in work order plans.
- [Returning issued items](#)  
You can return issued items to a storeroom. The Issued Items tab lists items that were issued with and without reservations.
- [Issuing, transferring, or deleting reservation batches](#)  
You can create batches of reservations and issue, transfer, or delete the batch.

---

## Issuing items

In the Inventory Work Center, you can issue items directly from a storeroom or from a list of items that are reserved in work order plans.

---

### About this task

When you issue items, material use transactions are created and item costs are charged to one of several debit GL accounts. If items are issued from a reservation, the charged entity is already specified on the associated work order or task. If items are issued from a storeroom, you specify the entity to issue to, and the following rules are used to charge the associated GL account:

- When you issue items to a task or work order, the cost is charged to the GL account for the task or work order.
- When you issue items to an asset, the cost is charged to the GL account for the asset.
- When you issue items to a location that has a single asset, the cost is charged to the GL account for the asset. If more than one asset is in the location, the cost is charged to the location.
- If none of these situations apply, such as for a set of cleaning items, specify a debit GL account to be charged for the item cost.

---

### Procedure

Issue items in one of the following ways:

Task	Description
<b>Issue items from a storeroom</b>	<ol style="list-style-type: none"><li>1. In the Balances tab of a storeroom that is opened from the Storerooms page, select the row detail for the item and then select Issue.</li><li>2. Specify the charging entity to which the item is issued. A rotating item is always issued to a location. For a rotating item, you also need to specify identifiers for the rotating assets that this item quantity represents</li></ol>
<b>Issue reserved items</b>	<ul style="list-style-type: none"><li>• Issue a single reservation: in the Reservations tab of the Reservations page, select the row detail of the reserved item and then select Issue. A rotating item is always issued to a location. For a rotating item, you also need to specify identifiers for the rotating assets that this item quantity represents.</li><li>• Create a batch of reservations and issue the batch.</li></ul>

---

## Returning issued items

You can return issued items to a storeroom. The Issued Items tab lists items that were issued with and without reservations.

---

### Procedure

1. On the Issued Items tab of the Reservations page, go to the item issue row that you want to act on.
2. Click the Return icon and specify the return quantity. Specify the lot or bin, if applicable.  
The return quantity can be less than the number that was issued.

---

### Results

When the return is saved, a return type transaction with a negative line cost is recorded for this inventory item. The affected GL accounts are the same accounts that were used in the item issue transaction. The returned items increase the item current balance.

---

## Issuing, transferring, or deleting reservation batches

You can create batches of reservations and issue, transfer, or delete the batch.

---

### Procedure

1. In the Reservations tab of the Reservations page, select one or more reservations to manage.  
You can use filter criteria to find reservations and use the multiselect check box at the top of the list to select them all.
2. In the action bar that appears, select the action to issue all or delete all of the selected reservations.  
The issue action includes the ability to transfer to another storeroom. If you choose to issue all, each reservation detail appears in sequence for you to review and specify more information. You can issue or transfer and continue, or you can skip that issue or transfer and continue. If you exit from any selection, the remaining issues are canceled.

## Results

---

Inventory issues change the inventory balances in the originating storeroom. Inventory transfers change the inventory balances in the originating and in any receiving storeroom.

---

## Picking and staging inventory

To help maximize efficient movement of inventory out of storage locations, you can add inventory pick lists and issue inventory by line or by batch. Optionally, you can specify intermediate staging locations. You can monitor list status as all lines move forward through the process.

To create a pick list, select one or more inventory reservations for a storeroom. You add pick lists for reservations on the Reservations page of the Manage Inventory Work Center. Complete any of the following tasks in pick lists:

- Select multiple item reservations and add a pick list for them. Add more reservation lines to a list as needed.
- Move list items through the different states of a pick list to indicate their position in the process. You can move list items to a Picked, Staged, or Issued state either by line or by batch. All inventory transactions have corresponding inventory usage documents.
- Use scanning technology when you are managing inventory from a bin, lot, or rotating asset list.
- Automatically select and split quantities between multiple bins, lots, or rotating assets to fulfill a needed inventory quantity, whether you are scanning or manually progressing inventory.
- Return or restock inventory by line or by batch.
- Review all state changes and transaction history for pick lists.
- [Inventory pick and stage](#)  
You can create and manage pick lists of reserved inventory in ways that model your business processes. You can issue from a picked list or from intermediate staging locations. You can work with individual lines or batched lines. The autosplit feature helps with bin and lot selection. All transactions are recorded for later review.
- [Creating and processing pick lists](#)  
You can improve storeroom management efficiency by creating lists of reserved inventory to be picked and issued. You also can specify intermediate staging locations and then issue from those locations. You can work with reservation lines individually or by batch.

---

## Inventory pick and stage

You can create and manage pick lists of reserved inventory in ways that model your business processes. You can issue from a picked list or from intermediate staging locations. You can work with individual lines or batched lines. The autosplit feature helps with bin and lot selection. All transactions are recorded for later review.

---

## Pick and stage overview

The pick and stage process starts when you select one or more inventory reservations for a storeroom and add them to a new pick list. For example, you might search for all reservations for a high priority work order, and select those reservations for a new pick list.

A pick list has several states. States are similar to statuses and correspond to phases of the pick and stage process. Each state has a tab to show items and their quantities that are in that state. A corresponding InvUseLine document that references the pick list also lists items and their quantities for each state.

In a new pick list, lines from the selected reservations are added to the Open state of a pick list and are removed from the reservations list. From the Open state, you can move your inventory in a way that matches your business processes. If you pick and stage inventory before you issue it, you select item quantities to move from the Open state to the Picked state and then to the Staged state. Unselected quantities remain in the Open state until they are acted on. If your processes are simpler, you can issue item quantities either from the Open or Picked state and any unselected quantities remain in the Open state.

---

## Pick lists

A pick list can be created for reserved items from a single storeroom. After you select reservations, you select the Create picks action to add a list for those reservation lines. The list specifies the required date for the reservations to be processed. If needed, you can add other reservations from the same storeroom to an unclosed list.

After you pick, stage, or issue quantities for items on a line, the specified quantity is moved from the Open state and the Open tab to the state and tab that matches the action that you take.

The count value on each tab is the number of reservation lines that have some or all of the quantity in that state. Partial picks or other partial moves mean that the same line can be included in the count value for more than one tab.

In the InvUseLine document, when an item's quantity is moved to another state in a pick list, its quantities for the former state and the new state are updated.

---

## Batch actions

You can work with the pick list lines individually or add several lines to a batch and work with the batch. When you work with a batch, each pick line detail appears in sequence for you to review and specify more information. You can take the action on the line and continue, or you can skip that line and continue. If you cancel the action from any line, actions on the remaining lines are canceled.

---

## Autosplit selection of inventory

When inventory is being picked, staged, or issued, the required quantity is selected from the default bin or lot. If the default bin or lot does not contain the required quantity, the selection is automatically split to other bins or lots. You can modify quantities and select different values. To refresh the original view, select Autosplit.

Whenever more than one bin or lot is required, an InvUseSplit document is created for the line to specify details about the split.

## Condition-enabled items

When a reservation specifies a condition for an item, items that meet the condition requirement are selected as you work with the list. If you need to select a different item, you can see the item conditions on the selection lists.

## Lotted items

Similar to condition-enabled items, if a lot is specified on the reservation, items that are in the specified lot are selected as you act on the item. If you need to select a different item, you can see the lot information in the selection lists.

## Removing, restocking, and returning

You can remove pick list lines that are in the Open state. This action lists the reservation lines again on the Reservations page.

You can restock inventory in pick lists that are in the Picked or Staged state. Inventory can be restocked to a different bin than the original bin. Lot and condition code cannot be changed. These actions list the reservation lines again on the Reservations page.

You can return inventory to the storeroom from the Issued state.

## Transaction history

On the Review tab of the pick list, you can view transaction history for the list items. A transaction occurs whenever list lines move from the Open state to any other state and whenever further actions are taken on the inventory.

## Pick list statuses

A new pick list has a status of Entered. The list status changes to In Progress if any list items are picked, staged, or issued. You also can change to In Progress manually.

From the In Progress status, a list can be manually changed to Completed or Canceled. Lists are changed to the Completed status automatically when quantities that are open, picked, or staged are equal to zero. Lists can be manually canceled if quantities that are picked, staged, or issued are equal to zero. Canceling a pick list returns the reservation lines to the Reservations page, where they can be acted on again.

From the Completed status, a list can be changed to In Progress, or it can be changed to Closed.

Lists that have a Closed status cannot be modified further.

## Creating and processing pick lists

You can improve storeroom management efficiency by creating lists of reserved inventory to be picked and issued. You also can specify intermediate staging locations and then issue from those locations. You can work with reservation lines individually or by batch.

## About this task

Pick lists are created from material reservations for items that originate from the same storeroom. You can sort and filter to select reservation criteria, such as required date, work order, bin, item, and quantity. Process the pick list lines individually or select several lines to process as a batch.

When using many list actions, you can select the Scan icon to scan bar codes and then scan by bin, lot, or rotating asset as applicable. For example, when you are picking items, you scan for the default bin. If there is no default bin, you are shown results either for the default lot or rotating asset. Quantities are automatically split to select bins or lots from the storeroom that fulfill the reservation requirement.

Pick lists have various states as inventory is moved through the picking and issuing process. Each state has a corresponding tab to show the inventory that is in that state. A single reservation can be split among more than one state.

## Procedure

1. On the Reservations page of the Manage Inventory Work Center, select one or more reservations for a storeroom and then select Create picks.
2. Add a description, specify the date by which the items must be issued, and create the list.  
The list is created and reservation lines are put into the Open state and are displayed on the Open tab. Reservations that are added to the pick list are removed from the Reservations list.
3. Select one of the following choices, depending on whether you want to work with single lines or with batched lines:

Option	Description
Single lines	<div>a. From the Actions menu at the end of a row, select whether to pick, stage, or issue the items.</div> <div>b. Specify the item quantity for the new item state and then select the action.</div> <div>The required quantity is selected and automatically split between bins, lots, or rotating assets. Default entities are chosen first.</div> <div>You can modify quantities and select different values. You can refresh the original view by selecting Autosplit.</div>

Option	Description
<b>Batched lines</b>	<p>a. Select list lines to create a batch. From the actions bar, select whether to pick, stage, or issue the lines. Each line opens so that you can review and update quantities. You can act on the line or skip the line.</p> <p>The required quantity is selected and automatically split between bins, lots, or rotating assets. Default entities are chosen first. You can modify quantities and select different values. You can refresh the original view by selecting Autosplit.</p>

4. Select the tab for the new inventory state and continue processing the inventory by line or by batch.  
You can restock the inventory either from the Picked or Staged state. You can return the inventory from the Issued state. All transaction history is available on the Review tab.

## Managing assets and locations

In the Manage Assets Work Center, you manage corporate assets and locations.

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, this work center is no longer available. The information that is provided here applies only to Maximo Manage 8.4 and earlier versions.

Before you can access the Manage Assets Work Center, an administrator must add you to the security group template for the Work Center. Security group templates are provided to enable access to work centers and tools and tasks.

The Manage Assets Work Center organizes asset management activities into the following pages:

### Summary

A quick view of the number of assets and locations that you have. On the Summary page, you can quickly add a single asset or location, or you can download a template file and use that file to import data about many assets or locations.

### Assets

The resources that you maintain and repair, such as equipment, machinery, or technology. Use the Assets page to manage these resources.

### Places

The locations where you store, operate, or repair your assets. Use the Places page to manage locations.

- [Assets](#)  
Assets are the resources that you maintain and repair, such as equipment, machinery, or technology. To view, add, or edit asset information, use the Assets page in the Manage Assets Work Center.
- [Locations](#)  
A location is a place where assets are operated, stored, or repaired. You can use the Places page in the Manage Assets Work Center to view, add, or edit information about locations, service addresses, or systems.
- [Configuring autonumbering for assets and locations](#)  
To automatically generate a unique identifier when a user creates an asset or location record in the Manage Assets Work Center, administrators can configure autonumbering for locations and assets.

## Assets

Assets are the resources that you maintain and repair, such as equipment, machinery, or technology. To view, add, or edit asset information, use the Assets page in the Manage Assets Work Center.

After you enter the initial details for an asset, essential information about the asset is displayed on a card on the Assets page. When you select a card, you can add, review, and edit the following information:

- A unique name and a description that identify the asset
- Location of the asset. If necessary, you can move the asset to a new site when you specify a location.
- A type to group assets that are similar so that you can search for any asset in that category. When you specify a type, you can add or edit asset types.
- Status to indicate whether the asset is not ready, active, or decommissioned
- Serial number
- Priority
- Failure class. When you specify a failure class, you can also go to the Failure Codes application to manage failure classes.
- Rotating item if the asset is associated with a rotating item
- Files or images that are attached to the asset record
- Parent asset
- A list of child assets that are related to the asset
- A history of the work orders that are associated with the asset
- [Adding asset types](#)  
In the Manage Assets Work Center, you can add asset types to organize your assets into meaningful categories for your business.
- [Importing assets](#)  
In the Manage Assets Work Center, you can upload a CSV file to import multiple assets all at once.
- [Asset import guidelines](#)  
The CSV template file that you download from the Manage Assets Work Center includes eight columns. You must provide a value for ASSETNUM. All other columns either contain a default value or are optional.
- [Moving assets](#)  
You can move an asset from one location to another location in the same site or to a location in a different site.

# Adding asset types

In the Manage Assets Work Center, you can add asset types to organize your assets into meaningful categories for your business.

## About this task

The asset type value that you add must be a unique identifier. An asset type that you add is a synonym of an internal value that is provided for asset types in the product's business logic.

You cannot add or remove internal values. However, you can create new asset type values that are based on an internal value. For example, PRODUCTION is an internal value for asset types. You can specify values, such as Turbines, HVAC, or Robotic, all of which use the internal value PRODUCTION. Your users can select the value that is the best match for their asset type.

You cannot delete an asset type if it is a default asset type. You cannot edit the asset type to remove its default status. Instead, you must designate a different type as the default asset type, which removes the original type as the default. After you save, you can delete the original asset type.

## Procedure

- 1. In the Manage Assets Work Center, select the Assets page and open an asset.
- 2. Edit the Type tile.
- 3. On the Asset Type panel, click Manage asset types.
- 4. Click Add type.
- 5. Enter the following information:

Field	Description
Asset type description	A meaningful, short description of the asset type
Asset type	A unique identifier for the asset type
Internal value	The internal value to associate with the new asset type

- 6. Click Add asset type.  
The asset type that you added is displayed in the list of asset types.
- 7. Optional: If you want to make the new asset type the default, edit the row for the asset type, select ☒ in the Default field, and save the asset type.  
The type that you designated becomes the default asset type, and the original default asset is no longer the default.
- 8. When the asset type is complete, click Done.

# Importing assets

In the Manage Assets Work Center, you can upload a CSV file to import multiple assets all at once.

## About this task

Uploading an asset file adds and replaces asset data. If an existing asset is not included in the CSV file, its data will remain unchanged.

Before you upload asset data, review the requirements for asset records. Some fields are required. Note that in most cases, the values that you specify must be uppercase alphanumeric values.

Information about the required data is provided in the template help page in the product and in [Asset import guidelines](#).

## Procedure

- 1. In the Manage Assets Work Center, select the Summary page.
- 2. On the Assets tile, click Import list.
- 3. Download the CSV template for asset data.
- 4. Review the template help and add the information about your assets to the downloaded CSV template file.
- 5. When your CSV file is complete, click Upload .csv to import the asset data.  
When the upload is complete, a message is displayed to indicate the number of records that were added.

# Asset import guidelines

The CSV template file that you download from the Manage Assets Work Center includes eight columns. You must provide a value for ASSETNUM. All other columns either contain a default value or are optional.

Table 1. Guidelines for importing asset data

Field	Description	Field Type	Max Characters	Notes
ASSETNUM	The short unique identifier of the asset.	Uppercase alphanumeric	12	This field is required.

Field	Description	Field Type	Max Characters	Notes
DESCRIPTION	The name or description of the asset.	Alphanumeric	100	Add a description to provide a meaningful reference about the asset.
LOCATION	The unique identifier of the location of the asset.	Uppercase alphanumeric	12	You must specify the unique identifier of a location that already exists in the system. Import or add all your locations first, then import assets.
PARENT	The unique identifier of the parent asset.	Uppercase alphanumeric	12	When importing assets, import parent assets first. Then import child assets and specify the unique identifier of a parent asset in this field.
STATUS	The status of the asset.	Uppercase alphanumeric		Values for asset status include <code>OPERATING</code> , <code>NOT READY</code> , and <code>DECOMMISSIONED</code> . If no status is specified, the default status <code>OPERATING</code> , which is displayed as Active in the Work Center, is applied to the asset.
ASSETTYPE	The type of the asset.	Uppercase alphanumeric		Values for asset types include <code>PRODUCTION</code> , <code>FACILITIES</code> , <code>FLEET</code> , and <code>IT</code> . You can create synonym values for asset types if needed. If you want to use a custom asset type, add the asset type before you import asset data.
SERIALNUM	The serial number of the asset.	Uppercase alphanumeric	64	
SITEID	The unique identifier of the site for the asset.	Uppercase alphanumeric	8	You must create at least one site for an organization. Sites are facilities or subdivisions in an organization where work and supply chain activities are managed. Each site can track inventory and related data separately from other sites. Sites do not have to be physical locations.  If you want to load assets for a site that is not your default site, you must supply a site ID.

## Moving assets

You can move an asset from one location to another location in the same site or to a location in a different site.

### About this task

To move assets to a different site or to a new location in the same site, use the Locations tile on the Assets page in the Manage Assets Work Center.

If you try to move an asset to a new site where an asset with that number already exists, you get an error message. You can then edit the New asset number field to add a new number for the asset that you are moving.

### Procedure

1. On the Assets page, edit the Location tile.
2. Click the Lookup icon to open the Location panel.
3. From the list of locations, select one of the following options:

Option	Description
<b>Move the asset to a new location</b>	On the Location panel, select the new location for the asset.
<b>Move the asset to a new site</b>	On the Location panel, complete the following steps: <ol style="list-style-type: none"> <li>a. Click Move to new site.</li> <li>b. Specify a new site, location, and parent.</li> <li>c. Click Move.</li> </ol>

## Locations

A location is a place where assets are operated, stored, or repaired. You can use the Places page in the Manage Assets Work Center to view, add, or edit information about locations, service addresses, or systems.

Using systems of locations and specifying the location for assets on asset records provides the groundwork for gathering and tracking valuable information about assets, including the history of the asset's movement from location to location and asset performance at specific sites.

After you enter initial details about a location, essential information about the location is displayed on a card on the Places page. When you select a card, you can use the following tabs to add, change, or view information about the location.

Tab	Description
-----	-------------

Tab	Description
Locations	<p>The Locations tab displays tiles with the following information about a location:</p> <ul style="list-style-type: none"> <li>• Service address</li> <li>• Type of location, such as operating or repair location</li> <li>• Status of the location, such as operating or decommissioned</li> <li>• GL Account that is associated with the location</li> <li>• Assets that are in this location</li> <li>• Other locations that are related to this location, such as child or parent locations</li> </ul> <p>In addition, you can perform the following actions on the tab:</p> <ul style="list-style-type: none"> <li>• Add the location to one or more systems</li> <li>• Add and edit custom location types</li> </ul>
Service Addresses	You can add, view, or change details about the physical address of the location.
Systems	You can add, view, or change the systems that organize your locations into logical hierarchies. You can also designate the primary system for a site.

## Defining locations

Defining locations is an important part of planning your asset management implementation. Locations are associated with assets and affect many asset management processes, including work management, purchasing, and asset tracking.

When planning locations, analyze the way that your teams and business segments define locations.

For some businesses, a location can be a city, a town, multiple buildings, a single building, a room in a building, or segmented parts of a room. To meet your business requirements, ask questions about why your company needs locations that are defined in these ways. You need to differentiate what is considered a location from what is considered an organization, a site, or even a storeroom. The answers to the questions can help you to build your location hierarchies. This location-related information is used with many areas of asset management, including work orders, assets, and service requests.

You can organize locations into systems, which are logical hierarchies that represent functional areas of your organization. One system in a site must be designated as the primary system. The primary system is the first system that is associated with a site and represents the primary location hierarchy for the site. If necessary, you can add other systems. The systems can be based on usage or physical qualities that locations have in common. For example, you can create an Electrical system to help you manage electrical equipment.

Analyze the types of locations that you need to manage and use that analysis to plan a successful implementation.

## Related concepts

- [Systems](#)

## Systems

A system is a group of locations that is organized into a logical hierarchy of parent and child locations to help you track assets and manage work more effectively.

You can use systems to categorize the use or physical qualities of locations and to build a hierarchy of locations within a site. For example, a system can represent a group of buildings at a site or even the whole site.

A site can have multiple systems, but one system in the site must be designated as the primary system. The first system that is associated with a site is automatically the primary system, but you can designate a different system as the primary system if necessary. The primary system must be hierarchical, meaning that there is a parent-child relationship between each location in the system.

Consider the following factors when you add locations to systems.

### Location Type

Each location has a location type. Location types are associated with internal type values that are provided for locations in the product's business logic. For example, OPERATING and SALVAGE are internal type values in the business logic. You cannot add or remove internal values. However, you can create new location type values that are associated with an internal value.

For example, you might specify custom values, such as Datacenter or Warehouse, and associate them with the internal value OPERATING. Then, your users can select the value that is the best match for their location type.

Only locations that have a type that is based on the internal value OPERATING can be assigned to systems.

#### Parent-child Relationships

The first location that is added to a system is the top-level location in the system.

The second location that is added becomes the child to the top-level location.

Any location that is added later must be a child to the top-level location or to another location that exists in the system.

A location can belong to more than one system. When a location belongs to more than one system, it can have a different parent in each system. However, within a system, a location can have only one parent.

## Location import guidelines

The CSV template file that you download from the Manage Assets Work Center includes ten columns for importing locations data.

You must provide a value for the LOCATION and SITEID columns. For columns that are optional, a default value is supplied if you do not provide a value. For columns that are conditional, values are required under specific conditions, which are described in the notes in the following table.

Table 1. Guidelines for importing location data

Field	Description	Field Type	Required	Max Characters	Notes
LOCATION	The short unique identifier of the location.	Upper case alphanumeric	Required	12	
DESCRIPTION	The name or description of the location.	Alphanumeric	Optional	100	Add a description to provide a meaningful reference to the location.
TYPE	The type of the location.	Uppercase alphanumeric	Optional	16	Values for location type include REPAIR, OPERATING, and HOLDING. If no location type is specified, the default value OPERATING is applied to the location. You can specify only one HOLDING location per site.
STATUS	The status of the location.	Uppercase alphanumeric	Optional	20	Values for location status include ACTIVE, NOT READY, and DECOMMISSIONED. If no status is specified, the default status ACTIVE is applied to the location.
SITEID	The unique identifier of the site for the location.	Uppercase alphanumeric	Required	8	Site ID of the location to be added or modified. Sites are facilities or subdivisions in an organization where work and supply chain activities are managed. Each site can track inventory and related data separately from other sites. Sites do not have to be physical locations.
LOCHIER_LOCATION	The unique identifier of the location that you are adding or modifying.	Uppercase alphanumeric	Conditional	12	The unique identifier of the location within the system hierarchy. When you add a location to a system or change the parent of a location in a system, you must provide a value in this field. The value must be the same value that is specified in the LOCATION field.
LOCHIER_SITEID	The unique identifier of the site that you are assigning the location to.	Uppercase alphanumeric	Conditional	8	When you add a location to a system or change the parent of a location in a system, you must provide the Site ID of the location that you specified for LOCATION.
LOCHIER_SYSTEMID	The unique identifier of the system that you are assigning the location to.	Uppercase alphanumeric	Conditional	12	When you add a location to a system or change the parent of a location in a system, you must provide the System ID of the location that you specified for LOCATION.
LOCHIER_PARENT	The unique identifier of the parent that you are assigning the location to.	Uppercase alphanumeric	Conditional	12	If the location that you are adding is the first location in a system, do not provide a value for this attribute. By default, the first location that you add becomes the top-level location, which has no parent. For other locations that you add, you must specify a parent location.
LOCHIER_NEWPARENT	The unique identifier of the new parent that you are assigning the location to.	Uppercase alphanumeric	Conditional	12	When you assign an existing location in a system to a different parent location that already exists in the system, specify a value for the LOCHIER_NEWPARENT attribute. Assigning a new parent removes the original parent assignment of the location.

## Adding locations to systems

In the Manage Assets Work Center, you can add operating locations to systems.

## About this task

Only locations that have a type that is based on the internal value of OPERATING can be assigned to systems.

Because there can be only one top-level parent location in a system, in most cases, when you add a location to a system, you must also specify a parent for the location. After you select a system, a list of the locations in that system is displayed, and you can select a parent for the location that you are adding.

## Procedure

1. On the Locations tab of the Places page, select the card for the location that you want to add to a system.
2. In the Relationship section of the card details page, click Add to system.
3. From the System list, select the system that you want to add the location to.
4. From the Location list, which appears after the system is selected, select the parent location that you want to add this location to.  
The parent that you select is displayed in the Relationship section.

## Related concepts

- [Systems](#)

## Adding location types

On the Places page in the Manage Assets Work Center, you can add location types to organize your locations into meaningful categories for your business.

## About this task

Each custom type that you add is a synonym of an internal value that is provided for location types in the product's business logic.

You cannot add or remove internal values. However, you can create new location type values that are based on an internal value. For example, OPERATING is an internal value for location types. You can specify values, such as Warehouse, Datacenter or Office, all of which use the internal value OPERATING. Your users can select the type that is the best match for their location. The same rules that apply to locations of type OPERATING also apply to locations with the type Warehouse, Datacenter or Office.

The following business rules apply to location types that you create:

- You cannot delete a location type if it is a default location type.
- You cannot delete a location type if it is associated with any location record.
- You cannot edit a location type to remove its default status. Instead, you must designate a different type as the default location type, which removes the original type as the default. After you save, you can delete the original location type.

The location type value that you add must be a unique identifier.

## Procedure

1. In the Manage Assets Work Center, select the Places page and open a location.
2. Edit the Type tile.
3. On the Location Type panel, click Manage location types.
4. Click Add type.
5. Enter the following information:

Field	Description
Location type description	A meaningful, short description of the location type
Location type	A unique identifier for the location type
Internal value	The internal value to associate with the new location type

6. Click Add location type.  
The location type that you added is displayed in the list of location types.
7. Optional: If you want to make the new location type the default, edit the row for the location type, select ▾ in the Default field, and save the location type.  
The type that you designated becomes the default location type, and the original default location is no longer the default.
8. When the location type is complete, click Done.

## Location import guidelines

The CSV template file that you download from the Manage Assets Work Center includes ten columns for importing locations data.

You must provide a value for the LOCATION and SITEID columns. For columns that are optional, a default value is supplied if you do not provide a value. For columns that are conditional, values are required under specific conditions, which are described in the notes in the following table.

Table 1. Guidelines for importing location data

Field	Description	Field Type	Required	Max Characters	Notes
-------	-------------	------------	----------	----------------	-------

Field	Description	Field Type	Required	Max Characters	Notes
LOCATION	The short unique identifier of the location.	Upper case alphanumeric	Required	12	
DESCRIPTION	The name or description of the location.	Alphanumeric	Optional	100	Add a description to provide a meaningful reference to the location.
TYPE	The type of the location.	Uppercase alphanumeric	Optional	16	Values for location type include REPAIR, OPERATING, and HOLDING. If no location type is specified, the default value OPERATING is applied to the location. You can specify only one HOLDING location per site.
STATUS	The status of the location.	Uppercase alphanumeric	Optional	20	Values for location status include ACTIVE, NOT READY, and DECOMMISSIONED. If no status is specified, the default status ACTIVE is applied to the location.
SITEID	The unique identifier of the site for the location.	Uppercase alphanumeric	Required	8	Site ID of the location to be added or modified. Sites are facilities or subdivisions in an organization where work and supply chain activities are managed. Each site can track inventory and related data separately from other sites. Sites do not have to be physical locations.
LOCHIER_LOCATION	The unique identifier of the location that you are adding or modifying.	Uppercase alphanumeric	Conditional	12	The unique identifier of the location within the system hierarchy. When you add a location to a system or change the parent of a location in a system, you must provide a value in this field. The value must be the same value that is specified in the LOCATION field.
LOCHIER_SITEID	The unique identifier of the site that you are assigning the location to.	Uppercase alphanumeric	Conditional	8	When you add a location to a system or change the parent of a location in a system, you must provide the Site ID of the location that you specified for LOCATION.
LOCHIER_SYSTEMID	The unique identifier of the system that you are assigning the location to.	Uppercase alphanumeric	Conditional	12	When you add a location to a system or change the parent of a location in a system, you must provide the System ID of the location that you specified for LOCATION.
LOCHIER_PARENT	The unique identifier of the parent that you are assigning the location to.	Uppercase alphanumeric	Conditional	12	If the location that you are adding is the first location in a system, do not provide a value for this attribute. By default, the first location that you add becomes the top-level location, which has no parent. For other locations that you add, you must specify a parent location.
LOCHIER_NEWPARENT	The unique identifier of the new parent that you are assigning the location to.	Uppercase alphanumeric	Conditional	12	When you assign an existing location in a system to a different parent location that already exists in the system, specify a value for the LOCHIER_NEWPARENT attribute. Assigning a new parent removes the original parent assignment of the location.

## Configuring autonumbering for assets and locations

To automatically generate a unique identifier when a user creates an asset or location record in the Manage Assets Work Center, administrators can configure autonumbering for locations and assets.

### About this task

After you set up autonumbering, when a user creates a record, the record identifier field begins with the seed value that you specify as a starting point. Each time a record is added, the autonumber is incremented by one.

### Procedure

1. In the Organizations application, select the organization for which you want to set up autonumbering.
2. From the More Actions menu, select the Autonumber Setup action and choose the Site Level option.
3. In the Site Level window, select the site that you want to specify autonumbers for.
4. In the Autonumber for Site table, click New Row.
5. In the Autonumber Name field, search for the attribute that you want to autonumber.  
For example, you can search for asset to find the assetnum attribute.
6. In the Seed field, specify the value for the starting point for the numbering.
7. Optional: To display a value before the autonumber, specify a value for prefix.  
For example, AN, for asset number, can precede the autonumber.
8. Click OK.

## Work Supervision Work Center

The Work Supervision Work Center facilitates the work management activities of supervisors. As a supervisor, you can manage the workload of technicians and assign owners to the work.

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, this work center is no longer available. The information that is provided here applies only to Maximo Manage 8.4 and earlier versions.

Before you can access the Work Supervision Work Center, an administrator must add you to the security group template for the Work Center. Security group templates are provided to enable access to work centers and tools and tasks.

The Work Supervision Work Center organizes your activities into three main pages: Work Progress, Closed Work, and Review Service Requests.

## Work Progress

Work supervisors create and manage work orders on the Work Progress page.

The Work Progress page displays a card for each work order. The page organizes your work orders into four sections that correspond to the tasks you perform as the work progresses through its lifecycle. On laptops and tablets, the sections are sequential, and a work order progresses through its lifecycle from approving work to completing work.

The following table summarizes the tasks that you can perform in each section.

Section	Description
Approve Work	<p>The Approve Work section displays work orders that are not approved.</p> <p>When you review work orders, you can complete the following actions:</p> <ul style="list-style-type: none"><li>• Quickly approve a work order directly from a card after you review the description of the problem, the priority, the location, and when the work is scheduled to start</li><li>• Add details to the work plan, such as the tasks, labor, items, tools, or services that are needed to complete the work</li><li>• Assign an owner or owner group to the work order</li><li>• Assign labor and crafts</li><li>• Add comments to communicate with your technicians</li><li>• Add attachments</li></ul>
Assign Owner	<p>The Assign Owner section displays work orders that are not assigned to an owner or owner group.</p> <p>You can specify an owner or owner group. The owner can then access the work order in the Work Execution Work Center.</p>
Monitor Work	<p>The Monitor Work section displays work that is assigned to an owner or owner group.</p> <p>You can monitor work orders that are in progress. You can view when the work started and the scheduled finish time, and you can add comments to communicate with the owner of the work order.</p>
Close Work	<p>The Close Work section displays work that your technicians completed.</p> <p>When a work order is completed, you can close the work order, or you can select multiple work orders to close. Before you close the work order, you can review the work details that technicians reported, such as the time that was spent and the items, materials, tools, and services that were used.</p> <p>You can also approve outstanding labor transactions and create labor transactions for your technicians. If required, you can create follow-up work.</p>

You can expand each section to full screen mode.

After you expand the sections, you can choose to display work orders in either a card format or a list format.

When work orders are in list format, you can select multiple records and apply actions to them. For example, you can select 10 work orders and approve them in one action.

## Closed Work

When work is completed and you close the work order, you can review all work orders that you closed on the Closed Work page. You can also view any work that was canceled.

## Review Service Requests

On the Review Service Requests page, you review requests and then create work orders for service, provide comments to the requester, or close requests. The page provides search capability and the ability to filter and sort service requests.

- [Work order management](#)  
In the Work Supervision Work Center, a card displays essential information about each work order. You can select the card to view, enter, or update details about the work.
- [Work orders and job plans](#)  
As a supervisor, you can add job plans to work orders that you create in the Work Supervision Work Center.
- [Work orders and inspections](#)  
As a supervisor, you can add inspections to work orders that you create in the Work Supervision Work Center.
- [Creating work orders](#)  
Work supervisors create work orders on the Work Progress page in the Work Supervision Work Center.
- [Reviewing service requests](#)  
As a supervisor, you can review service requests on the Review Service Requests page in the Work Center and create work orders to fulfill requests.

## Work order management

In the Work Supervision Work Center, a card displays essential information about each work order. You can select the card to view, enter, or update details about the work.

To create work orders for assets and locations, click Create work on the Work Progress page and enter information about the work.

After you enter initial details about the work and save the work order, you can use the additional tiles on the Details tab and extra tabs to add other information about the work. Each tab displays the tiles and action features that help you manage technicians and work orders, as shown in the following table.

Tab	Description
Details	<p>You can view, add, or edit the following important information about the work:</p> <ul style="list-style-type: none"><li>• Details about the work's status, priority, and type of work</li><li>• Assets that are associated with the work</li><li>• Locations and the site that are associated with the work</li><li>• Problems and failures that are associated with the work</li><li>• Job plan that is associated with the work</li><li>• Inspections that are associated with the work</li><li>• Site address</li><li>• Schedule for the work, including scheduled start and finish dates, target start and finish dates, and duration of the work</li><li>• Related records, such as follow-up work orders, parent or child work orders, and the originating record</li><li>• Responsible parties for the work, including the person who reported it, the technician or group that owns it, and the supervisor or lead who manages the work</li></ul>
Inspections	You can view inspections that are associated with this work order.
Plans	You can add tasks, labor, items and materials, services, and tools that are required to complete the work.
Assignments	You can use Assignments as an alternative way to find labor for a work order if you do not want to use the Owner or Owner Group features. Assignments are a more powerful way to assign work. Using Assignments, you can add crews and you can assign multiple labors to a job, for example, crafts with different craft and skill levels. Assignments also use a labor's shift and calendar to determine availability.
Comments	You can add comments to communicate with your technician about the work.
Attachments	You can add attachments, such as pictures or other files.
Reported Work	<p>You can review the work that was reported by the technician.</p> <ul style="list-style-type: none"><li>• Time that was spent completing the work</li><li>• Items or materials that were used</li><li>• Tools that were used</li><li>• Services that were used</li><li>• Reported failures and information about problems, causes, and remedies</li></ul> <p>If necessary, you can add time to the work order.</p>

---

## Work orders and job plans

As a supervisor, you can add job plans to work orders that you create in the Work Supervision Work Center.

Job plans that are used in the Work Supervision and Work Execution Work Centers are created in the Job Plans application.

In the Work Supervision Work Center, supervisors can add job plans to work orders on the Job Plan tile that is available when a work order is created. When a job plan is associated with a work order, the Plans tab displays information about tasks, labor, items, services, and tools that are associated with the work. Supervisors can also add tasks, labor, items, services, and tools if necessary.

For more information about creating job plans, see the documentation for the [Job Plans application](#).

---

## Work orders and inspections

As a supervisor, you can add inspections to work orders that you create in the Work Supervision Work Center.

Inspections that are used in the Work Supervision and Work Execution Work Centers are created with the Manage Inspection Forms tool.

In the Work Supervision Work Center, supervisors can add inspections to work orders on the Inspections tile, which is available after a work order is created and saved. Supervisors can also associate a specific inspection form with the tasks that they add on the Plans tab.

When an inspection is associated with a work order, an Inspections tab is displayed for that work order in the Work Supervision and Work Execution Work Centers. Supervisors and technicians can view information about the inspection and, if necessary, launch an inspection to complete the work.

For more information about creating inspections, see [Manage Inspection Forms tool](#).

---

## Creating work orders

Work supervisors create work orders on the Work Progress page in the Work Supervision Work Center.

## About this task

When you click Create work on the Work Progress page, you can enter essential details about the work. After you save the work order, a number is assigned to the work order, and you can enter more details about the work.

## Procedure

1. Click Create work and enter the essential details about the work, such as status, scheduling information, and related records.
2. Save the work order.  
A number is assigned to the work order, and additional tiles and tabs are available.
3. Add more details, such as information about failures, problems, and inspections. On the tabs, enter information, such as plans, comments, and attachments.

## Reviewing service requests

As a supervisor, you can review service requests on the Review Service Requests page in the Work Center and create work orders to fulfill requests.

The Review Service Requests page displays service requests for your default site. If necessary, you can choose to view service requests for all sites.

From the Review Service Requests page, you can use the multi-select feature to perform the following actions on the service requests that you select:

- create work orders
- change the status of the service request
- assign an owner or owner group

When a service request is canceled, the status on the Originating Record tile on the Details tab of a work order is updated. You can check the status to determine whether to create a work order or to cancel one that you already created.

## Work Execution Work Center

As a maintenance technician, you can use the Work Execution Work Center on a computer or mobile device to manage work orders that you own.

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, this work center is no longer available. The information that is provided here applies only to Maximo Manage 8.4 and earlier versions.

Before you can access the Work Execution Work Center, an administrator must add you to the security group template for the Work Center. Security group templates are provided to enable access to work centers and tools and tasks.

The Work Execution Work Center organizes your work orders and displays them on tabs that are based on due dates: Overdue, Today, Tomorrow, Next 3-5 Days, Completed, and All.

Each work order card displays the most essential information about the work. Select a card to open a work order. When you open a work order, several tabs organize the tasks that are needed to review and manage the work order: Details, Inspections, Plans, Comments, and Attachments. Each tab displays the tiles and action features that help you complete your work.

When you select Start on a card to begin work, the work order's status changes to in progress, and the timer tracks the time that you spend resolving the issue. You can stop and restart the timer if needed.

The following table summarizes the tasks that you can perform in each tab.

Tab	Description
Details	<p>You can add details or view important information about the work, including status, priority, the assets and locations that are associated with the work, work schedule, and other related records.</p> <p>You can also perform the following actions:</p> <ul style="list-style-type: none"><li>• Create follow-up work orders</li><li>• Report asset downtime</li><li>• Enter meter readings for assets and locations</li><li>• Select Report Work to report the following information:<ul style="list-style-type: none"><li>◦ The actual time that you spent completing the work</li><li>◦ The items or materials that you used</li><li>◦ The tools that you used</li><li>◦ Any failures and information about problems, causes, and remedies</li></ul></li></ul>
Inspections	You can view inspections that are associated with this work order and, if necessary, complete an inspection as part of the work.
Plans	You can review work plans, which can include the tasks, items and materials, and tools that are required to complete the work.
Comments	You can add comments to communicate with your supervisor about the work.
Attachments	You can add attachments, such as pictures or other files.

When all work is done, you can change the status of the work order to completed. Completed work orders are reviewed and closed by the supervisor.

- [Creating work orders](#)  
If your administrator gives technicians the ability to create work orders, you can create a work order in the Work Execution Work Center.

---

## Creating work orders

If your administrator gives technicians the ability to create work orders, you can create a work order in the Work Execution Work Center.

### About this task

---

If your administrator configures the Work Center to allow technicians to create work orders, you can click Create work and enter essential details about the work. After you save the work order, a number is assigned to the work order, and you can enter more details about the work.

Administrators can also configure the Work Center to display work that you create in a separate tab.

### Procedure

---

1. Click Create work and enter the essential details about the work, such as priority, assets or locations that are associated with the work, and scheduling information.
2. Save the work order.  
A number is assigned to the work order, and additional tiles and tabs are available.
3. Add more details, such as information about failures and problems, service addresses, and follow-up work orders. On the tabs, enter information, such as plans, comments, and attachments.

---

## Work Center Configuration

Business analysts and administrators can evaluate business requirements and configure the top-level information for the Work Supervision and Work Execution Work Centers to make them more specific to certain user roles.

### Getting started

---

You can log in to a Work Center and enter Design mode to see a representation of that Work Center. When you hover on parts of the Work Center, configurable elements are outlined. You can configure the following parts the Work Execution Work Center and the Work Progress page of the Work Supervision Work Center:

- Header elements, such as the name of the Work Center and the display name.
- The subheader in Work Execution.
- The subset of cards that each panel or tab can display.
- Field labels and attributes in cards.

After you configure the content, you can save configurations as a draft version and save comments to your draft version. The next time that you open the Work Center in Design mode, you can view or modify the saved draft. When you're finished making changes, you can add comments about the version and publish the configured Work Centers to your users. You also can delete the saved draft and start from the most recent published version. Version history is available to view.

### A few other things to know

---

- One person at a time can configure a Work Center, because changes might be overwritten or not saved.
- The configuration features are supported on desktops and notebooks that have a recent Chrome browser. They are not supported on tablets or smartphones or with other browsers.
- Configuration changes are available in the base language only.
- [Configuring header information](#)  
You can configure the text for header elements in the Work Centers. Header elements are the display name of the Work Center and the header label.
- [Configuring panel or tab information](#)  
You can configure or hide several types of information in panels or tabs of the Work Centers.
- [Configuring cards](#)  
You can configure cards on a panel or tab of the Work Execution or Work Supervision Work Center to [hide and show field labels and attributes](#), [change field labels](#), or [replace field attributes or labels and attributes](#).
- [Saving and publishing configurations](#)  
As you configure a Work Center, you can save your changes. After you review your changes, publish the Work Center so that the configuration changes are available to your users.
- [Viewing revision history](#)  
You can view information about the revisions to the Work Center, including the current draft version, the current published version, and previously published versions.

---

## Configuring header information

You can configure the text for header elements in the Work Centers. Header elements are the display name of the Work Center and the header label.

### About this task

---

- Configuration changes that you make to the header label and the Work Center display name are available immediately. They do not need to be published.

- You can delete the text for the header label if you don't want to show a label.
- Changes that you make to the display name of the Work Center appear to all users of that Work Center and appear in the list of Work Centers in the Go To menu.

## Procedure

---

1. In the Work Execution or Work Supervision Work Center, click Edit to enter Design mode.
2. Select the header label or display name to open the Configure workspace component dialog box. Edit the text and save your changes.

- **Configuring subheader information**

In the Work Execution Work Center, you can configure the label that says Work Orders.

## Configuring subheader information

In the Work Execution Work Center, you can configure the label that says Work Orders.

## Procedure

---

1. In the Work Execution Work Center, click Edit to enter Design mode.
2. Select the Work Orders text to open the Configure component dialog box.
3. Make any of the following changes and then save them:
  - Edit the Label text. Label text is required, even if the label is hidden.
  - Hide or show the label by setting Display to Off or On.

## Configuring panel or tab information

You can configure or hide several types of information in panels or tabs of the Work Centers.

## About this task

---

The records that are displayed in the six work panels in the Work Execution Work Center and the four tabs in the Work Supervision Work Center are derived from queries. You can edit the applied query for a panel or tab to show different record results. For example, you can configure a panel in the Work Execution Work Center to show only emergency work orders that are due within the next four hours.

The product is delivered with each panel and tab configured with an object structure query and REST query. If you configure a panel or tab to use different queries or types of queries and save the change, the default information is removed. You can retrieve copies of the default queries by clicking Get help and reviewing the REST query document.

## Procedure

---

1. In the Work Execution or Work Supervision Work Center, click Edit to enter Design mode.  
You can make any of the following changes:
  - Hide or show the display of a panel or tab by setting Display to Off or On. If a panel or tab is hidden, a strikethrough mark is shown on the label text in Design mode. If the change is published, the other panels or tabs resize to take more space.
  - Edit the panel or tab name. A name is required, even if the panel or tab is hidden.
  - Edit the query that selects the content that is shown in a panel or tab. A help document that contains examples is available for these queries by selecting Get Help.  
Select one the following queries or combination of queries:
    - Object structure query  
Displays content from the object structure that is applicable to a user of this Work Center. You can select a different query from the list.
    - Saved query  
Select from a public query for work orders, including queries for the Quick Reporting application. To view more information about a public query, click Launch to open the associated application. Then, view public queries on the List tab.
    - REST query  
Retrieves and filters records based on parameters that you specify. You can test the REST query before you save it.
    - Object structure and REST query  
A combination of the object structure query and the REST query. You can test the REST query before you save it.
    - Saved and REST query  
A combination of the Saved and the REST query. You can test the REST query before you save it.
2. Save your changes.

## Configuring cards

You can configure cards on a panel or tab of the Work Execution or Work Supervision Work Center to [hide and show field labels and attributes](#), [change field labels](#), or [replace field attributes or labels and attributes](#).

## Before you begin

---

1. In the Work Execution or Work Supervision Work Center, click Edit to enter Design mode.
2. In a panel or tab, select the representation of the card to open the Design card dialog box.

## About this task

---

- In the Work Execution Work Center, you work with one card for all tabs in the Work Center. In the Work Supervision Work Center, you work with one card for each panel in the Work Center.
- Some fields consist of a label and a field value, or *attribute*. Other fields consist of the attribute only. When you configure different elements on a card, you might work with different configuration dialog boxes. In the following tasks, these dialog boxes are described generically as "the configuration dialog box."
- Image attributes and card actions are not currently configurable.

## Hiding or showing field labels or attributes

---

Hidden fields are shown in Design mode with a strikethrough style. If the change is published, other fields move to take the space.

### Procedure

1. Select a field in the card to open the configuration dialog box.
2. Set the Display control to Off or On.
3. Click OK to close this dialog box.
4. In the Design card dialog box, save your changes.

## Changing field labels

---

The first label changes that you want to make available to users must be published. Subsequent changes are made available to users when the changes are saved. They do not need to be published.

### Procedure

1. Select a field label in the card to open the configuration dialog box.
2. In the Label field, edit the text.  
If the field also has an attribute, you also can delete the label text so that only the associated attribute value is displayed on the card.
3. Click OK to close this dialog box.
4. In the Design card dialog box, save your changes.

## Replacing field labels and attributes or field attributes

---

In some fields, you can replace both labels and attributes. In other fields, you can replace only attributes. Examples of attribute-only fields include statuses and work types.

The Objects list includes the WORKORDER object and child objects that have a 1:1, or *single cardinality*, relationship with the WORKORDER object. For example, a work order can be associated with one location.

### Procedure

1. In the Objects list, select the WORKORDER object or an object that has a relationship with the WORKORDER object.  
You can expand or narrow the selection scope by setting the Show only required database fields control to Off or On.
2. If a selected child object has more than one relationship to the WORKORDER object, select the appropriate relationship in the Relationships list.
3. In the Search for field value field, enter a term to search field and attribute names and descriptions.
4. In the Fields list, select and drag a field to replace a field in the card and save your changes.

### Example

In the following example, you are configuring a card for a work supervisor. This work supervisor approves PM work orders and often wants to know the identifier of the originating PM record. You want to replace the Location field label and attribute with the PM field label and attribute.

1. In the Work Supervision Work Center, you enter Design mode and select the card in the Approve Work panel. The Design card dialog box opens.
2. You narrow the selection scope by setting the Show only required database fields control to On.
3. In the Objects list, select the child PM object. The Relationships list includes one relationship for PM. You select the Information icon to learn more about the relationship.
4. In the Search for field value field, you enter "pmnum" and search.
5. In the Fields list, you select the PM field. You select the Information icon to learn more about the field. This field is the field that you want on the card, so you select PM and drag it to replace the Location field in the card.
6. You save your changes.

---

## Saving and publishing configurations

As you configure a Work Center, you can save your changes. After you review your changes, publish the Work Center so that the configuration changes are available to your users.

## About this task

As you work in various configuration dialog boxes, you can save changes to the draft Work Center. All saved, unpublished changes accumulate in this draft. When you publish the draft, it becomes the active version, and the previous active version becomes an inactive version.

## Procedure

1. In the Work Execution or Work Supervision Work Center, click Edit to enter Design mode.
2. Click Manage to open the Manage Work Center configuration dialog box.
3. Select one of the following options:

Option	Description
<b>View revision history</b>	Opens the Work Center design history dialog box, where you can review data and remarks about each revision and delete the current draft. The active version is the published version. Inactive versions are previously published versions.
<b>Save as draft</b>	Opens the Save your Work Center dialog box, where you can enter and save comments about the draft.
<b>Publish as active Work Center</b>	Opens the Publish your Work Center dialog box, where you can enter comments about the version and then publish it as the active version. The active version is available to your users.
<b>Exit design</b>	Exits Design mode without publishing. If you made changes and want to enter comments about them, select Save as draft before you exit.
<b>Close</b>	Closes the dialog box and returns you to the Work Center in Design mode.

## Viewing revision history

You can view information about the revisions to the Work Center, including the current draft version, the current published version, and previously published versions.

## Procedure

Select **Manage** > **View revision history** to open the Work Center design history dialog box. Depending on the configuration activity in this Work Center, you might see any of the following revision statuses:

### Draft

The version of the Work Center that contains unpublished changes to the active version. A draft is viewable in Design mode only. A Work Center can have one draft version. The draft can be deleted.

### Active

The version of the Work Center that is active to your users. This Work Center is visible when you leave Design mode. A Work Center can have one active version.

### Inactive

The previous active versions of the Work Center. The most recent one was replaced by the active version. A Work Center can have multiple inactive versions.

## Managing inspection forms

In the Manage Inspection Forms tool, you create inspection forms by adding questions and defining responses. The inspection forms that you create are then available to inspectors in the Conduct an Inspection tool.

Before you can access the Manage Inspection Forms tool, an administrator must add you to the security group template for the tool. Security group templates are provided to enable access to work centers and tools and tasks.

When you create an inspection form, the form is added to the form library in draft status. You can add optional or required questions and define the type of answers, such as text, numbers, meters, attachments, or selectable options that you can choose as a valid answer. You can also provide extra instructions for the inspector, and you can group questions together. You can also specify a type for the form, such as a condition assessment or inspection.

You can add conditions to the response fields of existing questions on inspection forms to gather more information. You can determine which additional response fields appear to inspectors, depending on the answers they gave to inspection form questions. For example, a question might ask, "Is corrosion present?" If the response is yes, another question might ask, "What percentage of the area has corrosion?"

When you complete the draft form, you can change the form to active status. Activated forms are then available to use for inspections. You can also revise forms to change existing information. While the form is pending revision, the current active version is still available for use by the inspector.

When you complete an inspection form, you can view the asset, location, work order, and inspection details that are associated with the work.

You configure the REP\_INSPRESULTFORM object structure so that users can create reports from inspections.

When inspections are completed, you can review the results. To view the results of a completed inspection, in the Go To menu, select Conduct Inspections and then select the Completed tab.

Because inspection forms can become complex with many form questions and conditions, the Manage Inspections Forms tool is best viewed on a full-sized screen.

- [Creating inspection forms](#)  
You can create inspection forms that detail the questions and types of responses that you want to collect. The inspection forms that you create are then available to inspectors in the Conduct an Inspection tool.
- [Revising inspection forms](#)  
You can create revisions of active inspection forms from the Inspection Form Library.
- [Adding conditions to inspection form responses](#)  
You can add conditions to the response fields of existing questions on inspection forms to gather more information. You can determine which additional response fields appear to inspectors, depending on the answers they gave to inspection form questions.
- [Duplicating inspection forms](#)  
If you want to reuse an existing inspection form as a template for a new form, you can duplicate the form and then add or remove questions and instructions.
- [Associating inspections with work records](#)  
After you create inspection forms, you can associate them with assets, locations, and work orders.
- [Configuring actions for inspections](#)  
By using automation scripts, system administrators can define custom actions that are available to inspectors and inspector supervisors when they complete an inspection.
- [Enabling voice-guided inspections](#)  
You enable the voice inspection feature so that inspectors can complete hands-free inspections on a mobile device. The inspection form is read aloud to the inspector and the inspector's verbal responses are recorded in the inspection form.

---

## Creating inspection forms

You can create inspection forms that detail the questions and types of responses that you want to collect. The inspection forms that you create are then available to inspectors in the Conduct an Inspection tool.

### Procedure

---

1. In the Manage Inspection Forms tool, click Create Form.
2. Enter a name for the form.
3. Enter a form type. For example, select condition assessment.
4. Click Form Instructions to add any specific instructions for inspectors to the inspection form. Click Save.
5. Click Add Question. In the Question field, enter the question that you want to add to the inspection form. For example, to record an odometer reading, enter `What is the odometer reading?`.
6. From the Response Fields menu, choose the type of response that you want the inspector to record for that question. For example, if you want the inspector to record the time and date of the reading, select Date/Time.
7. If you want a response to be required, set Required to Yes.
8. Enter an example of the response you want to see for inspectors to reference.
9. Optional: Choose multiple options from the Response Fields menu for a single question. For example, select Meter Readings to give the inspector a location to record the odometer reading.
10. When you have finished adding the response fields for the question, click Done.
11. Optional: Add more questions to the form.
12. Click Save to save the inspection form.

### What to do next

---

- To make the inspection form available to inspectors, you must change the status of the form to Active. In the Inspection Form Library, click the Draft switch to activate the form.
- You can associate the inspection form with specific assets and locations. In the Assets or Locations application, select the record, and choose Associate Inspection Form from the Actions menu.

---

## Revising inspection forms

You can create revisions of active inspection forms from the Inspection Form Library.

### Procedure

---

1. In the Manage Inspection Forms tool, in the Inspection Form Library, select the inspection form that you want to revise.
2. On the Revision History page, click Create Revision.  
The new revision line appears in the revision list.
3. Click the pencil icon for the revision line that you want to edit.
4. Edit the inspection form. You can change the form type, or add and delete questions and instructions.
5. When you're finished making your changes, click Save.
6. Click the preview icon to review the form.

### What to do next

---

To replace the existing inspection form, you must change the status of the form to Active. From the Inspection Form Library, click the Draft switch to activate the form.

---

## Adding conditions to inspection form responses

You can add conditions to the response fields of existing questions on inspection forms to gather more information. You can determine which additional response fields appear to inspectors, depending on the answers they gave to inspection form questions.

### About this task

---

Conditions can only be added to responses on existing form questions that are defined as single choice response or characteristic meter readings. The inspection form must be in Draft or Pending Revision status.

### Procedure

---

1. In the Manage Inspection Forms tool, in the Inspection Form Library, select the inspection form that you want to add conditions to.
2. On the Revision History page, click Conditional Settings .
3. In the Groups and Questions column, select the question whose response you want to add a condition to. Click Add Condition.
4. Select the response that you want to add a condition to, and then select the response field that you want managed by the condition.
5. Define whether the selected response field is visible. If you want the response field to be hidden from inspectors, turn off the Visible toggle.
6. Define whether the selected response field is required.
7. Click Save.

---

## Duplicating inspection forms

If you want to reuse an existing inspection form as a template for a new form, you can duplicate the form and then add or remove questions and instructions.

### Procedure

---

1. In the Manage Inspection Forms tool, in the Inspection Form Library, click the Duplicate icon for inspection form that you want to duplicate.
2. Change the name of the inspection form. You can choose a new form type or add additional instructions.
3. Add, edit, or delete inspection form questions.
4. Save the inspection form.

### What to do next

---

To make the inspection form available to inspectors, you must change the status of the form to Active. In the Inspection Form Library, click the Draft switch to activate the form.

---

## Associating inspections with work records

After you create inspection forms, you can associate them with assets, locations, and work orders.

### Associating inspection forms with assets and locations

---

In the Assets application or the Locations application, select the records that you want to associate with an inspection form and choose Associate Inspection Form from the Actions menu. Select the inspection form, click OK, and save the record.

### Associating inspection forms with work orders

---

You can associate inspection forms with work orders in the Work Order Tracking application. When you open the work order, you can associate an inspection form with it in any of the following ways:

- In the Job Details section of the Work Order tab, click the Detail menu in the Inspection Form field to open the Select an Inspection Form window.
- In the Multiple Assets, Locations and CIs section of the Work Order tab, click the Detail menu in the Inspection Form field for the line you want to associate the form with.
- On the Plans tab, you can associate an inspection form with a child work order in the Children section or a task in the Tasks section.

---

## Configuring actions for inspections

By using automation scripts, system administrators can define custom actions that are available to inspectors and inspector supervisors when they complete an inspection.

### Procedure

---

1. In the Automation Scripts application, from the More Actions menu, select Create, then select Script for Integration.
2. In the Create Script for Integration window, in the Object Structure field, type `MXAPIINSPECTIONRES`.
3. Select the Action Processing radio button. In the Action Name field, enter a name for your script.
4. In the Script Details section, enter a description for your script.
5. In the Source Code field, enter the source code for your script.
6. Click Create.

The action is now available to associate with inspection forms in the Manage Inspection Forms tool.

7. Optional: Enable security for the action in the Object Structures application.
  - a. In the Object Structures application, open the `MXAPIINSPRESULT` record.
  - b. From the More Actions menu, select the security option that you want to apply.

## Enabling voice-guided inspections

You enable the voice inspection feature so that inspectors can complete hands-free inspections on a mobile device. The inspection form is read aloud to the inspector and the inspector's verbal responses are recorded in the inspection form.

### Before you begin

Voice inspections are available to customers who have IBM® Maximo® Manage, IBM Maximo Assist, and IBM Maximo Mobile. To enable voice inspections, you must ask your sales representative for the IBM Watson® service instance and API key information.

### Procedure

1. In Maximo Application Suite, configure Maximo Assist for IBM Watson™ services:
  - a. Log in to Maximo Application Suite.
  - b. On the Suite administration page, select catalog from the menu, then click the Assist tile.
  - c. Select View deployment details, find your workspace, and select Go to workspace details page.
  - d. From the Actions menu, select Update configuration.
  - e. In the Configurations list, edit one of the IBM Watson services.
  - f. In the Endpoint field, specify your IBM Watson service instance.
  - g. Required: Configure the API key for IBM Watson services:
  - h. Repeat steps 1d - 1f for all other IBM Watson services in the Configurations list.
  - i. Select Apply changes and then select Activate.

Option	Description
<b>If you are configuring IBM Watson services for the first time</b>	Enter the API key for your IBM Watson service.
<b>If you are updating an existing configuration for IBM Watson services.</b>	Click Replace secret.

2. Assign the Assist user role to the inspectors who want to complete voice inspections:
  - a. On the Suite administration page, select Users from the menu, and open the user record for the inspector.
  - b. Click Edit and in the Application access section of the user record, in the Assist row, in the Access field, select User as the user role.
  - c. Save the changes and wait for the update to complete.
  - d. Repeat steps 2a - 2c for other inspectors who want to complete voice inspections.
3. In Maximo Assist, create the Assist API key:
  - a. Log in to Maximo Assist, select Configuration, API keys, and click Create API key.
  - b. Specify a name and description for the new API key.
  - c. In the Role association section, select the Voice APIs role and then click Save.
  - d. Required: In the API key successfully created dialog box, copy and save the generated API key.

The API key details are required to configure a system property for voice inspections.

4. In Maximo Manage, configure voice inspections:

- a. Log in to Maximo Manage and in the System properties application, add the following properties:

Property	Description	Type	Value
<code>mxe.mobile.inspection.features.assistvoice</code>	Enables the voice assistant in mobile inspection forms in Maximo Application Suite.	Yorn	1
<code>mxe.mobile.inspection.features.assistvoice.epname</code>	Defines the endpoint name that is used by the voice assistant.	ALN	ASSIST_VOICE
<code>mxe.mobile.inspection.features.assistvoice.domain</code>	Defines the voice assistant domain. The domain must contain the protocol, hostname, and port of the service.	ALN	The URL of the Maximo Assist application
<code>mxe.mobile.inspection.features.assistvoice.apikey</code>	Defines the API key that is used to authenticate the voice assistant.	ALN	The API key generated in step 3d

- b. Save your changes, select the four new properties, and then click Live Refresh.

5. Add a crontask for voice inspections:

- a. In the Cron Task Setup application, select New crontask Definition and enter the following details:

```

Cron Task
 AssistVoiceCronTask
Class
 psdi.app.inspection.AssistVoiceCronTask
Access Level
 FULL

```

- b. Add a crontask instance with the following details:

Cron Task Instance Name  
DailyTask  
Schedule  
1d,0,0,0,\*\*\*\*  
Run as User  
MAXADMIN

- c. Set the crontask to active and save the definition.
6. Enable voice inspections:
  - a. In the Manage Inspection Forms tool, create a revision of the inspection that you want to enable voice inspections for.
  - b. Open Form settings, select Enable voice inspection, save the inspection, and set the revision to active.

## Results

---

In Maximo Mobile, in the inspection record, the inspector can tap the microphone icon to start a voice inspection. Voice inspections can be completed on inspections that have a status of in progress.

## Conducting inspections

In the Conduct an Inspection tool, you conduct inspections that have been defined in the Manage Inspection Forms tool. You can also review the results of completed inspections, and create unscheduled inspections as necessary.

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, this work center is no longer available. The information that is provided here applies only to Maximo Manage 8.4 and earlier versions.

As an inspector, you complete inspections and record inspection results. You can also create an unscheduled inspection form or view inspection results from the Assets, Locations, and Work Order Tracking applications. Select Go To > Conduct an Inspection in the Inspection Result field or by using the Create > Unscheduled Inspection action in the Assets and Locations applications. You can conduct bulk unscheduled inspections on assets or locations.

When an inspection form is activated, use the form to inspect an asset or location. Filter your inspections by pending, in progress, and completed status. During an inspection, filter the list of questions on the form to show the required or incomplete questions. Answers to each question are automatically saved. After you answer all required questions, review your responses in the Inspections Summary window and complete the inspection.

- [Conducting inspections](#)  
As an inspector, you can complete inspections and record inspection results.
- [Creating unscheduled inspections](#)  
As an inspector, you can conduct an unscheduled inspection if the need arises.

## Conducting inspections

As an inspector, you can complete inspections and record inspection results.

## Procedure

---

1. In the Conduct an Inspection tool, select the inspection that you want to conduct. You can choose from inspections that are pending or in progress.  
To conduct multiple inspections at the same time, hover over each inspection card until a check box appears and then select it. When you're done selecting inspections, click Open Selected.
2. When the inspection form opens, click Start or Start Batch if you're conducting multiple inspections.
3. Answer the questions in the inspection.  
Answers to your questions are saved automatically. You can click Hide optional questions to see only the required questions on the form.
4. Click Complete when the inspection is finished.
5. Click Exit to return to the inspection form.
6. Optional: Click Take Action to view an inspection summary or details about the associated location or asset.
7. Click Exit again to return to the Inspections page.

## Creating unscheduled inspections

As an inspector, you can conduct an unscheduled inspection if the need arises.

## Procedure

---

1. On the Inspections page of the Conduct an Inspection tool, click Unscheduled Inspection.
2. Specify the asset or location that you want to create an inspection for.
3. Select an inspection form to use for the inspection. You can choose from recommended forms that are associated with the asset or location, or you can search through all forms.
4. When the inspection form opens, click Start.
5. Conduct the inspection.
6. Click Complete when the inspection is finished.

7. Click Exit to return to the inspection form.
8. Click Exit again to return to the Inspections page.

---

## Submitting service requests

You use the Submit a Service Request tool to quickly create service requests by using your computer or mobile device. You can also monitor the status of existing service requests that you created or are affected by.

Note: Starting in Maximo Application Suite 8.9 and Maximo Manage 8.5, this work center is no longer available. The information that is provided here applies only to Maximo Manage 8.4 and earlier versions.

You add new service requests by specifying the request category, identifying the location, defining the asset, and providing a description. You can upload photographs or videos to requests to provide more information.

After you enter a service request, you automatically receive notifications when the request is resolved or closed.

Before you can access the Submit a Service Request tool, an administrator must add you to the security group template for service requests. Security group templates are provided to enable access to Work Centers and Tools and Tasks.

- **[Creating service requests](#)**  
You create service requests to report issues and monitor their resolution.
- **[Example: Responding to a user problem](#)**  
When a user opens a service request to report a problem, a work order is created. A maintenance supervisor reviews and approves the work order, then selects a technician as the owner. A storeroom clerk supplies any parts that are required to fix the problem. As the technician completes the work, the user who opened the service request can track the progress until it is completed.

---

## Creating service requests

You create service requests to report issues and monitor their resolution.

---

### Procedure

1. In the Submit a Service Request tool, choose from the list of service request categories, or click Describe the Issue.
2. Describe the issue that the service request is being created for.
3. Click Next.
4. If you are entering the service request on behalf of another person, edit the information on the Affected Person screen.
5. Click Next.
6. Optional: Attach a photo or video of the problem.
7. Specify the location of the issue. You can search for a location, or you can find the location in the following ways:
  - Scan a QR code for the location.
  - Click the compass icon to use GPS to get a list of locations near you.
8. Click Set Location.
9. Specify the asset. You can search for an asset, or you can locate the asset in the following ways:
  - Scan a QR code for the asset.
  - Click the compass icon to use GPS to get a list of assets near you.
10. Click Set Asset.
11. Review your request. Select the High priority check box if applicable.
12. Click Submit Request.

---

## Example: Responding to a user problem

When a user opens a service request to report a problem, a work order is created. A maintenance supervisor reviews and approves the work order, then selects a technician as the owner. A storeroom clerk supplies any parts that are required to fix the problem. As the technician completes the work, the user who opened the service request can track the progress until it is completed.

---

### Who are the users involved?

Fran, an administrator in the warehouse of a beverage manufacturer, arrives to work and finds that her office is uncomfortably hot. She also notices that a rattling sound is coming from one of the air vents in the ceiling. Fran must use the Manage Service Requests application to report this problem.

Ed, a maintenance supervisor in the same company as Fran, begins his day by checking the Work Supervision Work Center to review the status of all maintenance work.

Sam, an electrician, is a technician on Ed's team. When Sam arrives to work, he opens the Work Execution Work Center to decide which work order to complete first.

---

## Step 1: Fran opens a service request

1. Fran opens the Service Request application on her phone, scrolls through the listed categories, and selects Heating & Air.

2. On the Describe the issue screen, Fran chooses It's too hot, then clicks Next.
3. In the Additional Comments box, Fran enters The air conditioning vent is not working and it's making weird noises.
4. To illustrate the problem, Fran takes a video of the vent and attaches it to the service request.
5. Fran specifies her location and reviews the details of the service request to confirm that everything is correct.
6. Fran selects the Urgent request check box, because she knows she can't work in the current conditions.
7. Fran submits the service request.

## Step 2: Ed reviews Fran's request

---

1. In the Work Supervision Work Center, Ed opens the Review Service Requests page and sees Fran's request for service.
2. Ed opens Fran's service request, reviews the problem, determines that a work order is needed, and selects Create Work to create a work order.
3. On the work order, Ed adds the tasks and items that are required to complete the work.
4. After Ed adds all the tasks and items that are needed for the work, he selects the Status tile and approves the work.
5. On the Owner tile, Ed selects Sam as the owner because this problem requires an electrician.
6. Ed enters the following comment: Sam, I passed Fran's office on my way in and the noise from the vent is really awful.

## Step 3: Sam investigates the problem

---

1. In the Work Execution Work Center, Sam reviews all the work orders that he owns. He sees that Fran's problem is high priority and reads Ed's comment about the noise, so he clicks Start on that work order.
2. Sam checks the location of the problem, views the video that Fran uploaded, then grabs his tools and heads to Fran's office.
3. While Fran leaves to get a coffee, Sam inspects the fan and discovers that two of the fan blades are badly damaged and must be replaced.
4. Sam remembers that about six months ago, the company switched to a new HVAC vendor, and recently, many of the work orders involve faulty blades. Sam suspects that the blades from this new vendor might be of lower quality, so when he removes the damaged blades, he takes a photo and attaches the photo to the work order.
5. Sam also opens the Comments screen and enters the following comment to his supervisor: Ed, we must investigate these blades from the new vendor. I seem to be replacing a lot of them recently. See the photo.
6. Sam leaves Fran's office to get replacement blades.

## Step 4: Sam fixes the problem

---

1. Sam returns to Fran's office and replaces the fan blades.
2. Sam clicks Stop on the work order to indicate that he is finished working and sets it to complete.
3. The work took longer than anticipated and required new fan blades, so on the Report My Work screen, Sam adds an additional 30 minutes to the time and specifies the blades as unplanned items.

## Step 5: Ed closes the work order

---

1. In the Work Supervision Work Center, Ed monitors Sam's work and sees that the work order is now in the Close Work section.
2. Ed opens the photo that Sam attached to the work order and also suspects that the blades from the new vendor are poor quality.
3. Ed reads Sam's comment about the new HVAC vendor and enters the following comment: Yeah recently I've noticed a lot of work orders for fans too. We'll look into it.
4. After he reviews the work order, Ed is confident that Sam did the work correctly, so he clicks Close Work.

## Step 6: Fran sees that her request is closed

---

1. After finishing her coffee, Fran takes out her phone and checks the Service Requests application for an update.
2. Fran sees a notification that says her service request is complete.
3. Fran returns to work in a nice cool office.

---

## Application development

You can develop new applications and modify existing applications using the Application Designer application. You can also use Application Designer to export XML presentations, which you can then modify using a text editor before importing them with Application Designer.

- [Application framework](#)  
The application framework includes user interface components for developing applications and organizational components that provide access to them.
- [Preparing the development environment](#)  
Before using the Application Designer, set up the development environment and familiarize yourself with the workspace and with the design guidelines.
- [Developing applications](#)  
Before you create or modify applications, review the design guidelines and explore the workspace in the Application Designer.
- [Application developer properties](#)  
Each control has its own set of properties that you can set. You can also set user interface properties to control the behavior of many aspects of user interface behavior.

---

## Application framework

The application framework includes user interface components for developing applications and organizational components that provide access to them.

The user interface consists of controls, such as text boxes, buttons, and tabs, and each control has attributes that determine its behavior. Each application has a presentation.xml file that contains all of the information that is required to build the application user interface. When you create an application, it is automatically added to the navigation structure for modules and applications.

## User interface controls

---

Controls are predefined components that are used to construct the elements of an application window. In Application Designer, you can select individual controls, view and modify the control properties, or drag new controls into the application from the Control Palette. You cannot change the code of a control, but you can modify its behavior by specifying appropriate values in the properties window for the control. For example, you can set a control to be a required field, associate a control with a lookup table, or link a control to an event.

Some controls, such as sections, tab groups, or button groups are container controls. Most container controls serve no purpose other than to contain other controls. Controls that are not containers must be placed within a container control. In Application Designer, you can drag controls from the Control Palette onto the application workspace, and then modify the control in the Control Properties window.

The positioning of controls is relative to other controls and is not based on pixels or a grid and provides for dynamic sizing of the width of a section and its columns. For example, if a section contains fields of various widths, the width of each field is automatically set to the width of the widest field in that section.

## Application XML files

---

Every application has a presentation.xml file that contains all the information that is required to build the application user interface. All presentation.xml files are stored in the MAXPRESENTATION table in the database. Controls are predefined components that are used to construct the elements of an application window. In Application Designer, you can select individual controls, view and modify the control properties, or drag new controls into the application from the Control Palette. You cannot change the code of a control, but you can modify its behavior by specifying appropriate values in the properties window for the control. For example, you can set a control to be a required field, associate a control with a lookup table, or link a control to an event.

The presentation.xml file for an application includes a tag for each control that is used in the application user interface. Each control has a unique ID and attributes that determine how the control behaves when you view the application. The relative location of control tags in the presentation.xml file determines the order and sequence of the user interface elements that you see in an application window.

When a user starts an application, the presentation.xml file is retrieved from the database and is placed in the memory of the application server. The application framework retrieves the code for each control and creates an HTML description of it, based on the attributes specified in the presentation.xml. The rendering process is incremental, and the application server stores HTML descriptions for each control in memory until all controls in an application window are rendered. When all HTML elements are rendered, the application server passes the HTML to the user's web browser (client). The presentation.xml file is retained in the server cache, ready for the next time a user accesses the application.

When you open an application in the Application Designer, the presentation.xml file is loaded into memory. Any changes that you make apply only to the stored version of the file until you save the application. When you save the presentation.xml, the modified information is committed to the database and you can then see the changes when you open the application.

Although you can perform most modifications to an application in Application Designer, you can edit the presentation.xml file if required. Sometimes, modifying the presentation.xml file is the most efficient approach to use, for example to change a specific term by using search and replace. In an application with multiple tabs and windows, this task requires that you open each individual window in Application Designer, which is both time-consuming and prone to error. Some applications use hidden tabs that are not visible in Application Designer. You cannot modify these tabs in Application Designer and must edit the presentation.xml file to change them.

## Application organization

---

All applications are contained within modules. When you create an application, you must specify its module and the type of application to create. Applications are categorized into three different types although each type uses the same structure and components. The available application types are:

- A power application is the standard type of application that contains multiple tabs, a Select Action menu, and toolbar buttons.
- A self-service application is used to create a record and does not include a List Table window or a toolbar.
- A single-page application is a non-tabbed application but it can include a Select Action menu and toolbar buttons.

After you create an application, it is added to Go To menu within the module that you specify when you create it.

---

## Preparing the development environment

Before using the Application Designer, set up the development environment and familiarize yourself with the workspace and with the design guidelines.

- **Setting up the environment**  
Plan and prepare the development environment before you start working with Application Designer.
- **Exploring the workspace**  
When you open an application in the Application Designer, the Workspace tab opens, containing the layout of the controls that make up the application. Within the workspace, you can select individual controls to modify them and to position new controls in the application user interface.
- **Design guidelines**  
Use the Application Designer and, if necessary, the application XML files, with an appropriate design process to develop applications that are easy and efficient to use.
- **Data validation**  
The system validates data to ensure that users are working with the correct data. Data can be validated on the server-side or the client-side.
- **Property configurations**  
The behavior and characteristics of various user interface components can be determined by the values set as system properties or by values set for

individual controls. Filter for **webclient** in the System Properties application to view and modify interface properties. Modify properties for an individual control in the Application Designer.

---

## Setting up the environment

Plan and prepare the development environment before you start working with Application Designer.

---

### Procedure

1. Establish separate environments for the following activities to protect your development environment against configuration changes you make.
  - a. Perform development activities on a dedicated workstation.
  - b. Merge your configurations to a server for testing.
  - c. Migrate the tested configurations to the production environment.
2. Set the screen resolution of your monitor to 1280x768 to optimize the amount of information that you can see without scrolling.  
With this screen resolution, it is easier to position the Control Palette and Properties windows outside of the application workspace where you perform configurations.

---

## Exploring the workspace

When you open an application in the Application Designer, the Workspace tab opens, containing the layout of the controls that make up the application. Within the workspace, you can select individual controls to modify them and to position new controls in the application user interface.

---

### About this task

The workspace opens the main tab of an application but some tabs, windows, controls, and configuration tools are not immediately visible. Before you start developing applications with the Application Designer, use the following procedures to familiarize yourself with the workspace.

---

### Procedure

1. Open an application that you are familiar with in the Application Designer.  
The application opens in the workspace, typically on the application List tab.
2. Review the contents of the workspace when it opens, clicking on controls to select them.
3. In the Select Action menu, click Toggle/Show All Controls.  
You can use this action repeatedly to show or hide controls that are less frequently modified to conserve space on the workspace.
4. Select any control in the workspace and either right-click and select Properties or click the Control Properties icon on the toolbar.  
The properties window for the control opens where you can review the properties that are configured for the control.
5. In the Workspace, select a Section control and click the Control Palette icon on the toolbar.
6. Drag a control icon from the palette into the selected Section control.  
If the control cannot be placed within a Section control, it is not added to it. For example, you must place a Tab control within a Tab Group control and you must place a Button control within a Button Group control.
7. Click the Edit Dialogs icon on the toolbar to see a list of the dialog windows that are configured for the application.
8. Select a dialog to open it for review or modification in a temporary workspace.
9. Click on the Applications tab to close the workspace and do not save the changes when you are prompted to do so.  
Changes you make in the workspace are stored temporarily until you click Save, when the changes are committed to the database.

---

## Design guidelines

Use the Application Designer and, if necessary, the application XML files, with an appropriate design process to develop applications that are easy and efficient to use.

---

### Review user goals

Before you start developing or modifying an application, review the user goals for the application. Divide users into groups, based on the tasks that they perform. Instead of creating one large application to serve all users, consider creating smaller applications that serve specific needs. Give users only what they need, and nothing more.

---

### Prioritize information

Consider the circumstances when users need access to secondary information and choose where to locate this information from the following options:

- On a separate tab.  
If you place secondary information on a separate tab, it does not load until the user clicks the tab, which makes startup performance faster. The information is available with one click when the user needs it.
- Below the screen area (fold line)

Users can ignore information at the bottom of the screen and can scroll down to see it when it is necessary. Including the information on the lower screen can increase load-time, but vertical scrolling is easier, faster, and less error-prone than clicking.

When an application requires a lot of data entry, arrange the input fields to optimize the use of the Tab key to navigate between fields. The tabbing order of a window goes from top to bottom and from left to right.

If you want to change the location of a number of data input fields in an application, consider duplicating the application and then changing the order of the input fields. When you are modifying an application, you can delete fields that are not needed for data entry, or move those fields to another screen.

## Use appropriate controls

---

Controls are predefined components, such as text boxes, buttons, and tabs, that are used to build the application user interface. In the Application Designer, you can select a control from the Control Palette and drag it to the workspace to add it to the user interface. You then configure properties for the control, for example specifying an image file to use for a button control or setting a text control as a required field.

The following controls are the main layout controls:

- Presentation
- Page
- Dialog

The presentation control is the main control for an application, representing the presentation.xml file that defines all of the user interface components. Each application has just one page control, typically the main tab of the application. Use tab controls or dialog controls to create additional windows. These controls are the outermost containers for application components. Other container controls include:

- Section
- Tab group
- Table
- Push-button group

Within a container control, you can place multiple controls such as placing multiple text boxes, combination boxes, and list boxes into a section, or placing multiple buttons into a button group. There are a number of benefits in grouping related content within the same container control. The grouping provides a logical order and convenience for the user and, if you move the container to another location, all of the controls that it contains move with it.

## Organize navigation

---

The application framework includes a number of predefined navigation structures that you can use to provide quick and easy access to your application and application components. Use the following navigation structures:

- The Go To menu lists all of the product modules and their applications. When you create an application, you must specify its module. When you duplicate an application, the new application is automatically added to the same module as the application that you copied.
- You can add buttons and links to the application toolbar to provide quick access to application features.
- You can create an option in the Select Action menu for a common task. You can also restrict access to this option based on user group or conditions.

## Data validation

---

The system validates data to ensure that users are working with the correct data. Data can be validated on the server-side or the client-side.

- [Server-side validation](#)  
When you enter information in an application, it is placed in the queue for server-side validation where the data is validated with data on the server. Server-side validation consists of asynchronous and synchronous validation. Asynchronous validation helps users to work faster because they can move from field to field, entering data without waiting for information to be validated.
- [Client-side validation](#)  
To improve performance, the system validates data on the client browser before validating on the server.
- [Best practices for data validation types](#)  
In some circumstances, one type of data validation can be more efficient to use than another. All validation types work on textboxes, multiple-part textboxes, and check boxes. Synchronous and asynchronous validation also work on multiple-part text boxes and check boxes while client-side validation works on the first part of multiple-part check boxes.

## Server-side validation

---

When you enter information in an application, it is placed in the queue for server-side validation where the data is validated with data on the server. Server-side validation consists of asynchronous and synchronous validation. Asynchronous validation helps users to work faster because they can move from field to field, entering data without waiting for information to be validated.

Asynchronous validation is disabled automatically when a screen reader is being used.

In synchronous processing, values are validated when they are entered; asynchronous values remain in the queue until one of three conditions is met:

- When the threshold for the number of asynchronous values in the queue is reached. The default value is 2.
- When there is no action on the user interface, and the default timeout is reached. The default value is 10 seconds.
- When a user completes an action that triggers a synchronous validation.

When one or more of these conditions is met, all values in the queue are then sent to the server to be validated. Asynchronous validation of user-entered data is enabled at the system level by default. You can disable asynchronous validation for the system, you can disable it for individual controls, and you can change the validation process for the system.

Table 1. Data validation levels

Data validation level	Where	How
Enable background validation at the system level	System Properties application	Disable or enable the <code>mx.webclient.async</code> system property.
Configure background validation for individual controls	Application Designer application	Configure autofill properties: type-ahead, set values, and filters.
Modify the validation process system-wide	System Properties application	<ul style="list-style-type: none"><li>Change the value for the <code>mx.webclient.asyncrendertimelimit</code> system property.</li><li>Change the value for the <code>mx.webclient.asyncerrortooltipwaitbeforeopen</code> system property.</li><li>Change the value for the <code>mx.webclient.asyncrequestsbeforerender</code> system property.</li></ul>

## Error notification during asynchronous validation

If an error occurs during asynchronous validation, an error indicator appears on the relevant field. When you click the error icon, a message opens. If there are errors on more than one tab, an error icon is also set at tab level for each tab that contains unresolved messages.

The threshold for the queue ensures that only asynchronous values are sent to the server for validation when the default value is passed.

## Client-side validation

To improve performance, the system validates data on the client browser before validating on the server.

- Autofill properties**  
The autofill function populates fields based on the data that you enter in other fields. You can configure autofill properties so that fields are populated with cached data instead of server data to improve performance.
- Configuring autofill properties**  
To improve performance, fields in forms can be automatically filled with cached data. If your network latency is over 100 milliseconds, you can specify the fields to be automatically filled.
- Example: Configuring autofill for the Affected Person field in service requests**  
If you frequently open service requests for the same users, you can configure autofill on the Affected Person field. The next time you open a service request, as you type in the Affected Person field a list of one or more possible matches for the data is listed.
- Error notification for client-side validation**  
The values for data type fields are validated locally in the browser. If an error occurs, the user is notified immediately before a server round trip is needed.

## Autofill properties

The autofill function populates fields based on the data that you enter in other fields. You can configure autofill properties so that fields are populated with cached data instead of server data to improve performance.

On a high latency network, the use of cached data can be more efficient. A high latency network is a network with a latency of more than 100 milliseconds.

You can configure autofill for a text box or a multipart text box. When you configure autofill properties, a data store is created in the user's browser. The data store on a browser is limited in size so configure autofill properties for the most important text boxes and multipart text boxes.

The autofill properties that you can configure are type-ahead, set values, and filters.

Type-ahead is an incremental search feature. As you type data in a field, one or more possible matches for the data is listed. You can configure type-ahead so that the list of possible matches includes one or more business objects. You must set the `mx.webclient.ClientDataValidation` property to a value of `1` for type-ahead to work. You must configure type-ahead before you can configure set values and filters.

All fields that are associated with ALN, numeric, or synonym domains support type-ahead when you set the value of the `mx.webclient.ClientDataValidation` property to `1`, but you can also configure autofill for additional fields. Simple client-side error validation is also enabled with the `mx.webclient.ClientDataValidation` property.

You configure set values so that the data that a user enters in one field populates other fields. For example, if you configure a set value for the Asset field, when a user enters a value in the Asset field, other text boxes, multipart text boxes, combination boxes, or check boxes are populated with data.

You configure filters in a field to limit the type-ahead choices for a user based on information in another text box, multipart text box, combination box, or check box.

After you configure autofill properties, the information is validated with the data on the server. If the autofill configuration data is different from the server data, the fields are updated with the server data.

## Configuring autofill properties

To improve performance, fields in forms can be automatically filled with cached data. If your network latency is over 100 milliseconds, you can specify the fields to be automatically filled.

## About this task

You can configure autofill for a text box or a multipart text box. The autofill properties that you can configure are type-ahead, set values, and filters. You can configure type-ahead so that the list of possible matches includes one or more business objects. You configure set values so that the data that a user enters in one field populates other fields. You configure filters in a field to limit the type-ahead choices for a user based on information in another text box, multipart text box, combination box, or check box.

## Procedure

1. In the System Properties application, set the value of the `mxe.webclient.ClientDataValidation` property to `1`.
2. In the Application Designer application, select an application, highlight the field to configure, and open the properties sheet.
3. Click the Advanced tab. In the Autofill Properties section, configure the type-ahead feature.
  - a. If a domain is not specified, complete the Domain field by identifying a domain in the Database Configuration application.
  - b. Add the key domain attribute.  
To specify a domain attribute, you choose the primary key of that object as an attribute in the Attribute table that the domain is pointing to, and set the key Boolean value to `true`.
  - c. Optional: To provide more information about the key attribute and to distinguish it from other type-ahead choices, add another attribute.
  - d. Click OK.
4. Configure the set values.
  - a. Specify an attribute that corresponds to the field whose value you want to set.
  - b. Specify the domain attribute of the field where the set value comes from and click OK.
5. Configure filters.
  - a. Specify the field to act as a filter for the type-ahead choices.
  - b. Specify the domain attribute of the field with the type-ahead choices.
6. Save the application definition.

## Example: Configuring autofill for the Affected Person field in service requests

If you frequently open service requests for the same users, you can configure autofill on the Affected Person field. The next time you open a service request, as you type in the Affected Person field a list of one or more possible matches for the data is listed.

## Procedure

1. In the System Properties application, set the value of the `mxe.webclient.ClientDataValidation` property to `1`.
2. In the Application Designer application, select the Create Service Request application, highlight the Affected Person field and open the properties sheet.
3. Click the Advanced tab. In the Autofill Properties section, click Configure Type-Ahead.
4. If a domain is not specified, go to the Database Configuration application to define a domain and complete the Domain field.
5. Add the domain attribute.  
To specify a domain attribute, you choose the primary key of that object as an attribute in the Attribute table that the domain is pointing to, and set the key Boolean value to `true`.
6. Optional: To provide more information about the key attribute and to distinguish it from other type-ahead choices, add another attribute.
7. Click OK and then save the application definition.

## Error notification for client-side validation

The values for data type fields are validated locally in the browser. If an error occurs, the user is notified immediately before a server round trip is needed.

For example, when you specify a value in an alphabetic field, the length of the value is validated in the browser. The error is added to the queue with the asynchronous values, but the error value is not counted in the threshold for the queue.

The error values are validated the next time the queue is validated, either when the threshold or timeout for asynchronous values is reached or when a synchronous event is triggered.

Error values for smart-fill fields and simple data entry values are also not included in the queue threshold.

## Best practices for data validation types

In some circumstances, one type of data validation can be more efficient to use than another. All validation types work on textboxes, multiple-part textboxes, and check boxes. Synchronous and asynchronous validation also work on multiple-part text boxes and check boxes while client-side validation works on the first part of multiple-part check boxes.

Table 1. Data validation types and use cases

Validation type	Behavior setting	Configuration options	User interaction	Best practice	Interaction with smart-fill
-----------------	------------------	-----------------------	------------------	---------------	-----------------------------

Validation type	Behavior setting	Configuration options	User interaction	Best practice	Interaction with smart-fill
Synchronous	Available if the asynchronous setting is turned off.	System Properties application or Application Designer application	Users must correct the errors in the current field before moving to next field.	Fields that affect the behavior of other fields. For example, if a particular entry in field A causes field B to become read-only, you can turn off asynchronous validation for field A. Users then cannot tab out to field B inadvertently before field A validates.	When users tab out of a field, the Select Value window opens containing filtered values. Users can specify the necessary value.
Asynchronous	Default behavior	System Properties application or Application Designer application	Errors and warnings are indicated at the field level. Users can resolve the errors and warnings at any time, in any order before saving.	In applications where users enter data quickly.	When users tab out of a field, the Smart Fill icon appears in the field. Users can click the icon and the Select Value windows opens containing filtered values. Alternatively, while in field users can press Ctrl+Enter on the keyboard to invoke the Select Value windows containing filtered values.
Client-side	Default behavior for data type validation	Asynchronous system setting must be turned on. Configurable for filters and set values in the Application Designer application.	Errors and warnings icons are indicated at the field level before server validation. Users can also see values in fields. If type-ahead is configured, users can see the information before server validation.	In applications where users experience network latency and for whom server round-trips for validation takes too long.	You can configure type-ahead to allow users to see a list of available options as drop-down values for a field. The available options in the list reduce as each successive letter is typed. The filtered Select Value window does not appear when a choice is made using the type-ahead list.

## Property configurations

The behavior and characteristics of various user interface components can be determined by the values set as system properties or by values set for individual controls. Filter for **webclient** in the System Properties application to view and modify interface properties. Modify properties for an individual control in the Application Designer.

Common user interface (webclient) properties include properties that determine browser behavior when a connection is lost and properties that identify the location of login and log out pages. It can be practical to change these and other property values, depending on the type of application behavior you want to develop.

If the **webclient.smartfill** system property is enabled, when a user enters partial data in a field and an exact match is found in the database, the field updates with this value. If multiple possible matches are found, the user can select from a list of possible matches to update the field. The combined use of smartfill and asynchronous validation on a field can, in some cases, cause confusion. If required, you can disable smartfill for the system or for an individual control.

If you intend to use rich text editing capabilities that use custom fonts, you can add these fonts to the **webclient.richtext.fontlist** property. The Rich Text Editor control supports generic fonts by default, such as serif and sans-serif.

## Developing applications

Before you create or modify applications, review the design guidelines and explore the workspace in the Application Designer.

- [Creating and modifying applications](#)  
You can either create an application or duplicate an existing application to use as a template. You can then modify the application to suit your business needs. You can also delete user-defined applications but you cannot delete predefined applications.
- [Arranging the layout of controls](#)  
The layout of components is relative to the other components in a user interface. Use container controls, like sections and tables, to group associated controls. Arrange controls to make it easy for users to enter information in an orderly and efficient manner.
- [Configuring default values for controls](#)  
You can change the labels for fields, specify default values and filters for fields, and you can configure value lists for fields.
- [Moving application controls](#)  
Use the Application Designer to move controls across tabs or across applications. You can also move controls and applications to a different server and export multiple applications.
- [Adding navigation components](#)  
You can link to applications and to external URLs, and you can add menus and buttons to organize application navigation.
- [Configuring related information for fields](#)  
To see information related to a field without leaving the record, you add a hover window to the field. Hover windows are immediately enabled on some fields but you can also enable these existing hover windows on other fields or you can create a hover window depending on your requirements.
- [Providing user information](#)  
You can provide information to help users in the windows and tabs in the user interface. You can create links from windows and tabs, and also from field

help, to topics in the product Knowledge Center. You can also add new error messages to an application.

- [Configuring dialog windows for an application](#)  
You can modify dialog windows that are specific to an application in the Application Designer. To modify dialog windows that are shared with other applications, you must modify a system XML file. You can also create a dialog and add it to an application.
- [Transferring data between applications](#)  
To move data from a field in an application to another field in a different application, you can use linked objects and .
- [Configuring conditional user interface components](#)  
By applying conditions to control application behavior and to the user interface (UI), you can configure the UI to support your business processes. You can achieve the user interface behavior you require by configuring conditional data restrictions, by configuring conditional UI control behavior in Application Designer, or by configuring conditional security restrictions. For example, you can apply conditions to change the color of controls, the content of menus for different user groups, or the properties of the data shown.

---

## Creating and modifying applications

You can either create an application or duplicate an existing application to use as a template. You can then modify the application to suit your business needs. You can also delete user-defined applications but you cannot delete predefined applications.

- [Duplicating applications](#)  
You can duplicate an existing application to use as a template for a new application. You can then extend and modify the functionality of the base application in the Application Designer.
- [Creating applications](#)  
You can create three types of application in the Application Designer; a power application, a single-page application, or a self-service application. After you create an application, it is automatically added to the Go To menu.
- [Deleting an application](#)  
You can only delete an application that you created or duplicated in the Application Designer. You must use a database editor (for example, SQL Plus) to delete an application.
- [Creating restrictions](#)  
To restrict the records that a user can see in an application, you add a query to the application. To restrict the data that users see for a control, you add the `allowqualifiedrestriction` property to the XML for a control in an application.
- [Defining signature options for an application](#)  
Signature options specify privileges for using applications, menu options, and toolbar items. You apply signature options to groups of users to control their access to data, to applications, and to controls. New applications are automatically assigned a READ signature option. You can add more signature options in the Application Designer.

---

## Duplicating applications

You can duplicate an existing application to use as a template for a new application. You can then extend and modify the functionality of the base application in the Application Designer.

---

### Procedure

1. Open the application you want to duplicate in the Application Designer.
2. Select the Duplicate Application Definition action to open the Duplicate Application window.
3. In the Application field, specify a unique name for the application.  
Use a clear and consistent naming convention, such as using your company name as a prefix. Choose application names that are easy to identify in menus, and easy to recognize in log files and during a system upgrade.
4. In the Description field, specify a text description.  
This text shows in the navigation bar of the application.
5. Click OK and then click Save.

---

### Results

The duplicated application is listed in the Go To menu in the same module as the original application. To view the new application, sign out of the system to refresh the list of applications in the Go To menu. When you sign back into the system, the new application is available in the Go To menu.

---

### What to do next

Open the application in the Application Designer and make the changes needed to adapt the application to your business needs.

---

## Creating applications

You can create three types of application in the Application Designer; a power application, a single-page application, or a self-service application. After you create an application, it is automatically added to the Go To menu.

---

### Before you begin

Before you create an application, the main object for the application must exist in the database. If you intend to associate the application with a new object, define the object in the Database Configuration application before you create the application.

## Procedure

---

1. Click New Application Definition in the toolbar of the Application Designer.
2. In the Application field, specify a unique name for the application.  
Use a clear and consistent naming convention, such as using your company name as a prefix. Choose application names that are easy to identify in menus, and easy to recognize in log files and during a system upgrade.
3. In the Description field, specify a text description.  
This text shows in the navigation bar of the application.
4. Specify a key attribute for the application.
5. Specify the name of the main object for the application.
  - a. If the object is set at the SYSTEMORGSITE level, you must create a site text box field and an organization text box field.
6. Specify the name of the module that is to include the application.  
Every application must be located within a module.
7. Click the button that corresponds to the type of application that you want to create.  
The new application opens in the workspace.
8. Click Save Application Definition.

## Results

---

To view the new application in the Go To menu, sign out and then sign back into the system.

## What to do next

---

Filter for the new application in the List tab of the Application Designer to start working on the new application.

The default security setting for new applications is Read. All users who have access to the application in their security profiles can read records but cannot insert or delete information. Select Add/Modify Signature Options in the Select Action menu to define additional signature options for the new application.

---

## Deleting an application

You can only delete an application that you created or duplicated in the Application Designer. You must use a database editor (for example, SQL Plus) to delete an application.

## Before you begin

---

You must shut down the application server before you delete an application. If you delete an application, you do not remove any custom tables, fields, or domains that you created to support the application.

## Procedure

---

1. Login to a database editor as an administrator.
2. Enter the following commands, and replace the variable *<APPLICATION NAME>* with the name of the application you want to delete. Enter the application name in all uppercase. For example, if the name of the application you want to delete is Test, replace APPLICATION NAME with TEST in all the commands.
  - a. `delete from maxapps where app='<APPLICATION NAME>';`
  - b. `delete from maxpresentation where app='<APPLICATION NAME>';`
  - c. `delete from sigoption where app='<APPLICATION NAME>';`
  - d. `delete from applicationauth where app='<APPLICATION NAME>';`
  - e. `delete from maxlabels where app='<APPLICATION NAME>';`
  - f. `delete from maxmenu where app='<APPLICATION NAME>' and menutype != 'MODULE';`
  - g. `delete from maxmenu where where elementtype='APP' and keyvalue='<APPLICATION NAME>';`
  - h. `delete from appdoctype where app='<APPLICATION NAME>';`
  - i. `delete from sigoptflag where app='<APPLICATION NAME>';`
3. Logout of the database editor.

---

## Creating restrictions

To restrict the records that a user can see in an application, you add a query to the application. To restrict the data that users see for a control, you add the allowqualifiedrestriction property to the XML for a control in an application.

- [Creating application restrictions](#)

You add a query to an application to restrict the records that a user can see. To hide inactive users in the Users application for example, you use the query "status != 'INACTIVE'". You create restrictions for power applications and single-page applications in Application Designer.

- [Restricting data](#)

You add the `allowqualifiedrestriction` property to the XML for an application to restrict the data that is returned from the database. You can add the restriction when data is shown but not used for calculations. You can add the restriction for data that is used to route a process through steps. You can also restrict the records that are returned when using lookups.

---

## Creating application restrictions

You add a query to an application to restrict the records that a user can see. To hide inactive users in the Users application for example, you use the query "status != 'INACTIVE'". You create restrictions for power applications and single-page applications in Application Designer.

---

### Procedure

1. Open the application in Application Designer.
2. In the Select Action menu, click **Toggle Show All Controls**.
3. Select the presentation control and click the **Control Properties** icon.
4. In the Presentation Properties window, enter the query in the Application Restrictions field.
5. Save the application definition.

---

## Restricting data

You add the `allowqualifiedrestriction` property to the XML for an application to restrict the data that is returned from the database. You can add the restriction when data is shown but not used for calculations. You can add the restriction for data that is used to route a process through steps. You can also restrict the records that are returned when using lookups.

- [Restricting the data returned from the database](#)

You restrict data by adding the `allowqualifiedrestriction` property. For example, you can restrict the classifications available to users who are classifying a service request.

- [Examples of restrictions on the data that users see](#)

You control the data that users see by restricting the data that is returned from the database. For example, you can restrict the person groups that users see when selecting an owner in the Change application.

---

## Restricting the data returned from the database

You restrict data by adding the `allowqualifiedrestriction` property. For example, you can restrict the classifications available to users who are classifying a service request.

---

### About this task

You do not apply the restriction to child objects. You manually add the `allowqualifiedrestriction` property to the XML controls that create a data source. The controls that create a data source have an object, a relationship, or a bean class. The following controls are supported:

- `datasrc`
- `section`
- `simpleheadertable`
- `tab`
- `table`
- `tree`

Some controls inherit data sources from higher-level controls. When you add the property to the XML, you also make the data read-only. Editing a restricted data set can have unexpected results.

---

### Procedure

1. Open the application XML and search for the control where the data source is needed.
2. Add `allowqualifiedrestriction= true` to the XML.
3. Import the modified XML.

---

## Examples of restrictions on the data that users see

You control the data that users see by restricting the data that is returned from the database. For example, you can restrict the person groups that users see when selecting an owner in the Change application.

## Example: Restricting the person groups that users see when selecting an owner in the Change application

In this example, you set the `allowqualifiedrestriction` property into the XML for the tab in the window:

```
<dialog
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_owner"
label="Select Owner">
 <tabgroup
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_owner_labor">
 <tab
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_owner_labor_group" label="Person Groups" mboname="persongroup" allowqualifiedrestriction="true"
beanclass="psdi.webclient.beans.common.OwnerGroupBean">
```

## Example: Restricting when users see the 'View Work Details' window in the Assets application

In this example, you set the `allowqualifiedrestriction` property into the XML for the tab in the table in the window:

```
<dialog
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_wopms_byasset"
label="View Work Details" relationship="VIEWWOPMS"
beanclass="psdi.webclient.beans.common.ViewWOPMSBeanAsset" width="975" height="400">
 <section
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewWOandPMS_ViewWOandPMSFieldGridAsset" border="true">
 <multiparttextbox
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewWOandPMS_ViewWOandPMSFieldGrid_2" dataattribute="assetnum" inputmode="readonly"
descdataattribute="asset.description" longdescinputmode="readonly" descinputmode="readonly" />
 <checkbox
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewWOandPMS_ViewWOandPMSFieldGrid_3a" dataattribute="showchildren" />
 <checkbox
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewWOandPMS_ViewWOandPMSFieldGrid_3b" dataattribute="showparents" />
 <buttongroup
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewWOandPMS_ViewWOandPMSFieldGridAsset99">
 <pushbutton
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewWOandPMS_ViewWOandPMSFieldGridAsset98" label="Refresh" default="true" mxevent="doRefresh"
targetid=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_wopms_byasset"/>
 </buttongroup>
</section>
 <tabgroup
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewWOandPMS_viewWOandPMSAsset">
 <tab
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewWOandPMS_viewWOandPMSAsset_ViewWO_tab" default="true" label="Work">
 <table
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewWOandPMS_viewWOandPMSAsset_ViewWO" label="Work" relationship="VIEWWORK_BYASSET"
allowqualifiedrestriction="true" beanclass="psdi.webclient.beans.common.ViewWOByAssetBean" selectmode="multiple">
 <defaultvalue
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewwoasset_historyflag_default" dataattribute="historyflag" value="N"
defaulttype="query" />
 <defaultvalue
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_viewwoasset_istask_default" dataattribute="istask" value="N" defaulttype="query" />
```

## Example: Restricting the classifications that users see when classifying a service request in the Service Request application

In this example, you set the `allowqualifiedrestriction` property into the XML for the table in the tree in the window:

```
<dialog
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_associateClassification" label="Classify">
 <tree mboname="CLASSSTRUCTURE" allowqualifiedrestriction="true"
id=" home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_eg_data_restrictions_associateClassification_tree">
```

```
beanclass="psdi.webclient.beans.assetcat.AssociateSpecBean" width="600" height="250" openfirstlevel="false"
maxchildren="1000">
```

---

## Defining signature options for an application

Signature options specify privileges for using applications, menu options, and toolbar items. You apply signature options to groups of users to control their access to data, to applications, and to controls. New applications are automatically assigned a READ signature option. You can add more signature options in the Application Designer.

---

### Procedure

1. Open the application in the Application Designer.
2. Select the Add Modify Signature Options in the Select Action menu and click New Row.
3. Specify a signature option in the Option field.
4. Optional: Add additional signature options in the Option Also Grants field.  
Use commas to separate multiple entries if you want to enable more than one additional signature option.  
For example, if the signature option grants access to the People application, you can add signature options that grant access to a related application, such as the Users application.
5. Optional: In the Option Also Revokes field, specify any signature options that are revoked as a result of adding the primary option.  
For example, you add a signature option that allows read-only access to an application. You want to remove any write access to the application that users with the read-only signature option have. To remove the write access, you specify the signature option that grants write access to the application in the Option Also Revokes field.
6. Save the signature options.

---

## Arranging the layout of controls

The layout of components is relative to the other components in a user interface. Use container controls, like sections and tables, to group associated controls. Arrange controls to make it easy for users to enter information in an orderly and efficient manner.

- [Laying out a new tab](#)  
In standard applications, the information is contained in multiple tabs, including the List tab, the application main tab, and additional tabs as required.
- [Merging classification attribute values into one column](#)  
Multiple columns are used to display classification attributes and their values which makes the display complex. You can merge the data for the three columns into one column to make more space available in the table for additional columns to be added. This size reduction ensures that the table is not so large that users have to scroll to see columns.
- [Controlling the size of fields](#)  
You change the size of a single field by modifying the width value for that field in the presentation.xml file. You can also define a range of values for a data type in the field-size-config.xml file.
- [Adding images](#)  
The Application Designer includes controls that you can use to add images such as icons, to an application. The images directory contains existing images that you can reuse or you can add new images to the directory. Images must be in a file format supported by a browser.

---

## Laying out a new tab

In standard applications, the information is contained in multiple tabs, including the List tab, the application main tab, and additional tabs as required.

---

### Procedure

1. Optional: To add a new tab, highlight the Tab Group control in the Application Designer and drag a Tab control to it from the Control Palette.
2. Highlight this new tab control and drag a Section control to it from the Control Palette. Repeat this step if you want to create multiple sections that create vertical division in the tab.  
A section control is a container for other controls and is not visible in the application.
3. Add section column controls to a section if you want to divide a section horizontally.
4. After you create horizontal and vertical sections, you can add data controls, such as text boxes or buttons, within each section or section column.

---

## Merging classification attribute values into one column

Multiple columns are used to display classification attributes and their values which makes the display complex. You can merge the data for the three columns into one column to make more space available in the table for additional columns to be added. This size reduction ensures that the table is not so large that users have to scroll to see columns.

---

## Before you begin

The Maximo® business object (MBO) that the Classification Specifications table is bound to must contain ALNVALUE, NUMVALUE, and TABLEVALUE attributes. If the MBO does not contain the attributes, you cannot merge classification attribute values.

The Classification Specifications table must also contain either a field class or a MBO validation class. The inclusion of either a field class or a MBO validation class ensures that all the value fields are read-only. The only exception is the value field associated with the data type of an attribute. For example, if the datatype is alphanumeric, the alphanumeric MBO attribute is read/write while the numeric and table value MBO attributes are read-only.

## About this task

---

You can merge classification attribute values only for the classification specification attributes.

## Procedure

---

1. In the Application Designer application, open the application that you want to change.
2. In the Specifications table on the Specifications tab, click the attribute that you want to change.
3. Delete the alphanumeric value column, the numeric value column, and the table value column by using the Context menu.
4. In the toolbar, click Control Palette and select the Table Column icon.
5. Drag the table column onto the Specifications table and close the Controls window.
6. Open the Context menu, click Properties, and specify the label name for the column.  
If you do not specify a name, the label from the alphanumeric value attribute is used.
7. Specify {CLASSSPECVALUE} as the attribute value, and clear the Show Filter check box.
8. Ensure that the Sortable check box and the Filterable check box are clear.
9. Save the changes.

## Controlling the size of fields

---

You change the size of a single field by modifying the width value for that field in the presentation.xml file. You can also define a range of values for a data type in the field-size-config.xml file.

- [Specifying size ranges for data types](#)  
You control the size range of a data type in the user interface by modifying the value in the field-size-config.xml file. The size of a field in the user interface depends on a setting for each data type and the length of the column in the database. This dependency creates a uniform appearance in the UI when fields of different lengths are beside or on top of each other in the same section.
- [Specifying the size of single fields](#)  
You modify the width attribute in the presentation.xml file to change the width of a single field.

## Specifying size ranges for data types

---

You control the size range of a data type in the user interface by modifying the value in the field-size-config.xml file. The size of a field in the user interface depends on a setting for each data type and the length of the column in the database. This dependency creates a uniform appearance in the UI when fields of different lengths are beside or on top of each other in the same section.

## About this task

---

Field sizes are defined in the <root>\applications\maximo\properties\field-size-config.xml. For example, for an ALN field:

```
<maxtype name="aln">
<range below="2" size="2"/>
<range upper="30" size="10"/>
<range upper="31" size="40"/>
</maxtype>
```

In this example if the ALN value is defined with a length of 1 or 2, the field displays 2 characters. If the value is defined from 3 to 30, the field displays 10 characters. If the field is defined with a size of 31 or greater, the field displays 40 characters.

## Procedure

---

1. Open the field-size-config.xml file in a text editor.
2. Search for the data type and change the size range that is specified for the field.
3. Save the file.
4. Rebuild and redeploy the .EAR files on the application server for your changes to take effect.

## Specifying the size of single fields

---

You modify the width attribute in the presentation.xml file to change the width of a single field.

## Procedure

---

1. Open the presentation.xml file.
2. Identify the field that you want to change the width of.
3. Check that the **description id** has a width attribute and add a width attribute if it is absent.
4. Change the width attribute in the **description id** to specify the size of the field.

For example, you use the following code to change the width of a field to 100 pixels:

```
<tablecol dataattribute="description"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_t_define_value_field_results_sh
owlist_tablebody_3" width="100"/>
```

5. Save the presentation.xml file.

---

## Adding images

The Application Designer includes controls that you can use to add images such as icons, to an application. The images directory contains existing images that you can reuse or you can add new images to the directory. Images must be in a file format supported by a browser.

- [Adding images to the images directory](#)  
All images used in applications must be stored in the images directory. You can add new images to this directory.
- [Adding a record image to an application](#)  
You can add a record image control to an application to create a placeholder for a record image, typically an expandable thumbnail image that a user can click to enlarge. When you add the record image to the application, the image displays automatically in the placeholders you created with the record image control.

---

## Adding images to the images directory

All images used in applications must be stored in the images directory. You can add new images to this directory.

---

### Before you begin

Images must be in a format that is supported by a browser, such as .gif, .jpg, or .bmp formats.

---

### Procedure

1. Copy an image (in a supported format) into the images directory, at <root>\applications\maximo\maximouiweb\webmodule\webclient\images.
2. If the image is .gif format, no further action is necessary before you use the image in the Application Designer.
3. If the image is not in .gif format, you must redeploy the .EAR files on the application server before you can use it.

---

## Adding a record image to an application

You can add a record image control to an application to create a placeholder for a record image, typically an expandable thumbnail image that a user can click to enlarge. When you add the record image to the application, the image displays automatically in the placeholders you created with the record image control.

---

### Before you begin

The record image file must be located in the images directory before you can add it to an application. If the Add Modify Image option is not included in the Select Action menu, you must add this menu option before you can add the record image to the application.

---

### About this task

You can add only one record image to an application but you can use the same image multiple times within the application by inserting multiple record image controls.

---

### Procedure

1. Highlight a container control and drag the Record Image control to it from the Control Palette.  
You can place a record image control into any container control.
2. Select the Record Image control and click Control Properties to open the Record Image Properties window.
3. Optional: Deselect Is Thumbnail if you only want to display a full-size version of the image.  
The default behavior for record images is to display an expandable thumbnail image that a user can click to enlarge. If you do not want to provide a thumbnail version of the image, you must specify a value in the Label field that overwrites the default label, Click to enlarge.
4. Optional: You can specify a label for the image or you can leave this field blank to use the default label text, Click here to enlarge.
5. Specify appropriate values in the Height and Width fields, based on the size of the image you intend to use.  
The default values generate a thumbnail image of 100 x 100 pixels, appropriate for a square image. To avoid distortion of the image, ensure that the size values are proportionate to the size of the image.
6. Provide a text description of the image in the ALT Text on Image field.

- Alternative text is used as a substitute for the image when images are not supported, for example by screen readers.
7. Repeat the preceding steps if you want to add placeholders for the record image in other positions in the application, such as on another tab.
  8. Select the Add Modify Image option in the Select Action menu to specify the record image to use for the application.  
The image can be in .gif or .jpg format and must be located in the images directory.

---

## Configuring default values for controls

You can change the labels for fields, specify default values and filters for fields, and you can configure value lists for fields.

- [Assigning a default label to an attribute](#)  
You can specify a default value for an attribute, and all text box controls that bind to the attribute inherit this value. The value is saved in the database.
- [Saving changes to the database](#)  
After you make changes to the database in the Database Configuration application, you must commit the changes to the database. The data on the server is then reloaded and the user interface (UI) is updated with the changes that you made. For example, new fields are added or field labels are updated.
- [Overriding a value in the default label field](#)  
You can specify a label for a text box that overrides the default label.
- [Assigning a default value to an application field](#)  
You can assign a default value for a field that is specific to an application. The default value does not apply to fields in other applications that are associated with the same attribute.
- [Setting default filters for a table window](#)  
You can define a default filter for a table window using the Default Value control in the Application Designer.
- [Adding a value list to a text field](#)  
You can add a lookup icon to a text box control and configure a list of values that users can select from when they click the icon.

---

## Assigning a default label to an attribute

You can specify a default value for an attribute, and all text box controls that bind to the attribute inherit this value. The value is saved in the database.

---

### Before you begin

This procedure describes how to update objects in the database. Backup the database and make any necessary arrangements before you restart the database and the application server.

---

### Procedure

1. In the Database Configuration application, select the appropriate object.
2. Select the appropriate attribute or click New Row to specify a new attribute.
3. In the Attributes table, complete the following steps to find a supplemental attribute for the comment field:
  - a. Click Filter.
  - b. In the Description field, enter `supplemental`.
4. Specify the value you want to use as the default label for the attribute in the Title field.
5. Click Save.
6. Run the `configdb` command to save the changes to the database. Sign out of the system and stop the application server.
7. To add the attribute to an application, in the Application Designer, drag a text box control from the Control Palette into a section control in the workspace.
8. Select the text box control and click Control Properties.
9. Specify the attribute that you configured.  
The window refreshes, and the Default Label field contains the value that you configured.

---

## Saving changes to the database

After you make changes to the database in the Database Configuration application, you must commit the changes to the database. The data on the server is then reloaded and the user interface (UI) is updated with the changes that you made. For example, new fields are added or field labels are updated.

---

### Procedure

1. In the Database Configuration application, make your changes.
2. From the More Actions menu, select Manage Admin Mode.
3. In the Turn Admin Mode ON window, click Turn Admin Mode ON and click Close.
4. From the Select Action menu, select Apply Configuration Changes.
5. From the More Actions menu, select Manage Admin Mode.
6. In the Turn Admin Mode ON window, click Cancel Admin Mode and click Close.
7. Sign out of Maximo® Manage.
8. Sign in to Maximo Manage.

---

## Restarting the server

Although you do not have to stop and restart the server when you apply configuration changes, you can also choose that option to apply database changes.

### Procedure

1. Log in to Maximo Application Suite as a system administrator.
2. From the catalog, on the Applications tab, select the Manage tile.
3. On the application details page, click Actions and select Update configuration.
4. In the Update Manage configuration window, select Update configuration.
5. Click Show advanced settings.
6. To turn off the server, complete the following steps:
  - a. In the Server mode section of the deployment window, in the Mode field, select Off.
  - b. Click Activate.
  - c. In the Confirmation window, click Activate.
7. To restart the server, complete the following steps:
  - a. In the Server mode section of the deployment window, in the Mode field, select On.
  - b. Click Activate.
  - c. In the Confirmation window, click Activate.

---

## Overriding a value in the default label field

You can specify a label for a text box that overrides the default label.

### About this task

The label that you specify applies to this specific application and does not replace the default value that you configured for the attribute.

### Procedure

1. Select the text box in the workspace and click Control Properties.
2. Specify the value that you want to use in the Label field.  
The label for the text box updates in the workspace.
3. Click Save.

---

## Assigning a default value to an application field

You can assign a default value for a field that is specific to an application. The default value does not apply to fields in other applications that are associated with the same attribute.

### Procedure

1. Select the section control that contains the field and click Control Properties.
2. Drag the Default Value control to the section from the Control Palette.  
If you do not see the Default Value control when the workspace refreshes, click Toggle Show All Controls in the Select Action menu.
3. Select the Default Value control and click Control Properties.
4. Specify an attribute in the Attribute field and specify its default value in the Value field.  
When you associate a text box in the section with the same attribute, the default value is set to this value.
5. Optional: To use the value you selected for each new record, specify Insert as the Default Type.
6. Optional: To inherit the default value from another data source and attribute, complete the From Data Source ID and From Attribute fields.

---

## Setting default filters for a table window

You can define a default filter for a table window using the Default Value control in the Application Designer,

### Procedure

1. Drag the Default Value control from the Control Palette into the section control that contains the table to filter.  
If the Default Value control is not visible after the workspace refreshes, click Toggle Show All Controls in the Select Action menu.
2. Specify the attribute to filter.
3. Specify one or more values to use as filters in the Value field.  
Use commas to separate multiple values. You can also use % as a wildcard or = to specify an exact match.
4. Select Query in the Default Type field.
5. Click Save.

---

## Adding a value list to a text field

You can add a lookup icon to a text box control and configure a list of values that users can select from when they click the icon.

## Before you begin

You can use an existing lookup value list or you can configure a new one.

To create a value list, configure a domain that contains the values, associate the domain with an attribute, and update the presentation XML for the application to include the value list.

To use an existing lookup value list, export the system XML and locate the relevant Lookup ID in the lookups.xml file.

When you assign lookups for a field that has a table domain, you use a lookup from the application that the field is in. You cannot use the VALUelist lookup with table domains.

## Procedure

1. In the Domains application, click Add New Domain > Add New ALN Domain.
2. In the ALN Domain window, specify values in the required fields.  
You must use precisely the same values when you configure the associated attribute in the Database Configuration application. The data type determines whether options in the list are displayed as uppercase, lowercase, or either. The length determines the width of the list. A length of 10 is adequate for most purposes.
3. Click New Row, specify a value, and click OK.  
This value becomes an item in the value list.
4. Repeat Step 3 for each additional value.
5. Click Save.
6. In the Database Configuration application, open the application to which you intend to add the value list.
7. In the Attributes tab, click New Row and configure the attribute by using the precise values you specified for the domain.
8. To save the changes to the database:
  - a. From the More Actions menu, select Manage Admin Mode.
  - b. In the Turn Admin Mode ON window, click Turn Admin Mode ON and click Close.
  - c. From the Select Action menu, select Apply Configuration Changes.
  - d. From the More Actions menu, select Manage Admin Mode.
  - e. In the Turn Admin Mode ON window, click Cancel Admin Mode and click Close.
  - f. Sign out of Maximo® Manage.
  - g. Sign in to Maximo Manage.
9. In the Application Designer, open the application that you want to change and drag a text box control from the Control Palette to a section in the workspace.  
An Invalid binding message is displayed in the text box. When you associate the control with an attribute, the message no longer displays.
10. Select the text box control and click Control Properties.
11. In the Textbox Properties window, specify values in the following fields:

Option	Description
Label	Label to display for the field.
Attribute	Attribute for this field. Specify the same name for the attribute as the name you configured in the database.
Lookup	Valuelist

A lookup icon is displayed next to the text box control and the Invalid message is no longer displayed.

12. Click Save.

## Moving application controls

Use the Application Designer to move controls across tabs or across applications. You can also move controls and applications to a different server and export multiple applications.

- [Moving controls across tabs](#)  
You can move a control or a group of controls from one tab to another within an application.
- [Moving controls across applications](#)  
You must edit the presentation.xml files to move a control or a group of controls from one application to another.
- [Moving components and applications across servers](#)  
You can move user interface components and applications across servers, for example to move from a nonproduction environment to a production environment. Different members of the organization can configure different applications and then move them to a centralized test environment.
- [Exporting multiple applications](#)  
You can copy multiple applications at the same time to another server by exporting the presentation XML for each application to a single XML file.

## Moving controls across tabs

You can move a control or a group of controls from one tab to another within an application.

## About this task

When you move a container control, all of the controls it contains move with it.

---

## Procedure

---

1. Select a control or a group of controls, typically a section.
2. Right click the mouse, and click Copy or Cut.
3. Click the tab where you want to copy or move the control.
4. Select the target control (usually a section).
5. Click Paste.

---

## Moving controls across applications

You must edit the presentation.xml files to move a control or a group of controls from one application to another.

---

## Procedure

---

1. Open the source application in the Application Designer and click Export Application Definition.  
The XML definition opens in the browser.
2. Save the XML definition to a file.
3. Open the target application and perform the same steps to export the XML definition and save it to a file.
4. Open the XML file for the source application in a text editor.
5. Locate the control ID or the section control ID that you want to move.  
You can use the unique control ID that is listed in the Control Properties window to search for the control in the XML file.
6. Select the relevant code and copy it to the clipboard.
7. Open the XML file for the target application in a text editor.
8. Navigate to where you want to insert the control and Paste the code that is stored on the clipboard.
9. Save both XML files.
10. Open the target application in the Application Designer and click Import Application Definition.
11. Specify the target application XML file that you modified, and click OK.

---

## Results

---

When you copy a multipart text box control to a different application, the control must link to an attribute that exists in the main object table for both applications. If the attribute relationship does not exist, the multipart text box control in the target application does not contain any property values.

---

## Moving components and applications across servers

You can move user interface components and applications across servers, for example to move from a nonproduction environment to a production environment. Different members of the organization can configure different applications and then move them to a centralized test environment.

---

## Procedure

---

1. Create a backup directory for the XML files you are moving.  
You can use the backup files to restore application definitions in the future, if necessary.
2. Open the application on the source server, and click Export Application Definition.
3. Save the code as an XML file in the backup directory you created.
4. Repeat steps 2 and 3 for each application that you want to export.
5. Make a copy of the XML file(s) you created.
6. Paste the copy of the XML files onto the target server.
7. Open the Application Designer on the target server, click Import Application Definition, and navigate to the XML files.  
When you import an application, you overwrite the application in the database and not in the directory of presentation.xml files.

---

## Exporting multiple applications

You can copy multiple applications at the same time to another server by exporting the presentation XML for each application to a single XML file.

---

## Procedure

---

1. In the Applications tab of the Application Designer, press the Return key.  
The screen refreshes with a list of all applications.
2. Scroll to the end of the screen and click Select Records check box.  
The screen refreshes and includes a selection check box for each record.
3. Check each application whose XML presentation you want to export.
4. In the Workspace tab, click Export Application Definition from the Select Action menu.
5. An XML file opens in a browser window that includes the presentation code for each application you selected for export.  
You can find the start point for an application by searching for the **presentation id** string.
6. Save the XML file to a directory.

## What to do next

---

To import the XML file into another system, in the Application Designer click Import Application Definition and navigate to the XML file. The import reads the beginning and end point for each application embedded in the XML file and loads the applications accordingly.

---

## Adding navigation components

You can link to applications and to external URLs, and you can add menus and buttons to organize application navigation.

- [Navigation components](#)  
There are several ways that you can integrate a new application into the existing navigation and you can add new navigation components if required.
- [Linking to an external URL](#)  
You can create a link to an external website from an application using a hyperlink control.
- [Linking to an application from a text field](#)  
You can configure a pull-down menu associated with a text field to have options that take the user to different applications.
- [Adding buttons to the application toolbar or Common Actions menu](#)  
You can include extra buttons on the application toolbar or in the Common Actions section of the side navigation menu. Toolbar buttons provide quick access to common actions, such as Save and Insert, and can be seen in all application tabs or can be limited to a specific tab.
- [Adding buttons next to text boxes](#)  
You can add buttons next to text boxes for the menu items that are most frequently used. You can add up to three buttons to a text box.
- [Adding options to the Select Action menu or More Actions menu](#)  
You can include options in the Select Action menu or in the More Actions menu. You add more options to give users access to the actions that they occasionally require.
- [Modifying links in a self-service application](#)  
To change the links in the application bar of a self-service application, you must configure a property in the presentation.xml file for the application. You can configure these links for a self-service application that you duplicated from an existing application or for a new self-service application that you create.

---

## Navigation components

There are several ways that you can integrate a new application into the existing navigation and you can add new navigation components if required.

The Application Designer provides several navigation components that you can modify to add a link to an application, an application tab, or an application popup window.

- Go To menu
- Application toolbar
- Select Action menu
- Menu templates
- Application bar menu in self-service applications

---

### Go To menu

The Go To menu lists all of the modules and applications that a user can access. The menu is hierarchical and lists modules at the top level. When the user clicks a module, a submenu lists the applications in that module. When you create an application in the Application Designer, you specify its module and the application name is added under this module in the Go To menu. When you duplicate an application, the new application is added to the same module as the original application.

The contents of the Go To menu are generated automatically and you cannot customize them in the Application Designer.

---

### Application toolbar

The application toolbar contains buttons that are arranged in a horizontal line at the top of the application window. You can add new buttons to the toolbar and modify existing ones in the Application Designer. Buttons can be specific to the toolbar in one application tab, or can be visible in all tabs.

Button images are stored in the images directory and you can add new images or reuse existing images.

---

### Select Action menu

The Select Action menu lists application-specific actions. You can add new options to the Select Action menu and modify its existing options in the Application Designer.

---

### Menu templates

You can reuse the code for existing menus as a template for a new menu. Use the Application Designer to export the menus.xml file, modify the file in a text editor, and then import the updated file back into the Application Designer.

You can use the XML code for any of the menus in the menus.xml file as a template for a new menu.

---

### Application bar menu

Self-service applications do not have a Go To menu and provide access to applications in a menu at the top of the application window. You can export the presentation.xml file to add a navigation property to the application bar of a self-service application. If you customize the application bar menu, any preconfigured links are ignored.

---

## Linking to an external URL

You can create a link to an external website from an application using a hyperlink control.

---

### Procedure

1. Open the application in the Application Designer.
2. Select either a section control or a table control and drag a hyperlink control to it from the Control Palette.
3. Specify a value in the Label field.  
This value becomes the text link that a user clicks to go to the URL.
4. Specify a valid URL for the destination site.
5. Optional: Specify values in the Image Filename and Image Alignment fields if you want to associate an image with the hyperlink.
6. Optional: Specify a value in the CSS Class Name field if you want to change the appearance of the hyperlink.

---

### Results

When a user clicks the link within the application, the destination website opens in a new browser window.

---

## Linking to an application from a text field

You can configure a pull-down menu associated with a text field to have options that take the user to different applications.

---

### Procedure

1. Open the application in the Application Designer.
2. Select a text box control and click Control Properties.  
You can also configure an application menu for multipart text box control and a table column control.
3. Add the name of an application that you want to link to in the GOTO Application field.
4. Specify a value in the Menu Type field that corresponds to the application you specified.  
Click Export System XML in the Select Action menu to export the menus.xml file. You can search this file for the appropriate menu type value.

---

## Adding buttons to the application toolbar or Common Actions menu

You can include extra buttons on the application toolbar or in the Common Actions section of the side navigation menu. Toolbar buttons provide quick access to common actions, such as Save and Insert, and can be seen in all application tabs or can be limited to a specific tab.

---

### About this task

If the side navigation menu is enabled, any buttons that you add to the toolbar are displayed in the Common Actions section of the side navigation menu.

---

### Procedure

1. Open the application in the Application Designer.
2. In the Select Action menu, select the Add/Modify Toolbar Menu option.
3. Create a row and select an Element Type.
4. Select a Key Value.  
The key value represents the button action and is visible when the user moves the mouse over the button.
5. Specify an image to use for the button that is located in the images directory and is in a supported format.
6. Enter position values that determine the location of the button relative to the other buttons in the toolbar.
7. Specify the tabs where the option is visible.

---

### Example

To add a Change Password button to the toolbar in the Main tab of the Person application:

1. Set the Element Type to App (application).
2. Select ChgPassword as the Key Value.
3. Set Position to 60 and Subposition to 0.
4. Specify the nav\_icon\_changepassword.gif file in the Image field.
5. Select the Main tab option.

## What to do next

You can add buttons that act as separators if you want to group several buttons together in a section.

## Adding buttons next to text boxes

You can add buttons next to text boxes for the menu items that are most frequently used. You can add up to three buttons to a text box.

### About this task

You can select existing menus from the menus.xml file, or you can define new menus in the menus.xml file. The menu items must contain the label, event, and image attributes, for example:

```
label="Select Value" event="selectvalue" image="menu_icon_find.gif"
```

The following restrictions apply when you add buttons next to text boxes and multipart text boxes:

- Select Value menu items are not displayed if there is no lookup attribute defined for the text box. For example, Select Value menu items are not displayed next to Long description fields.
- If the button is a link to an application and the user does not have access to the application, the button is not displayed.
- If the menu item is defined with any conditional expressions, the button is not displayed.

### Procedure

1. In Application Designer, select the field that you want to add buttons to and open the Control Properties window.
2. Specify the ID of the menu.
3. Save the application definition.

- **Example: Adding buttons next to a multipart text box**

You want to add buttons next to a multipart text box so that users do not have to search the Select Action or Detail menus. You identify the menu items that users require most frequently for the multipart text box. No existing menus include the items so you create a menu that is called ICONTEST1 in the menus.xml file.

## Example: Adding buttons next to a multipart text box

You want to add buttons next to a multipart text box so that users do not have to search the Select Action or Detail menus. You identify the menu items that users require most frequently for the multipart text box. No existing menus include the items so you create a menu that is called ICONTEST1 in the menus.xml file.

When there are no restrictions on the text box or user, the first three menu items that are defined in the menu are displayed. When there are restrictions on the text box or user, a menu item might not be displayed and the next menu item is displayed instead.

You identified the five menu items that users require most often:

- Select Value
- Application link to the Configuration Items application
- Application link to the Assets application
- Classification search
- Attribute search

You create a menu that is called ICONTEST1 that specifies five menu items:

```
<menu
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_example_add_buttons_textbox_ICONTEST1">
 <menuitem
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_example_add_buttons_textbox_icontest1_mi1" label="Select Value" event="selectvalue" image="menu_icon_find.gif" />
 <menuitem
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_example_add_buttons_textbox_icontest1_mi2" label="Go To" event="applink" image="menu_icon_link.gif"
applinkid="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_example_add_buttons_textbox_ci" />
 <menuitem
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_example_add_buttons_textbox_icontest1_mi3" label="Go To" event="applink" image="menu_icon_link.gif"
applinkid="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_example_add_buttons_textbox_asset" />
 <menuitem
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_example_add_buttons_textbox_icontest1_mi4" label="Classifications(w/Sigopt)" event="searchClassificationCI"
image="action_insert_launch.gif" sigoption="REFICONS" />
 <menuitem
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_c_example_add_buttons_textbox_icontest1_mi5" label="Attributes" event="searchAttributeCI" image="menu_icon_catalog.gif" />
</menu>
```

In the Control Properties window of Application Designer, you specify `ICONTEST1` as the ID.

Look up icons or Select value menu items are not shown next to Long description fields so the first button is not displayed. If the user group does not have access to the `sigoption` `REFICONS`, the fourth menu item is also not displayed. In this case, only the buttons for menu items 2, 3, and 5 are displayed as buttons next to the Long description field.

---

## Adding options to the Select Action menu or More Actions menu

You can include options in the Select Action menu or in the More Actions menu. You add more options to give users access to the actions that they occasionally require.

---

### About this task

If the side navigation menu is enabled, options that you add to the Select Action menu are displayed in the More Actions section of the side navigation menu.

---

### Procedure

1. Open the application in the Application Designer.
2. In the Select Action menu, select the Add/Modify Select Action Menu option.
3. Create a row and select an Element Type and Key Value.
4. Enter position values that determine the location of the option in the menu.
5. Specify the tabs where the option is visible in the Select Action or More Actions menu.

---

## Modifying links in a self-service application

To change the links in the application bar of a self-service application, you must configure a property in the `presentation.xml` file for the application. You can configure these links for a self-service application that you duplicated from an existing application or for a new self-service application that you create.

---

### About this task

When you configure the `appbarlinks` property, any existing links that are found in the database are ignored, and only the customized links are displayed.

---

### Procedure

1. Open the application in the Application Designer.
2. Select the Export System XML option in the Select Action menu.
3. Save the XML file to a local directory and open it in a text editor.
4. Search for the `appbar` tag in the XML file.
5. Add `appbarlinks=" "` to the `appbar` tag to add the navigation menu to the application bar control.
6. Insert the links, separated by semicolons.
7. For each link, you can specify up to three attributes, separated by commas.
  - a. ID of the linked application
  - b. Text description to display in the application bar
  - c. Image to display next to the description

For example:

```
appbarlinks="Application1,Description1,image1.gif:
Application2,Description2,image2.gif"
```

8. Save the changes to the XML file.
9. Import the file into the Application Designer to save the new menu information.

---

## Configuring related information for fields

To see information related to a field without leaving the record, you add a hover window to the field. Hover windows are immediately enabled on some fields but you can also enable these existing hover windows on other fields or you can create a hover window depending on your requirements.

- [Example: Enabling an existing hover window](#)  
You can enable existing hover windows on fields to suit your needs. For example, you can add a hover window to show the contact details for the owners of service requests. In general, you can show related information on any fields that support lookup.
- [Example: Creating hover windows](#)  
If none of the existing hover windows suit your needs, you can create a hover window. For example, you can create a hover window to show the organizations where failure classes occur. You design the hover window and specify the fields that appear.

---

## Example: Enabling an existing hover window

You can enable existing hover windows on fields to suit your needs. For example, you can add a hover window to show the contact details for the owners of service requests. In general, you can show related information on any fields that support lookup.

## About this task

The following hover windows are immediately available on some fields but can be enabled on other fields:

Field	ID
Asset	<i>asset_recordhover</i>
Work Order	<i>wo_recordhover</i>
Person	<i>person_recordhover</i>
Item	<i>item_recordhover</i>

In a large company, a supervisor is responsible for ensuring that service requests are assigned to the correct responder. To get contact information for the owner, the supervisor typically navigates to the Person record, which takes time and decreases efficiency. The supervisor wants to be able to hover the mouse over the Owner field and see the details of the owner of a service request. You can enable a hover window on the Owner field in the Service Requests application so that the supervisor can hover over the field and see the full name, email address and telephone number of the owner of the service request, without leaving the record.

## Procedure

1. In Application Designer, open the Service Requests application, click the Owner field and select Control Properties.
2. On the Advanced tab, specify *person\_recordhover* as the ID of the hover window and save the application definition.

## Example: Creating hover windows

If none of the existing hover windows suit your needs, you can create a hover window. For example, you can create a hover window to show the organizations where failure classes occur. You design the hover window and specify the fields that appear.

## About this task

The following widget types are supported:

- recordhoversection
- recordhoversectioncol
- recordhoversectionrow
- recordhovertextbox
- recordhovermultiparttextbox

In a multinational company, an administrator is noting the organizations where failure classes are reported as assets seem to be failing more frequently in some organizations. The administrator wants to hover over the Failure Class field to see the name of the organization where the failure occurred.

You review the list of hovers and determine that none suit this scenario, so you create a hover for the Failure Class field.

## Procedure

1. In Application Designer, select the Export System XML action and export the RECHOVERS.XML file.
2. Open the RECHOVERS.XML file in a text editor and add the following lines:

```
</recordhover>
<recordhover
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_t_eg_create_hover_window_fc_rec
ordhover">
 <recordhoversection
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_t_eg_create_hover_window_fc_rhs
_1" label="Failure Class Details">
 <recordhoversectioncol
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_t_eg_create_hover_window_fc_rhs
c_1">
 <recordhoversection
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_t_eg_create_hover_window_fc_rhs
_2">
 <recordhovertextbox dataattribute="ORGID"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_designer_t_eg_create_hover_window_fc_rh
_1" label="Organization">
 </recordhovertextbox>
 </recordhoversection>
 </recordhoversectioncol>
 </recordhoversection>
</recordhover>
```

3. Save the RECHOVERS.XML file and import it.
4. Open the Assets application, click Failure Class and select Control Properties.
5. In the Advanced tab, specify *fc\_recordhover* as the ID of the hover window and save the application definition.

## Providing user information

You can provide information to help users in the windows and tabs in the user interface. You can create links from windows and tabs, and also from field help, to topics in the product Knowledge Center. You can also add new error messages to an application.

- [Adding messages to the messages table](#)

You can add new messages to an application that help the user to resolve issues when the application encounters errors. Messages are displayed to the user and are added to logs to help with error resolution. When you add a message in the Application Designer, it becomes available for translation into supported languages.

- [Linking to user information](#)

You can add a link to a topic in the product Knowledge Center from a help grid control, or from the field help for any other control.

---

## Adding messages to the messages table

You can add new messages to an application that help the user to resolve issues when the application encounters errors. Messages are displayed to the user and are added to logs to help with error resolution. When you add a message in the Application Designer, it becomes available for translation into supported languages.

---

### About this task

Single quotation marks (') do not appear in the displayed message. To include quotation marks in the displayed message, you must use double quotation marks (") when you write the text of the message.

---

### Procedure

1. Open the application in the Application Designer.
2. Select the Messages option from the Select Action menu.
3. Specify the identifier for the Message Group.
4. Specify a Message Key that is unique in this message group.
5. Select a Message ID.
6. Specify the text of the message in the Value field.
7. Complete any other relevant fields and click OK.

---

## Linking to user information

You can add a link to a topic in the product Knowledge Center from a help grid control, or from the field help for any other control.

---

### About this task

The URL for an Knowledge Center topic must have the following format: `com.ibm.mbs.doc,application/helpfile.html`

---

### Procedure

1. To create a link from a help grid control, specify the URL for the topic in the More information field in the Help Grid Properties window.
  2. To create a link from the field help for a control, specify the URL for the topic in the More information field in the control properties window
- When the user clicks Alt + F1, a More information link is available in the help window.

---

### Results

When the user clicks a more information link, the relevant topic in the Knowledge Center opens in a new tab. You can add links from multiple controls to one topic, or you can link to multiple topics. You must add links manually to each individual control. If an Knowledge Center topic is moved or deleted, users can encounter broken links if you do not update each control.

---

## Configuring dialog windows for an application

You can modify dialog windows that are specific to an application in the Application Designer. To modify dialog windows that are shared with other applications, you must modify a system XML file. You can also create a dialog and add it to an application.

- [Modifying an application dialog window](#)

You can modify a dialog window that is specific to an application in the Application Designer.

- [Modifying a system dialog window](#)

To modify a system dialog window, you must export the library.xml file and modify the XML file in a text editor.

- [Creating a dialog window](#)

You can add a new dialog window to a specific application or you can make it available for use by all applications. You must modify an XML file to create a dialog window and import the modified file into the Application Designer. After importing it, you can modify the new dialog window in the Application Designer.

---

## Modifying an application dialog window

You can modify a dialog window that is specific to an application in the Application Designer.

### About this task

---

This procedure applies to dialog windows that are specific to the current application. If the dialog window is not available in the Edit Dialogs window, the window is probably a system dialog window that is shared by other applications.

### Procedure

---

1. In the Application Designer, click Edit Dialogs and select the dialog window that you want to modify.
2. In the Workspace, perform the modifications in the same manner as you modify an application.
3. Click Save.

---

## Modifying a system dialog window

To modify a system dialog window, you must export the library.xml file and modify the XML file in a text editor.

### Before you begin

---

Do not modify the library.xml file while other applications are using it.

### About this task

---

System dialog windows, such as the Change Status window, are shared by multiple applications and any changes you make apply to all applications that use the dialog. If you do not want to modify the window for all applications, copy the XML code for the dialog element and use this as a template for a new window that is specific to an application.

### Procedure

---

1. In the Application Designer, click the Export System XML option in the Select Action menu.
2. In the Export System XML window, select the Library option and click the Export XML icon.  
The library.xml file opens in a new browser window.
3. Save the library.xml file to a local file and open it in a text editor.
4. Locate the dialog element that you want to change in the XML file and modify as required.
5. Save the XML file.
6. In the Workspace of the Application Designer, click the Import Application Definition icon on the toolbar.
7. Browse to the local copy of the library.xml file that you changed and select it.  
The modified XML definition is saved to the database and the changes that you made are now available to all applications.

---

## Creating a dialog window

You can add a new dialog window to a specific application or you can make it available for use by all applications. You must modify an XML file to create a dialog window and import the modified file into the Application Designer. After importing it, you can modify the new dialog window in the Application Designer.

### Procedure

---

1. In the Application Designer, export one of the following XML files:
  - a. In the List tab, click Export System XML in the Select Action menu to export the library.xml file if you want to add a new dialog for use by all applications.
  - b. In the Workspace tab, click the Export Application Definition icon to export the presentation.xml file if you want to add a new dialog for use by a specific application.The XML definition opens in a new browser window.
2. Save the XML definition to a local file and open it with a text editor.
3. Add a code snippet for the dialog at the end of the XML file, just before the final closing tag, either the `</systemlib>` tag or the `</presentation>` tag.  
The following code creates a View History dialog window to the end of a presentation.xml file:

```
<dialog id="newviewhist" label="View History">
</dialog>
</presentation>
```

4. Save the changes to the XML file.
5. In the Application Designer, click the Import Application Definition icon, navigate to the modified XML file and import it.
6. Click the Edit Dialogs icon and select the dialog window you created.
7. In the Workspace tab, modify the dialog window as required.

---

## Transferring data between applications

To move data from a field in an application to another field in a different application, you can use linked objects and .

- [Data transfer options](#)

Although similar in purpose, there are distinct differences between the two configuration options that you can use to transfer data from a field in one application to a field in another. These data transfer options are based on either linked objects or on crossover domains.

- [Linking objects to share data between applications](#)

User interface controls are bound to database attributes that present data from the application parent (and child) objects in a browser window. Most applications present data that resides in other objects and you can use relationships, defined in the Relationships application, to indicate the connection between these objects. This scenario describes how to add user comments about an asset to a work order when you add the asset to a work order.

- [Using crossover domains to share data between applications](#)

The following scenario describes how to use a crossover domain to display comments about an asset on work orders. In this case, you use a crossover domain value to establish a link between the Workorder and Asset objects instead of using a database relationship to link objects. When using a crossover domain to copy data across applications, you cannot edit the asset comment value in the destination application.

---

## Data transfer options

Although similar in purpose, there are distinct differences between the two configuration options that you can use to transfer data from a field in one application to a field in another. These data transfer options are based on either linked objects or on crossover domains.

Linked objects can pass data from a source application to a target application using database relationships. In the destination application, the data value can be read, or read/write, depending on how you configure the input field. If you configure the destination input field to be read/write, the application framework automatically updates the source application and parent object if you update a displayed value.

Crossover domains pass data from one application to a different application using domains. A copy of the data value from a source application is passed to a destination application using the crossover domain as a trigger mechanism. You cannot edit the data value in the destination application, and the copied data value is static.

Database relationships that link objects and crossover domains enable the export of information from a source object to a destination object using WHERE clauses to filter for list and validation values. You can use a database relationship or a crossover domain to accomplish the following objectives:

- Enter an asset number in the Items application, retrieve the serial number of the asset from the ASSET object, and copy this value into a field.
- Enter an asset number for a new work order, retrieve the parent asset number from the ASSET object, and insert this value into a field.
- Enter a user name in an application, retrieve the user's phone number and address from the PERSON object, and insert the information into two different fields.
- Enter the user name for a person that is creating a material receipt record, retrieve the name of the user's supervisor from the PERSON object, and insert it into a field.

---

## Linking objects to share data between applications

User interface controls are bound to database attributes that present data from the application parent (and child) objects in a browser window. Most applications present data that resides in other objects and you can use relationships, defined in the Relationships application, to indicate the connection between these objects. This scenario describes how to add user comments about an asset to a work order when you add the asset to a work order.

- [Adding a comment attribute to an asset](#)

You must add an attribute (if one does not already exist) to the asset object as the first step in capturing user comment information about an asset.

- [Linking objects in different applications](#)

To capture comments associated with an asset on a work order, you must create a relationship or link between the ASSET and WORKORDER objects. Linking these objects enables the Work Order Tracking application to display and update information stored in the ASSET object.

- [Adding a text box for comments](#)

Your next step in the scenario is to add text box controls to the Assets application and to the Work Order Tracking application . The text box in the Assets application lets you input or edit a comment value for an asset. You can view these comments in the text box in the Work Order Tracking application.

---

## Adding a comment attribute to an asset

You must add an attribute (if one does not already exist) to the asset object as the first step in capturing user comment information about an asset.

### Procedure

1. In the Database Configuration application, filter for the ASSET object and click the Attributes tab.
2. In the Details section, click New Row.
3. Specify values in the following required fields or accept default values where appropriate:

Field label	Input value	Description
Attribute	Assetcomment	Attribute name
Description	User comments regarding the asset	Text description of attribute

Field label	Input value	Description
Type	ALN	The default
Length	100	Field length
Title	Comment	Alias name to substitute in messages and window labels
Search Type	Wildcard	Search on this attribute using wild card characters like * and %

- Click Save.
- Perform the usual procedures to run the ConfigDB tool to update the database to enable these database changes to take effect.

## Linking objects in different applications

To capture comments associated with an asset on a work order, you must create a relationship or link between the ASSET and WORKORDER objects. Linking these objects enables the Work Order Tracking application to display and update information stored in the ASSET object.

### Procedure

- In the Database Configuration application, select the Work Order application and then open the Relationships tab.
- Click New Row.
- In the Details window, specify the following values:

Field label	Input value	Description
Relationship	ASSET2WOLINK	The name of the database relationship
Child Object	ASSET	The name of the child object. WORKORDER is the parent object.
Where Clause	assetnum=:assetnum and siteid=:siteid	SQL Where Clause condition or conditions. The system does not validate your input in the Where Clause field. Verify that your syntax is correct.
Remarks	<text>	A description of the relationship. For example: This relationship binds WORKORDER and ASSET objects when you enter an asset number in a work order.

The following table describes the logic of the Where Clause conditions for this example:

WHERE clause syntax	Description
:assetnum	Represents asset number value entered in work order screen
assetnum=	Look in Asset object for the asset number that matches the value entered in the work order screen
:siteid	The Site value entered in work order screen
siteid=	Look in Asset object for the Site value that matches the current value in the work order screen

The Where Clause above joins the Work Order and Asset objects and locates a unique record.

- Click Save.

## What to do next

To complete the process of capturing asset comment information on work orders, continue to the next procedure that describes how to add a textbox control to Work Order Tracking in the Application Designer.

## Adding a text box for comments

Your next step in the scenario is to add text box controls to the Assets application and to the Work Order Tracking application. The text box in the Assets application lets you input or edit a comment value for an asset. You can view these comments in the text box in the Work Order Tracking application.

### Before you begin

Before you start, verify that you have added the assetcomment attribute to the Asset object.

### Procedure

- In the main tab of the Assets application in Application Designer, click the section that holds the Asset field.
- Click Control Palette and drag a text box control into the Asset section.
- Open the Control Properties window for the text box control.
- Specify the following information to bind the control to the assetcomment attribute:

Field input	Value	Description
Default Label	Defaults to the default label for the attribute	When you specify <code>assetcomment</code> in the Attribute field, this field defaults to the default label value of the attribute (if available). You can assign your own label value for this attribute that is specific to the application in the Label field. For example, you might enter <code>Asset Comments</code> .
Label	Comments	The value you enter here, for example, <code>Comments</code> , overrides the Default Label setting within the application. The value you enter for Label is specific to the application and not stored in an object.
Attribute	assetcomment	The name of the asset comment attribute in the Asset object.
Input Mode	DEFAULT	The Default option configures the Input Mode for the Comment field to be Read/Write or Edit mode.

- Click Save.
- In Application Designer, open the Work Order Tracking application and then select the Asset section of the application.
- Drag a text box control from the Control Palette to the workspace and position it between the Asset and the Parent WO fields.

8. Open the Control Properties for the text box and specify the following values:

Field input	Value	Description
Default Label	Defaults to the default label for the attribute	When you specify <code>assetcomment</code> in the Attribute field, this field defaults to the default label value of the attribute (if available). You can assign your own label value for this attribute that is specific to the application in the Label field. For example, you might enter <code>Asset Comments</code> .
Label	Comments	The value you enter here, for example, Comments, overrides the Default Label setting within the application. The value you enter for Label is specific to the application and not stored in an object.
Attribute	<code>asset2wolink.assetcomment</code>	Type the name of the asset comment attribute in the Asset object. You must preface the attribute with the name of the database relationship that binds the Asset and Workorder objects and a dot. For example, <code>asset2wolink.assetcomment</code> .
Input Mode	DEFAULT or READONLY	The Default option configures the Input Mode for the Comment field to be Read/Write or Edit mode. You can also configure the Comment field to be Read Only.

## Results

After this configuration, the Comments field is populated in the Work Order Tracking application whenever you add an asset record to a work order.

## Using crossover domains to share data between applications

The following scenario describes how to use a crossover domain to display comments about an asset on work orders. In this case, you use a crossover domain value to establish a link between the Workorder and Asset objects instead of using a database relationship to link objects. When using a crossover domain to copy data across applications, you cannot edit the asset comment value in the destination application.

- [Adding a comment attribute to an asset](#)  
You must add an attribute (if one does not already exist) to the asset object as the first step in capturing user comment information about an asset.
- [Adding a comment attribute to a work order](#)  
You must add an attribute (if one does not already exist) to the work order object.
- [Creating a crossover domain](#)  
You can create a crossover domain in the Domains application.
- [Applying a crossover domain](#)  
After you create a crossover domain, you must apply the domain that you created to a field that triggers the crossover conditions.
- [Adding a text box for comments](#)  
Your next step in the scenario is to add text box controls to the Assets application and to the Work Order Tracking application. The text box in the Assets application lets you input or edit a comment value for an asset. You can view these comments in the text box in the Work Order Tracking application.

## Adding a comment attribute to an asset

You must add an attribute (if one does not already exist) to the asset object as the first step in capturing user comment information about an asset.

### Procedure

1. In the Database Configuration application, filter for the ASSET object and click the Attributes tab.
2. In the Details section, click New Row.
3. Specify values in the following required fields or accept default values where appropriate:

Field label	Input value	Description
Attribute	<code>Assetcomment</code>	Attribute name
Description	User comments regarding the asset	Text description of attribute
Type	ALN	The default
Length	100	Field length
Title	Comment	Alias name to substitute in messages and window labels
Search Type	Wildcard	Search on this attribute using wild card characters like * and %

4. Click Save.
5. Perform the usual procedures to run the ConfigDB tool to update the database to enable these database changes to take effect.

## Adding a comment attribute to a work order

You must add an attribute (if one does not already exist) to the work order object.

### Procedure

1. In the Database Configuration application, filter for the WORKORDER object and click the Attributes tab.
2. In the Details section, click New Row.
3. Specify values in the following required fields or accept default values where appropriate:

Field label	Input value	Description
-------------	-------------	-------------

Field label	Input value	Description
Attribute	Woassetcomment	Attribute name
Description	User comments regarding the asset	Text description of attribute
Type	ALN	The default
Length	100	Field length
Title	Comment	Alias name to substitute in messages and window labels
Search Type	Wildcard	Search on this attribute using wild card characters like * and %

4. Click Save.
5. Perform the usual procedures to run the ConfigDB tool to update the database to enable these database changes to take effect.

## Creating a crossover domain

You can create a crossover domain in the Domains application.

### Procedure

1. In the Domains application, click Add New Domain > Add New CROSSOVER Domain to open the Crossover Domain window.
2. Specify a domain name and full description for the domain, for example `ASSET2WO` as the domain name and `Asset to Work Order Crossover Domain` as the full description.
3. Click New Row in the Crossover Domain section to open the detail section.
4. Specify `Asset` in the Object field to define Asset as the source object of the crossover.
5. Enter `assetnum=:assetnum` and `siteid=:siteid` in the Validation Where Clause field.
6. Click New Row in the Crossover Fields section to open the detail section.
7. Use the lookup to select the attribute that you chose from the Asset object in the Source field.
8. In the Destination field, type the attribute that you chose for the work order.
9. Click OK.

### What to do next

After you create the crossover domain for the asset, apply the crossover domain to a work order field that triggers the crossover conditions.

## Applying a crossover domain

After you create a crossover domain, you must apply the domain that you created to a field that triggers the crossover conditions.

### Procedure

1. In the Database Configuration application, open the Workorder object and click the Attributes tab.
2. Click Filter, and specify `ASSETNUM` in the Attribute field.
3. Press Enter to open the `ASSETNUM` details section, and specify `asset2wo` in the Domain field.
4. Click Save.

### What to do next

After you apply the crossover domain for the asset, add the crossover domain to the application for work orders.

## Adding a text box for comments

Your next step in the scenario is to add text box controls to the Assets application and to the Work Order Tracking application. The text box in the Assets application lets you input or edit a comment value for an asset. You can view these comments in the text box in the Work Order Tracking application.

### Before you begin

Before you start, verify that you have added the `assetcomment` attribute to the Asset object.

### Procedure

1. In the main tab of the Assets application in Application Designer, click the section that holds the Asset field.
2. Click Control Palette and drag a text box control into the Asset section.
3. Open the Control Properties window for the text box control.
4. Specify the following information to bind the control to the `assetcomment` attribute:

Field input	Value	Description
-------------	-------	-------------

Field input	Value	Description
Default Label	Defaults to the default label for the attribute	When you specify <code>assetcomment</code> in the Attribute field, this field defaults to the default label value of the attribute (if available). You can assign your own label value for this attribute that is specific to the application in the Label field. For example, you might enter <code>Asset Comments</code> .
Label	Comments	The value you enter here, for example, <code>Comments</code> , overrides the Default Label setting within the application. The value you enter for Label is specific to the application and not stored in an object.
Attribute	<code>assetcomment</code>	The name of the asset comment attribute in the Asset object.
Input Mode	DEFAULT	The Default option configures the Input Mode for the Comment field to be Read/Write or Edit mode.

- Click Save.
- In Application Designer, open the Work Order Tracking application and then select the Asset section of the application.
- Drag a text box control from the Control Palette to the workspace and position it between the Asset and the Parent WO fields.
- Open the Control Properties for the text box and specify the following values:

Field input	Value	Description
Default Label	Defaults to the default label for the attribute	When you specify <code>assetcomment</code> in the Attribute field, this field defaults to the default label value of the attribute (if available). You can assign your own label value for this attribute that is specific to the application in the Label field. For example, you might enter <code>Asset Comments</code> .
Label	Comments	The value you enter here, for example, <code>Comments</code> , overrides the Default Label setting within the application. The value you enter for Label is specific to the application and not stored in an object.
Attribute	<code>asset2wolink.assetcomment</code>	Type the name of the asset comment attribute in the Asset object. You must preface the attribute with the name of the database relationship that binds the Asset and Workorder objects and a dot. For example, <code>asset2wolink.assetcomment</code> .
Input Mode	DEFAULT or READONLY	The Default option configures the Input Mode for the Comment field to be Read/Write or Edit mode. You can also configure the Comment field to be Read Only.

## Results

After this configuration, the Comments field is populated in the Work Order Tracking application whenever you add an asset record to a work order.

## Configuring conditional user interface components

By applying conditions to control application behavior and to the user interface (UI), you can configure the UI to support your business processes. You can achieve the user interface behavior you require by configuring conditional data restrictions, by configuring conditional UI control behavior in Application Designer, or by configuring conditional security restrictions. For example, you can apply conditions to change the color of controls, the content of menus for different user groups, or the properties of the data shown.

- Conditional user interface**  
 Conditions are clauses or classes that evaluate to true or false when they are evaluated against an object. Conditions can be applied to user interface (UI) controls to control how the UI is shown to users and to support your business processes. You can apply conditional data restrictions, signature options to conditionally control access to controls, or conditional control properties to configure the UI.
- Creating conditions**  
 You can create conditions in the Conditional Expression Manager. Then, you can apply the conditions to fields, tabs, and other user interface controls in applications to control how the UI looks and behaves. You can also apply conditions to security groups to control access to applications, controls, and data.
- Applying conditional security**  
 You can limit access to data and to elements of the user interface to users that have the right level of access.
- Applying conditional data restrictions**  
 To support your business processes, you can apply conditions to restrict access to data for a user or for a user group. The data can be hidden, read-only, or required.
- Adding conditions to the properties of UI fields**  
 You can control how the user interface (UI) is shown to users and to support your business processes. When a control is bound to a signature option or an attribute, you can configure conditional properties in the Application Designer.

## Related information

-  [Technotes about conditional user interface features delivered with your product.](#)

## Conditional user interface

Conditions are clauses or classes that evaluate to true or false when they are evaluated against an object. Conditions can be applied to user interface (UI) controls to control how the UI is shown to users and to support your business processes. You can apply conditional data restrictions, signature options to conditionally control access to controls, or conditional control properties to configure the UI.

You can bind any UI control to a signature option to grant or revoke access to the control by groups of users. You can also apply conditions to the properties of a control so that the control looks or behaves differently for specified groups of users based on the evaluation of the applied conditions. For example, you can apply conditions to a control so that the color of the control changes depending on the value shown.

You can use the Application Designer to associate a control with a signature option and conditions. When a control is bound to a signature option or an attribute, you can take the following actions:

- Configure its behavior by setting a data restriction or conditional data restriction in Security Groups
- Grant the option in the Security Groups application

- [Configure conditional properties in the Application Designer](#)

When you are planning your conditional user interface system, you choose between the implementation methods listed. Data restrictions are useful for implementations where you want the restriction that you create to apply to every user interface element or application that uses an object or attribute. Security restrictions are useful when you want to restrict access to a control or to data to a specific group of users.

## Example: Showing status options based on the status of the current record

---

XYZ Corporation requires that the work order status that is available to work order dispatchers is based on the current work order status. For this company, when a work order status is Waiting on Approval, only the values Approved and Canceled are available to the dispatchers.

To implement this business process, in the Condition Expression Manager, create the following conditional expression:

```
WOSTATUSAPPR :status = 'WAPPR'
```

Then in the Application Designer application, apply that condition to the domain values WOSTATUS|APPR and WOSTATUS|CAN. The status options shown on the UI reflect the status of the current work order.

## Example: Changing historical data to read-only

---

ABC Inc. requires that all users see completed work orders from previous financial accounting periods as read-only. To implement this behavior, the application developer creates a condition that is true if the date checked is in the past. The date condition is evaluated against the date on completed work order records. The developer applies the condition to work order data in the Security Groups application for the security group that contains all users.

When the condition is evaluated, it returns a value of true if the work order date is from a previous financial period. All users see work order records from previous financial periods as read-only on the UI.

- [Hierarchy of restrictions](#)  
The conditional restrictions that you define are applied hierarchically. For example, if you make an attribute read-only by using a data restriction, you cannot use the Application Designer application to make a field that is bound to the attribute editable.

---

## Hierarchy of restrictions

The conditional restrictions that you define are applied hierarchically. For example, if you make an attribute read-only by using a data restriction, you cannot use the Application Designer application to make a field that is bound to the attribute editable.

The restrictions are applied as follows:

1. Database configurations
2. Data restrictions
3. Application configurations

Database configurations take priority over data restrictions and data restrictions take priority over application configurations.

If you define an object as read-only in the database, you cannot use data restrictions or the Application Designer application to make the object editable.

Data restrictions take priority over application configurations made in the Application Designer application. For example, if an attribute is made read-only using a data restriction, you cannot use the Application Designer application to make the attribute editable.

Configurations that are made with data™ restrictions apply everywhere an attribute is used. Application configurations made in Application Designer apply to that application only. For example, if you want to restrict access to a field that is in the header section of multiple tabs, you can put a data restriction on the field every instance of the field has the access restriction. If you configure the restriction in Application Designer, you must apply the restriction to each instance of the field on each tab.

---

## Creating conditions

You can create conditions in the Conditional Expression Manager. Then, you can apply the conditions to fields, tabs, and other user interface controls in applications to control how the UI looks and behaves. You can also apply conditions to security groups to control access to applications, controls, and data.

- [Conditions overview](#)  
A condition is a clause or class that evaluates to true or false when evaluated against an object. You can create and maintain a library of conditions. You can apply the conditions to fields, tabs, and other user interface controls to control the presentation. You can also apply conditions to security groups to control access to data, applications, and controls.
- [Creating conditional expressions and classes](#)  
You can create conditional expression-type and class-type conditions. Then you can apply the conditions to control access to data and to user interface controls.
- [Conditional expression syntax](#)  
You enter conditional expressions using a syntax similar to Structured Query Language (SQL) with some additional variables.
- [Sample conditional class files](#)  
Sample condition class files are stored in a folder under the root directory of the product installation. You can use the sample files when you create class-type conditions.

---

## Conditions overview

A condition is a clause or class that evaluates to true or false when evaluated against an object. You can create and maintain a library of conditions. You can apply the conditions to fields, tabs, and other user interface controls to control the presentation. You can also apply conditions to security groups to control access to data, applications, and controls.

There are two types of conditions:

### Expression-type condition

An expression-type condition is a clause that evaluates data and returns a result of true or false. The expression syntax is similar to structured query language (SQL) expressions, but it supports substitution variables. Use expressions to define simple conditions.

### Class-type condition

For class-type conditions, the condition logic is contained in Java™ classes that are stored in a file under the root product folder. You can create the class files that contain the condition logic. When the class-type condition is evaluated, it returns a true or false result. Use a class-type condition if the logic to be evaluated is too complex to be accomplished with a simple expression.

Conditions are created and managed in the Conditional Expression Manager. Describe each condition that you create to help you identify the conditions to apply to user interface elements or security groups.

You can use the Application Designer to apply conditions to user interface elements. You can also apply conditions in the Security Groups application to control access to applications and to actions within applications.

You can modify expression-type conditions. When you modify the condition, access to all data and to all user interface controls that use the condition is modified. You can determine whether a condition is applied to user interface controls, security groups, or data restrictions by checking the reference count field. If the reference count field is zero then the condition is not applied.

---

## Creating conditional expressions and classes

You can create conditional expression-type and class-type conditions. Then you can apply the conditions to control access to data and to user interface controls.

### About this task

To handle complex operations with multiple conditions, you can create an automation script that contains the condition logic. For more information, see [Automating routine tasks with automation scripts](#). Then, you can create a single condition that references the automation script and applies the condition as needed.

### Procedure

1. In the Conditional Expression Manager, add a row and change the auto-generated Condition identifier to a meaningful identifier. Enter a complete description of the condition in the Description field.  
A meaningful identifier and a complete description help you identify a condition later.
2. Select the condition type and enter the condition.
  - a. If you selected expression type, enter an expression, or click Condition Expression Builder to build an expression in the Condition Expression Builder.
  - b. If you selected class type, enter the class file name. The file must be in a folder under the root of the product folder, for example  
*Maximo\_home\maximo\samples*
3. Save the condition.

---

## Conditional expression syntax

You enter conditional expressions using a syntax similar to Structured Query Language (SQL) with some additional variables.

When you create a conditional expression, use a colon (:) to define a variable. The colon is used to avoid ambiguity when you create expressions that relate the current record to a different, specific record.

You can have subselect in an expression,

```
exists (select 1 from workorder where wonum=:wonum).
```

The first *wonum* is the *wonum* attribute on the work order object. At run time, the second *wonum* is replaced with the value of the *wonum* attribute for the current record.

### Replacement variables

Syntax	Description	Comments
:yes	true	Logically true, 1 if stored in the database
:no	false	Logically false, 0 if stored in the database
:%date%	Current® date	
:%datetime%	Current date and time	

Syntax	Description	Comments
:&user&	Logged in user	For example, if a user is signed in as Smith, :owner.id=&user& converts to :ownerid='SMITH'
:&personid&	Person ID of logged in user	For example, if a user is logged in as Smith, :reportby=&personid& converts to :reportby='SMITH'
:&appname&	Application name	For example, in the Work Order Tracking application, :&appname& = WOTRACK converts to WOTRACK = WOTRACK. This variable is useful for setting different behavior for different copies of an application.
:&mboname&	Name of the current business object	For example, in the work order object, object = :&mboname& converts to object = WORKORDER
:&ownername&	Name of the owner business object	For example, in the Work Order Tracking application, :&ownername&.jobplan.priority>&ownername&.priority converts to workorder.jobplan.priority>workorder.priority

## Bind variables

Syntax	Description	Examples
:<relationship name>.<attrname>	Value of an attribute of a related business object of the current business object	:location.description
:&owner&.<attrname>	Value of an attribute of the owner business object	When you apply a job plan to a work order, the system copies the priority of the job plan to the child work order. The condition can be: :&owner&.jobplan.priority>&owner&.priority. In this example, the system copies this information if the job plan has a higher priority than the parent work order.
:&owner&.<relationship name>.<attrname>	Value of an attribute of the related business object of the owner business object	See the example for :&owner&.<attrname>
:&old_<attrname>	The initial value from the database of the attribute	For example, if you change the value of a field from 1 to 2 to 3 to 4, the original value is 1.

## Conditional expressions examples

- :wostatus='APPR'
- :type='EM'
- :ownerid=:&user&
- :supervisor!=:&personid&
- :asset.assettype = 'IT' and :&personid&=:owner
- :reportby=:&personid&
- :assetspec.classstructureid = 122
- :po.poline.receivedqty=0
- :&owner&.jobplan.priority>&owner&.priority
- :owner&.po.\$old\_description like '%Turbin%'

## Sample conditional class files

Sample condition class files are stored in a folder under the root directory of the product installation. You can use the sample files when you create class-type conditions.

To use a sample condition class, enter the file name in the Class field in the Conditional Expression Manager application.

## Sample condition classes

- Evaluates to true: psdi.common.condition.AlwaysTrue
- Evaluates to false: psdi.common.condition.AlwaysFalse

## Applying conditional security

You can limit access to data and to elements of the user interface to users that have the right level of access.

- [Conditional security](#)  
You can apply these conditions to security groups, to enforce security measures, for example, you can limit access to certain elements of the user interface to users with the right level of access.
- [Defining signature options for an application](#)  
Signature options specify privileges for using applications, menu options, and toolbar items. You apply signature options to groups of users to control their access to data, to applications, and to controls. New applications are automatically assigned a READ signature option. You can add more signature options in the Application Designer.
- [Removing a signature option from a UI control](#)  
To remove a signature option from a user interface (UI) control, you must first delete all security groups that are associated with the signature option.
- [Applying signature options to show user interface controls](#)  
You can grant access to a user interface (UI) control by associating it with a signature option. Then, users who belong to the security groups that are

associated with this signature option are granted access to the control. Security groups that are not associated with the signature option do not have access to the control.

- **[Showing controls to some users](#)**

A user can be a member of many security groups. A user can have read-only access to an application in one group. As a member of another group the same user can have conditional access to the application. When the security groups combine, the user can access the application when the condition is true. When the condition is false, the user cannot access the application.

---

## Conditional security

You can apply these conditions to security groups, to enforce security measures, for example, you can limit access to certain elements of the user interface to users with the right level of access.

In the condition library, you can define conditions, either as expressions or as custom class files. You can control access to applications and to controls in applications by applying conditions to security groups. The conditions are applied to signature options (SIGOPTION) that are then granted to the security group. Conditional access is granted in the security groups application. If a user is in multiple security groups, the highest level of access is granted when the security groups are joined.

The following are some examples of the types of conditional access that you can set:

- Give read-only access to the information that is shown in a field.
- Give read/write access to the information that is shown in a field.
- Give a user group read-only access to a specific field in an application.
- Give all members of a user group read/write access to an application.
- Hide a field or tab in an application from certain users.
- Grant access to application options in the Select Action menu or side navigation menu for a security group.
- Configure any property in a control for a group, such as making a control hidden, masked, read-only, or required.
- Configure other properties, such as color, label, and application link, to be different for on the user group that is accessing the UI.
- Show or hide a data attribute globally or for a security group.

---

## Defining signature options for an application

Signature options specify privileges for using applications, menu options, and toolbar items. You apply signature options to groups of users to control their access to data, to applications, and to controls. New applications are automatically assigned a READ signature option. You can add more signature options in the Application Designer.

---

### Procedure

1. Open the application in the Application Designer.
2. Select the Add Modify Signature Options in the Select Action menu and click New Row.
3. Specify a signature option in the Option field.
4. Optional: Add additional signature options in the Option Also Grants field.  
Use commas to separate multiple entries if you want to enable more than one additional signature option.  
For example, if the signature option grants access to the People application, you can add signature options that grant access to a related application, such as the Users application.
5. Optional: In the Option Also Revokes field, specify any signature options that are revoked as a result of adding the primary option.  
For example, you add a signature option that allows read-only access to an application. You want to remove any write access to the application that users with the read-only signature option have. To remove the write access, you specify the signature option that grants write access to the application in the Option Also Revokes field.
6. Save the signature options.

---

## Removing a signature option from a UI control

To remove a signature option from a user interface (UI) control, you must first delete all security groups that are associated with the signature option.

---

### Procedure

1. In the Application Designer workspace, select the control and click Control Properties.
2. In the Control Properties window, click Configure Conditional Properties.
3. Delete all rows in the Security Groups section and click OK.
4. Delete the signature option in the Control Properties window.
5. Click Save.

---

### Results

The default behavior of the UI control is restored.

---

## Applying signature options to show user interface controls

You can grant access to a user interface (UI) control by associating it with a signature option. Then, users who belong to the security groups that are associated with this signature option are granted access to the control. Security groups that are not associated with the signature option do not have access to the control.

### About this task

---

Multiple controls can be associated with one signature option. Then, access to the controls can be granted or revoked as a group.

### Procedure

---

1. In the Application Designer workspace, select the application that you want to configure.
2. Select Add/Modify Signature Options and create a signature option.
3. Select the control that you want to configure and click Control Properties. Select the signature option that you created and close the window.
4. Click Save.
5. In the Security Groups application, create a group or select an existing group.
6. In the Options for Actions section of the Applications tab, select the Grant Access check box for the access types that you want to provide to the application.
7. Select the Grant Access check box for the signature option that you applied to the control in step 2.
8. Click Save.

### Results

---

The control is visible only to the users in the security groups that this signature option is granted to.

---

## Showing controls to some users

A user can be a member of many security groups. A user can have read-only access to an application in one group. As a member of another group the same user can have conditional access to the application. When the security groups combine, the user can access the application when the condition is true. When the condition is false, the user cannot access the application.

### Procedure

---

1. In the Application Designer workspace, select the control and click Control Properties.
2. Select a signature option and close the window.
3. Click Save.
4. In the Conditional Expression Manager application, create a condition that grants access to a control when the condition is true.
5. In the Security Groups application, select the security group that contains all users.  
For example, select the MAXEVERYONE security group.
6. Click the Applications tab and filter for the application that you want to apply the condition to.
7. In the signature options row, check Grant Access, and specify the identifier of the condition you created in Step 4 in the Condition field.
8. On the List tab, select another security group.  
For example, select the PROJECTMANAGERS security group.
9. In the Applications tab, check Grant Access in the Read Access to Actions row.
10. Add the same user to both security groups.

### Results

---

You have one group of users, PROJECTMANAGERS that has read-access to the application. The security group that contains all users, MAXEVERYONE, has conditional access to the control. When the two groups are combined, users have access to the control when the condition is true. Users who do not have read-access to the application in any group do not have access to the control.

---

## Applying conditional data restrictions

To support your business processes, you can apply conditions to restrict access to data for a user or for a user group. The data can be hidden, read-only, or required.

- [Conditional data restrictions](#)  
Data restrictions can be conditional or unconditional. You can restrict access to data for a user or user group. The data can be hidden, read-only, or required.
- [Specifying data restrictions for security groups](#)  
To customize your security settings, you can specify restrictions on which records a security group can access. You can use a conditional expression or a conditional class file to define and apply these restrictions.
- [Specifying global data restrictions for security groups](#)  
Using global data restrictions, you can use a condition to specify restrictions on which records can be accessed by security groups.

---

## Conditional data restrictions

Data restrictions can be conditional or unconditional. You can restrict access to data for a user or user group. The data can be hidden, read-only, or required.

You can use these methods to restrict a user's access to data:

- Database configuration of objects and attributes
- Data restrictions on objects and attributes
- Application configurations

Data restrictions are configured in the Security Groups application. You can also set data restrictions for attributes in objects, either with or without a specified application. Data restrictions that are applied to an object do not apply to views of the object. You must create a separate restriction for the object view.

You can apply conditions to objects to hide them, to make them required, or to make them be read-only. You can apply the condition for every user, or just to a particular security group. Objects or objects within the context of an application can also be associated with a condition to determine what data is shown in the application. Only data that satisfies the condition is returned when the database is queried.

You can also apply conditions to attributes within objects, either with or without an associated application. When you view records in an application, the evaluation of conditions can change the presentation of controls bound to objects or attributes with conditional restrictions applied.

You associate objects or attributes with conditions in the Security Groups application.

If you apply multiple conditions, the conditions are joined by an OR operator when they are evaluated.

You can apply two or more conditions joined by an AND operator to an object or attribute. You can append the second and subsequent conditions to the first one with an AND function between them.

As an application developer, you are implementing a data restriction that causes information about an asset to be shown on the UI. The asset is shown if the following conditions are met:

- The asset is a calibration asset
- The asset has asset meter records

You create two conditions in the Condition Expression Manager:

- Condition 1 displays calibration-related fields for the asset if it is a calibration asset:

```
iscalibration=1:
```

- Condition 2 checks for any asset meter records:

```
exists (select 1 from assetmeter where assetnum = :assetnum and orgid =:orgid)
```

You append Condition 2 to Condition 1 with an AND operator:

```
iscalibration=1:and exists (select 1 from assetmeter where assetnum = :assetnum and orgid =:orgid)
```

You apply the appended condition to the required asset object or attribute.

---

## Specifying data restrictions for security groups

To customize your security settings, you can specify restrictions on which records a security group can access. You can use a conditional expression or a conditional class file to define and apply these restrictions.

### Procedure

---

1. In the Security Groups application, select the group for which you want to set restrictions.
2. On the Data Restrictions tab, select the type of restriction:
  - To specify restrictions on objects, click Object Restrictions.
  - To specify restrictions on attributes, click Attribute Restrictions.
3. Click New Row.
4. In the Object field, specify the table or view on which to set the restriction.
5. Optional: If you are specifying an attributes restriction, specify the attribute that you want to restrict.
6. Optional: In the Application field, specify the application to which you are applying the restriction. Leave the field blank to apply the restriction to all applications that use the object or attribute.
7. Specify the type of restriction.
8. Optional: Specify the following options for restrictions:

Option	Description
Reevaluate	Select this option for the restriction condition to be reevaluated when the user tabs to another field. If you do not select this option, the restriction conditions are evaluated after the changes to a field are saved.
Condition	Specify a conditional expression.

9. Save your changes.

---

## Specifying global data restrictions for security groups

Using global data restrictions, you can use a condition to specify restrictions on which records can be accessed by security groups.

## Procedure

1. Optional: In the Conditional Expression Manager application, create one or more conditions to be evaluated to control access.
2. In the Security Groups application, select the Global Data Restrictions action.
3. In the Global Data Restrictions window, select the type of restriction, and specify the details of the restriction.

## Adding conditions to the properties of UI fields

You can control how the user interface (UI) is shown to users and to support your business processes. When a control is bound to a signature option or an attribute, you can configure conditional properties in the Application Designer.

- [Adding conditions to determine access to UI controls](#)  
You can conditionally modify the default access to user interface (UI) controls. UI controls include text boxes, check boxes, and radio buttons.
- [Adding conditions to hide UI controls](#)  
You can create and apply a signature option to a user interface (UI) control to deny access based on satisfying a condition. When the condition is true, access is granted to all of the controls who are associated with the signature option. Conditional access is granted to all users who belong to the security groups that are associated with the signature option.

## Adding conditions to determine access to UI controls

You can conditionally modify the default access to user interface (UI) controls. UI controls include text boxes, check boxes, and radio buttons.

### Procedure

1. In the Conditional Expression Manager application, create one or more conditions that grant access to a UI control when the condition is true.
2. In the Security Groups application, create or identify the security groups that can access the UI control.
3. In the Application Designer workspace, select Add/Modify Signature Options, and create a signature option.
4. Select the UI control that you want to configure, and select Control Properties.
5. Click Configure Conditional Properties and specify the following options:

Option	Description
<b>Signature Option</b>	Specify the signature option you created for the control.
<b>Security Groups</b>	Specify the groups that you want to provide with access to the control.
<b>Conditions for a Security Group</b>	Specify the conditions you created in step 1. The conditions apply only to the security groups that you specified.
<b>Property Values for Condition</b>	Specify the names and values of the properties to be controlled by the condition.

6. In the Security Groups application, grant the signature option to the security group.

### Results

The users in the security groups that you specified can see the UI control when the conditions you apply are true. Other users cannot see the UI control.

## Adding conditions to hide UI controls

You can create and apply a signature option to a user interface (UI) control to deny access based on satisfying a condition. When the condition is true, access is granted to all of the controls who are associated with the signature option. Conditional access is granted to all users who belong to the security groups that are associated with the signature option.

### Procedure

1. In the Conditional Expression Manager application, create one or more conditions that denies access to a UI control when the condition is true.
2. In the Security Groups application, create or identify the security groups that cannot access the UI control.
3. In the Application Designer workspace, select Add/Modify Signature Options, and create a signature option.
4. Select the UI control that you want to configure, and select Control Properties.
5. Click Configure Conditional Properties and specify the following options:

Option	Description
<b>Signature Option</b>	Specify the signature option you created for the control.
<b>Security Groups</b>	Specify the groups that you want to hide the UI control from.
<b>Conditions for a Security Group</b>	Specify the conditions you created in step 1. The conditions apply only to the security groups that you specified.
<b>Property Values for Condition</b>	Specify the names and values of the properties to be controlled by the condition.

6. In the Security Groups application, grant the signature option to the security group.

### Results

The users in the security groups that you specified do not see the UI control when the condition you apply is true. Users in other security groups can see the UI control.

---

## Application developer properties

Each control has its own set of properties that you can set. You can also set user interface properties to control the behavior of many aspects of user interface behavior.

- [Control properties](#)  
You can configure the properties for each individual user control in an application user interface.

---

## Control properties

You can configure the properties for each individual user control in an application user interface.

- [Application bar control](#)  
The application bar (or appbar) control, is a menu bar that lists all applications in a module except the currently active application. An application bar is always open at the top of the window in a self-service application.
- [Attachments control](#)  
You can activate the drop-down menus and windows associated with attachments by dropping the control into any section container in an application. However, you cannot access the functions used to build the attachments control through the interface of the Application Designer.
- [Blank line control](#)  
A blank line control inserts vertical white space in a section. Blank lines provide spacing between controls to improve readability or to visually separate different types of controls within a section.
- [Breadcrumbs control](#)  
You can use the breadcrumb control to enhance navigational functionality in an application. Breadcrumb navigation tracks the steps you take in an application and helps you to retrace steps quickly. You can use a breadcrumb control by itself or in conjunction with another control, such as a tree control. You can place this control inside any container control.
- [Button group control](#)  
A button group is a container control that holds push button controls. The button group defines the layout for the buttons it contains, including alignment within the container and the title for the group. Place this control within a section control or a table control.
- [Check box control](#)  
With a check box control, a user can indicate a yes or no response to a question or select one or more items from a list. A check box is a text type control because it has a text field or a label that is visible to the user. Place this control inside a section control.
- [Combo box control](#)  
With a combo box control, a user can select one or more options from a list drop down menu. Place this control inside a section control.
- [Data source control](#)  
Use a data source control to override the default data source, or the current data source, for an application. This control is used primarily in dialog windows to reference a business object that controls in the window can use as a data source. A data source control is transparent and does not render any visible element.
- [Default value control](#)  
You can use a default value control to speed up a database insert or query by restricting the action to a limited set of records. The default value control is transparent and does not render anything visible in the user interface. You can place the default value control in a section control, a table control, or in the presentation control.
- [Help grid control](#)  
A help grid control contains HTML text that you can insert in the user interface, typically to provide brief instructions on how to enter data and perform tasks. For complex information, help grids can include hyperlinks to additional information in a Knowledge Center topic. You can place help grid controls within Section, Section Column, Tab, and Dialog controls.
- [Hover window control](#)  
A hover window is a read-only pop-up window that is applied to a user interface control to display more information about an attribute.
- [Hyperlink control](#)  
You can configure text or a graphic as a hyperlink that opens a menu or window, or a destination inside or outside the application. Place this control inside a section control.
- [Icon menu control](#)  
The icon menu control displays menu items next to a text box or multipart text box. You can use the `mxe.webclient.iconsToDisplay` system property to limit the number of menu items to display but the default is three.
- [Image control](#)  
You can add an image control to create a visual marker to identify an application you can open or an action you can perform. You can configure the height, width, and alignment for the specified image file. You can place an image control with a section control.
- [Include control](#)  
You can use include controls to reuse dialog windows, layouts, and data tables from an existing application in the presentation.xml file of a new application. You can place an include control within a page, tab, or section control.
- [List box control](#)  
A list box control displays a list of items in a box that is always open. Place this control inside a section control.
- [Menu bar control](#)  
The menu bar control is similar to an application bar control but the menu options typically contain drop down menus with additional option choices. The menu bar at the top of the List tab in most applications is a typical example. You can place a menu bar control only in a tab control.
- [Multiline text box control](#)  
A multiline text box control is a large text box that can display several lines of text or accept this text from user input. Text boxes are often linked to select value lookups and detailed menus. You can place a multiline text box control within a section control.
- [Multipart text box control](#)  
A multipart text box contains two text boxes, positioned side-by-side, that can contain information from different sources. You can input information, populate a box by selecting a value from a list, or show an attribute description from a table. You can place a multipart text box within a section control.
- [Parameter value control](#)  
A parameter value control can display dynamic values in the label of a section control or a table control.

- **[Parameter values control](#)**  
A parameter values control is a container control that can contain a parameter value to show a dynamic value that represents a replaceable value in the label of a Section Header control.
- **[Presentation control](#)**  
The presentation control manages the appearance of the user interface display, and all other controls are contained by this control. The presentation control contains only one page control. The page control specifies the main page of an application and uses the entire client area of the browser. All other application windows are dialogs that open as popup windows. You can add the definition for a dialog window to the PRESENTATION.XML file, or you can include the definition of an existing dialog from the LIBRARY.XML file.
- **[Push button control](#)**  
A push button control initiates an event such as opening a window with a list of records or opening an empty row where a user can enter a record. Place this control inside a button group control.
- **[Radio button control](#)**  
A radio button is a control that allows users to choose one of a predefined set of options. Radio buttons are organized in groups of two or more. Radio buttons typically appear as little circles that are either empty (for unselected) or contain a dot (selected). When you select a radio button, the previously selected button in the same group is deselected.
- **[Radio button group control](#)**  
A radio button group is a container control that holds radio buttons. The radio button group defines the layout for the buttons it contains, including a group title, text alignment for button labels, and whether or not to show a border. You can place a radio button group control within a section control.
- **[Record image control](#)**  
You can use the record image control to associate an image with a record, including an expandable thumbnail image. You can then add this image to an application from within the application user interface. A user can click on a thumbnail image to view its full size and can drag the mouse over the image to see a text description. You can place a record image control in any container control.
- **[Rich text editor control](#)**  
The rich text editor control provides the ability to add rich text formatting to a field with long description characteristics.
- **[Rich text viewer control](#)**  
The rich text viewer control provides the ability to view rich text formatting in a field with long description characteristics.
- **[Section control](#)**  
A section control is one of the core container controls that you use to organize the layout of an application. Container controls occupy space on a page and provide storage for other controls, such as tables, buttons, and text fields.
- **[Section column control](#)**  
A section column control is a vertical column that you can use to divide a section row into columns with headings. A section column is a container that can hold child section controls and is also a child to the parent section control. When you move a section control, all of its child controls automatically move with it.
- **[Section header control](#)**  
Use a section header control to display a text heading for a section or a table. The text in the heading can be dynamic, based on variables you configure in parameter and parameter values controls. A section header control is a container control and is transparent in the user interface.
- **[Section row control](#)**  
A section row control is a layout control that contains section column controls. A section row creates a horizontal row that you can partition into columns that hold child sections. A section row is a child to a parent section control. When you move a section, all of its child controls automatically move with it.
- **[Static text control](#)**  
You can use a static text control to add text to a section control or to specify a database attribute that you can configure and position within a section as if it were unbound text. Static text is, typically, used in Date search windows in applications, where To and From labels are static text controls.
- **[Tab properties](#)**  
A tab control is a container in which you place other controls such as tables and sections. Formatting tabs is, typically, the starting point for designing the structure and layout of a new application or extending the layout of an existing application. Place this control inside a tab group control.
- **[Tab group control](#)**  
A tab group control is a container control that holds tabs. Tab groups are part of the template for power applications. When you create a power application, a tab group control is provided with the standard List and Workspace tabs.
- **[Table control](#)**  
The table control is a container with the basic layout elements of a table window, including a toolbar with filter and search functionality and icons for previous and next row and page. You can place a table control within a section, tab, or window control and you can place a table column control or a section control within a table control.
- **[Table column control](#)**  
The table column control is a container that you can use to add columns and column headings to a table. You can place a table column control within a table control.
- **[Text box control](#)**  
A text box control is a single-line text box that displays information the user either enters or selects from a list. Text boxes have labels that are typically visible in the user interface. Labels are text fields that describe the type of information displayed in the box. You can place a text box within a section control.
- **[Tree control](#)**  
Use a tree control as a container for tree node and tree attribute controls to build dynamic, hierarchical tree structures with specific business objects that support hierarchical data. You can place a tree control within a dialog control or a tab control. You can place a tree node control into a tree control.
- **[Tree attribute control](#)**  
The tree attribute control describes the data that appears in each tree node. For example, the tree attributes in the Classifications application display classification IDs and descriptions in the user interface. You can place a tree attribute control within a tree node control.
- **[Tree node control](#)**  
The Tree Node control is a container type of control that works with the Tree and Tree Attribute controls. A Tree Node defines the structure of a hierarchical tree.

---

## Application bar control

The application bar (or appbar) control, is a menu bar that lists all applications in a module except the currently active application. An application bar is always open at the top of the window in a self-service application.

You can place an application bar inside the client area control. You can also place this control in a section control if you use the correct layout options.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	Specify a text value in this field if you want the application bar to have a label. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Appbarlinks	Specify the links to add to the application bar.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Attachments control

You can activate the drop-down menus and windows associated with attachments by dropping the control into any section container in an application. However, you cannot access the functions used to build the attachments control through the interface of the Application Designer.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	You can specify a text value in this field to override the default label for the control, which is Attachment. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Blank line control

A blank line control inserts vertical white space in a section. Blank lines provide spacing between controls to improve readability or to visually separate different types of controls within a section.

A blank line control functions as a graphic element, is transparent in the user interface, and does not have configurable properties. Place a blank line control inside a section container control.

## Breadcrumbs control

You can use the breadcrumb control to enhance navigational functionality in an application. Breadcrumb navigation tracks the steps you take in an application and helps you to retrace steps quickly. You can use a breadcrumb control by itself or in conjunction with another control, such as a tree control. You can place this control inside any container control.

A breadcrumb trail complements a hierarchical tree structure by showing a horizontal representation of where the user is in a menu structure or a service catalog. You can configure a delimiter character to separate items in the breadcrumb trail, such as the greater than character (>) or a colon (:). Each phrase or identifier between delimiters represents one step in a hierarchy.

To synchronize a tree control and a breadcrumb controls, copy the Data Source ID property from the tree control to the breadcrumb control. The following table describes how a tree control and breadcrumb control behave in the user interface when they are used in combination.

When you click . . .	This happens
The label of any node	A new breadcrumb trail replaces any existing breadcrumb trail and: <ul style="list-style-type: none"><li>Highlights the node label in the tree</li><li>Displays the node label in breadcrumb</li><li>All levels in the tree hierarchy above the highlighted node label appear in the breadcrumb (in descending order from left to right)</li></ul>
The plus sign in a tree	No effect.
The minus sign in a tree	Highlights the right-most breadcrumb, which is the same as the node label next to the minus sign.
The dot sign in a tree	The corresponding node label highlights in the tree and displays in the breadcrumb. All levels in the tree hierarchy above the highlighted node label appear in the breadcrumb (in descending order from left to right).
Any node label in the breadcrumb	Equivalent to clicking the node label in the tree. The tree contracts to the level of the node label and any breadcrumb links to the right of the clicked node label disappear.

When you click . . .	This happens
A delimiter in the breadcrumb	No effect.

You can expect the following user interface behavior when navigating a tree or breadcrumb:

- Any time you highlight a node label in a tree or breadcrumb, the window displays information related to that label.
- Clicking a plus sign in a tree expands the node, but does not affect window content, label highlighting, or the breadcrumb.
- Clicking a minus sign in a tree does not affect window content, but does highlight the node label associated with the minus sign and the breadcrumb reflects the new hierarchy ending with the highlighted node.
- The highlighted node label in a tree always reflects the right-most element in the breadcrumb. The breadcrumb elements to the left reflect the intervening levels in the tree hierarchy.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	You can specify a text value to use as a label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Bean Class	You can specify the name of a data bean class to use when creating the data source for the control. If not defined and the control is creating a data source, the default <code>psdi.webclient.system.DataBean</code> class is used. Typically, you use this property to create custom event methods or to override the manner in which the data source obtains its <code>MboSet</code> .
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
Business Object	Specify the name of a MBO in this field to determine which MBO the control uses to show and process information. If a MBO is not specified, the control uses the data source of its parent control. When you set a MBO for this control a data source is created that can be referenced from other controls.
CSS Class Name	If you want to change the layout and appearance of the hyperlink, enter the name of the CSS class to use. For example, the "powerwhite" class name changes the font color of a hyperlink to white. You can search for CSS class names in the <code>&lt;root&gt;\applications\maximo\maximouiweb\webmodule\webclient</code> directory.
Separator	Specify the delimiter to use between breadcrumb trail entries, for example <code>&gt;</code> .
Relationship	If you specified a value in the Parent Data Source ID field, specify a value in this field that identifies the relationship between this control and the new data source. A relationship uses a WHERE clause to determine what to show and process from the data source. The control creates a datasource that is by default used by the child controls. You can search for relationship values in the Database Configuration <code>&gt; Relationships</code> tab.
Breadcrumbs	The source ID of the breadcrumb control.
Source Method	Specify a source method to apply to the source
Align	Specify the alignment options for the breadcrumbs.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Button group control

A button group is a container control that holds push button controls. The button group defines the layout for the buttons it contains, including alignment within the container and the title for the group. Place this control within a section control or a table control.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	You can specify a text value in this field to provide a label for the button group. Most button groups do not have a label, because the control functions primarily as a container that holds a layout for its children push button controls. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Text Alignment	If you specified a label for the control, you can set the label to align to the Left, Center, or Right. The text label always displays to the left of any push buttons you add to the group.
Button Alignment	Reserved for future use.
Show Container	If you select this property, a shaded background of horizontal lines is visible for the button group. You cannot show background shading for a button group control in a table container.

## Check box control

With a check box control, a user can indicate a yes or no response to a question or select one or more items from a list. A check box is a text type control because it has a text field or a label that is visible to the user. Place this control inside a section control.

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the label associated with the database attribute bound to this control.  The label for a check box control ends with a question mark, for example GL Account?.
Label	You can specify a text value in this field to override the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
Input Mode	Input mode options are: <ul style="list-style-type: none"><li>• Blank: An input mode with no value is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li><li>• Default: This mode is used for quick entry of default table data in tables.</li><li>• Query: This mode is read-only and shows a typed value.</li><li>• Readonly: This mode is read-only and shows grayed-out text.</li><li>• Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li></ul>

## Advanced properties

Attribute name	Description
Data Change Event	You can configure a control to perform one of the following actions in the event of a data change to the control: <ul style="list-style-type: none"><li>• The <b>REFRESHABLE</b> event refreshes the data source table for the control.</li><li>• The <b>RESETCHILDREN</b> event deletes any child objects of the data bean of the control which then reacquires its <b>MBOSetRemote</b> references.</li></ul>
Always Synchronous	If deselected, the control can communicate with the database without pausing user activities. If cleared, the user cannot perform activities in other fields until validations for this field are completed. Synchronous activity is disabled by default. If there are dependencies between values specified for this control and other controls in the application, you can enable synchronous activity for the dependent controls.
Notify Portlets	If selected, this control can send notifications to a portlet, if communication with a Tivoli® Integration Portlet is configured.
More information	You can specify the values to construct a URL for an Knowledge Center topic using the following format: <b>com.ibm.mbs.doc,application/helpfile.html</b> The server address and other information for the URL are controlled by the <b>mx.help</b> properties which you can review and configure in the System Properties application.  If you specify a URL, a More Information link is added to the field help (Alt + F1) for the control. When the user clicks the link, the target topic opens in the Knowledge Center.  The property is specific to the field ID in the presentation XML file. If you want to provide the same link in other controls or other applications, you must manually add the URL to each individual control.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Combo box control

With a combo box control, a user can select one or more options from a list drop down menu. Place this control inside a section control.

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the label associated with the database attribute bound to this control.
Label	You can specify a text value in this field to override the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.

Attribute name	Description
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
Display Attribute	Specify the attributes to show as options in the drop down menu for the combo box control. For example, if you create a combo box called Status, you can specify values such as Waiting for Approval and Approved. The values are bound to the data source and the attribute specified for the control.
Input Mode	Input mode options are: <ul style="list-style-type: none"> <li>Blank: An input mode with no value is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li> <li>Default: This mode is used for quick entry of default table data in tables.</li> <li>Query: This mode is read-only and shows a typed value.</li> <li>Readonly: This mode is read-only and shows grayed-out text.</li> <li>Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li> </ul>
Width	The standard width for a combo box control is 120 pixels. To make the control narrower or wider, enter a numeric value, for example 60 (narrower) or 200 (wider).

## Advanced properties

Attribute name	Description
Select Attribute	This value provides a synonym or abbreviation for the Display Attribute in the text box area of the combo box. For example, for the Status combo box, you can specify WAPPR and APPR as Select Attributes abbreviations for the Waiting for Approval and Approved display attributes.
Data Change Event	You can configure a control to perform one of the following actions in the event of a data change to the control: <ul style="list-style-type: none"> <li>The <b>REFRESHABLE</b> event refreshes the data source table for the control.</li> <li>The <b>RESETCHILDREN</b> event deletes any child objects of the data bean of the control which then reacquires its <b>MBOSetRemote</b> references.</li> </ul>
More information	You can construct a URL for an Knowledge Center topic using the following format: <b>com.ibm.mbs.doc,application/helpfile.html</b>  If you construct a URL, a more information link is added to the field help (Alt + F1) for the control. When the user clicks the link, the target topic opens in the Knowledge Center.  The property is specific to the field ID in the presentation XML file. If you want to provide the same link in other controls or other applications, you must manually add the URL to each individual control.
Notify Portlets	Reserved for future use.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Data source control

Use a data source control to override the default data source, or the current data source, for an application. This control is used primarily in dialog windows to reference a business object that controls in the window can use as a data source. A data source control is transparent and does not render any visible element.

You can place a data source control inside the following controls:

- Client area
- Dialog
- Page
- Section
- Tab
- Table

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Bean Class	You can specify the name of a data bean class to use when creating the data source for the control. If not defined and the control is creating a data source, the default <code>psdi.webclient.system.DataBean</code> class is used. Typically, you use this property to create custom event methods or to override the manner in which the data source obtains its <code>MboSet</code> .
Business Object	Specify the name of a MBO in this field to determine which MBO the control uses to show and process information. If a MBO is not specified, the control uses the data source of its parent control. When you set a MBO for this control a data source is created that can be referenced from other controls.
Parent Data Source ID	You can specify the ID of a data source to use as the parent object for a relationship, or to specify a parent object for a bean class if necessary. Then specify the relationship that uses this parent in the Relationship field. If the field is left blank, the control uses the data source ID of its parent control as the Parent Data Source ID.

Attribute name	Description
Relationships	If you specified a value in the Parent Data Source ID field, specify a value in this field that identifies the relationship between this control and the new data source. A relationship uses a WHERE clause to determine what to show and process from the data source. The control creates a datasource that is by default used by the child controls. You can search for relationship values in the Database Configuration > Relationships tab.
Order By	You can specify the order in which a SQL query fetches data for the data source for this control.
Where Clause	You can specify a WHERE clause that the data source for this control uses to retrieve data. This WHERE clause is used in addition to any default WHERE clause used by the business object of the data source.
Listeners	Enter the ID or IDs of one or more data sources that you want to refresh whenever there are changes to this control. Listener controls can be located anywhere within the application. Separate multiple values with a comma.

## Default value control

You can use a default value control to speed up a database insert or query by restricting the action to a limited set of records. The default value control is transparent and does not render anything visible in the user interface. You can place the default value control in a section control, a table control, or in the presentation control.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Attribute	Select an attribute from a data source to update or query. You can set an update or query value using one of the following methods: <ul style="list-style-type: none"> <li>Specify a static value in the Value field.</li> <li>Specify values in the From Data Source ID and the From Attribute fields to read a value from the database.</li> </ul>
Value	The alphanumeric value in this field provides a static default value for an insert or query action for the specified Attribute value. In the Person application, for example, you can specify DEPARTMENT in the Attribute field and MAINTENANCE in the Value field, to restrict queries to people working in the maintenance department.
From Data Source ID	If you do not configure a static default value in the Value field, specify the data source ID to use as the data source for the From Attribute field.
From Attribute	If you do not configure a static default value in the Value field, specify a From Attribute that updates or queries the database with its value.
Default Type	Specify the appropriate type of action for this default query.

## Help grid control

A help grid control contains HTML text that you can insert in the user interface, typically to provide brief instructions on how to enter data and perform tasks. For complex information, help grids can include hyperlinks to additional information in a Knowledge Center topic. You can place help grid controls within Section, Section Column, Tab, and Dialog controls.

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	You can specify a text value in this field if you want to associate a label with this control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
HTML Content	You can add text and a More Information link to a help grid control. A help grid control can contain HTML text for the user interface, typically to provide brief instructions about how to enter data and perform tasks. For complex information, help grids can include hyperlinks to additional information in a Knowledge Center topic. You can place help grid controls within Section, Section Column, Tab, and Dialog controls: <ol style="list-style-type: none"> <li>In Application Designer, select the help grid control to modify. Modify the HTML Content attribute to add display text.</li> <li>Optionally, link from that text to a Knowledge Center topic by specifying the URL for the topic in the morehelp attribute. The URL is in this format: &lt;documentation plugin name&gt;,&lt;path and filename.extension&gt;. For example, a link from an assets tab to an overview topic about assets could take this form: com.ibm.mam.doc,asset/c_asset_overview.html.</li> </ol>
More information	You can add a More information button and link to field help. A more information button and link in field help can provide technical or contextual details that do not fit in field help. <ol style="list-style-type: none"> <li>In Application Designer, select the control that you want to modify, such as a field or check box.</li> <li>In the More information property, specify the URL to the help topic. The URL is in this format: &lt;documentation plugin name&gt;,&lt;path and filename.extension&gt;. For example, a link from an asset check box to a topic about classifying assets could take this form: com.ibm.mbs.doc,assetcat/c_classify_item_desc.html.</li> </ol>
Signature Option	You can specify a signature option to restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click Configure Conditional Properties.
Sig Option Data Source ID	A MBO must be used to evaluate whether a user has access to a signature option. Specify the value of the data source if it is different to the data source that is configured for this control.

## Hover window control

A hover window is a read-only pop-up window that is applied to a user interface control to display more information about an attribute.

### Properties

Attribute name	Description
Hover Window ID	Can be applied to the multiline text box, multipart text box, table column, and text box controls. At runtime, a circular icon with an i in the center indicates that a hover window is enabled for a control. Available hover windows are defined in the RECHOVERS.XML file in the system library. To apply one of these hover windows to a control, you specify the ID of the hover window as defined in the RECHOVERS.XML file.
Hover Window Attribute	By default, a hover window uses the data attribute of the field. Use this attribute when you want the hover window to use a different attribute than the data attribute of the field.

## Hyperlink control

You can configure text or a graphic as a hyperlink that opens a menu or window, or a destination inside or outside the application. Place this control inside a section control.

### General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	If you specify a text value, it forms a link that the user clicks to initiate the hyperlink.
Event Type	<p>You can associate a hyperlink with an event and, when the user clicks the hyperlink, the event is triggered. To configure a hyperlink event, you must specify the event type, the event value, and, optionally, the ID of a control that processes the event. For example, to configure an event that opens the Go To menu, specify <code>showmenu</code> in the Event Type field, specify <code>goto</code> in the Event Value field, and specify <code>pageTitlebar</code> in the Control Target ID field.</p> <p>Events are processed in the following order:</p> <ol style="list-style-type: none"><li>1. If you specify a control target ID, the event is sent to this data source for processing.</li><li>2. If you do not specify a control target ID, the event is sent to the main JSP page of the application for processing.</li><li>3. The window associated with the specified event loads.</li></ol> <p>To view all of the events defined in the system, export the system .XML files and search these files for <b>MXEVENT</b> entries.</p>
Control Target ID	If you associate an event with the hyperlink, you can specify the ID of a target control to process the event that is different from the current control. The target ID for the Go To hyperlink, for example, is <code>pageTitlebar</code> .
Event Value	If you associate an event with the hyperlink, specify the value of the event. The event value for the Go To hyperlink, for example, is <code>goto</code> .
Text Alignment	Aligns the hyperlink label to the left, right, or center within a section.
Image Filename	You can associate an image with the hyperlink. Specify the name of an image file that is stored in the <code>&lt;root&gt;\applications\maximo\maximouiweb\webmodule\webclient\images</code> directory. It is not necessary to enter the path to the images directory.
Image Alignment	If the hyperlink includes an image, aligns the image to the left or right of the hyperlink label.
CSS Classname	If you want to change the layout and appearance of the hyperlink, enter the name of the CSS class to use. For example, the <b>powerwhite</b> class name changes the font color of a hyperlink to white. You can search for CSS class names in the <code>&lt;root&gt;\applications\maximo\maximouiweb\webmodule\webclient</code> directory.
Access key	Specify a letter that is used in the hyperlink label that acts as a keyboard shortcut. For example, the access key for the Go To hyperlink is G and when the user presses ALT + G the Go To menu drops down. The access key is underlined in the user interface.
Separator	Reserved for future use.

### Advanced properties

Attribute name	Description
Column	You can specify a number that positions a hyperlink in a specific column. Each section control has 7 columns that are not visible to the user. If you specify the value 3 in this field and set text alignment to center, the hyperlink is centered above or below column three. If the hyperlink is wider than its column, the width of the column extends automatically to contain the hyperlink.
URL	If you want the hyperlink to link to a URL, specify the value here.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Icon menu control

The icon menu control displays menu items next to a text box or multipart text box. You can use the `mxe.webclient.iconsToDisplay` system property to limit the number of menu items to display but the default is three.

## Properties

Attribute name	Description
Icon Menu ID	Displays detail menu items as buttons next to a text box or the first part of a multipart text box.
Description Icon Menu ID	Displays detail menu items as buttons next to the second part of a multipart text box.

## Image control

You can add an image control to create a visual marker to identify an application you can open or an action you can perform. You can configure the height, width, and alignment for the specified image file. You can place an image control with a section control.

The image files provided as application icons are in the `<root>\applications\maximo\maximouiweb\webmodule\webclient\images` directory. You can access the files in this directory using the image control.

Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Filename	You can specify the filename of any file stored in the images directory at <code>&lt;root&gt;\applications\maximo\maximouiweb\webmodule\webclient\images</code> . You can reuse any existing images or you can add new images to the directory.  Images can be in any format supported by a browser. When you add a .gif file, you can use it immediately. If you add other file formats, such as .jpg or .bmp files, you must redeploy the .EAR file on the application server to add the images to the user interface.
Height	Enter a numeric value in this field that will increase or decrease the height of the image. If you change the default dimensions, the image can become distorted.
Width	Enter a numeric value in this field that will increase or decrease the width of the image. If you change the default dimensions, the image can become distorted.
Align Image	Specify where to align the image, to the Left, Center, or Right of the section that contains it.
Column	You can use columns to manipulate the position of an image. A section has four invisible columns. You can specify a number (1-4) to position an image in the corresponding column. You can change the position of the image by moving the graphic into one of the columns.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Include control

You can use include controls to reuse dialog windows, layouts, and data tables from an existing application in the presentation.xml file of a new application. You can place an include control within a page, tab, or section control.

The include control is used with the presentation, page, and client area controls to create the presentation.xml file for an application. Include controls are typically used to obtain common application functions like header and footer from the LIBRARY.XML file. You can also use an include control within the client area to, for example, obtain table definitions for application log files from the LIBRARY.XML file.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Control ID to Clone	You can specify any Control ID from the library.xml file. This property enables you to include the same library element multiple times in a presentation.

## List box control

A list box control displays a list of items in a box that is always open. Place this control inside a section control.

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the text value that is associated with the database attribute bound to this control.

Attribute name	Description
Label	You can specify a text value in this field to override the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.
Business Object Name	Specify the name of a MBO in this field to determine which MBO the control uses to show and process information. If a MBO is not specified, the control uses the data source of its parent control. When you set a MBO for this control a data source is created that can be referenced from other controls.
Parent Data Source ID	You can specify the ID of a data source to use as the parent object for a relationship, or to specify a parent object for a bean class if necessary. Then specify the relationship that uses this parent in the Relationship field. If the field is blank, the control uses the data source ID of its parent control as the Parent Data Source ID.
Key Attribute	You can specify a different attribute of the business object to use as a key attribute for the list other than the key attribute specified for the MBO.
Key Value	You can specify an option in the list to display as the default value.
Input Mode	Input mode options are: <ul style="list-style-type: none"> <li>Blank: An input mode with no value is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li> <li>Default: This mode is used for quick entry of default table data in tables.</li> <li>Query: This mode is read-only and shows a typed value.</li> <li>Readonly: This mode is read-only and shows grayed-out text.</li> <li>Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li> </ul>
Height	To make the control shorter or longer, enter a numeric value.
Width	To make the control narrower or wider, enter a numeric value.

## Advanced properties

Attribute name	Description
Bean class	You can specify the name of a data bean class to use when creating the data source for the control. If not defined and the control is creating a data source, the default <code>psdi.webclient.system.DataBean</code> class is used. Typically, you use this property to create custom event methods or to override the manner in which the data source obtains its <code>MboSet</code> .
Where Clause	You can specify a WHERE clause that the data source for this control uses to retrieve data. This WHERE clause is used in addition to any default WHERE clause used by the business object of the data source.
Order By	You can specify the order in which a SQL query fetches data for the data source for this control.
Auto-Refresh	If selected, information in this control refreshes automatically when there is a change to the business object.
Always Synchronous	If deselected, the control can communicate with the database without pausing user activities. If cleared, the user cannot perform activities in other fields until validations for this field are completed. Synchronous activity is disabled by default. If there are dependencies between values specified for this control and other controls in the application, you can enable synchronous activity for the dependent controls.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Menu bar control

The menu bar control is similar to an application bar control but the menu options typically contain drop down menus with additional option choices. The menu bar at the top of the List tab in most applications is a typical example. You can place a menu bar control only in a tab control.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	You can specify a label for the menu bar. The label is not visible in the user interface. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Source Method	Specify the name of the method used in the code to call the menu bar, including its signature options, and layout information. The method that calls the standard search menu bar is <code>getAppSearchOptions</code> .
Event Value	Specifies the event called when you select an option on the menu bar. For example, the event value for the search menu bar is <code>search</code> .

## Multiline text box control

A multiline text box control is a large text box that can display several lines of text or accept this text from user input. Text boxes are often linked to select value lookups and detailed menus. You can place a multiline text box control within a section control.

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the text value that is associated with the database attribute bound to this control.
Label	If you enter a text value in this field, it overrides the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Hide Label	By default, the label is visible in the user interface. Select this check box to hide the label.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.
Rows	Enter the number of rows you want in the multi line textbox.
Columns	Most multiline text boxes have a default width of 35. To increase or decrease the width of the box, enter a different value.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
Lookup	You can specify a lookup ID to link this control to a pre-formatted lookup table that pulls records from the main table. A user can select a record from the lookup table to use in this control.  Lookup IDs are stored in the lookups.xml file. To view the content of this file, export the system XML files.
Input Mode	Input mode options are: <ul style="list-style-type: none"> <li>Blank: An input mode with no value is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li> <li>Default: This mode is used for quick entry of default table data in tables.</li> <li>Password: This input mode is not available for multiline text box controls.</li> <li>Password Readonly: This input mode is not available for multiline text box controls.</li> <li>Password Required: This input mode is not available for multiline text box controls.</li> <li>Query: This mode is read-only and shows a typed value.</li> <li>Readonly: This mode is read-only and shows grayed-out text.</li> <li>Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li> </ul>
Menu Type	You can specify the value of a menu ID in this field to link the control to a preformatted drop-down menu. Menu IDs are stored in the menus.xml file. To view the content of this file, export the system XML files.

## Advanced properties

Attribute name	Description
Data Change Event	You can configure a control to perform one of the following actions if there is any data change to the control: <ul style="list-style-type: none"> <li>The <b>REFRESHTABLE</b> event refreshes the data source table for the control.</li> <li>The <b>RESETCHILDREN</b> event deletes any child objects of the data bean of the control which then reacquires its <b>MBOSetRemote</b> references.</li> </ul>
Always Synchronous	When deselected, the control can communicate with the database without pausing user activities. If selected, the user cannot perform activities in other fields until validations for this field are completed. Synchronous activity is disabled by default. If there are dependencies between values specified for this control and other controls in the application, you can enable synchronous activity for the dependent controls.
Notify Portlets	If selected, this control can send notifications to a portlet, if communication with a Tivoli® Integration Portlet is configured.
More information	You can specify the values to construct a URL for a Knowledge Center topic using the following format: <b>com.ibm.mbs.doc,application/helpfile.html</b> The server address and other information for the URL are controlled by the mx.help properties which you can review and configure in the System Properties application.  If you specify a URL, a More Information link is added to the field help (Alt + F1) for the control. When the user clicks the link, the target topic opens in the Knowledge Center.  The property is specific to the field ID in the presentation XML file. If you want to provide the same link in other controls or other applications, you must manually add the URL to each individual control.
Move to Data Source ID	Specify a record stored in a different object that the user can move to. You can select any data source ID from the presentation control.  By default, the system sends the move to event to the <b>ResultsBean</b> , which contains a set of records displayed in the List tab. The move to event affects the Move to Data Source ID object.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Multipart text box control

A multipart text box contains two text boxes, positioned side-by-side, that can contain information from different sources. You can input information, populate a box by selecting a value from a list, or show an attribute description from a table. You can place a multipart text box within a section control.

Typically, a multipart text box has a visible label, a pull-down menu in one text box, and the description of an attribute in the second box. Labels describe the type of information displayed in the box. Text boxes are often linked to select value lookups and detailed menus. Most applications typically use the second part of a multipart text box to provide a description for the value contained in the first text box.

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the text value that is associated with the database attribute bound to this control.
Label	If you enter a text value in this field, it overrides the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.
Attribute for Part 2	You can associate the second part of a multipart text box with a different attribute than the one specified in the Attribute field. Typically, you configure the second part of a multipart control to display the description information for the record selected in the first part.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.  In a multipart text box, the attributes for both parts must reference the same object.
Lookup	You can specify a lookup ID to link the first part of a multipart text box to a pre-formatted lookup table that pulls records from the main table. A user can select a record from the lookup table to use in this control.  Lookup IDs are stored in the lookups.xml file. To view the content of this file, export the system XML files.
Lookup for Part 2	You can specify a lookup ID to link the second part of a multipart text box to a pre-formatted lookup table that pulls records from the main table. A user can select a record from the lookup table to use in this control.  Lookup IDs are stored in the lookups.xml file. To view the content of this file, export the system XML files.
Go To Applications	You can associate a pull-down menu with this control and add application names to it that take the user to different applications.
Input Mode	Input mode options are: <ul style="list-style-type: none"> <li>Blank: An input mode with no value is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li> <li>Default: This mode is used for quick entry of default table data in tables.</li> <li>Password: This mode is read/write and displays asterisks.</li> <li>Password Readonly: This mode is read-only and displays asterisks.</li> <li>Password Required: This mode is read/write and displays asterisks. The record cannot be saved unless there is a value in the field.</li> <li>Query: This mode is read-only and shows a typed value.</li> <li>Readonly: This mode is read-only and shows grayed-out text.</li> <li>Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li> </ul>
Input Mode for Part 2	In most cases, where the second part of a multipart text box contains a full description, the property value will be read-only.  In other cases, standard input mode options can apply.
Menu Type	You can specify the value of a menu ID in this field to link the control to a preformatted drop-down menu. Menu IDs are stored in the menus.xml file. To view the content of this file, export the system XML files.

## Advanced properties

Attribute name	Description
Change Event	You can configure a control to perform one of the following actions in the event of a data change to the control: <ul style="list-style-type: none"> <li>The <b>REFRESHABLE</b> event refreshes the data source table for the control.</li> <li>The <b>RESETCHILDREN</b> event deletes any child objects of the data bean of the control which then reacquires its <b>MBOSetRemote</b> references.</li> </ul>
Turn Smart Fill Off?	Check this option if you want to disable smart fill which is turned on by default. Smart fill enables a user to enter a partial value in a text box which the system attempts to match to a valid value, or values, in the database. When a matching value is found, the value is entered in the text box. If the system finds more than one matching value, the user can select one from a list of matching values. If you turn smart fill off, user text is not validated during entry.
Readonly Long Description	If the value of Attribute for Part 2 is a long description, you can select this box to set the description to read only. If you leave this field cleared (the default), users can edit the long description.
Always Synchronous	If deselected, the control can communicate with the database without pausing user activities. If selected, the user cannot perform activities in other fields until validations for this field are completed. Synchronous activity is disabled by default. If there are dependencies between values specified for this control and other controls in the application, you can enable synchronous activity for the dependent controls.
Part 2 Always Synchronous	If deselected, the control can communicate with the database without pausing user activities. If selected, the user cannot perform activities in other fields until validations for this field are completed. Synchronous activity is disabled by default. If there are dependencies between values specified for this control and other controls in the application, you can enable synchronous activity for the dependent controls.
Notify Portlets	If selected, this control can send notifications to a portlet, if communication with a Tivoli® Integration Portlet is configured.

Attribute name	Description
More information	<p>You can specify the values to construct a URL for a Knowledge Center topic using the following format:  <b>com.ibm.mbs.doc,application/helpfile.html</b> The server address and other information for the URL are controlled by the mx.help properties which you can review and configure in the System Properties application.</p> <p>If you specify a URL, a More Information link is added to the field help (Alt + F1) for the control. When the user clicks the link, the target topic opens in the Knowledge Center.</p> <p>The property is specific to the field ID in the presentation XML file. If you want to provide the same link in other controls or other applications, you must manually add the URL to each individual control.</p>
Move to Data Source ID	<p>Specify a record stored in a different object that the user can move to. You can select any Data Source ID from the presentation control.</p> <p>By default, the system sends the Move To event to the <b>ResultsBean</b>, which contains a set of records displayed in the List tab. The Move To event affects the Move to Data Source ID object.</p>
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Parameter value control

A parameter value control can display dynamic values in the label of a section control or a table control.

### Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Parameter Position	This property points to the Parameter Values Property field you want to replace. See the Parameter Values Property field for more information.
Attribute	You can associate this control with a database attribute to display as the Label property in a table or section control.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.

## Parameter values control

A parameter values control is a container control that can contain a parameter value to show a dynamic value that represents a replaceable value in the label of a Section Header control.

### Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Property	The Property field has a default value of Label, which is a variable that displays dynamic values inherited from the Parameter Value control in the Table or Section control.

## Presentation control

The presentation control manages the appearance of the user interface display, and all other controls are contained by this control. The presentation control contains only one page control. The page control specifies the main page of an application and uses the entire client area of the browser. All other application windows are dialogs that open as popup windows. You can add the definition for a dialog window to the PRESENTATION.XML file, or you can include the definition of an existing dialog from the LIBRARY.XML file.

### Rules

The presentation control is the outermost control for all presentations and can contain all other controls.

### General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.

Attribute name	Description
Business Object	Specify the name of a MBO in this field to determine which MBO the control uses to show and process information. If a MBO is not specified, the control uses the data source of its parent control. When you set a MBO for this control a data source is created that can be referenced from other controls.
App Bean Class	You can specify the name of a data bean class to use when creating the data source for the control. If not defined and the control is creating a data source, the default psdi.webclient.system.DataBean class is used. Typically, you use this property to create custom event methods or to override the manner in which the data source obtains its MboSet.
Order By	You can specify the order in which a SQL query fetches data for the data source for this control.
Where Clause	You can specify a WHERE clause that the data source for this control uses to retrieve data. This WHERE clause is used in addition to any default WHERE clause used by the business object of the data source.
Application Restrictions	You can set restrictions for the application at the level of the presentation.xml.
Results Table ID	You can specify the ID of the results table.
Application help	You can specify the URL that takes the user to context-specific help for this application in a Knowledge Center.

## Advanced properties

Attribute name	Description
Viewport	If this application is optimized to be viewed in a viewport other than the standard viewport, specify that viewport in this field.
Is Mobile	A Boolean value that indicates whether the application is designed for access on a mobile device.
Always Synchronous	If deselected, the control can communicate with the database without pausing user activities. If cleared, the user cannot perform activities in other fields until validations for this field are completed. Synchronous activity is disabled by default. If there are dependencies between values specified for this control and other controls in the application, you can enable synchronous activity for the dependent controls.
Debug	You can set a debug level for the application.

## Push button control

A push button control initiates an event such as opening a window with a list of records or opening an empty row where a user can enter a record. Place this control inside a button group control.

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	You can specify a label that identifies the control to the user. If you do not enter a label, the button is blank. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Event	<p>You can associate a push button with an event and, when the user clicks the button, the event is triggered. To configure a push button event, specify the event and, optionally, the ID of a control that processes the event.</p> <p>Events are processed in the following order:</p> <ol style="list-style-type: none"> <li>1. If you specify a control target ID, the event is sent to this data source for processing.</li> <li>2. If you do not specify a control target ID, the event is sent to the main JSP page of the application for processing.</li> <li>3. The window associated with the specified event loads.</li> </ol> <p>To view all of the events defined in the system, export the system .XML files and search these files for <b>MXEVENT</b> entries.</p>
Target ID	If you associate an event with the hyperlink, you can specify the ID of a target control to process the event that is different from the current control. The target ID for the Go To hyperlink, for example, is pageTitlebar.
Value	Reserved for future use.
Default Button	If selected, this button becomes the default button in a button group. You can configure the most frequently used button, for example, New Row, as the default button.
Menu Type	You can specify the value of a menu ID in this field to link the control to a preformatted drop-down menu. Menu IDs are stored in the menus.xml file. To view the content of this file, export the system XML files.

## Advanced properties

Attribute name	Description
Image Filename	You can associate an image with the push button. Specify the name of an image file that is stored in the <root>\applications\maximo\maximouiweb\web module\webclient\images directory. It is not necessary to enter the path to the images directory.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Radio button control

A radio button is a control that allows users to choose one of a predefined set of options. Radio buttons are organized in groups of two or more. Radio buttons typically appear as little circles that are either empty (for unselected) or contain a dot (selected). When you select a radio button, the previously selected button in the same group is deselected.

### Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the label defaults to the database attribute bound to the radio button group control.
Label	You can specify a label that identifies the control to the user. If you do not enter a label, the button is blank. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Button Value	Specify a data attribute for an individual button control. If you do not automatically populate a Radio Button Group with a predefined list of values linked to a data attribute, then you can enter individual values for each button that you manually add to a group.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Radio button group control

A radio button group is a container control that holds radio buttons. The radio button group defines the layout for the buttons it contains, including a group title, text alignment for button labels, and whether or not to show a border. You can place a radio button group control within a section control.

You can bind a radio button group to a database attribute that automatically populates the group with buttons, label values, and so on. Binding to a database attribute saves time because you do not have to define the individual radio button controls for the group. When the user makes a selection in the radio button group, the value automatically updates the attribute in the database. If you link a radio button group to a database attribute, you can then edit the group in the Database Configuration application and in the Domains application.

### General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the text value that is associated with the database attribute bound to this control.
Label	You can specify a text value in this field to override the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Hide Label	By default, the label value always appears in the user interface. Select this check box if you want the label to be invisible.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.
Value Attribute	Optionally, if you do not automatically populate a radio button group with a list of buttons, you can specify a value in this field that automatically updates the database when you select a button. For example, if you have a button with a Description Attribute of Waiting for Approval, you can define a Value Attribute of WAPPR. When the user clicks the radio button, WAPPR is written to the database and Waiting for Approval is shown in the user interface.
Description Attribute	Optionally, you can specify a data attribute that displays a text label for the Value Attribute in the user interface.
Show Border	Select this check box to show a rectangular border around the control.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.

### Advanced properties

Attribute name	Description
Text Alignment	Select Left, Center, or Right to align button text relative to button images. The label for the radio button group always aligns to the left of any buttons that you add to the group.

Attribute name	Description
Input Mode	<p>Input mode options are:</p> <ul style="list-style-type: none"> <li>• Default: The default input mode is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li> <li>• Password: This mode is read/write and displays asterisks.</li> <li>• Password Readonly: This mode is read-only and displays asterisks.</li> <li>• Password Required: This mode is read/write and displays asterisks. The record cannot be saved unless there is a value in the field.</li> <li>• Query: This mode is read-only and shows a typed value.</li> <li>• Readonly: This mode is read-only and shows grayed-out text.</li> <li>• Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li> </ul>
Change Event	<p>You can configure a control to perform one of the following actions in the event of a data change to the control:</p> <ul style="list-style-type: none"> <li>• The <b>REFRESHABLE</b> event refreshes the data source table for the control.</li> <li>• The <b>RESETCHILDREN</b> event deletes any child objects of the data bean of the control which then reacquires its <b>MBOSetRemote</b> references.</li> </ul>
Always Synchronous	If deselected, the control can communicate with the database without pausing user activities. If cleared, the user cannot perform activities in other fields until validations for this field are completed. Synchronous activity is disabled by default. If there are dependencies between values specified for this control and other controls in the application, you can enable synchronous activity for the dependent controls.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Record image control

You can use the record image control to associate an image with a record, including an expandable thumbnail image. You can then add this image to an application from within the application user interface. A user can click on a thumbnail image to view its full size and can drag the mouse over the image to see a text description. You can place a record image control in any container control.

When you add a record image to an application, you are inserting a placeholder but not the actual image. You can add only one record image to an application but you can use the same image multiple times within the application. For example, you can show an image in more than one application tab.

After creating a record image control, open the application and click the Add Modify Image option from the Select Action menu. If necessary, use an autodb script to add the Add Modify Image option to the Select Action menu item. You can add images that have a .jpg or .gif extension.

You can configure the record image control to view images associated with other records that are not part of the current application. Use View Image in the Details menu to open an image in a popup window. To add View Image to a Details menu, edit the **menu.xml** file. When you are finished, use Import Application Definition in the Application Designer to import the menu.xml file.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	You can specify a text value in this field to override the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
CSS Class Name	You can specify the name of a CSS class to use if you want to change the layout or appearance of the record image. You can search for CSS class names in the <root>\applications\maximo\maximouiweb\webmodule\webclient directory.
Height	Enter a numeric value in this field that will increase or decrease the height of the image. If you change the default dimensions, the image can become distorted.
Width	Enter a numeric value in this field that will increase or decrease the width of the image. If you change the default dimensions, the image can become distorted.
Is Thumbnail	Identifies whether or not the image is an expandable thumbnail image.
ALT Text on Image	You can specify a text description of the image that is visible when the user drags a mouse over the image. An ALT text description provides a text substitute for the image to users with a visual impairment that use screen readers.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Rich text editor control

The rich text editor control provides the ability to add rich text formatting to a field with long description characteristics.

The rich text editor control can be placed inside standard container controls, including sections, tabs, and tables. A rich text editor control provides users with a toolbar that helps them to apply rich text formats to the text entered in the text area. Rich text formatting is not appropriate for a field that is the subject of routine searches or for fields that contain a large quantity of information, because the addition of HTML tags to the text can exceed the character limit set for the field in the database.

Table 1. General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the text value that is associated with the database attribute bound to this control.
Label	If you enter a text value in this field, it overrides the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Hide Label	By default, the label value always appears in the user interface. Select this check box to make the label invisible.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
Lookup	Specify a lookup ID to link this control to a pre-formatted lookup table that pulls records from the main table. A user can select a record from the lookup table to use in this control.  Lookup IDs are stored in the lookups.xml file. To view the content of this file, export the system XML files.
Input Mode	Input mode options are: <ul style="list-style-type: none"><li>• Blank: An input mode with no value is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li><li>• Default: This mode is used for quick entry of default table data in tables.</li><li>• Query: This mode is read-only and shows a typed value.</li><li>• Readonly: This mode is read-only and shows grayed-out text.</li><li>• Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li></ul>
Menu Type	You can specify the value of a menu ID in this field to link the control to a preformatted drop-down menu. Menu IDs are stored in the menus.xml file. To view the content of this file, export the system XML files.
Width	You can enter a numeric value in this field to change the width of the editor area.
Height	You can enter a numeric value in this field to change the height of the editor area.

## Advanced properties

Attribute name	Description
Plug-ins	The plug-ins that you specify determine the items that are displayed in the editor toolbar. The default value for plug-ins in the toolbar is <pre>['undo','redo',' ',' ','cut','copy','paste',' ','bold','italic','underline','strikethrough',' ','insertOrderedList','insertUnorderedList','indent','outdent',' ','justifyLeft','justifyRight','justifyCenter','justifyFull']</pre> You can remove, reorder, or add additional plug-ins. To remove all these items from the toolbar, set the value to [].  For more information about available plug-ins, go to the Dojo Toolkit website ( <a href="http://www.dojotoolkit.org">http://www.dojotoolkit.org</a> ) and search for the reference guide.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Rich text viewer control

The rich text viewer control provides the ability to view rich text formatting in a field with long description characteristics.

The rich text viewer control can be placed inside standard container controls, including sections, tabs, and tables.

Table 1. General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	If you enter a text value in this field, it overrides the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Hide Label	By default, the label value always appears in the user interface. Select this check box to make the label invisible.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.

Attribute name	Description
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
Width	You can enter a numeric value in this field to change the width of the viewer area.
Height	You can enter a numeric value in this field to change the height of the viewer area.

## Section control

A section control is one of the core container controls that you use to organize the layout of an application. Container controls occupy space on a page and provide storage for other controls, such as tables, buttons, and text fields.

Section controls without labels do not have visible borders and are transparent in an application page. A section control with a label includes a visible horizontal blue bar with a minimize icon at the top of the section. You start all new application layouts by inserting a section container. Most applications have multiple pages with many sections and columns.

## Rules

You can place the following controls in a section:

- Attachments
- Blank Line
- Button Group
- Checkbox
- Combobox
- Data Source
- Default Value
- Hyperlink
- Image
- Include
- Listbox
- Multiline Textbox
- Radio Button Group
- Section Header
- Section Row
- Static Text
- Textbox

You can place a section inside the following container controls:

- Dialogs
- Tab
- Table
- Section Columns

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	This value identifies the control to the user. If you do not enter a label, the section does not have a title. The label you enter here is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Show Border	Select this option to add a horizontal rule to the top and bottom of the section. If you define a label for the section, the horizontal rules are not added.
Collapsed	If you check this box, the section is collapsed by default in the user interface and the user must click to maximize the section.
Description	You can specify text to show under the label in the title bar of the section.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
Business Object	Specify the name of a MBO in this field to determine which MBO the control uses to show and process information. If a MBO is not specified, the control uses the data source of its parent control. When you set a MBO for this control a data source is created that can be referenced from other controls.
Parent Data Source ID	You can specify the ID of a data source to use as the parent object for a relationship, or to specify a parent object for a bean class if necessary. Then specify the relationship that uses this parent in the Relationship field. If the field is left blank, the control uses the data source ID of its parent control as the Parent Data Source ID

Attribute name	Description
Input Mode	<p>Input mode options are:</p> <ul style="list-style-type: none"> <li>• Default: The default input mode is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li> <li>• Password: This mode is read/write and displays asterisks.</li> <li>• Password Readonly: This mode is read-only and displays asterisks.</li> <li>• Password Required: This mode is read/write and displays asterisks. The record cannot be saved unless there is a value in the field.</li> <li>• Query: This mode is read-only and shows a typed value.</li> <li>• Readonly: This mode is read-only and shows grayed-out text.</li> <li>• Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li> </ul>

## Advanced properties

Attribute name	Description
Listeners	Enter the ID or IDs of one or more data sources that you want to refresh whenever there are changes to this control. Listener controls can be located anywhere within the application. Separate multiple values with a comma.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Section column control

A section column control is a vertical column that you can use to divide a section row into columns with headings. A section column is a container that can hold child section controls and is also a child to the parent section control. When you move a section control, all of its child controls automatically move with it.

You can insert section columns into section rows. When you drag a section column into a section row, it automatically creates two section columns. A section column does not have a label and is transparent in the user interface. A child section can hold, for example, a section header that lets you assign column headings for a multicolumn section. Except for tables, all graphical elements with multiple columns have a transparent section column within a section row, all contained within a parent section.

A section column control has only one property, the control ID property.

## Section header control

Use a section header control to display a text heading for a section or a table. The text in the heading can be dynamic, based on variables you configure in parameter and parameter values controls. A section header control is a container control and is transparent in the user interface.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	The label contains a variable that displays dynamic values inherited from the parameter value and values controls in the section control.
Plain Text	If selected, the CSS (cascading style sheet) class definition for the label is removed so that it looks like plain text in the user interface.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Section row control

A section row control is a layout control that contains section column controls. A section row creates a horizontal row that you can partition into columns that hold child sections. A section row is a child to a parent section control. When you move a section, all of its child controls automatically move with it.

You can insert section columns into section rows. A section row does not have a label and is transparent in the user interface. A section row control has only one property, the control ID.

## Static text control

You can use a static text control to add text to a section control or to specify a database attribute that you can configure and position within a section as if it were unbound text. Static text is, typically, used in Date search windows in applications, where To and From labels are static text controls.

You can also configure the text to function as a hyperlink that takes the user to a URL when clicked. When configured as a URL, the static text displays in a larger font and is styled to look more like a URL string than plain text. You can place static text within a section control.

### General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the text value that is associated with the database attribute bound to this control.
Label	If you enter a text value in this field, it overrides the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.
Text Alignment	Select Left, Center, or Right to align static text in a section control. Typically, you associate static text with a control in a section. You can place the text above or below the control.
Span	You can specify a number in this field if you want the static text to span more than one column.

### Advanced properties

Attribute name	Description
Column	You can specify a number in this field to position static text in a specific column. Each section control has seven columns that are transparent to the user. If you enter the value 3 in this field and select the Center value for Text Alignment, the static text is centered above or below column three. If the text is wider than its column, the width of the column extends automatically to contain it.
Display as Link	By default, static text does not display as a URL link. Select this option if you want to configure the control to display as a URL link
Display as Plain Text	Selecting this check box removes the CSS (cascading style sheet) class definition so that text is displayed as plain text in the user interface.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Tab properties

A tab control is a container in which you place other controls such as tables and sections. Formatting tabs is, typically, the starting point for designing the structure and layout of a new application or extending the layout of an existing application. Place this control inside a tab group control.

### General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	Specify the label for the tab control.  This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Type	Some tabs have a type attribute that you must set: <ul style="list-style-type: none"><li>• Set the type as "list" if the tab is a List tab.</li><li>• Set the type as "insert" if the tab is a Main tab.</li><li>• Leave this field blank for all other tabs.</li></ul>
Default	Select this option if you want this tab to be the default tab that opens when a user opens an application. The default tab can be a list tab or an insert tab except in a power application, when the default tab must be a list tab.
Bean Class	You can specify the name of a data bean class to use when creating the data source for the control. If not defined and the control is creating a data source, the default psdi.webclient.system.DataBean class is used. Typically, you use this property to create custom event methods or to override the manner in which the data source obtains its MboSet.
Business Object	Specify the name of a MBO in this field to determine which MBO the control uses to show and process information. If a MBO is not specified, the control uses the data source of its parent control. When you set a MBO for this control a data source is created that can be referenced from other controls.
Parent Data Source ID	You can specify the ID of a data source to use as the parent object for a relationship, or to specify a parent object for a bean class if necessary. Then specify the relationship that uses this parent in the Relationship field. If the field is left blank, the control uses the data source ID of its parent control as the Parent Data Source ID

Attribute name	Description
Relationship	If you specified a value in the Parent Data Source ID field, specify a value in this field that identifies the relationship between this control and the new data source. A relationship uses a WHERE clause to determine what to show and process from the data source. The control creates a datasource that is by default used by the child controls. You can search for relationship values in the Database Configuration > Relationships tab.

## Advanced properties

Attribute name	Description
Where Clause	You can specify a WHERE clause that the data source for this control uses to retrieve data. This WHERE clause is used in addition to any default WHERE clause used by the business object of the data source.
Order By	You can specify the order in which a SQL query fetches data for the data source for this control.
Listeners	Enter the ID or IDs of one or more data sources that you want to refresh whenever there are changes to this control. Listener controls can be located anywhere within the application. Separate multiple values with a comma.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Tab group control

A tab group control is a container control that holds tabs. Tab groups are part of the template for power applications. When you create a power application, a tab group control is provided with the standard List and Workspace tabs.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Format	Leave blank (the default) or specify one of the following layout options: <ul style="list-style-type: none"> <li>CARDDECK</li> <li>DEFAULT</li> <li>WIZARD</li> </ul> <p>The wizard option replaces the standard tab layout with arrows that point to the tab headings. The cardeck option appears in single-page applications that do not use tabs.</p>
Style	The Style option defaults to FORM, which is a style attribute for the control. The Form style defines the appearance of the main tab group.
Change Event	Reserved for future use.

## Table control

The table control is a container with the basic layout elements of a table window, including a toolbar with filter and search functionality and icons for previous and next row and page. You can place a table control within a section, tab, or window control and you can place a table column control or a section control within a table control.

The table control layout also includes a table column control and a details box where you can enter a section. The table control is similar to the table window in the List tab of most applications. The tables enable the user to search for and display records from one or more tables in a columnar format. You can use the standard filter feature to display only records that meet specified criteria.

You can insert a section control into the details section of a table control. The details section is an empty, rectangular box at the bottom of the window.

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Label	Enter a text value for the label.  This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Input Mode	Input mode options are: <ul style="list-style-type: none"> <li>Blank: An input mode with no value is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li> <li>Default: This mode is used for quick entry of default table data in tables.</li> <li>Query: This mode is read-only and shows a typed value.</li> <li>Readonly: This mode is read-only and shows grayed-out text.</li> <li>Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li> </ul>

Attribute name	Description
Select Mode	The select mode controls whether a table shows a single record or multiple records.
Bean Class	You can specify the name of a data bean class to use when creating the data source for the control. If not defined and the control is creating a data source, the default <code>psdi.webclient.system.DataBean</code> class is used. Typically, you use this property to create custom event methods or to override the manner in which the data source obtains its <code>MboSet</code> .
Order By	You can specify the order in which a SQL query fetches data for the data source for this control.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.  Each application has a presentation file that defines the main MBO for the application, the <b>MAINRECORD</b> . To inherit data from a different MBO for this control (or group of controls) specify an alternative Data Source ID in this field.
Business Object	Specify the name of a MBO in this field to determine which MBO the control uses to show and process information. If a MBO is not specified, the control uses the data source of its parent control. When you set a MBO for this control a data source is created that can be referenced from other controls.
Parent Data Source ID	You can specify the ID of a data source to use as the parent object for a relationship, or to specify a parent object for a bean class if necessary. Then specify the relationship that uses this parent in the Relationship field. If the field is left blank, the control uses the data source ID of its parent control as the Parent Data Source ID
Relationship	If you specified a value in the Parent Data Source ID field, specify a value in this field that identifies the relationship between this control and the new data source. A relationship uses a WHERE clause to determine what to show and process from the data source. The control creates a datasource that is by default used by the child controls. You can search for relationship values in the Database Configuration > Relationships tab.
Width	Specify a number to change the default width of the table. The default width for a table is 1000. You can decrease the width of a table to 400°, the minimum width required to maintain the contents of the toolbar, including the table title and icons.
Description	Text in this field displays under the label in the title bar of the table.
Title Attributes	Reserved for future use.
Start Empty	If you select this option, the table always opens without displaying records. If you do not select the option (the default), the table automatically shows records that match the search query when opened.
Filterable	If you select this option, a filter row is provided to enable the user to search the table. The Filterable property is enabled by default and the setting automatically applies to table columns in the table. This option must be selected if you want to use the Filter Expanded property.
Collapsed	If you select this check box, the section is collapsed by default in the user interface and the user must click to maximize the section.

## Advanced properties

Attribute name	Description
Collapsed Empty Label	You can specify a value that will override the table title (label property) when the table is collapsed and empty.
Collapsed Label	You can specify a value that will override the table title (label property) when the table is collapsed.
Parent Empty Label	If this table is a child of a parent table, and that table is empty, this value overrides the title of the parent table.
Row Details Expanded	Select this check box if you want a table to display the expanded detail sections for each record in the table. The default setting is not to expand the detail sections for a table row.
Application Restrictions	Enter a Where Clause that filters information displayed in the table. If you enter a restriction, it modifies the overall Where Clause for the application. You cannot change the restriction at runtime.
Listeners	Enter the ID or IDs of one or more data sources that you want to refresh whenever there are changes to this control. Listener controls can be located anywhere within the application. Separate multiple values with a comma.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Table column control

The table column control is a container that you can use to add columns and column headings to a table. You can place a table column control within a table control.

At runtime, a table column dynamically generates either a text box control or a check box control to show its data. A check box is used if the data type for the field is YORN. If the data type for the field is not YORN, a text box is used.

You can add a text box to a table column if you want to bind a field with a YORN data type to a text box, instead of to a check box. Unless you want to override the use of a check box for a field with a YORN data type, do not add a control to a table column control.

You can use the standard filter feature to display only records that meet specified criteria.

## General properties

Attribute name	Description
----------------	-------------

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the text value that is associated with the database attribute that is bound to this control.
Label	If you enter a text value in this field, it overrides the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.
Type	<p>A table column can trigger an event or provide a link. If you select Link, the value, such as a record number, is underlined. When the user clicks this link, the record opens.</p> <p>If you select Event, enter appropriate values for the Event Type, Event Description, and Event Icon properties. For example, if you specify the <b>TOGGLEDETAILSTATE</b> event, the user can click a View/Show icon to open or close the details section for a selected record.</p>
Sortable	If you select this option, the user can sort records in a table by clicking the label of a column. The first click sorts the records in ascending order. The second click a label sorts the records in descending order.
Turn Smart Fill Off	Select this option to disable smart fill, which is turned on by default. Smart fill enables a user to enter a partial value in a text box, which the system attempts to match to a valid value, or values, in the database. When a matching value is found, the value is entered in the text box. If the system finds more than one matching value, the user can select one from a list of matching values. If you turn smart fill off, user text is not validated during entry.
Show Filter	If you select the Filterable and Show Filter properties, a filter text box for this column is displayed in the filter row of the table.
Filterable	If you set the Filterable property for a table, the setting also applies to each column in the table. You can override the Filterable setting for a table at the table column level. When you select this option, the user can search on the attribute that is associated with the label of the table column.
Event	<p>If you select Event as the Type property, specify the event in this field.</p> <p>There is no directory of events but you can search for events and event descriptions in the system XML files. To export the files, in a main tab in the Application Designer, choose <b>Select Action &gt; Export System XML</b>. This action exports the library.xml, lookups.xml, and menus.xml files to the <code>&lt;root&gt;\resources\presentation\system</code> directory. You can search these files for <b>MXEVENT</b> and <b>mxevent_desc</b> entries. You can also create your own events.</p>
Target ID	Enter a target control ID, if different from the current control, where an event (if defined) is sent for processing.
Event Description	This property provides a tooltip for an event (if defined).
Event Icon	This property can point to a .gif file of an image that represents an event. The icons in the user interface are stored in the <code>&lt;root&gt;\applications\maximo\ maximouiweb\webmodule\webclient\images</code> directory. The image control in the Application Designer provides access to the files in the images directory.
Change Event	<p>You can configure a control to perform one of the following actions in the event of a data change to the control:</p> <ul style="list-style-type: none"> <li>The <b>REFRESHTABLE</b> event refreshes the data source table for the control.</li> <li>The <b>RESETCHILDREN</b> event deletes any child objects of the data bean of the control, which then reacquires its <b>MBOSetRemote</b> references.</li> </ul>
CSS Class Name	If you want to change the layout and appearance of the control, enter the CSS class name to use. You can search for CSS class names in the <code>applications\maximo\maximouiweb\webmodule\webclient</code> directory.
Lookup	<p>You can specify a lookup ID to link this control to a preformatted lookup table that pulls records from the main table. A user can select a record from the lookup table to use in this control.</p> <p>Lookup IDs are stored in the lookups.xml file. To view the content of this file, export the system XML files.</p>
Go To Applications	You can associate a pull-down menu with this control and add application names to it that users can click to go to different applications.
Input Mode	<p>Input mode options are:</p> <ul style="list-style-type: none"> <li>Blank: An input mode with no value is read/write. Any information that is entered in this field is stored in the database column that is specified in the Attribute field.</li> <li>Default: This mode is used for quick entry of default table data in tables.</li> <li>Password: This mode is read/write and displays asterisks.</li> <li>Password Readonly: This mode is read-only and displays asterisks.</li> <li>Password Required: This mode is read/write and displays asterisks. The record cannot be saved unless there is a value in the field.</li> <li>Query: This mode is read-only and shows a typed value.</li> <li>Readonly: This mode is read-only and shows disabled text.</li> <li>Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li> </ul>

## Advanced properties

Attribute name	Description
Label Attributes	You can enter a comma-separated list of data attributes used to create the Default Label for this control. Label Attributes and Label Source ID enable you to display dynamic values in the Default Label for a table column.
Label Source ID	Enter an object name that is the data source for the Label Attributes property.
Title Attributes	Reserved for future use.
URL Attribute	Enter a URL value if you set the Type property for this control to Link. The URL value becomes a hyperlink.
Is LD Readonly	By default, the system sets a long description that is associated with a table column attribute to editable. Select this field to make the long description read-only.
Always Synchronous	If cleared, the control can communicate with the database without pausing user activities. If cleared, the user cannot perform activities in other fields until validations for this field are completed. Synchronous activity is disabled by default. If there are dependencies between values that are specified for this control and other controls in the application, you can enable synchronous activity for the dependent controls.

Attribute name	Description
Linked Controls ID	You can enter a control ID that is automatically updated whenever there is a change to the attribute value in this column. The control ID must exist somewhere within the application.
More information	<p>You can specify the values to construct a URL for an IBM® Knowledge Center topic using the following format: <b>com.ibm.mbs.doc,application/helpfile.html</b>. The server address and other information for the URL are controlled by the mx.help properties, which you can review and configure in the System Properties application.</p> <p>If you specify a URL, a More Information link is added to the field help (Alt + F1) for the control. When the user clicks the link, the target topic opens in the Knowledge Center.</p> <p>The property is specific to the field ID in the presentation XML file. If you want to provide the same link in other controls or other applications, you must manually add the URL to each individual control.</p>
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	A MBO must be used to evaluate whether a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different from the data source that is configured for this control.

## Text box control

A text box control is a single-line text box that displays information the user either enters or selects from a list. Text boxes have labels that are typically visible in the user interface. Labels are text fields that describe the type of information displayed in the box. You can place a text box within a section control.

Text boxes are often linked to select value lookups and detailed menus. A select value lookup lets you select and then display a single value from a list of records. A text box linked to a detailed menu can contain diverse options, such as a Select Value window, jumps to other applications, or views of different records. The Menu Type property you configure for a text box controls the format and content of the detailed menu.

## General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Default Label	This read-only value is the text value that is associated with the database attribute bound to this control.
Label	If you enter a text value in this field, it overrides the Default Label for the control. This label is specific to the application and is not stored in the <b>MAXATTRIBUTE</b> or <b>APPFIELDDEFAULTS</b> tables.
Hide Label	By default, the label value always appears in the user interface. Select this check box to make the label invisible.
Turn Smart Fill Off	Select this option to disable smart fill which is turned on by default. Smart fill enables a user to enter a partial value in a text box which the system attempts to match to a valid value, or values, in the database. When a matching value is found, the value is entered in the text box. If the system finds more than one matching value, the user can select one from a list of matching values. If you turn smart fill off, user text is not validated during entry.
Attribute	You can associate this control with a database attribute. Not all attributes have a Default Label value.
Data Source ID	Specify a data source ID if you want this control to use a different data source than the parent. If the control is creating a data source and the Data Source ID property is not set, the ID defaults to the ID of the control. If the data source is blank, the control inherits the data source from the parent. If no parent controls have a data source specified or if the parent is the application, <b>MAINRECORD</b> is the data source because it is the primary data source for the application.
Lookup	<p>You can specify a lookup ID to link this control to a pre-formatted lookup table that pulls records from the main table. A user can select a record from the lookup table to use in this control.</p> <p>Lookup IDs are stored in the lookups.xml file. To view the content of this file, export the system XML files.</p>
Go To Applications	You can associate a pull-down menu with this control and add application names to it that users can click to go to different applications.
Input Mode	<p>Input mode options are:</p> <ul style="list-style-type: none"> <li>Blank: An input mode with no value is read/write. Any information entered in this field is stored in the database column specified in the Attribute field.</li> <li>Default: This mode is used for quick entry of default table data in tables.</li> <li>Password: This mode is read/write and displays asterisks.</li> <li>Password Readonly: This mode is read-only and displays asterisks.</li> <li>Password Required: This mode is read/write and displays asterisks. The record cannot be saved unless there is a value in the field.</li> <li>Query: This mode is read-only and shows a typed value.</li> <li>Readonly: This mode is read-only and shows grayed-out text.</li> <li>Required: This mode is read/write and the record cannot be saved unless the user enters a value in the field.</li> </ul>
Menu Type	You can specify the value of a menu ID in this field to link the control to a preformatted drop-down menu. Menu IDs are stored in the menus.xml file. To view the content of this file, export the system XML files.

## Advanced properties

Attribute name	Description
Detail Image	Reserved for future use.

Attribute name	Description
QBE Prepend	If you set the Input Mode to Query, you can filter the search by adding a text prefix that acts as filter. For example, the More Search Fields window uses QBE Prepend to add date search filters similar to ">=". You can specify the value here to save key strokes when searching for records that meet specific date criteria.
Change Event	You can configure a control to perform one of the following actions in the event of a data change to the control: <ul style="list-style-type: none"> <li>The <b>REFRESHABLE</b> event refreshes the data source table for the control.</li> <li>The <b>RESETCHILDREN</b> event deletes any child objects of the data bean of the control which then reacquires its <b>MBOSetRemote</b> references.</li> </ul>
Always Synchronous	If deselected, the control can communicate with the database without pausing user activities. If cleared, the user cannot perform activities in other fields until validations for this field are completed. Synchronous activity is disabled by default. If there are dependencies between values specified for this control and other controls in the application, you can enable synchronous activity for the dependent controls.
Readonly Long Description	By default, the system sets a long description associated with a table column attribute to editable. Select this field to make the long description read-only.
Display Type	Reserved for future use.
More information	You can specify the values to construct a URL for a Knowledge Center topic using the following format: <b>com.ibm.mbs.doc,application/helpfile.html</b> The server address and other information for the URL are controlled by the mx.help properties which you can review and configure in the System Properties application.  If you specify a URL, a More Information link is added to the field help (Alt + F1) for the control. When the user clicks the link, the target topic opens in the Knowledge Center.  The property is specific to the field ID in the presentation XML file. If you want to provide the same link in other controls or other applications, you must manually add the URL to each individual control.
Move To Data Source ID	Specify a record stored in a different object that the user can move to. You can select any Data Source ID from the presentation control.  By default, the system sends the Move To event to the <b>ResultsBean</b> , which contains a set of records displayed in the List tab. The Move To event affects the Move to Data Source ID object.
Signature Option	You can specify a signature option that can restrict access to this control or change the properties of this control based on a condition that you specify. To create a signature option, click Add/Modify Signature Options in the Select Action menu. To specify a condition, click the Configure Conditional Properties button.
Sig Option Data Source ID	An MBO must be used to evaluate whether or not a user has access to a signature option. Specify the value of the data source that performs this evaluation if it is different to the data source that is configured for this control.

## Tree control

Use a tree control as a container for tree node and tree attribute controls to build dynamic, hierarchical tree structures with specific business objects that support hierarchical data. You can place a tree control within a dialog control or a tab control. You can place a tree node control into a tree control.

The Classifications application uses tree controls to construct classification hierarchies and the Users application uses tree controls to construct the security profile hierarchy.

When you click	What happens
Plus sign	Expands the tree node without highlighting the corresponding node label. The plus sign becomes a minus sign. If you highlighted a node label prior to clicking a plus sign, it remains highlighted.
Minus sign	Contracts the tree node and highlights the corresponding node label.
Dot sign (If node label is not selected)	Highlights the node label and removes any existing highlights.
Dot sign (If node label is selected)	No effect.
Node label (Next to a plus sign)	Highlights the node label and removes any existing highlights. Highlighted node does not expand. window displays hierarchical levels below the highlighted node.
Node label (Next to a minus sign)	Highlights the node label and removes any existing highlights. Highlighted node does not contract. window displays hierarchical levels below the highlighted node.
Node label (Next to a dot sign)	Highlights the node label and removes any existing highlights. Highlighted node does not expand or contract. window displays any items or information related to the node label.

## Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Height	Enter a numeric value in this field that will increase or decrease the height of the image. If you change the default dimensions, the image can become distorted.
Width	Enter a numeric value in this field that will increase or decrease the width of the image. If you change the default dimensions, the image can become distorted.
Bean Class	You can specify the name of a data bean class to use when creating the data source for the control. If not defined and the control is creating a data source, the default psdi.webclient.system.DataBean class is used. Typically, you use this property to create custom event methods or to override the manner in which the data source obtains its MboSet.

Attribute name	Description
Business Object	Specify the name of a MBO in this field to determine which MBO the control uses to show and process information. If a MBO is not specified, the control uses the data source of its parent control. When you set a MBO for this control a data source is created that can be referenced from other controls.
Relationship	If you specified a value in the Parent Data Source ID field, specify a value in this field that identifies the relationship between this control and the new data source. A relationship uses a WHERE clause to determine what to show and process from the data source. The control creates a datasource that is by default used by the child controls. You can search for relationship values in the Database Configuration > Relationships tab.
Use Data Source	Reserved for future use.
Order By	You can specify the order in which a SQL query fetches data for the data source for this control.

## Tree attribute control

The tree attribute control describes the data that appears in each tree node. For example, the tree attributes in the Classifications application display classification IDs and descriptions in the user interface. You can place a tree attribute control within a tree node control.

### Properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Display	Select this option to display the Attribute value in the tree node.
Attribute	You can associate the values that display in a tree node with a database attribute. To create a classification example, you can enter "=classstructure" in the Object field to display all the attributes in the CLASSSTRUCTURE table. Select the "CLASSIFICATIONID" attribute to display Classification ID as one of the Tree Node properties. In the Tree example, you also define another Tree Attribute property called "CLASSIFICATION.DESCRPTION" to display the Classification Description value.

## Tree node control

The Tree Node control is a container type of control that works with the Tree and Tree Attribute controls. A Tree Node defines the structure of a hierarchical tree.

### Rules

You can place the Tree Attribute control in this container control.

You can place this control inside the Tree container control.

### General properties

Attribute name	Description
Control ID	Each control in a presentation is assigned a unique Control ID that is read-only.
Image	You can specify the file name of any file stored in the images directory at <root>\applications\maximo\maximouiweb\webmodule\webclient\images. You can reuse any existing images or you can add new images to the directory.  Images can be in any format supported by a browser. You must redeploy the .EAR file on the application server to add the images to the user interface.
Display Key Attribute	Select this property to display the Key Attribute as part of the tree node label.
Display Object Name	Select this property to display the Object Name as part of the tree node label.
Key Attribute	You can specify a different attribute of the business object to use as a key attribute, other than the key attribute specified for the MBO.
Key Value	You can specify an option to display as the default value.
Return Attribute	Enter an attribute name whose value gets returned to the browser when you click the icon of a tree node line item.
Enable Return	Select this property to enable the Return Attribute property functionality.

## Financial processes reference

Financial managers can refer to detailed information about financial processes, such as how the default GL account codes are determined.

- [Security and database configuration](#)  
You use the applications in the security module to implement and to manage security for users and groups. You use the Database Configuration application to perform different actions, such as configuring the GL account and applying configuration changes.
- [Valid GL accounts](#)  
You can set up GL accounts so that they correspond to accounts that you use in your external accounting system.

- [Financial processes common information](#)  
The information in these topics is common for financial processes in all applications.
- [Financial processes in the Assets module](#)  
Various financial processes occur in the Assets and Locations applications.
- [Financial processes in the Inventory module](#)  
Various financial processes occur in the Item Master, Inventory, Inventory Usage, and Tools applications.
- [Financial processes in the Preventive Maintenance module](#)  
Various financial processes occur in the Preventive Maintenance application.
- [Financial processes in the Purchasing module](#)  
Various financial processes occur in the Companies, Purchase Requisitions, Purchase Orders, Receiving, and Invoices applications.
- [Financial processes in the Resources module](#)  
Various financial processes occur in the Labour application.
- [Financial processes in the Service Desk module](#)  
Various financial processes occur in the Service Requests, Incidents, and Problems applications.
- [Financial processes in the Work Orders module](#)  
Various financial processes occur in the Work Order Tracking, Quick Reporting, and Labor Reporting applications.
- [General ledger database columns](#)  
The table in this appendix lists the GL account columns found in user applications. It shows the application, table, and column name for each column. The table also indicates whether you must fully specify the GL account.

---

## Security and database configuration

You use the applications in the security module to implement and to manage security for users and groups. You use the Database Configuration application to perform different actions, such as configuring the GL account and applying configuration changes.

- [Security](#)  
Security is important when implementing GL account codes so that the application can communicate with a financial system.
- [Database configuration](#)  
You can configure the relationships, objects, queries, and other aspects of databases using the Database Configuration application.

---

## Security

Security is important when implementing GL account codes so that the application can communicate with a financial system.

You can implement security to manage which users can log in and which applications users can access. You can set up security privileges for users by group. You create the groups using the Security Groups application. For each group, you specify security settings, such as application privileges and restrictions. You grant security rights to users by assigning them membership in one or more groups. The combination of groups to which a user belongs determines the security privileges for the user.

---

## Database configuration

You can configure the relationships, objects, queries, and other aspects of databases using the Database Configuration application.

- [Authorizing general ledger component access](#)  
You can restrict users from editing GL account codes. You can also restrict users from updating specified general ledger components.
- [Configuring your GL account](#)  
You can use the GL Account Configuration action in the Database Configuration application to specify the basic format of GL account codes. You can create general ledger account structures that are specific to organizations in your enterprise. To support different configurations for each organization, configure your general ledger components to the maximum length that any organization might use.
- [Using the Chart of Accounts application](#)  
In the Chart of Accounts application, you can set up organization-specific GL accounts and resource codes for standard accounting functions. You create accounts and resource codes to correspond with accounts that you use in your external accounting system. You can also set up financial periods, and specify general validation options.
- [Specifying validation options for GL account codes](#)  
You use validation options to specify how GL accounts are validated. GL accounts are validated when they are used in GL account fields.
- [Working with locations](#)  
Locations and location hierarchies represent functional areas of an organization. Use locations to track movement of assets from place to place. Locations typically are static areas while assets might move to various locations. Write work orders and tickets for locations and charge the costs either to the location or asset. Some locations are virtual, rather than physical.

---

## Authorizing general ledger component access

You can restrict users from editing GL account codes. You can also restrict users from updating specified general ledger components.

You set up GL account code formats using the GL Account Configuration action in the Database Configuration application in the Configuration module.

You use the GL Components tab in the Security Groups application to specify which groups can edit the account codes. You can specify edit privileges for each component of the account code.

---

## Configuring your GL account

You can use the GL Account Configuration action in the Database Configuration application to specify the basic format of GL account codes. You can create general ledger account structures that are specific to organizations in your enterprise. To support different configurations for each organization, configure your general ledger components to the maximum length that any organization might use.

- [Account components](#)  
Each GL account code consists of several components (segments) that are separated by delimiters, such as 6100-400-SAF.
- [Mandatory and optional components](#)  
Some GL account components are mandatory while other components are optional.

---

## Account components

Each GL account code consists of several components (segments) that are separated by delimiters, such as 6100-400-SAF.

You can define the number, length, and data type of components, whether the components are required, and any delimiter, in the Database Configuration application. The account structures that you define are the default, system-level structures.

For easy identification, use delimiters to separate components when they are shown. For example, use hyphens to separate components: 6100-400-SAF. Delimiters are written to the database. A component that has not been assigned a value is represented by placeholder characters, such as 6000-???-350.

The first component of the GL account code is the cost center. You can use up to three characters to define your own cost center, for example:

- FIN (Finance Group)
- RD (Research and Development)
- SM (Sales and Marketing)

---

## Mandatory and optional components

Some GL account components are mandatory while other components are optional.

In a fully defined account, specify all mandatory components. In a partially defined account, you can identify the mandatory component by the placeholder characters that it contains.

You do not have to specify an optional component. However, to display the optional component, you must specify it. Any optional components must come at the end of the account string. You cannot place an optional component between two mandatory components.

---

## Example

You designated the first three components of an account as mandatory and the fourth as optional, making **1234-567** an unacceptable account code. Since the third component is required, you must assign characters to the third component, even if you use placeholders. If both the third and fourth components are unknown, the account code would be **1234-567-???**. Since the fourth component is both optional and unknown, that component is not shown.

---

## Using the Chart of Accounts application

In the Chart of Accounts application, you can set up organization-specific GL accounts and resource codes for standard accounting functions. You create accounts and resource codes to correspond with accounts that you use in your external accounting system. You can also set up financial periods, and specify general validation options.

You use the Chart of Accounts application to identify GL accounts. By using the GL Account Configuration action in the Database Configuration application, you can configure the application to use the GL accounts in your external financial system. Using the same account structure, the application can work interactively with your external financial system.

To ensure that your system represents your external financial system GL accounts properly, check the Chart of Accounts application.

---

## Specifying validation options for GL account codes

You use validation options to specify how GL accounts are validated. GL accounts are validated when they are used in GL account fields.

---

## Before you begin

You specify the system-level, default format of GL account codes using the GL Account Configuration window in the Database Configuration application. You specify organization-specific GL account codes using the Add/Modify Account Structure option in the Chart of Accounts application.

## Procedure

1. In the Chart of Accounts application, select the organization for which you want to specify validation rules.
2. From the Select Action menu, select Validation Options.
3. Select or clear the appropriate check boxes in the following list:

Option	Description
Deactivate GL Validations	If this option is selected, general ledger fields are not validated. If this option is not selected, the entries in GL account fields are validated by using the values in the Chart of Accounts application.
Validate GL Component Combinations	If this option is selected, only valid GL account entries are accepted. If you do not select this option, any combination of valid component values is accepted.
Validate Financial Periods	If this option is selected, checks are performed to ensure that a transaction occurs within an open, valid financial period. If this option is not selected, validations are not performed to require defined financial periods.
Require Valid GL Account for All Transactions	If this option is selected, valid general ledger debit and credit accounts must be present on all financial transactions. If this option is not selected, transactions without a valid GL account are allowed.

4. Click OK.

## Working with locations

Locations and location hierarchies represent functional areas of an organization. Use locations to track movement of assets from place to place. Locations typically are static areas while assets might move to various locations. Write work orders and tickets for locations and charge the costs either to the location or asset. Some locations are virtual, rather than physical.

- **Types of locations**

A location is defined as a place where assets are operated, are stored, or are repaired. Using systems of locations and specifying the location for assets on asset records provides the groundwork for gathering and tracking valuable information about the history of assets, including asset performance at specific sites, and as an asset is moved from location to location.

## Types of locations

A location is defined as a place where assets are operated, are stored, or are repaired. Using systems of locations and specifying the location for assets on asset records provides the groundwork for gathering and tracking valuable information about the history of assets, including asset performance at specific sites, and as an asset is moved from location to location.

Locations can be of the following types:

- Operating locations are the location in which an asset operates. Work orders and tickets are written either against the location itself or against the asset in an operating location. Use operating locations when building a location hierarchy.
- Asset types of locations are vendor, salvage, and repair. Assets can be located in asset types of locations. You can track an asset not only as it moves from one operating location to another, but as it moves to a vendor or to a repair location, and perhaps to a salvage location.
- Inventory types of locations are labor and courier. These locations can maintain a balance of an item or items issued from a storeroom. For example, a courier location holding a batch of items issued from a storeroom is responsible for the items until they are received into another location.

## Valid GL accounts

You can set up GL accounts so that they correspond to accounts that you use in your external accounting system.

When you create your chart of accounts, you can match the account codes in your accounting system to the account names in the Chart of Accounts application.

Transactions have a debit and a credit entry. For each transaction, an account is written to the database as the debit account. However, the cost of the transaction can be negative or positive to create the correct net accounting effect. In other words, the net effect of a credit is to create a given account by debiting that account with a negative cost amount.

Table 1. Valid GL accounts

GL Account	Description	Account type	Object and attribute	Application
<a href="#">Accounts payable control account</a>	Summarizes the amount that is owed to suppliers and other creditors.	Company-related	COMPANIES.APCONTR OLACC	Companies Action, > Default Company Accounts
<a href="#">Accounts payable suspense account</a>	The value of invoices that are approved, but not paid.	Company-related	COMPANIES.APSUSPE NSEACC	Companies Action, > Default Company Accounts
<a href="#">Asset GL account</a>	The default debit account for work orders, purchase orders, and other types of accounts against an asset.	Location and asset	LOCATIONS.GLACCOU NT ASSET.GLACCOUNT	Locations

GL Account	Description	Account type	Object and attribute	Application
<a href="#">Consignment suspense accounts</a>	The values of inventory that are owned by an external vendor.	Company-related	COMPANIES.CONSACCT	Companies
<a href="#">Currency variance account</a>	Differences between the receipt price and the invoice cost that result from changes in the exchange rate.	Inventory-related	LOCATIONS.CURVARACC	Storeroom
<a href="#">External labor control account</a>	The credit account for work done by outside vendors.	Resource control	ACCOUNTDEFAULTS.GLDEFAULT DFTLGROUP = LABRESCODE GROUPVALUE = 1	Chart of Accounts Action, External Labor Control Accounts
<a href="#">External tools control account</a>	The credit account for any external tool transaction.	Resource control	ACCOUNTDEFAULTS.GLDEFAULT DFTLGROUP = TOOLRESCODE GROUPVALUE = 0	Chart of Accounts Action, Resource Codes
<a href="#">Internal labor control account</a>	The credit account for work done by internal employees.	Resource control	ACCOUNTDEFAULTS.GLDEFAULT DFTLGROUP = LABRESCODE GROUPVALUE = 0	Chart of Accounts Action, Resource Codes
<a href="#">Internal tools control account</a>	The credit account for any internal tool transaction.	Resource control	ACCOUNTDEFAULTS.GLDEFAULT DFTLGROUP = TOOLRESCODE GROUPVALUE = 0	Chart of Accounts Action, Resource Codes
<a href="#">Inventory control account</a>	The monetary value of the stock in the associated storeroom location.	Inventory-related	LOCATIONS.CONTROLACC	Storeroom
<a href="#">Inventory cost adjustment account</a>	The changes in the average cost or standard cost of your inventory.	Inventory-related	LOCATIONS.INVCOSTADJACC	Storeroom
<a href="#">Inventory GL account</a>	The resource code that is associated with the commodity group that you set up in the Chart of Accounts application.	Inventory-related	LOCATIONS.CONTROLACC	Storeroom
<a href="#">Inventory resource code</a>	The inventory resource component of the debit account in a transaction.	Resource	ACCOUNTDEFAULTS.GLDEFAULT DFTLGROUP = INVRESCODE GROUPVALUE = Commodity Group Name	Chart of Accounts Action, Resource Codes
<a href="#">Invoice cost variance account</a>	The variances in the price, expressed in the vendor currency, between receipt and invoice for the associated storeroom location.	Inventory-related	LOCATIONS.CURVARACC	Storeroom
<a href="#">Labor resource code</a>	The labor resource component of the debit account in a transaction.	Resource	ACCOUNTDEFAULTS.GLDEFAULT DFTLGROUP = TOOLRESCODE GROUPVALUE = 0	Chart of Accounts Action, Resource Codes
<a href="#">Operating location GL account</a>	The default debit account for work orders, purchase orders, and other types of accounts against the location.	Location and asset	LOCATIONS.GLACCOUNT	Location
<a href="#">Paid tax GL account</a>	The accrual account for tax that you pay to a vendor or supplier.	Tax	TAXTYPE.INCLUSIVEGL	Organizations Action, Purchasing/Tax Options
<a href="#">Preventive maintenance GL account</a>	Used when a preventive maintenance record generates a work order.	Preventive maintenance	PM.GLACCOUNT	Preventative Maintenance
<a href="#">Purchase variance account</a>	The purchase variance account is not used for any transactions.	Inventory-related	LOCATIONS.PURCHVARACC	Storeroom
<a href="#">Receipts price variance account</a>	The differences between the inventory standard cost and the receipt cost for items in the associated storeroom location.	Inventory-related	LOCATIONS.RECEIPTVARACC	Storeroom
<a href="#">Received but not invoiced account</a>	The materials and services that you have received, but that you have not yet invoiced.	Company-related	COMPANIES.RBNIACC	Companies Action, Default Company Accounts
<a href="#">Rotating suspense account</a>	The accumulated cost of repairs to an asset until you move the asset into a storeroom.	Inventory-related	ASSET.ROTSUSPACCT	Chart of Accounts Action, Default Organization Accounts
<a href="#">Shrinkage cost account</a>	The differences between actual inventory quantities and calculated quantities.	Inventory-related	LOCATIONS.SHRIKAGEACC	Storeroom
<a href="#">Tool control accounts</a>	The default account used to track transactions on a tool that is owned by an external vendor.	Company-related	COMPANIES.TOOLCONTROLACCOUNT	Companies Action, Default Organization Accounts

GL Account	Description	Account type	Object and attribute	Application
<a href="#">Tool resource code</a>	The tool resource component of the debit account in a transaction.	Resource	ACCOUNTDEFAULTS.G LDEFAULT  DFTLGROUP = TOOLRESCODE GROUPVALUE = 0  ITEMORGINFO.GLACC OUNT	Chart of Accounts Action, Resource Codes  Action, Tool/Org Details
<a href="#">Unpaid tax GL account</a>	The accrual account for unpaid tax.	Tax	TAXTYPE.EXCLUSIVEG L	Organizations Action, Purchasing/Tax Options

- **[Company-related accounts](#)**  
Company-related accounts are default GL accounts for types of companies that use payment.
- **[Inventory-related accounts](#)**  
You can track the volume and the price of your stock, and the costs associated with your stock.
- **[Location and asset accounts](#)**  
The default debit accounts for work orders, purchase orders, and other types of accounts against locations and assets.
- **[Preventive maintenance GL account](#)**  
The preventive maintenance GL account is used when a preventive maintenance record generates a work order. Typically, you specify one segment of the account code to represent the type of work. You establish this account directly on the preventive maintenance record.
- **[Resource codes](#)**  
A resource code typically consists of one component of the account code. You can associate resource codes with resources used on work orders.
- **[Resource control accounts](#)**  
The credit accounts for labor and tool resources.
- **[Tax accounts](#)**  
You can specify default tax GL accounts to calculate the amount of tax that is due on a purchase requisition, request for quotation, purchase order, or invoice.

## Company-related accounts

Company-related accounts are default GL accounts for types of companies that use payment.

- **[Accounts payable suspense account](#)**  
The accounts payable suspense account holds the value of invoices that you have approved, but not paid. When you approve an invoice, the account payable suspense account for the invoice total transaction is credited, and the received but not invoiced account is debited.
- **[Received but not invoiced account](#)**  
The received but not invoiced account is used to track materials and services that you have received, but that you have not yet invoiced. When you receive an item, the received but not invoiced account is credited. When you approve the invoice for that item, the received but not invoiced account is debited for the invoice total transaction.
- **[Accounts payable control account](#)**  
The accounts payable control account summarizes the amount that is owed to suppliers and other creditors.
- **[Consignment suspense accounts](#)**  
In the consignment suspense account, you can track the values of inventory that are owned by an external vendor.
- **[Tool control accounts](#)**  
The tool control account is the default account used to track transactions on a tool that is owned by an external vendor.

## Accounts payable suspense account

The accounts payable suspense account holds the value of invoices that you have approved, but not paid. When you approve an invoice, the account payable suspense account for the invoice total transaction is credited, and the received but not invoiced account is debited.

You can establish the accounts payable suspense account on a company-by-company basis. If you do not specify an account for a particular company, the accounts payable suspense account defaults in the Chart of Accounts application. You can see the list of accounts payable suspense accounts by company type by selecting the Company-Related Accounts action.

## Received but not invoiced account

The received but not invoiced account is used to track materials and services that you have received, but that you have not yet invoiced. When you receive an item, the received but not invoiced account is credited. When you approve the invoice for that item, the received but not invoiced account is debited for the invoice total transaction.

You can establish the received but not invoiced account on a company-by-company basis. If you do not specify an account for a particular company, the received but not invoiced account defaults in the Chart of Accounts application. You can see the list of received but not invoiced accounts by company type by selecting the Company-Related Accounts action.

---

## Accounts payable control account

The accounts payable control account summarizes the amount that is owed to suppliers and other creditors.

You can see the list of accounts payable control accounts by company type by selecting the Company-Related Accounts action.

---

## Consignment suspense accounts

In the consignment suspense account, you can track the values of inventory that are owned by an external vendor.

The consignment suspense account is the holding account that is used for consignment inventory. This account valuation is external to your organization. When you consume consignment items from inventory, you purchase the items from the external vendor.

When you create an inventory record for consignment items, the consignment suspense account is set as the default control account. The consignment suspense account is credited and debited as an inventory control account similar to other inventory financial processes.

---

## Tool control accounts

The tool control account is the default account used to track transactions on a tool that is owned by an external vendor.

When you use external tools, you credit the tool control account for the rate and time you use the tool. The balance value of the tool control account is the value of the credit. You debit the work order charge account.

---

## Inventory-related accounts

You can track the volume and the price of your stock, and the costs associated with your stock.

- [Currency variance account](#)  
You can track differences between the receipt price and the invoice cost that result from changes in the exchange rate.
- [Inventory control account](#)  
You can track the monetary value of the stock in the associated storeroom location. When you transfer an item, the receiving storeroom is debited and the issuing storeroom is credited.
- [Inventory cost adjustment account](#)  
You can track changes in the average cost or standard cost of your inventory.
- [Inventory GL account](#)  
The inventory GL account holds the resource code associated with the commodity group that you set up in the Chart of Accounts application. The account is shown as a segment of merged accounts in transactions such as issues, returns, and transfers of the item from the storeroom location.
- [Invoice cost variance account](#)  
You can track variances in the price, expressed in the vendor currency, between receipt and invoice for the associated storeroom location.
- [Purchase variance account](#)  
The purchase variance account is not used for any transactions.
- [Receipts price variance account](#)  
You can track differences between the inventory standard cost and the receipt cost for items in the associated storeroom location.
- [Rotating suspense account](#)  
The rotating suspense account holds the accumulated cost of repairs to an asset until you move the asset into a storeroom.
- [Shrinkage cost account](#)  
You can track differences between actual inventory quantities and calculated quantities.

---

## Currency variance account

You can track differences between the receipt price and the invoice cost that result from changes in the exchange rate.

The currency variance account is debited if either of the following conditions are true:

- You cleared the Update Cost/Currency Variances on Inventory Costs check box.
- You selected the Update Cost/Currency Variances on Inventory Costs check box and the invoice amount exceeds the current balance.

If you use standard cost, clear the Update Cost/Currency Variances on Inventory Costs check box.

If you clear the check box, the transaction amount is written to the currency variance account. If you select the check box and the invoice amount exceeds its current balance, the difference is written to the currency variance account.

The Update Cost/Currency Variances on Inventory Costs check box is located in the Inventory Defaults window.

The currency variance account is written in a currency variance transaction. If an exchange rate change causes the invoice cost in base currency to exceed the receipt cost in base currency, the transaction amount is positive. If an exchange rate change causes the invoice cost in base currency to be less than the receipt

cost in base currency, the transaction amount is negative.

The currency variance account is paired with the inventory control account: when the currency variance account value increases, the inventory control account value decreases.

Variance accounts track price variances by storeroom location, not by item.

---

## Inventory control account

You can track the monetary value of the stock in the associated storeroom location. When you transfer an item, the receiving storeroom is debited and the issuing storeroom is credited.

The inventory control account is credited for the following transactions involving inventory items:

- Receipts price variance
- Invoice cost variance
- Currency variance
- Material issue or use

The inventory control account is debited for the following transactions involving inventory items:

- Receipt
- Total cost variance
- Return

The inventory control account is also the debit account when a stock adjustment results from the following actions:

- Adjust current balance
- Adjust standard cost
- Change capitalized status
- Reconcile balances

---

## Inventory cost adjustment account

You can track changes in the average cost or standard cost of your inventory.

The inventory cost adjustment account is credited in an average cost adjustment or standard cost adjustment transaction. The inventory cost adjustment account is paired with the inventory control account. When the inventory cost adjustment account is credited, it debits the inventory control account. When the average or standard cost increases, the transaction amount is positive.

---

## Inventory GL account

The inventory GL account holds the resource code associated with the commodity group that you set up in the Chart of Accounts application. The account is shown as a segment of merged accounts in transactions such as issues, returns, and transfers of the item from the storeroom location.

---

## Invoice cost variance account

You can track variances in the price, expressed in the vendor currency, between receipt and invoice for the associated storeroom location.

If the cost changes between receipt and invoice, this account is debited if either of the following conditions is true:

- UPDATEINVENTORY in the MAXVARS table is set to 0.
- UPDATEINVENTORY in the MAXVARS table is set to 1, and the invoice monetary value exceeds the current balance.

If you use the standard cost, set the UpdateInventory flag to 0.

If the flag is set to 0, the amount of the transaction is written to the invoice cost variance account. If the flag is 1 and the invoice amount exceeds the account balance, the difference is written to the invoice cost variance account.

The invoice cost variance account is debited in an invoice cost variance transaction. When the invoice line cost exceeds the receipt cost, the transaction amount is positive. When the invoice line cost is less than the receipt cost, the transaction amount is negative.

This account is paired with the inventory control account. When the invoice cost variance account value increases, the inventory control account value decreases.

Variance accounts track price variances by storeroom location, not by item.

---

## Purchase variance account

The purchase variance account is not used for any transactions.

---

## Receipts price variance account

You can track differences between the inventory standard cost and the receipt cost for items in the associated storeroom location.

The return price variance account is debited in an inventory standard receipt adjustment transaction. When the purchase price at receipt exceeds the standard cost, the transaction amount is positive. When the purchase price at receipt is less than the standard cost, the transaction amount is negative.

The receipts price variance account is paired with the inventory control account; when the receipts price variance account value increases, the inventory control account value decreases.

Variance accounts track price variances by storeroom location, not by item.

---

## Rotating suspense account

The rotating suspense account holds the accumulated cost of repairs to an asset until you move the asset into a storeroom.

The rotating suspense account is the debit account for work orders that you charge to a storeroom. This account is charged when you use material, labor, or tools to complete the work order. When this account is debited for resource use, it credits the appropriate resource control account.

The rotating suspense account is debited when you receive a service associated with rotating assets. If the cost of the service on the approved invoice exceeds the cost at receipt, this account is debited for the variance. When the rotating suspense account is debited for the received or invoiced service, it credits the received but not invoiced account for the vendor.

The rotating suspense account is the credit account when you move rotating assets from a non-storeroom location to an inventory-type location. When you move the assets into the storeroom, a transaction of type TRANSFER is written to the MATRECTRANS table. The transfer transaction causes the rotating suspense account to be credited and the rotating suspense account to be debited for the receiving storeroom.

In the Chart of Accounts application, you can specify a global rotating suspense account code. To specify this account code, select the Organization Default Account action and enter a value in the Global Rotating Suspense Account field. The value that you enter becomes the default for the Rotating Suspense Account field in the Assets application or you can specify a new value in this field.

By default, the Rotating Suspense Account field is not visible.

---

## Shrinkage cost account

You can track differences between actual inventory quantities and calculated quantities.

This account is credited in a current balance adjustment transaction and in a reconciling balances transaction. When the actual inventory quantity exceeds the calculated current balance, the transaction amount is positive.

This account is paired with the inventory control account, which is the debit account in a current balance adjustment transaction.

---

## Location and asset accounts

The default debit accounts for work orders, purchase orders, and other types of accounts against locations and assets.

- [Asset GL account](#)  
The asset GL account is the default debit account for work orders, purchase orders, and other types of accounts against an asset. You establish this GL account on the asset record.
- [Operating location GL account](#)  
The operating location GL account is the default debit account for work orders, purchase orders, and other types of accounts against the location. You can only establish this account on the operating location record.

---

## Asset GL account

The asset GL account is the default debit account for work orders, purchase orders, and other types of accounts against an asset. You establish this GL account on the asset record.

Assign GL accounts to locations instead of to assets. To specify a GL account for a particular asset, you must display the Asset GL Account field in the Assets application.

If you fully specify an asset GL account, work order costs are never charged related to that asset to the operating location GL account. This occurs regardless of the asset location. Any account components that you specify in creating the asset GL account overrides those same components in the operating location GL account.

For example, if you create a work order in asset with GL account 1111-222-???, and the work order is to be performed at an operating location with GL account 1111-333-444, the general ledger debit account for the work order is 1111-222-444.

---

## Operating location GL account

The operating location GL account is the default debit account for work orders, purchase orders, and other types of accounts against the location. You can only establish this account on the operating location record.

---

## Preventive maintenance GL account

The preventive maintenance GL account is used when a preventive maintenance record generates a work order. Typically, you specify one segment of the account code to represent the type of work. You establish this account directly on the preventive maintenance record.

On the work order, the account is merged with the asset and location GL account codes, if those codes exist. In the merger, if codes have defined components in the same segment, the preventive maintenance GL account components have the highest priority. This means that the preventive maintenance GL account code segments override defined segments in the same position from the location and asset GL account codes.

---

## Resource codes

A resource code typically consists of one component of the account code. You can associate resource codes with resources used on work orders.

- [Inventory resource code](#)  
Inventory resource codes are the inventory resource component of the debit account in a transaction. For example, when you create a work order requiring an inventory item, that work order line item includes the inventory resource account component in the general ledger debit account code.
- [Labor resource code](#)  
The labor resource code is the labor resource component of the debit account in a transaction. For example, when you create a work order requiring labor, the work order line item includes the labor resource account segment in the GL debit account code.
- [Tool resource code](#)  
Tool resource codes are the tool resource component of the debit account in a transaction. For example, when you create a work order requiring a tool, that work order line item includes the tool resource account component in the general ledger debit account code.

---

## Inventory resource code

Inventory resource codes are the inventory resource component of the debit account in a transaction. For example, when you create a work order requiring an inventory item, that work order line item includes the inventory resource account component in the general ledger debit account code.

In the Chart of Accounts application, you can define inventory resource codes by commodity group. To track items by identifiers, display the GL account field in the Item Master application and overwrite the code on the item record.

---

## Labor resource code

The labor resource code is the labor resource component of the debit account in a transaction. For example, when you create a work order requiring labor, the work order line item includes the labor resource account segment in the GL debit account code.

In the Chart of Accounts application, you can define one labor resource code for internal labor and another for external labor. Additionally, to track laborers by identifiers, display the GL account field in the Labor application and overwrite the code on the labor record.

---

## Tool resource code

Tool resource codes are the tool resource component of the debit account in a transaction. For example, when you create a work order requiring a tool, that work order line item includes the tool resource account component in the general ledger debit account code.

In the Chart of Accounts application, you can create two resource codes: one for internal resource tools and one for external resource tools. To change the default resource code by identifier, click Inventory > Tools and select the Tool tab. From the Select Action menu, select Tool/Organization Details.

---

## Resource control accounts

The credit accounts for labor and tool resources.

- [External labor control account](#)

The external labor control account is used as the credit account for work done by outside vendors. It is the accrual account for the value of external labor issued to work orders or other activities. For example, this account is credited when you report external labor use on a work order.

- [External tools control account](#)

The external tools control account is used as the credit account for any external tool transaction. The accrual account contains the value of external tools issued to work orders or other activities. For example, this account is credited when you report external tool use on a work order.

- [Internal labor control account](#)

The internal labor control account is used as the credit account for work done by internal employees.

- [Internal tools control account](#)

The internal tools control account is used as the credit account for any internal tool transaction. It is the accrual account for the value of internal tools issued to work orders or other activities. For example, this account is credited when you report internal tool use on a work order.

---

## External labor control account

The external labor control account is used as the credit account for work done by outside vendors. It is the accrual account for the value of external labor issued to work orders or other activities. For example, this account is credited when you report external labor use on a work order.

You define the external labor control account in the Chart of Accounts application for all external labor. You also can define default accounts by the external labor vendor.

You can overwrite the account code on the individual labor record. To do so, display the Labor Control Account field in the Labor application.

This account is paired with the debit account in the transaction, which includes the labor resource code as a component.

---

## External tools control account

The external tools control account is used as the credit account for any external tool transaction. The accrual account contains the value of external tools issued to work orders or other activities. For example, this account is credited when you report external tool use on a work order.

You define the external tools control account for each vendor in the Companies application for all external tools owned by that vendor. In the Chart of Accounts application, you can create two resource codes: one for internal resource tools and one for external resource tools. To change the default resource code by identifier, click Inventory...Tools, select the Tools tab. From the Select Action menu, select Tool/ Organization Details.

The external tools control account is paired with the debit account in the transaction, which includes the tool resource code as a component.

---

## Internal labor control account

The internal labor control account is used as the credit account for work done by internal employees.

Each labor record might have one or more craft and skill levels, and each craft and skill level might have a defined labor rate. If no vendor is specified on the defined labor rate, the rate is considered internal and has an internal labor control account. The internal labor control account is the internal labor account from the work location for the labor. When you update the work location, the internal labor account from the new work location is placed in each of the internal rates for the labor.

You can use the Application Designer to display or update the labor control account in the detail area of each of the labor rates. However, if the labor work location is then changed, the account that you entered is overwritten by the internal labor account of the new work location.

---

## Internal tools control account

The internal tools control account is used as the credit account for any internal tool transaction. It is the accrual account for the value of internal tools issued to work orders or other activities. For example, this account is credited when you report internal tool use on a work order.

To define the default internal tools control account, click Financial...Chart of Accounts. From the Select Action menu, select Organization Default Accounts.

You can overwrite the account code on the individual tool record. To display the Control Account field, click Inventory...Tools. From the Select Action menu, select Tool/Organization Details.

This account is paired with the debit account in the transaction, which would include the tool resource code as a component.

---

## Tax accounts

You can specify default tax GL accounts to calculate the amount of tax that is due on a purchase requisition, request for quotation, purchase order, or invoice.

- [Paid tax GL account](#)

The paid tax GL account is the accrual account for tax that you pay to a vendor or supplier. In most countries, you pay tax to a vendor or supplier, instead of a government tax authority.

- [Unpaid tax GL account](#)

This account is the accrual account for unpaid tax. You use this account for invoices that require you to pay tax directly to a government tax authority, instead of vendors or suppliers.

---

## Paid tax GL account

The paid tax GL account is the accrual account for tax that you pay to a vendor or supplier. In most countries, you pay tax to a vendor or supplier, instead of a government tax authority.

You can specify the paid tax GL account in two ways:

- You can specify a value for individual tax codes, or specify a tax type GL account.
- You can specify a paid tax GL account for tax types 1 through  $n$ , where  $n \leq 27$ .

When you approve an invoice that includes tax, the paid tax GL account is debited. The paid tax GL account is defined for each tax code. If an individual GL account has not been assigned for the tax code, the GL account that is specified for the tax type is used.

The transaction amount is the sum of the amounts specified for each tax type in the invoice lines. For a credit invoice, the amount is negative.

When the invoice includes tax, the paid tax GL account is paired with the received but not invoiced account. When the paid tax GL account is debited, it credits the received but not invoiced account.

When the invoice does not include tax, the paid tax GL account is paired with the unpaid tax GL account. When the unpaid tax GL account is debited, it credits the paid tax account.

---

## Unpaid tax GL account

This account is the accrual account for unpaid tax. You use this account for invoices that require you to pay tax directly to a government tax authority, instead of vendors or suppliers.

The Update Cost/Currency Variances on Inventory Costs check box is located in the Inventory Defaults window in the Organizations application.

To create and manage the unpaid tax GL account go to the Organizations application and from the Select Action menu, select Purchasing Options > Tax Options.

You can specify the unpaid tax GL account in two ways:

- Specify an unpaid tax GL account for tax type 1 through  $n$ , where  $n \leq 27$ . This account is used as the default.
- Specify a value for each individual tax code.

When you approve an invoice, the unpaid tax GL account is debited. The unpaid tax GL account is defined for each tax code. If an individual GL account has not been assigned for the tax code, the GL account for the tax type is used.

The transaction amount is the sum of the amounts specified for each tax type in the invoice lines. For a credit invoice, the amount is negative. When the unpaid tax GL account is debited, it credits the paid tax GL account.

---

## Financial processes common information

The information in these topics is common for financial processes in all applications.

- [GL account transaction processes](#)

Some processes cause GL account transactions to be written. Generally, the transactions are in transaction tables, which you can map to your external financial system.

- [GL account tracking](#)

Most users do not have to specify GL account codes. After you define the accounts and associated codes in the Chart of Accounts application or specify them in some records, most GL account fields default to the correct value.

---

## GL account transaction processes

Some processes cause GL account transactions to be written. Generally, the transactions are in transaction tables, which you can map to your external financial system.

---

### Default codes

Processes resulting in debit or credit transactions use decimal fields and amount (cost) fields. To minimize the effects of rounding in calculations, use the Database Configuration application. Use the application to set the scale of the fields to six or more places. The scale is the number of places calculated and displayed after the decimal point.

For a process to assign a default code to a particular account, you first must establish the default code in the Chart of Accounts application.

For example, if you insert a company record for a vendor, a default code is assigned to the received but not invoiced account. For the assignment to occur, you first must establish which code to use for the received but not invoiced account for vendors.

To establish your vendor received but not invoiced account code, use the Company-Related Accounts action in the Chart of Accounts application.

To overwrite the default code for an account, you must have authorization.

If you have authorization to edit account codes, you might have to display the field in the relevant application. For example, suppose that for a certain labor record, you want to use a code other than the default for the GL account. To overwrite the default account code, you first must make the GL Account field visible in the Labor application.

## Merged account codes

Some processes cause the creation or use of a merged account code. For example, reporting labor use against a work order typically causes a debit to a merged account. The sources of the merged account are the labor GL account and the work order GL account.

In the following example, both the labor GL account and the work order GL account are merged because neither one typically has all of its components specified. For example, if the labor GL account is ???-???-300, and the work order GL account is 6000-300-???, the debit account for labor use is 6000-300-300.

Table 1. Debit account for labor use  
from merger of labor and work order  
GL accounts

Account	Number
Labor GL account	???-???-300
Work order GL account	6000-300-???
Debit account for labor use	6000-300-300

However, if the two accounts both have the second component specified, the second component of one account code must take precedence over the second component of the other account code. Rules determine which accounts take precedence over other accounts.

For the relevant processes, a table is shown with a numbered list of source accounts. For these processes, the account with the higher priority (lower number) takes precedence over the account with the lower priority (higher number). For example, in the report internal labor usage process, the sources of the debit and credit accounts are displayed in priority in the following table:

Table 2. Debit and credit accounts for the report internal labor usage process

Source of GL account	Debit	Credit	Source of GL account
1. Labor GL account	\$15.00 x 2 = \$30.00	\$15.00 x 2 = \$30.00	Labor control account
2. Work Order GL account			
3. Asset GL account			
4. Operating Location GL account			

The merge order of the debit account components for this particular process illustrates a general rule: if you charge a financial transaction that involves a resource to a work order, an asset, or an operating location, the merge order of the components of the relevant GL accounts always has the listed priority.

## Example

For example, the following GL account codes are specified on the preventive maintenance, asset, and operating location records named in the Work Orders application:

Table 3. Merged accounts and account numbers

Account	Number
Preventive maintenance record GL account (priority 1)	2345-???-???
Asset GL account (priority 2)	6789-787-???
Operating location GL account (priority 3)	5555-999-XYZ
Work order GL account	2345-787-XYZ

## Example

For example, purchase a bearing that you charge to work order 1020:

- Work order 1020 is for repairing a forklift in the shipping and receiving department.
- The item resource code for a bearing is ???-???-200.
- The work order GL account for work order 1020 is ???-301-201.
- The forklift has no specified GL account.
- The location GL account for shipping and receiving is 6500-300-???

The resulting general ledger debit account for the transaction is 6500-300-200:

- You specify the first component for only the location general ledger (6500).
- You specify the second component both in the work order general ledger (301) and the location general ledger (300), and the location general ledger takes priority,
- You specify the third component for both the item resource code (200) and the work order general ledger (201), and the item resource code takes priority.

Table 4. General ledger debit account  
and account numbers

Account	Number
Item resource code	???-???-200

Account	Number
Work order GL account	????-301-201
Location GL account	6500-300-???
General ledger debit account	6500-300-200

## Merged account code errors

When account codes merge, the result can be an account code that is not established in the Chart of Accounts application. An error message is displayed and you cannot complete the current transaction.

If your company intends to use the merged account codes, an authorized user must establish the account code in the Chart of Accounts application before you can proceed with the attempted transaction.

If your company does not use the merged account codes, ensure that you are attempting a valid transaction.

## GL account tracking

Most users do not have to specify GL account codes. After you define the accounts and associated codes in the Chart of Accounts application or specify them in some records, most GL account fields default to the correct value.

- **Displayed fields**  
The displayed fields sections of the financial processes topics specify the general ledger field in the user interface, an associated field, or the field that is the source of the general ledger code.
- **Database fields**  
The Database fields sections of the financial processes topics provide the database table and column names.

## Displayed fields

The displayed fields sections of the financial processes topics specify the general ledger field in the user interface, an associated field, or the field that is the source of the general ledger code.

When the value in another field is used as the default source field, the field that contains the default value might be listed as the origin of the source.

The financial processes topics show the information in the following format:

Field name (COLUMNNAME) ⇐ Source field on source page ⇐ Source field or page

The ⇐ symbol in the financial processes topics means “comes from” or “defaults to.” When you read a statement starting on the left of the page, the symbol describes the path that is used to fill the general ledger field that is named before the first arrow.

## Example

For example, the GL Debit Account field on the PR Lines tab:

GL Debit Account (GLDEBITACCT) ⇐ GL Control Account field (not displayed) for storeroom location in the Inventory application.

The field after the last arrow must meet one of the following criteria:

- It is the field where a user entered the GL account code or segment, typically in the Chart of Accounts application.
- It is a field in another application and is described in another topic. To trace the GL account code to its entry in the Chart of Accounts application or other source application, see the related topic.

Most fields in applications are associated with a column in a database table. Although some fields are calculated for display on the page (that is, they have no associated database table column where the value is stored), all general ledger fields have associated database table columns. By using the standard page views, you can see some values from the general ledger-related columns in the database table.

However, other general ledger-related fields are not displayed automatically. Although a database column in the table is associated with the application, the data is not displayed in that column unless you make the field visible.

## Account code priorities

Some instances exist where the general ledger code in a field can come from more than one potential source field. If general ledger codes are in more than one potential source field, those codes are merged. When these codes merge, there is an order of priority for the multiple sources. This priority exists so that when codes or segments of codes compete, the codes or segments to use are known. The possible sources are listed in order of their priority in the potential merger. Codes or segments from higher-priority (lower number) sources take precedence over codes or segments from lower-priority (higher number) sources.

## Example

For example, the GL Account field in the Work Orders application:

GL Account (GLACCOUNT) ⇐

1. Preventive Maintenance GL Account field ⇐ manual entry (no default);
2. Asset GL Account field (not displayed) ⇐ manual entry (no default);
3. Locations GL Account field ⇐ manual entry (no default).

The preventive maintenance, asset, and location fields on a work order provide possible links to the preventive maintenance, asset, and operating location records of the GL accounts. For any fields that are filled on the work order record, the corresponding records are checked and the GL accounts are obtained from the fields according to the priorities 1 through 3.

For example, if GL accounts exist for all three, the preventive GL account takes priority over both the asset GL account and the location GL account. If no preventive maintenance record exists (or no preventive maintenance GL account), the GL account of the asset record has next priority. If a preventive maintenance GL account or an asset GL account does not exist, the location GL account is used.

The account inserted into the GL Account field in the Work Orders application can be a combination, or merger, of the three references accounts. If an account with higher priority is only partially defined (for example, 2345-??-??), and an account of lower priority has defined segments where the higher priority does not, the segments from the account with the lower priority complete the undefined segments in the higher priority account.

## Intermediate sources of account codes

Several cases of general ledger fields might have one or more intermediate source fields between the online field and its ultimate source. For example, the general ledger fields on a purchase order line come from the purchase requisition line if a purchase requisition exists; otherwise, they come directly from the source. Such possible intermediate sources are in parentheses.

## Example

For example, the GL Debit Account field on the inventory transactions report:

GL Debit Account (GLDEBITACCT) ⇐ GL Debit Account field on PO Lines tab ⇐ (GL Debit Account field on the PR Lines application) ⇐ GL Control Account field (not displayed) for storeroom location in the Inventory application

## Database fields

The Database fields sections of the financial processes topics provide the database table and column names.

Table and column name information is shown in the following format:

TABlename1.COLUMNNAME ⇐ TABlename2.COLUMNNAME

## Financial processes in the Assets module

Various financial processes occur in the Assets and Locations applications.

- [Financial processes in the Assets application](#)  
To enter an account code, you must expose the GL Account field on an asset record by modifying the presentation XML.
- [Financial processes in the Locations application](#)  
Besides the GLACCOUNT column, the LOCATIONS database table also contains the following columns: CONTROLACC, INVOICEVARACC, CURVARACC, SHRINKAGEACC, INVCOSTADJACC, and RECEIPTVARACC. These database columns are relevant to inventory-type locations only.

## Financial processes in the Assets application

To enter an account code, you must expose the GL Account field on an asset record by modifying the presentation XML.

The Rotating Suspense Account field contains a code when the asset is rotating (that is, an item number is specified on the asset record).

Database fields	ASSET.GLACCOUNT ⇐ manual entry (no default)
	ASSET.ROTSUSPACCT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRELACC and GROUPVALUE = ROTSPACCT) (Global Rotating Suspense Account field on the Inventory-Related Accounts window in the Chart of Accounts application)

- [Move/Modify Assets action](#)  
To complete this process, select Move/Modify Assets from the Select Action menu in the Asset application.
- [Move and modify assets between operating or other non-storeroom locations](#)  
Moving and modifying assets does not create any general ledger financial transactions, or change any GL account fields on asset or location records. However, when you enter the new location on the Move/Modify Assets window, if you have defined an asset GL account, a preliminary account validation is performed.
- [Move rotating assets from non-storeroom location to storeroom or inventory control location](#)  
Moving a rotating asset from a non-storeroom location to a storeroom or other inventory-type location (labor, courier) creates two transactions.
- [Move rotating assets from non-storeroom location to storeroom or other inventory-type location](#)  
A move to an inventory location results in an asset moving transaction (ASSETTRANS table) and a financial transaction (MATRECTrans table).
- [Swap Assets action](#)  
To swap an asset, select Swap Assets from the Select Action menu in the Assets application. Swapping assets involves replacing one asset with another.

## Move/Modify Assets action

To complete this process, select Move/Modify Assets from the Select Action menu in the Asset application.

Moving and modifying assets between non-storeroom locations (for example, between operating locations, or from an operating location to a repair location) has no financial implications. However, an asset-move transaction is recorded and validated GL accounts are listed.

Moving and modifying rotating assets from a non-storeroom location to an inventory-type location does have financial implications: an asset-move transaction and a financial transaction are recorded.

## Move and modify assets between operating or other non-storeroom locations

Moving and modifying assets does not create any general ledger financial transactions, or change any GL account fields on asset or location records. However, when you enter the new location on the Move/Modify Assets window, if you have defined an asset GL account, a preliminary account validation is performed.

More specifically, it is determined if merging the GL account of an asset and the GL account of a new location produces a valid account code.

The following table illustrates how a valid account code is determined.

Table 1. Move or modify assets account validation

Account	Number
Asset GL account	????-???-200
Destination location GL account	6004-304-???
Merged GL account	6004-304-200

If 6004-304-200 is a valid account, the asset can be moved and modified. The validated account codes are stored with the transaction record. To view the account stored with the transaction, select the View Asset History action from the Select Action menu.

If merging the asset GL account and the destination location GL account does not produce a valid account, entering the destination location in the Move/Modify Assets window produces an error message.

Using the previous example, suppose that 6004-304-200 is not valid. The first line of the error message reads, GL account 6004-304-200 is invalid. The message shows the source account codes (for example, 6004-304-?? and ???-300-200) that merged into the invalid account code. As stated in the error message, you move and modify the asset by changing the asset GL account and the destination location GL account to make the merger valid. Alternatively, an authorized user can establish the currently invalid account code as a valid account code in the Chart of Accounts application.

In the Move/Modify Assets window, and in the asset transaction record, the GL Credit Account field displays the old merged GL account (for example, of the asset and from the location) and the GL Debit Account field displays the new merged GL account (for example, of the asset and to the location). You cannot modify the credit or debit account while moving the asset.

In a standard move or modify transaction, no GL accounts are changed, credited, or debited that might have been associated with the asset by displaying the GL Account field on the asset record. If the asset is a rotating asset and has an associated rotating suspense account, moving and modifying it does not affect that suspense account, except when moving the rotating asset to a storeroom.

You can see the fields for an asset-move/modify transaction in the Move/Modify Assets window.

Displayed fields	GL Debit Account (GLDEBITACCT) ⇐ GL Account field in the Locations application for the destination or to location.
	GL Credit Account (GLCREDITACCT) ⇐ GL Account field in the Locations application for the source or from the location.

Again, these transactions in ASSETTRANS are not financial transactions, but rather, move and modify asset transactions.

Displayed fields	Again, these transactions in ASSETTRANS are not financial transactions, but rather, move and modify asset transactions.
	ASSETTRANS.GLDEBITACCT ⇐ ASSET.GLACCOUNT (GL Account field in Asset)
	ASSETTRANS.GLCREDITACCT ⇐ ASSET.GLACCOUNT (GL Account field in Asset)

## Move rotating assets from non-storeroom location to storeroom or inventory control location

Moving a rotating asset from a non-storeroom location to a storeroom or other inventory-type location (labor, courier) creates two transactions.

The two transactions are:

- An asset moving transaction
- A financial transaction (an inventory material receipt transaction, TRANSFER) written to the MATRECTRANS table.

The asset moving transaction displays, in the GL Debit Account field, the merger of the asset GL account (if any) and the storeroom location GL account. The move transaction shows, in the GL Credit Account field, the merger of the asset GL account and the from location GL account.

The storeroom control account of the location is debited, and the rotating suspense account is credited.

This financial transaction uses the control account of the storeroom location as the debit account and the rotating suspense account as the credit account.

## Primary transaction

When you click View Details tab for an asset record in the Move/Modify Assets window, the GL Credit Account and GL Debit Account fields are displayed. These fields are read-only.

The control account of the storeroom is debited and the rotating suspense account of the rotating asset is credited. Click OK to create both transactions:

- The asset moving transaction
- The material receipt of the storeroom transaction

The date and time are used in the Changed Date field in the Move/Modify Assets window to determine the financial period for the transaction. The Changed Date field defaults to the system date and time.

Move a rotating asset, asset #11430, from its current operating location to the central storeroom.

Table 1. Source of GL account for a moved rotating asset

Source of GL account	Debit	Credit	Source of GL account
Inventory control account	\$150.00	\$150.00	Rotating suspense account

If you have not applied any charges to the asset, the amount of the transaction is zero.

The charges against the rotating asset are stored in the rotating suspense account of the asset. At the time of the move, the storeroom control account is debited and the rotating suspense account is credited.

## Move rotating assets from non-storeroom location to storeroom or other inventory-type location

A move to an inventory location results in an asset moving transaction (ASSETTRANS table) and a financial transaction (MATRECTRANS table).

The fields are on the Move/Modify Assets window (asset moving transaction).

### Displayed fields

GL Debit Account (GLDEBITACCT) ⇐ Inventory Control Account field for item at destination location in the Inventory application (not displayed) ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application for the associated inventory-type location.

If the to location is a labor or courier location, the GL Debit Account field defaults to the Control Account field of the transit location record associated with the labor or courier.

GL Credit Account (GLCREDITACCT) ⇐ Rotating Suspense Account field (not displayed) in Asset ⇐ Global Rotating Suspense Account field on the Inventory-Related Accounts window in the Chart of Accounts application.

### Database fields

The following transactions in ASSETTRANS are move and modify asset transactions, not financial transactions:

ASSETTRANS.GLDEBITACCT ⇐ INVCOST.CONTROLACC (or INVLIFFIFOCOST.CONTROLACC) for item at destination location ⇐ LOCATIONS.CONTROLACC

ASSETTRANS.GLCREDITACCT ⇐ ASSET.ROTSUSPACCT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRELACC and GROUPVALUE = ROTSPACCT)

The following transactions to MATRECTRANS are financial transactions:

MATRECTRANS.GLDEBITACCT ⇐ INVCOST.CONTROLACC (or INVLIFFIFOCOST.CONTROLACC) for item at destination location ⇐ LOCATIONS.CONTROLACC

MATRECTRANS.GLCREDITACCT ⇐ ASSET.ROTSUSPACCT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRELACC and GROUPVALUE = ROTSPACCT)

## Swap Assets action

To swap an asset, select Swap Assets from the Select Action menu in the Assets application. Swapping assets involves replacing one asset with another.

If the asset you are replacing is moved from an operating location or a non-storeroom location to another operating location or another non-storeroom location, the general ledger financial transaction for swapping the asset is identical to moving and modifying assets between operating or other non-storeroom locations.

If the asset you are replacing is moved from an operating location or a non-storeroom location to a storeroom or other inventory control-type location, the general ledger financial transaction for swapping the asset is identical to moving rotating assets from non-storeroom locations to storerooms or inventory control locations.

You can move a replacement asset from a non-storeroom location to an operating location, and the general ledger financial transaction for swapping the asset is identical to moving and modifying assets between operating or other non-storeroom locations.

---

## Financial processes in the Locations application

Besides the GLACCOUNT column, the LOCATIONS database table also contains the following columns: CONTROLACC, INVOICEVARACC, CURVARACC, SHRINKAGEACC, INVCOSTADJACC, and RECEIPTVARACC. These database columns are relevant to inventory-type locations only.

---

### Displayed field

GL Account (GLACCOUNT) ⇐ manual entry (no default).

---

### Database field

LOCATIONS.GLACCOUNT ⇐ manual entry (no default)

---

## Financial processes in the Inventory module

Various financial processes occur in the Item Master, Inventory, Inventory Usage, and Tools applications.

- [Financial processes in the Item Master application](#)  
You can use the Change Capitalized Status action in the Item Master application to write GL account transactions.
- [Financial processes in the Inventory application](#)  
Eight accounts are associated with inventory records that are used for inventory transactions, for material receipt transactions, and for material usage transactions.
- [Financial processes in the Inventory Usage application](#)  
Various financial processes occur in the Inventory Usage application.
- [Financial processes in the Tools application](#)  
Both the tools GL accounts (tool resource codes) and the tools control accounts can be divided into two different types: internal and external. For the tools GL account, the tool resource code that you assign to Outside = N becomes the default for the internal tools GL account, whereas the code that you assign to Outside = Y becomes the default for the external tools GL account.
- [Financial processes in the Issues and Transfers application](#)  
Various financial processes occur in the Issues and Transfers application.

---

## Financial processes in the Item Master application

You can use the Change Capitalized Status action in the Item Master application to write GL account transactions.

- [Change status from non-capitalized to capitalized](#)  
To change the status of an item from non-capitalized to capitalized, select Change Capitalized Status from the Select Action menu.
- [Change status from capitalized to non-capitalized](#)  
To change the capitalized status to non-capitalized, select Change Capitalized Status from the Select Action menu in Item Master application.

---

## Change status from non-capitalized to capitalized

To change the status of an item from non-capitalized to capitalized, select Change Capitalized Status from the Select Action menu.

In the Change Capitalized Status window, enter an account code that you plan to use as the capital GL account. A default capital GL account is not provided.

When you change the status of an item, the storeroom status is changed to capitalized, and the average, last, and standard costs are set to zero in all storerooms containing the item.

The system date and time are used to determine the financial period for the transaction.

---

### Primary transactions

When you select the Current Capitalized Status check box on the Change Capitalized Status window, the account code you manually entered in the Capital GL Account field is associated with the item, for all storerooms containing the item. In the CONTROLACC column of the INVCOST table, the inventory control account code is replaced with the capital GL account code for all storerooms containing the item. In effect, this transfers the charge or value associated with the item from the inventory control account to the capital GL account.

In the INVCOST table, for each row that corresponds to an item, the SHRINKAGEACC and INVCOSTADJACC columns are cleared. For each storeroom that contains the item, a CAPCSTADJ transaction is written to the INVTRANS table.

Displayed fields	GL Debit Account (GLDEBITACCT) ⇐ manually entered Capital GL Account field in the Change Capitalized Status window in the Item Master application.
	GL Credit Account (GLCREDITACCT) ⇐ GL Control Account field (not displayed) in the Inventory application ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.

<b>Database fields</b>	INVTRANS.GLDEBITACCT ← manual entry on the Change Capitalized Status window (no default)
	INVTRANS.GLCREDITACCT ← INVCOST.CONTROLACC (or INVLIFOIFOCOST.CONTROLACC) ← LOCATIONS.CONTROLACC

## Example

For example, a pump is currently in the central storeroom at last, standard, and average costs of \$6400. The current balance of pumps in the central storeroom is 2. The same pump is in the garage storeroom at last, standard, and average cost of \$6500. The current balance of pumps in the garage storeroom is 3.

You change the capitalized status from non-capitalized to capitalized for the pump. Because two storerooms contain the pump, two transactions are shown in INVTRANS:

Table 1. Source of GL account for change capitalized status

Source of GL account	Debit	Credit	Source of GL account
Manually entered capital GL account	2 x \$6,400 <sup>0</sup> .00 = \$12,800.00	2 x \$6,400.00 = \$12,800.00	Inventory control account of central storeroom
Manually entered capital GL account	3 x \$6,500.00 = \$19,500.00	3 x \$6,500.00 = \$19,500.00	Inventory control account of garage storeroom

The value of a transaction is determined by using the following formula:

Line cost = current balance x issue cost

where

Issue cost = average cost or standard cost, depending on the setting specified in the Multisite Setup application for issue cost.

## Example

A pump is currently stored in one storeroom at last cost of \$6200, standard cost of \$6400, and average cost of \$6300. The current balance of pumps is 2. You change its capitalized status from non-capitalized to capitalized. The average cost is in place (that is, the default issue cost is set to average in the Multisite Setup application).

Table 2. Source of GL account for capitalized item

Source of GL account	Debit	Credit	Source of GL account
Manually entered capital GL account	2 x \$6,300.00 = \$12,600.00	2 x \$6,300.00 = \$12,600.00	Inventory control account

If you use standard cost, the value of the transaction is \$12,800, two times the standard cost of \$6400.

## Secondary transaction

The values in the Standard Cost and Average Cost fields are set to zero. When you issue the now-capitalized item, the item is issued at zero cost.

In the INVCOST table, both the SHRINKAGEACC (shrinkage cost account) and INVCOSTADJACC (inventory cost adjustment account) columns are cleared. If you later perform a transaction that causes a debit either to the shrinkage cost account or the inventory cost adjustment account, the GLDEBITACCT column is blank for that transaction. Similarly, if you perform a transaction that causes a credit either to the shrinkage cost account or to the inventory cost adjustment account, the GLCREDITACCT column is blank for that transaction.

In the INVCOST table, the CONTROLACC column contains the capital GL account code. If you perform a transaction, such as a transfer, with the capitalized item, the account code that you enter in the Capital GL Account field acts as the control account in the transaction.

For example, you capitalize a pump, and you enter 7000-800-900 as the capital GL account code. Now, you transfer the capitalized pump from the central storeroom to the garage storeroom.

If the pump is not capitalized, the debit account is the inventory control account of the garage storeroom, and the credit account is the inventory control account of the central storeroom. Since the pump is capitalized, the following transaction occurs:

Table 3. Source of GL account for capitalized item

Source of GL account	Debit	Credit	Source of GL account
7000-800-900 (capital GL account)	\$0.00	\$0.00	7000-800-900 (capital GL account)

## Change status from capitalized to non-capitalized

To change the capitalized status to non-capitalized, select Change Capitalized Status from the Select Action menu in Item Master application.

You can enter a memo in the Memo field, but the Current Capitalized Status field is read-only in the Change Capitalized Status window.

The status is changed to non-capitalized for all storerooms containing the item. The average, last, and standard costs remain at zero for all storerooms. You establish these default account codes in the Storeroom application.

The system date and time is used to determine the financial period for the transaction.

## Primary transaction

When you select Change Capitalized Status on the Change Capitalized Status window, TRANSTYPE = CAPCSTADJ is written to the INVTRANS table for each storeroom containing the item. The line cost of the transaction from Y to N is always zero.

To set the issue cost of an item to a non-zero value, select an action from the Select Action menu in the Inventory application.

If you issue items at average cost, select Inventory\_>Inventory Adjustments\_>Average Cost.

If you do not want the cost of an item to be zero in any storeroom, select Inventory\_>Inventory Adjustments\_>Standard Cost.

Displayed fields	GL Credit Account (GLDEBITACCT) ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
	GL Credit Account (GLCREDITACCT) ⇐ read-only Capital GL Account field on the Change Capitalized Status window in the Item Master application ⇐ GL Control Account field (not displayed) in the Inventory application ⇐ manual entry on displayed field; or
	⇐ account code manually entered on Change Capitalized Status window in the Item Master application if there was a previous transaction from non-capitalized to capitalized. (In that earlier transaction from non-capitalized to capitalized, the code you entered in the Capital GL Account field is written to the GL Control Account field on the item or location record.)
Database fields	INVTRANS.GLDEBITACCT ⇐ LOCATIONS.CONTROLACC.
	INVTRANS.GLCREDITACCT ⇐ INVCOST.CONTROLACC (or INVLIFOFIFOCOST.CONTROLACC) ⇐ manual entry (no default)

## Example

A capitalized pump is currently stocked both in the central storeroom and in the garage storeroom. Since the pump is capitalized, the last, standard, and average costs equal zero in both storerooms. You change the status from capitalized to non-capitalized for that pump.

Since two storerooms contain the pump, two transactions are shown in INVTRANS:

Table 1. Source of GL account for capitalized item

Source of GL account	Debit	Credit	Source of GL account
Inventory control account of central	\$0.00	\$0.00	Capital GL account
Inventory control account of garage	\$0.00	\$0.00	Capital GL account

## Secondary transaction

When the item becomes non-capitalized, the control, shrinkage, and inventory cost adjustment account codes default according to storeroom location. In the database, this event occurs in the INVCOST table. You establish these default account codes in the Storerooms application.

## Financial processes in the Inventory application

Eight accounts are associated with inventory records that are used for inventory transactions, for material receipt transactions, and for material usage transactions.

Inventory accounts default to the type and location of the item. Additionally, items can have item and location-specific accounts.

To establish the default inventory general ledger resource account code, use the Inventory Resource Code window in the Chart of Accounts application.

To establish the default account codes for location accounts, use the Inventory-Related Accounts window in the Chart of Accounts application.

Also, when adding a storeroom in the Storerooms application, you can specify the default account codes on the Storeroom tab.

When you add items to storerooms, the storeroom location accounts are used as the default for that item or location record. When you specify an item type, the general ledger resource account code is used for that item type as the default.

To edit codes assigned to the storeroom location accounts, display the fields in the Inventory application. Editing the code by using the Inventory application changes the code for the item and location record that is shown.

## Example

Suppose that all items in the central storeroom have the default inventory control account of 6600-800-800. Item #1001 is showing in the Inventory application, and you change the code showing in the Control Account field to 6600-800-801. As a result, item #1001 in the central storeroom now has control account code 6600-800-801, but other items in the central storeroom still have control account code 6600-800-800.

The remaining four inventory-related accounts are in the locations database table, not in the inventory table. The following four accounts are in the locations table:

- Currency variance account
- Invoice cost variance account
- Purchase variance account
- Receipts price variance account
- [Inventory costing](#)  
Several account fields are associated with the inventory cost record of the item and location account. Like the field for the inventory GL account, the Inventory application does not display these fields.
- [Insert Item action](#)  
Inserting a master item or item and location record is not a financial transaction.
- [Adjust Current Balance actions](#)  
The Current Balance Adjustment and Reconcile Balances actions create a CURBALADJ transaction. The account in the Control GL Account field is used as the debit account. The account in the Shrinkage Cost Account field is used as the credit account.
- [Adjust Physical Count action](#)  
When you select Physical Count Adjustment from the Select Action menu, a physical count adjustment transaction (PCOUNTADJ) is written to the inventory

transactions table.

- [Reconcile Balances action](#)  
When you select Reconcile Balances from the Select Action menu, a current balance adjustment (RECBALADJ) transaction is created.
- [Adjust Standard Cost action](#)  
When you select Standard Cost Adjustment from the Select Action menu, a standard cost adjustment (STDCSTADJ) transaction is written. The account in the Control GL Account field is used as the debit account. The account in the Cost Adjustment GL Account field is used as the credit account.
- [Adjust Average Cost action](#)  
When you select Average Cost Adjustment from the Select Action menu, an average cost adjustment (AVGCSTADJ) transaction is created. The Control GL Account field is used as the debit account and the Cost Adjustment GL Account field is used as the credit account.
- [Issue Current Item action](#)  
For both issues and returns, the GL account fields in the Issue Current Item window default in the same way that the GL account fields default in the Issues and Transfers application.
- [Return an Item action](#)  
To return an item, select Issue Current Item from the Select Action menu.
- [Transfer Current Item action](#)  
Transferring items in the Inventory application has implications on your financial processes.
- [Assemble and Disassemble Kit actions](#)  
You can gather items to create a kit or take a kit apart.
- [Receipt adjustment transactions](#)  
Transactions that adjust receipts.

## Inventory costing

Several account fields are associated with the inventory cost record of the item and location account. Like the field for the inventory GL account, the Inventory application does not display these fields.

For standard average costing, the INVCOST table is used. For last-in first-out (LIFO) and first-in first-out (FIFO) accounting, the accounts in the INVENTORY table are used.

For LIFO and FIFO transactions that increase inventory, multiple cost records can affect how financial transactions occur.

If you display any of these account fields, you can edit the codes in those fields to make them item-specific. Editing the account codes in the Inventory application does not change the account for all items in that inventory location, but rather, only for that location record.

Database fields	INVCOST.CONTROLACC $\Leftarrow$ LOCATIONS.CONTROLACC (Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application and on the Storeroom tab of the Storeroom application) $\Leftarrow$ direct entry (no default)
	INVCOST.SHRINKAGEACC $\Leftarrow$ LOCATIONS.SHRINKAGEACC (Shrinkage Cost Account field in the Inventory-Related Accounts window in the Chart of Accounts application and on the Storeroom tab of the Storeroom application) $\Leftarrow$ direct entry (no default)
	INVCOST.INVCOSTADJACC $\Leftarrow$ LOCATIONS.INVCOSTADJACC (Inventory Cost Adjustment account field both on the Inventory-Related Accounts window in the Chart of Accounts application and on the Storeroom tab of the Storeroom application) $\Leftarrow$ direct entry (no default)

## Accounts that are only in the Locations table

Four account fields are not associated with the inventory cost table, but with the locations table. You can view and edit these four fields on the Storeroom tab in the Storeroom application.

Displayed fields	Receipts variance account (RECEIPTVARACC) $\Leftarrow$ Receipts Price Variance Account field
	Invoice variance account (INVOICEVARACC) $\Leftarrow$ Invoice Cost Variance Account field
	Currency variance account (CURVARACC) $\Leftarrow$ Currency Variance Account field
	Purchase variance account (PURCHVARACC) $\Leftarrow$ Purchase Variance Account field

Do not use the purchase variance account for any transactions. If you want to use commitment accounting, you can customize this account to store differences between purchase order costs and invoice costs when using a budget.

Database fields	LOCATIONS.RECEIPTVARACC $\Leftarrow$ direct entry (no default)
	LOCATIONS.INVOICEVARACC $\Leftarrow$ direct entry (no default)
	LOCATIONS.CURVARACC $\Leftarrow$ direct entry (no default)
	LOCATIONS.PURCHVARACC $\Leftarrow$ direct entry (no default)

## Account that is only in the Inventory Cost table

One inventory GL account (item resource code) is associated with the inventory cost record (that is, the INVCOST table) of the item and location accounts. To establish the default inventory GL account (item resource) code, use the Inventory Resource Code window in the Chart of Accounts application. The codes on the Inventory Resource Code window vary by item type.

A GL Account field is also in the Inventory application that you can make visible. You can edit the account code to make the code specific to an item and location record.

Database fields	INVCOST.GLACCOUNT $\Leftarrow$ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRESCODE) (Inventory Resource field for the item type on
-----------------	----------------------------------------------------------------------------------------------------------------------------------------

Inventory Resource Codes window in the Chart of Accounts application. (This item resource code is typically only one component of the Inventory GL Account field.) ⇐ direct entry (no default)

## Insert Item action

Inserting a master item or item and location record is not a financial transaction.

Inserting items does not cause any GL account codes to be written to the GL Debit Account and GL Credit Account fields in the transaction record.

## Adjust Current® Balance actions

The Current Balance Adjustment and Reconcile Balances actions create a CURBALADJ transaction. The account in the Control GL Account field is used as the debit account. The account in the Shrinkage Cost Account field is used as the credit account.

The Current Balance Adjustment window in the Inventory application adjusts the current balance of a stocked item. The current balance is a running total of how many instances of that item are in a storeroom. For each bin in this storeroom, you can enter a new current balance and specify the control and shrinkage account numbers associated with this adjustment.

To adjust the current balance of an item, complete the following steps:

1. From the Inventory application, display the item record whose current balance you want to adjust.
2. From the Select Action menu, click Inventory Adjustments > Current Balance. The Current Balance Adjustment window opens, with the item name and description fields populated.
3. In the New Balance field, enter a new balance value for each bin that you want to adjust.
4. Click OK. The Current Balance Adjustment window closes, and the new balance for each bin is saved.

A CURBALADJ (current balance adjustment) transaction is written to the INVTRANS table.

The INVCOST table is the primary source of the default codes for the inventory control account and the shrinkage GL account.

The system date and time is used to determine the financial period for the transaction.

Important: For LIFO and FIFO costing, if the current balance is increased, you must specify a unit cost and date so that the LIFO and FIFO item has the correct cost basis. If the current balance is decreased, multiple financial transactions might be generated. The transactions correspond to the actual cost that is used from the INVLIFOFIFOCOST table.

## Example

Adjust the current balance of a bearing. The default issue cost in the Organizations application is set to average cost and the bearing in inventory has an average cost of \$22.00. Both the physical count and current balance are 4, but you know that the current balance is actually 3.

Table 1. Source of GL account for adjust current balance

Source GL account	Debit	Credit	Source of GL account
Inventory control account	(3-4) x \$22.00= -\$22.00	(3-4) x \$22.00= -\$22.00	Shrinkage cost account

If you capitalize the item, the default debit account is the capital GL account, the default credit account is empty, and the line cost is zero.

## Inventory transaction for Type=CURBALADJ

When you select Adjust Current Balance or Reconcile Balances from the Select Action menu, a current balance adjustment (CURBALADJ) transaction is written to the inventory transactions (INVTRANS) table.

Displayed fields	GL Debit Account (GLDEBITACCT) ⇐ GL Control Account field (not displayed) in the Inventory application ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
	GL Credit Account (GLCREDITACCT) ⇐ GL Shrinkage Account field (not displayed) in the Inventory application ⇐ Shrinkage Cost Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
Database fields	INVTRANS.GLDEBITACCT ⇐ INVCOST.CONTROLACC ⇐ LOCATIONS.CONTROLACC
	INVTRANS.GLCREDITACCT ⇐ INVCOST.SHRINKAGEACC ⇐ LOCATIONS.SHRINKAGEACC

## Adjust Physical Count action

When you select Physical Count Adjustment from the Select Action menu, a physical count adjustment transaction (PCOUNTADJ) is written to the inventory transactions table.

The physical count is typically a number you adjust at predefined intervals, such as monthly, quarterly, or annually. For each storeroom that carries an item, you can view the bin number, lot number, and the physical count that is currently reported.

After you perform an inventory count, you can adjust the physical count for any storeroom and enter the count date. You can then reconcile the balance to the current count.

To adjust the physical count of an item, complete the following steps:

1. From the List tab of the Inventory application, display the item you want.
2. From the Select Action menu, select Inventory Adjustments > Physical Count. The Physical Count Adjustment window opens, with item name location, and count information.
3. In the Count Date field, enter the date when you took the physical count or click Select Date and Time to retrieve the date. If you use the Physical Count Date field in the header section, the date for all rows in the table window is changed. If you do not want to adjust the count date for all rows, edit the Count Date field for each row you want to change.
4. Click Refresh to update the count dates in the table window.
5. For each bin that you want to adjust, enter a new physical count value in the New Count field.
6. Click OK. The Physical Count Adjustment window closes. The new physical count is saved for each storeroom and a record is written, TRANSTYPE = PCOUNTADJ, to the INVTRANS table.

## Example

Adjust the physical count of a bearing, currently in inventory at last, standard, and average cost of \$22.00. The physical count is shown as 4, but the new physical count is 2.

Table 1. Source of GL account for adjust physical count transaction

Source GL account	Debit	Credit	Source of GL account
Shrinkage cost account	$(-2) \times \$22.00 = -\$44.00$	$(-2) \times \$22.00 = -\$44.00$	Shrinkage cost account

Adjusting the physical count has no net effect accounts in the general ledger. The net effect occurs only when you complete the reconcile balances process.

## Inventory transaction for Type=PCOUNTADJ

A physical count adjustment writes a transaction to the INVTRANS table, and is shown in the Inventory Transactions application. Since the transaction uses the same account for the debit side and the credit side, the transaction has no net effect on the general ledger.

Displayed fields	GL Debit Account (GLDEBITACCT) $\Leftarrow$ GL Shrinkage Account field (not displayed) in the Inventory application $\Leftarrow$ Shrinkage Cost Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
	GL Credit Account (GLCREDITACCT) $\Leftarrow$ GL Shrinkage Account field (not displayed) in the Inventory application $\Leftarrow$ Shrinkage Cost Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
Database fields	INVTRANS.GLDEBITACCT $\Leftarrow$ INVCOST.SHRINKAGEACC $\Leftarrow$ LOCATIONS.SHRINKAGEACC
	INVTRANS.GLCREDITACCT $\Leftarrow$ INVCOST.SHRINKAGEACC $\Leftarrow$ LOCATIONS.SHRINKAGEACC

## Reconcile Balances action

When you select Reconcile Balances from the Select Action menu, a current balance adjustment (RECBALADJ) transaction is created.

This process sets the current balance equal to the physical count plus or minus any transactions that occur between the physical count and reconciliation. From a GL account perspective, the Reconcile Balances action is like the Adjust Current Balances action. In the Reconcile Balances window, both the Control GL Account field and the Shrinkage GL Account field display their respective default account codes, as defined for that item and location record.

For example, if you reconcile the current balance of an item in the central storeroom, the Control GL Account field defaults to the inventory control account for that item, in the central storeroom.

The INVCOST table is the primary source of the default codes for the inventory control account and the shrinkage GL account.

The system date and time is used to determine the financial period for the transaction.

When you click OK in the Reconcile Balances window, a reconcile balance adjustment (RECBALADJ) transaction is written to the INVTRANS table.

Important: For LIFO and FIFO costing, if the current balance is increased, you must specify a unit cost and date so that the LIFO and FIFO item has the correct cost basis. If the current balance is decreased, multiple financial transactions might be generated. The transactions correspond to the actual cost that is used from the INVLIFFIFOFOCOST table.

## Example

Reconcile the current balance of a bearing, currently in inventory at last, standard, and average cost of \$22.00. The physical count is 2, but the current balance is initially 3.

Table 1. Source of GL account for reconcile balance

Source GL account	Debit	Credit	Source of GL account
Inventory control account	$(4-3) \times \$22.00 = -\$22.00$	$(4-3) \times \$22.00 = -\$22.00$	Shrinkage cost account

If you capitalize the item, the default debit account is the capital GL account, the default credit account is blank, and the line cost is zero.

## Adjust Standard Cost action

When you select Standard Cost Adjustment from the Select Action menu, a standard cost adjustment (STDCSTADJ) transaction is written. The account in the Control GL Account field is used as the debit account. The account in the Cost Adjustment GL Account field is used as the credit account.

The INVCOST table is the primary source of the default code for the inventory control account. The system date and time is used to determine the financial period for the transaction.

The Standard Cost field on the Inventory tab is read-only so you must use the Adjust Standard Cost window to change the standard cost.

The Standard Cost Adjustment window contains the following columns:

- Condition code
- Condition rate
- Description
- Standard cost

The Standard Cost Adjustment window contains the following columns you can edit:

- Control account for the INVCOST record
- Cost adjustment account for the INVCOST record
- New standard cost

To adjust standard cost of an item, complete the following steps:

1. From the List tab of the Inventory application, display the item whose standard cost you want to adjust.
2. Click the Inventory tab to see the inventory information of that item.
3. From the Select Action menu, select Inventory Adjustments > Standard Cost. The Standard Cost Adjustment window opens. The standard cost value is shown in the Standard Cost field.
4. Type the adjusted standard cost value in the New Standard Cost field. If you are adjusting the cost of an item that is condition-enabled, you can adjust the costs for all condition levels.
5. Update the GL account information in the Control Account and Cost Adjustment fields. Adjusting the standard cost affects these values.
6. Click OK. The Standard Cost field on the Inventory tab displays the new value. The standard cost adjustment is recorded in the inventory transactions table and an STDCSTADJ (standard cost adjustment) transaction is written to the INVTRANS table.

Use the Standard Cost Adjustment action only if you use standard cost management.

## Example

Adjust the standard cost of a bearing from \$22.00 to \$25.00. The current balance of the item is 2.

Table 1. Source of GL account for adjust current balance

Source GL account	Debit	Credit	Source of GL account
Inventory control account	$(\$25.00 - \$22.00) \times 2 = \$6.00$	$(\$25.00 - \$22.00) \times 2 = \$6.00$	Inventory cost adjustment account

If you capitalize the item, the standard cost is zero, and you cannot perform the transaction.

## Inventory transactions for Type=STDCSTADJ

When you select Adjust Standard Cost from the Select Action menu, an STDCSTADJ transaction is written to the inventory transactions (INVTRANS) table.

Displayed fields	GL Debit Account (GLDEBITACCT) ⇐ GL Control Account field (not displayed) in the Inventory application ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.		
	GL Credit Account (GLCREDITACCT) ⇐ GL Cost Adjustment Account field (not displayed) in the Inventory application ⇐ Inventory Cost Adjustment Account field on the Inventory-Related Accounts window in the Chart of Accounts application.		
Database fields	INVTRANS.GLDEBITACCT ⇐ INVCOST.CONTROLACC (or INVLIFFOFIFOCOST.CONTROLACC) ⇐ LOCATIONS.CONTROLACC		
	INVTRANS.GLCREDITACCT ⇐ INVCOST.INVCOSTADJACC (or INVLIFFOFIFOCOST.INVCOSTADJACC) ⇐ LOCATIONS.INVCOSTADJACC		

## Adjust Average Cost action

When you select Average Cost Adjustment from the Select Action menu, an average cost adjustment (AVGCSTADJ) transaction is created. The Control GL Account field is used as the debit account and the Cost Adjustment GL Account field is used as the credit account.

If you issue items at average cost and want any price increases reflected immediately in the issue cost, you might want to adjust the average cost value.

To adjust the average cost of an item, complete the following steps:

1. From the List tab of the Inventory application, display the item whose average cost you want to adjust.
2. Click the Inventory tab and from Select Action menu, select Inventory Adjustments > Average Cost.
3. Enter the average cost value in the Average Cost field. If you are adjusting the cost of a condition-enabled item, you can adjust the costs for all condition levels. You can enter a new value for the average cost directly, or you can specify a percentage increase or decrease by which to adjust the average cost in the Cost % field. If you enter a figure in the Cost % field, the New Average Cost field is updated accordingly.

4. Update the GL account information in the Control Account and Cost Adjustment Account fields. Adjusting the current balance figure affects these values.
5. Click OK. The Average Cost field on the Inventory tab displays the new value. The average cost adjustment is recorded in the inventory transactions table.

The INVCOST table is the primary source of the default account code for the inventory control account.

The system date and time are used to determine the financial period for the transaction.

When you click OK on the Average Cost Adjustment window, an AVGCSTADJ transaction is written to the INVTRANS table.

## Example

Adjust the average cost of a bearing from \$22.00 to \$25.00. The current balance of the item is 2

Table 1. Source of GL account for average cost adjustment

Source GL account	Debit	Credit	Source of GL account
Inventory control account	$(\$25.00 - \$22.00) \times 2 = \$6.00$	$(\$25.00 - \$22.00) \times 2 = \$6.00$	Inventory cost adjustment account

If you capitalize the item, the average cost is zero, and you cannot perform the transaction.

## Inventory transactions for Type=AVGCSTADJ

When you select Adjust Average Cost from the Select Action menu, an AVGCSTADJ transaction is written to the inventory transactions (INVTRANS) table.

Displayed fields	GL Debit Account (GLDEBITACCT) $\Leftarrow$ GL Control Account field (hidden) in the Inventory application $\Leftarrow$ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
	GL Credit Account (GLCREDITACCT) $\Leftarrow$ GL Cost Adjustment Account field (hidden) in the Inventory application $\Leftarrow$ Inventory Cost Adjustment Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
Database fields	INVTRANS.GLDEBITACCT $\Leftarrow$ INVCOST.CONTROLACC $\Leftarrow$ LOCATIONS.CONTROLACC
	INVTRANS.GLCREDITACCT $\Leftarrow$ INVCOST.INVCOSTADJACC $\Leftarrow$ LOCATIONS.INVCOSTADJACC

## Issue Current® Item action

For both issues and returns, the GL account fields in the Issue Current Item window default in the same way that the GL account fields default in the Issues and Transfers application.

In the Inventory application, to issue an item, select Issue Current Item from the Select Action menu.

The date and time in the Entered Date field in the Issue Current Item window is used to determine the financial period for the transaction. The Entered Date field defaults to the system date and time.

When you click Save to issue the item, ISSUETYPE = ISSUE is written to the MATUSETRANS table.

Important: For LIFO and FIFO costing, if the current balance is decreased, multiple financial transactions might be generated. The transactions correspond to the actual cost that is used from the INVLIPOFIFOCOST table.

## Example

Issue 20 bearings at \$0.50 (issue cost).

Table 1. Source of GL account for average cost adjustment

Source GL account	Debit	Credit	Source of GL account
1. Inventory GL account (item resource code)	$20 \times \$0.50 = \$10.00$	$20 \times \$0.50 = \$10.00$	Inventory control account
2. If issued to a work order, uses work order GL account			
3. If issued to an asset <ul style="list-style-type: none"> <li>Asset GL account</li> <li>GL account of the location for an asset</li> </ul>			
4. If issued to a location <ul style="list-style-type: none"> <li>If only one asset at location, asset GL account</li> <li>Location GL account</li> </ul>			

If you capitalize the item (bearings), the default credit account is the capital GL account, and the line cost is zero.

## Return an Item action

To return an item, select Issue Current Item from the Select Action menu.

The date and time is used in the Entered Date field on the Issue Current Item page to determine the financial period for the transaction. The Entered Date field defaults to the system date and time.

When you click Save, ISSUETYPE = RETURN is written to the MATUSETRANS table.

When returning an item, the GL accounts remain the same as the issue transaction that is being returned. The sign of the line cost is changed to a negative to reverse the financial amount of the transaction.

## Example

Return 4 bearings at \$0.50 (issue cost).

Table 1. Source of GL account for returning an item

Source GL account	Debit	Credit	Source of GL account
1. Inventory GL account (item resource code)	4 x \$0.50 = -\$2.00	4 x \$0.50 = -\$2.00	Inventory control account
2. If returned from a work order GL account			
3. If returned from asset			
• Asset GL account			
• GL account of the location for an asset			
4. If returned from a location			
• If only one asset at location, asset GL account			
• Location GL account			

If you capitalize the item, the default debit account is the capital GL account, and the line cost is zero.

## Transfer Current® Item action

Transferring items in the Inventory application has implications on your financial processes.

Important: For LIFO and FIFO costing, if the current balance is decreased, multiple financial transactions might be generated. The transactions correspond to the actual cost that is used from the INVLIFOIFOCOST table.

<b>Displayed fields</b>	<p>GL Debit Account (GLDEBITACCT) ⇐</p> <p>If the item is transferred to a labor or courier location, the Control Account field for the labor or courier in the Location application; otherwise,</p> <p>If in response to an internal purchase order, the GL Debit Account field on the PO Lines tab; otherwise,</p> <p>GL Control Account field (not displayed) in the Inventory application for the to location ⇐ Inventory Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p> <p>GL Credit Account (GLCREDITACCT) ⇐</p> <p>the GL Credit Account on the PO Lines tab if in response to an internal purchase order; otherwise,</p> <p>GL Control Account (not displayed) in the Inventory application for from location &lt; Inventory Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p>
<b>Database fields</b>	<p>MATRECTRANS.GLDEBITACCT ⇐</p> <p>If transferred to a labor or courier location, LOCATIONS.CONTROLACC; otherwise,</p> <p>If in response to an internal purchase order, POLINE.GLDEBITACCT; otherwise,</p> <p>INVCOST.CONTROLACC for to location ⇐ LOCATIONS.CONTROLACC</p> <p>MATRECTRANS.GLCREDITACCT ⇐</p> <p>INVCOST.CONTROLACC for from location ⇐ LOCATIONS.CONTROLACC</p>

## Assemble and Disassemble Kit actions

You can gather items to create a kit or take a kit apart.

When you assemble a kit, you increase the balance of the kit record and you reduce the balance of the items in the kit.

When you disassemble a kit, you increase the balance of the items in the kit and you reduce the balance of the kit record.

If a discrepancy exists between the value of a kit and the combined cost of the components in that kit, a kit cost variance (KITCOSTVAR) transaction is written that represents the variance between the two (the cost of a kit and the combined cost of that kit components).

This financial transaction uses the control account for the storeroom location as the debit account and the receipt variance account as the credit account.

Important: For LIFO and FIFO costing of kits or kit items, multiple financial transactions might be generated.

## Example

Disassemble a kit using the standard cost: the value of the kit is \$430 (standard cost), the combined standard cost of the components is \$410. This action results in a cost variance of \$20.

Table 1. Source of GL account code for kit cost variance

Source GL account	Debit	Credit	Source of GL account
Control account of the storeroom location	\$20.00	\$20.00	Receipt variance account

## Receipt adjustment transactions

Transactions that adjust receipts.

## Transfer transactions

You can view transaction records for transfers on the Transactions tab in the Inventory application, just as you can view them in the Issues application and the Transfers application.

The issue type for this transaction is TRANSFER, which is written to the database table. However, it is not shown in the Issue Type field on the page.

## Purchase order material receipts transactions

For storeroom purchases (Issue on Receipt? = N) from an outside vendor:

<b>Displayed fields</b>	GL Debit Account (GLDEBITACCT) ⇐ GL Debit Account field on PO Lines tab ⇐ (GL Debit Account field on PR Lines tab) ⇐ GL Control Account field (hidden) for storeroom location in the Inventory application.  GL Credit Account (GLCREDITACCT) ⇐ GL Credit Account field on PO Lines tab ⇐ (GL Credit Account field on PR Lines tab) ⇐ RBNI field for vendor in Companies ⇐ RBNI field for company type for vendor on Company-Related Accounts window in the Chart of Accounts application.
<b>Database fields</b>	MATRECTRANS.GLDEBITACCT ⇐ POLINE.GLDEBITACCT ⇐ (PRLINE.GLDEBITACCT) ⇐ INVCOST.CONTROLACC  MATRECTRANS.GLCREDITACCT ⇐ POLINE.GLCREDITACCT ⇐ (PRLINE.GLCREDITACCT) ⇐ COMPANIES.RBNIACC ⇐ COMPANYACCDEF.RBNIACC (where TYPE = type of vendor company)

For storeroom purchases (where the Issue on Receipt check box is N) from an internal vendor (another storeroom):

<b>Displayed fields</b>	GL Debit Account (GLDEBITACCT) ⇐ GL Debit Account field on PO Lines tab ⇐ (GL Debit Account field on PR Lines tab) ⇐ GL Control Account field (hidden) for receiving storeroom location ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.  GL Credit Account (GLCREDITACCT) ⇐ GL Credit Account field on PO Lines tab ⇐ (GL Credit Account field on PR Lines tab) ⇐ GL Control Account field (hidden) for vendor storeroom location ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
<b>Database fields</b>	MATRECTRANS.GLDEBITACCT ⇐ POLINE.GLDEBITACCT ⇐ (PRLINE.GLDEBITACCT) ⇐ INVCOST.CONTROLACC (of receiving storeroom location)  MATRECTRANS.GLCREDITACCT ⇐ POLINE.GLCREDITACCT ⇐ (PRLINE.GLCREDITACCT) ⇐ INVCOST.CONTROLACC (of vendor storeroom location)

For direct issue purchases (Issue on Receipt? = Y) from an outside vendor:

<b>Displayed fields</b>	GL Debit Account (GLDEBITACCT) ⇐ GL Debit Account field on PO Lines tab ⇐ (GL Debit Account field on PR Lines tab) ⇐  1. GL Account field (hidden) in the Inventory application ⇐ Inventory Resource field for item Type field on Inventory Resource Codes window in the Chart of Accounts application;  2. Work Order GL Account field;  3. Asset GL Account field (hidden);  4. Location GL Account field.  GL Credit Account (GLCREDITACCT) ⇐ GL Credit Account field on PO Lines tab ⇐ (GL Credit Account field on PR Lines tab) ⇐ RBNI field for vendor in Companies ⇐ RBNI field for Company Type field (for vendor on purchase order line) on Company-Related Accounts window in the Chart of Accounts application.
<b>Database fields</b>	MATRECTRANS.GLDEBITACCT ⇐ POLINE.GLDEBITACCT ⇐ (PRLINE.GLDEBITACCT) ⇐  1. INVCOST.GLACCOUNT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRESCODE and GROUPVALUE = item type for item on purchase order line) 2. WORKORDER.GLACCOUNT 3. ASSET.GLACCOUNT 4. LOCATIONS.ACCOUNT  MATRECTRANS.GLCREDITACCT ⇐ POLINE.GLCREDITACCT ⇐ (PRLINE.GLCREDITACCT) ⇐ COMPANIES.RBNIACC ⇐ COMPANYACCDEF.RBNIACC (where TYPE = type of vendor company)

You can create direct issue purchase requisitions and purchase orders only for external vendors.

The sources for service receipt GL accounts are the same, except that no item resource code (Inventory GL Account field) is involved with services.

## Standard receipt adjustment transactions

When you use the standard cost, you can create this transaction as a secondary transaction to a material receipt transaction when the receipt price differs from the standard cost.

<b>Displayed fields</b>	GL Debit Account (GLDEBITACCT) ⇐ Receipts Price Variance Account field for storeroom location ⇐ Receipts Price Variance Account field on the Inventory-Related Accounts window in the Chart of Accounts application.  GL Credit Account (GLCREDITACCT) ⇐ GL Control Account field (not displayed) in the Inventory application ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
<b>Database fields</b>	INVTRANS.GLDEBITACCT ⇐ LOCATIONS.RECEIPTVARACC INVTRANS.GLCREDITACCT ⇐ INVCOST.CONTROLACC ⇐ LOCATIONS.CONTROLACC

## Financial processes in the Inventory Usage application

Various financial processes occur in the Inventory Usage application.

- **[Issue an item within one site](#)**  
In the Inventory Usage application, you can issue an item by inserting a record, similar to a purchase order. A financial transaction occurs only when the status changes.
- **[Issue an item between sites within the same organization](#)**  
In the Inventory Usage application, you can issue an item within the same organization by inserting a record, similar to a purchase order. A financial transaction occurs only when the status changes.
- **[Return a previously issued item](#)**  
To return an item, click Select Items for Return.
- **[Transferring items](#)**  
To transfer an item, click Select Items for Transfer.
- **[Transferring items via shipments](#)**  
In the Inventory Usage application, you can transfer items using an intermediary, such as a shipper or courier, by creating a shipment records.
- **[Database transactions](#)**  
In the Inventory Usage application, you can transfer an item against an internal purchase order. This section explains the general ledger transactions for all materials usage scenarios.

### Issue an item within one site

In the Inventory Usage application, you can issue an item by inserting a record, similar to a purchase order. A financial transaction occurs only when the status changes.

The date and time in the Actual Date field is used to determine the financial period for the transaction. The Actual Date field defaults to the system date and time.

When the document status changes to COMPLETE, a transaction of ISSUETYPE = ISSUE is written to the MATUSETRANS table.

### Example

Issue 20 bearings at \$0.50 (issue cost).

Table 1. Source of GL account for issuing an item

Source GL account	Debit	Credit	Source of GL account
1. Inventory GL account (item resource code)	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Inventory control account
2. If issued to a work order, uses work order GL account			
3. If issued to asset:			
• Asset GL account			
• GL account of location for the asset			
4. If issued to a location:			
• If only one asset at location, asset GL account			
• Location GL account			

If you capitalize the item, the default credit account is the capital GL account, and the line cost is zero.

### Issue an item between sites within the same organization

In the Inventory Usage application, you can issue an item within the same organization by inserting a record, similar to a purchase order. A financial transaction occurs only when the status changes.

The date and time is used in the Actual Date field to determine the financial period for the transaction. The Actual Date field defaults to the system date and time.

When the document status changes to COMPLETE, a transaction of ISSUETYPE = ISSUE is written to the MATUSETRANS table.

### Example

Issue 20 bearings at \$0.50 (issue cost) from the storeroom in Site A to the storeroom in Site B

Table 1. Source of GL account for issuing an item between sites in the same organization

Source of GL account	Debit	Credit	Source of GL account
1. Inventory GL account (item resource code)	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Inventory control account
2. If issued to a work order, uses work order GL account			
3. If issued to asset <ul style="list-style-type: none"><li>• Asset GL account</li><li>• GL account of location for the asset</li></ul>			
4. If issued to a location <ul style="list-style-type: none"><li>• If only one asset at location, asset GL account</li><li>• Location GL account</li></ul>			

If you capitalize the item, the default credit account is the capital GL account, and the line cost is zero.

## Return a previously issued item

To return an item, click Select Items for Return.

The date and time in used in the Actual Date field in the table window to determine the financial period for the transaction. The Actual Date field defaults to the system date and time.

To return items in the Inventory Usage application, select the applicable items from a list of previously issued items. The transaction is posted with a negative line cost and the accounts are the same debit and credit as the issue transaction. These accounts are read-only.

When the document status changes to COMPLETE, a transaction of ISSUETYPE = RETURN is written to the MATUSETRANS table.

### Example

Return 4 bearings that were issued at \$0.50 each. At issue, the debit account was 1111-111-111 and the credit account was 2224-224-222.

Table 1. Source of GL account for returning a previously issued item

Source GL account	Debit	Credit	Source of GL account
1111-111-111 general ledger debit account used when item was issued (read-only)	4 x \$0.50 = \$2.00	4 x \$0.50 = \$2.00	2224-224-222 general ledger credit used when item was issued (read-only)

## Transferring items

To transfer an item, click Select Items for Transfer.

### Primary transaction

When the document status changes to COMPLETE, a transaction of ISSUETYPE = TRANSFER is written to the MATRECTRANS table.

### Example

Transfer 20 bearings at \$0.50 (issue cost) from the central storeroom to the packaging storeroom.

Table 1. Source of GL account for transferring an item

Source GL account	Debit	Credit	Source of GL account
1. Inventory control account of destination storeroom.	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Inventory control account of source storeroom.
2. If in response to an internal purchase order, uses purchase order line general ledger debit account.			If in response to an internal purchase order, comes from purchase order line general ledger credit account

If you capitalize the item and it exists in the destination, the default for both the debit and credit accounts is the capital GL account, and the line cost is zero.

If you capitalize the item and your company is stocking it in the destination for the first time, the debit account for the transfer is the inventory control account of the destination. The credit account is the capital GL account.

Transferring a capitalized item to a new inventory location inserts the item as capitalized into the new inventory location. The control account for the item in that new inventory location is the inventory control account, not the capital GL account.

### Example

You transfer 20 bearings into the central storeroom at \$0.50 each (primary transaction), but the standard cost of the bearings in the central storeroom is \$0.45 each. Your company uses the standard cost.

If the item is capitalized, the default credit account is the capital GL account. Also, because the standard cost of a capitalized item is zero, the line cost for the standard receipt adjustment transaction equals the receipt price of the item.

Table 2. Source of GL account with different item cost

Source GL account	Debit	Credit	Source of GL account
Inventory control account of supplying storeroom	$(\$0.50 - \$0.45) \times 20 = \$1.00$	$(\$0.50 - \$0.45) \times 20 = \$1.00$	Inventory control account for destination storeroom

All cost entries and calculations are performed in the base currency.

## Transferring items via shipments

In the Inventory Usage application, you can transfer items using an intermediary, such as a shipper or courier, by creating a shipment records.

You insert an inventory usage record that has one or more transfer lines. By changing the status to shipped, you can fill out the details of the shipment, such as the shipper and waybill number. This creates the financial transaction for the deduction from the supplying storeroom. The transaction set is complete when the shipment is received at the destination storeroom, which occurs in the Shipment Receiving application.

## Primary transaction

When the document status changes to SHIPPED, a transaction of ISSUETYPE = SHIPTRANSFER is written to the MATRECTRANS table.

## Example

Transfer 20 bearings at \$0.50 (issue cost) from the central storeroom in site A to the packaging storeroom in site B within the same organization using a shipment record.

Table 1. Source of GL account for transferring an item within the same organization using a shipment record

Source GL account	Debit	Credit	Source of GL account
Inventory control account of central storeroom in site B.	$20 \times \$0.50 = \$10.00$	$20 \times \$0.50 = \$10.00$	Clearing account of organization B

Using the previous example to complete a transfer of items across organizations, two transactions are required:

- The central storeroom in site A will transfer the items out of the storeroom via the shipment.
- The packaging storeroom in site B will receiving the items against the shipment to the storeroom by using the Shipment Receiving application.

## Database transactions

In the Inventory Usage application, you can transfer an item against an internal purchase order. This section explains the general ledger transactions for all materials usage scenarios.

## Issuing items

When you issue an item, the default accounts are determined in the following ways:

Issue Type of Issue

GL Debit Account (GLDEBITACCT) ⇐

1. GL Account field (not displayed) in the Inventory application ⇐ Inventory Resource field for the item type on the Inventory Resource Codes window in the Chart of Accounts application (typically only one segment only of the GL Debit Account field);
2. GL Account field in the Work Orders application, if work order number specified; ⇐ GL Account field in the Preventive Maintenance application, if based on preventive maintenance record; or, GL Account field in Asset (not displayed); or, GL Account field in the Locations application;
3. GL Account field in the Asset application (not displayed);
4. GL Account field in the Locations application.

GL Credit Account (GLCREDITACCT) ⇐ GL Control Account field (not displayed) in the Inventory application.

Issue Type of Issue

MATUSETRANS.GLDEBITACCT ⇐

1. INVCOST.GLACCOUNT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRESCODE)
2. WORKORDER.GLACCOUNT ⇐ PM.GLACCOUNT; or, ASSET.GLACCOUNT; or, LOCATIONS.GLACCOUNT
3. ASSET.GLACCOUNT
4. LOCATIONS.GLACCOUNT

MATUSETRANS.GLCREDITACCT ⇐ INVCOST.CONTROLACC ⇐ LOCATIONS.CONTROLACC

Issue Type of Return

GL Debit Account (GLDEBITACCT) ⇐ GL Credit Account on Select Items for Return window for selected item.

GL Credit Account (GLCREDITACCT) ⇐ GL Debit Account on Select Items for Return window for selected item.

Issue Type of Return

MATUSETRANS.GLDEBITACCT ⇐ MATUSETRANS.GLCREDITACCT for the issue transaction of the item.

MATUSETRANS.GLCREDITACCT ⇐ MATUSETRANS.GLDEBITACCT for the issue transaction of the item.

## Transferring out

<b>Displayed fields</b>	<p>GL Debit Account field (GLDEBITACCT) ⇐</p> <p>the Control Account field for the labor or courier in the Locations application, if the item is transferred to a labor or courier location; between two storerooms at the same site.</p> <p>the GL Debit Account field on the PO Lines tab if in response to an internal purchase order; between two storerooms at the same site.</p> <p>the clearing account of the transferring out organization for the site, if in response to an internal purchase order between a transferring out site and a receiving site.</p> <p>GL Control Account field (not displayed) in the Inventory application for the to location ⇐ Inventory Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p> <p>GL Credit Account field (GLCREDITACCT) ⇐</p> <p>the GL Credit Account field on the PO Lines tab if in response to an internal purchase order; otherwise,</p> <p>GL Control Account field (not displayed) in the Inventory application for from location ⇐ Inventory Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p>
<b>Database fields</b>	<p>MATRECTRANS.GLDEBITACCT ⇐</p> <p>LOCATIONS.CONTROLACC, if transferred to a labor or courier location; otherwise,</p> <p>POLINE.GLDEBITACCT, if in response to an internal purchase order; between two storerooms at the same site.</p> <p>ORGANIZATION.CLEARING ACCOUNT, clearing account of the organization of the transferring out site, if in response to an internal purchase order between a transferring out site and a receiving site.</p> <p>INVCOST.CONTROLACC for to location ⇐ LOCATIONS.CONTROLACC</p> <p>MATRECTRANS.GLCREDITACCT ⇐</p> <p>POLINE.GLCREDITACCT, if in response to an internal purchase order; otherwise,</p> <p>INVCOST.CONTROLACC for from location ⇐ LOCATIONS.CONTROLACC</p>

## Transferring in

<b>Displayed fields</b>	<p>GL Debit Account (GLDEBITACCT) ⇐</p> <p>If in response to an internal purchase order, the GL Debit Account field on the purchase order line otherwise,</p> <p>GL Control Account field (not displayed) in the Inventory application for the to location ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p> <p>GL Credit Account (GLCREDITACCT) ⇐</p> <p>If the item is transferred from a labor our courier location, the Control Account field for the labor or courier in the Locations application, otherwise</p> <p>If in response to an internal purchase order, the GL Credit Account field on the purchase order line otherwise,</p> <p>If in response to an internal purchase order between a receiving site and a transferring out site, the clearing account of the receiving organization for that site.</p> <p>GL Control Account field (not displayed) in the Inventory application for the from location ⇐ GL Control Account field (not displayed) in the Locations application for the from location ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p>
<b>Database fields</b>	<p>MATRECTRANS.GLDEBITACCT ⇐</p> <p>If in response to an internal purchase order, POLINE.GLDEBITACCT; otherwise,</p> <p>INVCOST.CONTROLACC for to location ⇐ LOCATIONS.CONTROLACC</p> <p>MATRECTRANS.GLCREDITACCT ⇐</p> <p>If transferred from a labor or courier location, LOCATIONS.CONTROLACC; otherwise,</p> <p>If in response to an internal purchase order, POLINE.GLCREDITACCT; otherwise,</p> <p>If in response to an internal purchase order between a receiving site and a transferring out site, ORGANIZATION.CLEARING ACCOUNT, the clearing account of the receiving organization for that site.</p> <p>INVCOST.CONTROLACC for from location ⇐ LOCATIONS.CONTROLACC</p>

---

## Financial processes in the Tools application

Both the tools GL accounts (tool resource codes) and the tools control accounts can be divided into two different types: internal and external. For the tools GL account, the tool resource code that you assign to Outside = N becomes the default for the internal tools GL account, whereas the code that you assign to Outside = Y becomes the default for the external tools GL account.

As with the tools GL accounts (tool resource codes), there are internal and external tools control accounts. Thus, the tools control account code that you assign to Outside = N becomes the default for the internal tools control account, whereas the codes that you assign to Outside = Y become the defaults for the external tools control accounts.

Furthermore, for the external tools control accounts, you can assign a unique default code for each vendor.

If Outside Field = N

TOOL.GLACCOUNT  $\Leftarrow$  ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = TOOLRESCODE and GROUPVALUE = N) (Tool Resource field for Outside = N on Tool Resource Codes window in the Chart of Accounts application)  $\Leftarrow$  direct entry (no default)

TOOL.CONTROLACC  $\Leftarrow$  ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INTTOOLREC, and GROUPVALUE = ALL) (Control Account field on Internal Tools Control Accounts window in the Chart of Accounts application)  $\Leftarrow$  direct entry (no default)

If Outside Field = Y

TOOL.GLACCOUNT  $\Leftarrow$  ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = TOOLRESCODE, and GROUPVALUE = Y) (Tool Resource field for Outside = Y on Tool Resource Codes window in the Chart of Accounts application)  $\Leftarrow$  direct entry (no default)

TOOL.CONTROLACC  $\Leftarrow$  ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = EXTTOOLREC, and GROUPVALUE = vendor name) (Control Account field for vendor on External Tools Control Accounts window in the Chart of Accounts application)  $\Leftarrow$  direct entry (no default)

---

## Financial processes in the Issues and Transfers application

Various financial processes occur in the Issues and Transfers application.

Important: The Issues and Transfers application is replaced by the Inventory Usage application. The following topics are provided for reference only.

- [Issue an item within one site](#)  
In Issues and Transfers, you can issue an item from the Issue tab within the same site.
- [Issue an item between sites within the same organization](#)  
In the Issues and Transfers application, you can issue an item from the Issue tab between sites within the same organization.
- [Return a previously issued item](#)  
To return an item, click Select Items for Return on the Issue tab.
- [Transfer out](#)  
To transfer an item out, click Select Items for Transfer on the Transfer Out tab.
- [Transfer in](#)  
To transfer an item in, click Select Items for Transfer on the Transfer In tab.
- [Database transactions](#)  
In the Issues and Transfers application, you can transfer an item against an internal purchase order. This section explains the general ledger transactions resulting from Transfer In and Transfer Out actions.

---

## Issue an item within one site

In Issues and Transfers, you can issue an item from the Issue tab within the same site.

The date and time in the Actual Date field is used to determine the financial period for the transaction. The Actual Date field defaults to the system date and time.

When you click Save, ISSUETYPE = ISSUE is written to the MATUSETRANS table.

---

## Example

Issue 20 bearings at \$0.50 (issue cost).

Table 1. Source of GL account for issuing an item

Source GL account	Debit	Credit	Source of GL account
1. Inventory GL account (item resource code)	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Inventory control account
2. If issued to a work order, uses work order GL account			
3. If issued to asset, uses <ul style="list-style-type: none"><li>• Asset GL account</li><li>• GL account of location for the asset</li></ul>			
4. If issued to a location <ul style="list-style-type: none"><li>• If only one asset at location, asset GL account</li><li>• Location GL account</li></ul>			

If you capitalize the item, the default credit account is the capital GL account, and the line cost is zero.

## Issue an item between sites within the same organization

In the Issues and Transfers application, you can issue an item from the Issue tab between sites within the same organization.

The date and time in the Actual Date field is used to determine the financial period for the transaction. The Actual Date field defaults to the system date and time.

When you click Save, ISSUETYPE = ISSUE is written to the MATUSETRANS table.

### Example

Issue 20 bearings at \$0.50 (issue cost) from the storeroom in site A to the storeroom in site B

Table 1. Source of GL account for issuing an item between sites in the same organization

Source GL account	Debit	Credit	Source of GL account
1. Inventory GL account (item resource code)	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Inventory control account
2. If issued to a work order, uses work order GL account			
3. If issued to asset, uses:			
• Asset GL account			
• GL account of location for the asset			
4. If issued to a location:			
• If only one asset at location, asset GL account			
• Location GL account			

If you capitalize the item, the default credit account is the capital GL account, and the line cost is zero.

## Return a previously issued item

To return an item, click Select Items for Return on the Issue tab.

The date and time in used in the Actual Date field in the table window to determine the financial period for the transaction. The Actual Date field defaults to the system date and time.

To return items in the Issues and Transfers application, select the applicable items from a list of previously issued items. The transaction is posted with a negative line cost and the accounts are the same debit and credit as the issue transaction. These accounts are read-only.

When you click Save, ISSUETYPE = RETURN is written to the MATUSETRANS table.

### Example

Return 4 bearings that were issued at \$0.50 each. At issue, the debit account was 1111-111-111 and the credit account was 2224-224-222.

Table 1. Source of GL account for returning a previously issued item

Source GL account	Debit	Credit	Source of GL account
1111-111-111 general ledger debit used when item was issued (read-only)	4 x \$0.50 = \$2.00	4 x \$0.50 = \$2.00	2224-224-222 general ledger credit used when item was issued (read-only)

## Transfer out

To transfer an item out, click Select Items for Transfer on the Transfer Out tab.

The date and time are used in the Actual Date field to determine the financial period for the transaction. The Actual Date field defaults to the system date and time.

### Primary transaction

When you click Save, ISSUETYPE = TRANSFER is written to the MATUSETRANS table.

### Example 1

Transfer 20 bearings at \$0.50 (issue cost) from the central storeroom to the packaging storeroom in the same site.

Table 1. Source of GL account for transferring an item within the same site

Source GL account	Debit	Credit	Source of GL account
-------------------	-------	--------	----------------------

Source GL account	Debit	Credit	Source of GL account
1. Inventory control account of destination storeroom. 2. If in response to an internal purchase order uses purchase order line general ledger debit account	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Inventory control account of source storeroom.  If in response to an internal purchase order, uses purchase order line general ledger credit account

## Example 2

Transfer 20 bearings at \$0.50 (issue cost) from the central storeroom in site A to the packaging storeroom in site B within the same organization.

Table 2. Source of GL account for transferring an item within the same organization

Source GL account	Debit	Credit	Source of GL account
Inventory control account of central storeroom in site B.	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Clearing account of organization B

Using the previous example to complete a transfer of items across organizations, two transactions are required:

- The central storeroom in site A must issue items to a courier.
- The packaging storeroom in site B must transfer items in from the courier to the storeroom.

If you capitalize the item and it exists in the destination, the default for both the debit and credit accounts is the capital GL account, and the line cost is zero.

If you capitalize the item and your company is stocking it in the destination for the first time, the debit account for the transfer is the inventory control account of the destination. The credit account is the capital GL account.

Transferring a capitalized item to a new inventory location inserts the item as capitalized into the new inventory location. The control account for the item in that new inventory location is the inventory control account, not the capital GL account.

## Secondary transaction

Transferring against an internal purchase order creates the same transaction as receiving material against an internal purchase order.

Transferring against an internal purchase order produces a secondary transaction under the following conditions:

- Your standard cost is used as your issue cost
- The receipt price varies from the standard price in the destination storeroom

In either scenario, the following record is written to the INVTRANS table:

TRANSTYPE = STDRECADJ

The value of the transaction (line cost) is determined with the following equation:

Receipt quantity x (receipt price - standard price)

## Example

You transfer 20 bearings into the central storeroom at \$0.50 each (primary transaction), but the standard cost of the bearings in the central storeroom is \$0.45 each. Your company uses the standard cost.

If the item is capitalized, the default credit account is the capital GL account. Also, because the standard cost of a capitalized item is zero, the line cost for the standard receipt adjustment transaction equals the receipt price of the item.

Table 3. Source of GL account with different item cost

Source GL account	Debit	Credit	Source of GL account
Receipts price variance account	$(\$0.50 - \$0.45) \times 20 = \$1.00$	$(\$0.50 - \$0.45) \times 20 = \$1.00$	Inventory control account

All cost entries and calculations are performed in the base currency.

## Transfer in

To transfer an item in, click Select Items for Transfer on the Transfer In tab.

The Actual Date field defaults to the system date and time. The date and time in the Actual Date field determine the financial period for the transaction.

## Primary transaction

When you click Save, the following record is written to the MATRECTRANS table:

ISSUETYPE = TRANSFER

## Example 1

Transfer 20 bearings at \$0.50 (issue cost) to the packaging storeroom from the central storeroom.

Table 1. Source of GL account for transfer between storerooms

Source GL account	Debit	Credit	Source of GL account
1. Inventory control account of destination storeroom.	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Inventory control account of source storeroom
2. Inventory control account of destination storeroom.			Inventory control account of source storeroom

## Example 2

Transfer 20 bearings at \$0.50 (issue cost) from the central storeroom in site A to the packaging storeroom in site B within the same organization.

Table 2. Source of GL account for transfer between sites in the same organization

Source GL account	Debit	Credit	Source of GL account
1. Inventory control account of destination storeroom in site B.	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Inventory control account of source storeroom in site A.
2. If in response to an internal purchase order with a courier, uses purchase order line general ledger debit account.			If in response to an internal purchase order with a courier, ← defaults to the clearing account of the organization.

Transfer 20 bearings at \$0.50 (issue cost) from the central storeroom in site A, organization A to the packaging storeroom in site B, organization B.

Table 3. Source of GL account for transfer between sites in the same organization

Source GL account	Debit	Credit	Source of GL account
Inventory control account of central storeroom in site B.	20 x \$0.50 = \$10.00	20 x \$0.50 = \$10.00	Clearing account of organization B.

Using the previous example, to transfer items across organizations, two transactions are required:

- The central storeroom in site B must transfer items from the storeroom to the courier.
- The packaging storeroom in site A must receive items from a courier.

If the item is capitalized and it exists in the destination, the default for both the debit and credit accounts is the capital GL account, and the line cost is zero.

If the item is capitalized and your company is stocking it in the destination for the first time, the debit account for the transfer is the inventory control account of the destination. The credit account is the capital GL account.

Transferring a capitalized item to a new inventory location inserts the item as capitalized into the new inventory location. The control account for the item in that new inventory location is the inventory control account, not the capital GL account.

## Secondary transaction

Transferring against an internal purchase order creates the same transaction as receiving material against an internal purchase order.

Transferring against an internal purchase order produces a secondary transaction under the following conditions:

- Standard cost is used as your issue cost.
- The receipt price varies from the standard price in the destination storeroom.

Under these conditions, the following record is written to the INVTRANS table:

TRANSTYPE = STDRECADJ, to the INVTRANS table.

The value of the transaction (line cost) is determined with the following equation:

Receipt quantity x (receipt price - standard price)

## Example

You transfer 20 bearings into the central storeroom at \$0.50 each (primary transaction), but the standard cost of the bearings in the central storeroom is \$0.45 each. Your company uses the standard cost.

Table 4. Source of GL account for transfer with different costs

Source GL account	Debit	Credit	Source of GL account
Receipts price variance account	(\$0.50 - \$0.45) x 20 = \$1.00	(\$0.50 - \$0.45) x 20 = \$1.00	Inventory control account

If the item is capitalized, the default credit account is the capital GL account. Also, since the standard cost of a capitalized item is zero, the line cost for the standard receipt adjustment transaction equals the receipt price of the item.

All cost entries and calculations are performed in the base currency.

## Database transactions

In the Issues and Transfers application, you can transfer an item against an internal purchase order. This section explains the general ledger transactions resulting from Transfer In and Transfer Out actions.

## Issues tab

When you issue an item, the default accounts are determined in the following ways:

#### Issue Type of Issue

GL Debit Account (GLDEBITACCT) ⇐

1. GL Account field (not displayed) in the Inventory application ⇐ Inventory Resource field for the item type on the Inventory Resource Codes window in the Chart of Accounts application (typically only one segment only of the GL Debit Account field);
2. GL Account field in the Work Orders application, if work order number specified; ⇐ GL Account field in the Preventive Maintenance application, if based on the preventive maintenance record; or, GL Account field in Asset (not displayed); or, GL Account field in the Locations application;
3. GL Account field in the Asset application (not displayed);
4. GL Account field in the Locations application.

GL Credit Account (GLCREDITACCT) ⇐ GL Control Account field (not displayed) in the Inventory application.

#### Issue Type of Issue

MATUSETRANS.GLDEBITACCT ⇐

1. INVCOST.GLACCOUNT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRESCODE)
2. WORKORDER.GLACCOUNT ⇐ PM.GLACCOUNT; or, ASSET.GLACCOUNT; or, LOCATIONS.GLACCOUNT
3. ASSET.GLACCOUNT
4. LOCATIONS.GLACCOUNT

MATUSETRANS.GLCREDITACCT ⇐ INVCOST.CONTROLACC ⇐ LOCATIONS.CONTROLACC

#### Issue Type of Return

GL Debit Account (GLDEBITACCT) ⇐ GL Credit Account field on Select Items for Return window for selected item.

GL Credit Account (GLCREDITACCT) ⇐ GL Debit Account field on Select Items for Return window for selected item.

#### Issue Type of Return

MATUSETRANS.GLDEBITACCT ⇐ MATUSETRANS.GLCREDITACCT for the issue transaction of the item.

MATUSETRANS.GLCREDITACCT ⇐ MATUSETRANS.GLDEBITACCT for the issue transaction of the item.

## Transfer Out tab

This section provides general ledger field information for the Transfer Out tab.

<b>Displayed fields</b>	<p>GL Debit Account (GLDEBITACCT) ⇐</p> <p>the Control Account field for the labor or courier in Locations, if the item is transferred to a labor or courier location; between two storerooms at the same site.</p> <p>the GL Debit Account field on the PO Lines tab if in response to an internal purchase order; between two storerooms at the same site.</p> <p>the clearing account of the transferring out organization for the site, if in response to an internal purchase order between a transferring out site and a receiving site.</p> <p>GL Control Account field (not displayed) in the Inventory application for the to location ⇐ Inventory Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p> <p>GL Credit Account (GLCREDITACCT) ⇐</p> <p>the GL Credit Account field on the PO Lines tab if in response to an internal purchase order, otherwise,</p> <p>GL Control Account field (not displayed) in the Inventory application for from location ⇐ Inventory Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p>
<b>Database fields</b>	<p>MATRECTRANS.GLDEBITACCT ⇐</p> <p>LOCATIONS.CONTROLACC, if transferred to a labor or courier location, otherwise,</p> <p>POLINE.GLDEBITACCT, if in response to an internal purchase order; between two storerooms at the same site.</p> <p>ORGANIZATION.CLEARING ACCOUNT, clearing account of the organization of the transferring out site, if in response to an internal purchase order between a transferring out site and a receiving site.</p> <p>INVCOST.CONTROLACC for to location ⇐ LOCATIONS.CONTROLACC</p> <p>MATRECTRANS.GLCREDITACCT ⇐</p> <p>POLINE.GLCREDITACCT, if in response to an internal purchase order; otherwise,</p> <p>INVCOST.CONTROLACC for from location ⇐ LOCATIONS.CONTROLACC</p>

## Transfer In tab

This section provides general ledger field information for the Transfer In tab.

<b>Displayed fields</b>	GL Debit Account (GLDEBITACCT) ⇐
-------------------------	----------------------------------

	<p>If in response to an internal purchase order, the GL Debit Account field on the purchase order line otherwise,</p> <p>GL Control Account field (not displayed) in the Inventory application for to location ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p> <p>GL Credit Account (GLCREDITACCT) ⇐</p> <p>If the item is transferred from a labor our courier location, the Control Account field for the labor or courier in the Locations application, otherwise</p> <p>If in response to an internal purchase order, the GL Credit Account field on the purchase order line otherwise,</p> <p>If in response to an internal purchase order between a receiving site and a transferring out site, the clearing account of the receiving organization for that site.</p> <p>GL Control Account field (not displayed) in the Inventory application for the from location ⇐ GL Control Account field (not displayed) in the Locations application for the from location &lt; Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.</p>
Database fields	<p>MATRECTRANS.GLDEBITACCT ⇐</p> <p>If in response to an internal purchase order, POLINE.GLDEBITACCT; otherwise,</p> <p>INVCOST.CONTROLACC for to location ⇐ LOCATIONS.CONTROLACC</p> <p>MATRECTRANS.GLCREDITACCT ⇐</p> <p>If transferred from a labor or courier location, LOCATIONS.CONTROLACC; otherwise,</p> <p>If in response to an internal purchase order, POLINE.GLCREDITACCT; otherwise,</p> <p>If in response to an internal purchase order between a receiving site and a transferring out site, ORGANIZATION.CLEARING ACCOUNT, the clearing account of the receiving organization for that site.</p> <p>INVCOST.CONTROLACC for from location ⇐ LOCATIONS.CONTROLACC</p>

## Financial processes in the Preventive Maintenance module

Various financial processes occur in the Preventive Maintenance application.

- [Financial processes in the Preventive Maintenance application](#)  
Various financial processes occur in the Preventive Maintenance application.

## Financial processes in the Preventive Maintenance application

Various financial processes occur in the Preventive Maintenance application.

Any GL account (segment) entered in the Preventive Maintenance application is used on work orders that you generate from the preventive maintenance record.

<b>Displayed field</b>	GL Account field (GLACCOUNT) ⇐ manual entry (no default)
<b>Database field</b>	PM.GLACCOUNT ⇐ manual entry (no default)

## Financial processes in the Purchasing module

Various financial processes occur in the Companies, Purchase Requisitions, Purchase Orders, Receiving, and Invoices applications.

- [Financial processes in the Companies application](#)  
In the Companies application, the GL account fields, AP Control Account RBNI Account, and, Suspense Account default according to company type that is specified in the Company Type field.
- [Financial processes in the Purchase Requisitions application](#)  
You can select several material and service requisition actions from the PR Lines tab in the Purchase Requisitions application, that cause GL account transactions to be written.
- [Financial processes in the Purchase Orders application](#)  
The Material Orders from External Vendor action that is selected from the PO Lines tab in the Purchase Orders application, causes GL account transactions to be written.
- [Receiving application](#)  
The Receiving application is used to process receipts for materials.
- [Shipment Receiving application](#)  
A shipment record is used to transfer a shipment between two storerooms when an intermediary, such as a shipper, is used. Shipment records are created using the Inventory Usage application and receipts are created against these records using the Shipment Receiving application.
- [Financial processes in the Invoices application](#)  
Although records might be created to establish GL accounts, no general ledger transactions occur until you approve the invoice. Upon invoice approval, many transactions can occur.

- [Tax transactions](#)

An invoice can include tax. If so, in addition to the transaction of TRANSTYPE = TOTAL, a transaction is written to the INVOICETRANS table with TRANSTYPE = TAX $n$ , where  $1 \leq n \leq 27$ . The value of  $n$  depends on which tax type you selected for the tax in the Chart of Accounts application.

- [Cost variance transactions](#)

If time lapses between receiving the item and approving the invoice, the cost associated with the invoice line might differ from the cost of the item at receipt.

---

## Financial processes in the Companies application

In the Companies application, the GL account fields, AP Control Account RBNI Account, and, Suspense Account default according to company type that is specified in the Company Type field.

### Displayed fields

---

RBNI (RBNIACC)  $\Leftarrow$  RBNI field for Company Type on Company-Related Accounts window in the Chart of Accounts applications.

Suspense (APSUSPENSEACC)  $\Leftarrow$  AP Suspense field for Company Type on Company-Related Accounts window in the Chart of Accounts application.

AP Control (APCONTROLACC)  $\Leftarrow$  AP Control field for Company Type on Company-Related Accounts window in the Chart of Accounts application.

### Database Fields

---

COMPANIES.RBNIACC  $\Leftarrow$  COMPANYACCDEF.RBNIACC

COMPANIES.APSUSPENSEACC  $\Leftarrow$  COMPANYACCDEF.APSUSPENSEACC

COMPANIES.APCONTROLACC  $\Leftarrow$  COMPANYACCDEF.APCONTROLACC

---

## Financial processes in the Purchase Requisitions application

You can select several material and service requisition actions from the PR Lines tab in the Purchase Requisitions application, that cause GL account transactions to be written.

- [Material requisitions for a storeroom](#)

Specific information is held when material requisitions are made for a storeroom by an external vendor.

- [Material requisitions for a direct issue](#)

Specific information is held when material requisitions are made for a direct issue, when Issue on Receipts is set to Y.

- [Material requisitions from an internal vendor](#)

Specific information is held when material requisitions are made from the storeroom of an internal vendor.

- [Material requisitions from an internal vendor in a different organization](#)

Specific information is held when material requisitions are made from the storeroom of an internal vendor from a different organization.

- [Service purchase requisitions](#)

Specific information is held for purchase requisitions when the Line Type is set to Service.

- [Standard service purchase requisitions](#)

Specific information is held for purchase requisitions when the Line Type is set to Standard service.

- [Rotating asset purchase requisitions](#)

Specific information is held for rotating asset purchase requisitions, when the Issue on Receipts and Charge to Store check boxes are set to Y.

---

## Material requisitions for a storeroom

Specific information is held when material requisitions are made for a storeroom by an external vendor.

### Displayed fields

---

GL Debit Account (GLDEBITACCT)  $\Leftarrow$  GL Control Account field (not displayed) for storeroom location in the Inventory application.

GL Credit Account (GLCREDITACCT)  $\Leftarrow$  RBNI field for Vendor in Companies  $\Leftarrow$  RBNI field for Company Type field (for Vendor on PR line) on Company-Related Accounts window in the Chart of Accounts application.

### Database fields

---

PRLINE.GLDEBITACCT  $\Leftarrow$  INVCOST.CONTROLACC

PRLINE.GLCREDITACCT  $\Leftarrow$  COMPANIES.RBNIACC  $\Leftarrow$  COMPANYACCDEF.RBNIACC (where TYPE = company type of vendor)

---

## Material requisitions for a direct issue

Specific information is held when material requisitions are made for a direct issue, when Issue on Receipts is set to Y.

## Displayed fields

Direct issue requisitions and purchase orders can be created for an external vendor.

GL Debit Account (GLDEBITACCT) ⇐ GL Account field (not displayed) in the Inventory application ⇐ Inventory Resource field for item Type field on Inventory Resource Codes window in the Chart of Accounts:

1. Work Order GL Account field.
2. Asset GL Account field (not displayed).
3. Location GL Account field.

GL Credit Account (GLCREDITACCT) ⇐ RBNI field for Vendor in Companies ⇐ RBNI field for Company Type field (for Vendor on PR line) on Company-Related Accounts window in the Chart of Accounts application.

## Database fields

PRLINE.GLDEBITACCT ⇐

1. INVCOST.GLACCOUNT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRESCODE and GROUPVALUE = item type for item on purchase order line)
2. WORKORDER.GLACCOUNT
3. ASSET.GLACCOUNT
4. LOCATIONS.GLACCOUNT

PRLINE.GLCREDITACCT ⇐ COMPANIES.RBNIACC ⇐ COMPANYACCDEF.RBNIACC (where TYPE = company type of vendor)

## Material requisitions from an internal vendor

Specific information is held when material requisitions are made from the storeroom of an internal vendor.

This transaction involves internal purchase orders within the same site or between two sites within the same organization.

## Displayed fields

GL Debit Account (GLDEBITACCT) ⇐ GL Control Account field (not displayed) in the Inventory application for requisitioning storeroom location ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.

GL Credit Account (GLCREDITACCT) ⇐ GL Control Account field (not displayed) in the Inventory application for vendor storeroom location ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.

## Database fields

PRLINE.GLDEBITACCT ⇐ INVCOST.CONTROLACC (of requisitioning location) ⇐ LOCATIONS.CONTROL.ACC

PRLINE.GLCREDITACCT ⇐ INVCOST.CONTROLACC (of vendor location) ⇐ LOCATIONS.CONTROL.ACC

You cannot create a service requisition that names an internal vendor.

## Material requisitions from an internal vendor in a different organization

Specific information is held when material requisitions are made from the storeroom of an internal vendor from a different organization.

Displayed fields	GL Debit Account (GLDEBITACCT) ⇐ GL Control Account field (not displayed) in the Inventory application for requisitioning storeroom location ⇐ Inventory Control Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
	GL Credit Account (GLCREDITACCT) ⇐ Organization Clearing Account field in the Organization application for the organization of the receiving site.
Database fields	PRLINE.GLDEBITACCT ⇐ INVCOST.CONTROLACC (of requisitioning location) ⇐ LOCATIONS.CONTROL.ACC
	PRLINE.GLCREDITACCT ⇐ ORGANIZATION.CLEARINGACCOUNT

## Service purchase requisitions

Specific information is held for purchase requisitions when the Line Type is set to Service.

Displayed fields	The GL Debit Account and GL Credit Account fields for a service requisition default just as they do for a direct issue material requisition. However, the merger does not involve an item resource code, unless you do the following:
------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

- Order the service requisition for an asset
- Select the Charge to Store check box

## Standard service purchase requisitions

Specific information is held for purchase requisitions when the Line Type is set to `Standard service`.

### Displayed fields

GL Debit Account (GLDEBITACCT) ⇐ GL Account field for the Organization and Service item, as defined in the Service Items application using the Service Item / Organization Details action.

GL Credit Account (GLCREDITACCT) ⇐ RBNI field for vendor in Companies ⇐ RBNI field for Company Type field (for vendor on purchase requisition line) on Company-Related Accounts window in the Chart of Accounts application.

### Database fields

PRLINE.GLDEBITACCT ⇐ ITEMORGINFO.GLACCOUNT

PRLINE.GLCREDITACCT ⇐ COMPANIES.RBNIACC (of vendor) ⇐ COMPANYACCDEF.RBNIACC, where TYPE = company type of the vendor.

## Rotating asset purchase requisitions

Specific information is held for rotating asset purchase requisitions, when the Issue on Receipts and Charge to Store check boxes are set to Y.

<b>Displayed fields</b>	GL Debit Account (GLDEBITACCT) ⇐ Rotating Suspense Account field (not displayed) in Asset ⇐ Global Rotating Suspense Account field on the Inventory-Related Accounts window in the Chart of Accounts application.
	GL Credit Account (GLCREDITACCT) ⇐ RBNI field for vendor in Companies ⇐ RBNI field for Company Type field (for vendor on purchase requisition line) on Company-Related Accounts window in the Chart of Accounts application.
<b>Database fields</b>	PRLINE.GLDEBITACCT ⇐ ASSET.ROTSUSPACCT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRELACC and GROUPVALUE = ROTSUSPACCT)
	PRLINE.GLCREDITACCT ⇐ COMPANIES.RBNIACC (of vendor) ⇐ COMPANYACCDEF.RBNIACC, where TYPE = company type of the vendor.

## Financial processes in the Purchase Orders application

The Material Orders from External Vendor action that is selected from the PO Lines tab in the Purchase Orders application, causes GL account transactions to be written.

You can copy purchase order line items from purchase requisitions line items or you can enter them directly on a purchase order. In the first case, the general ledger fields are copied from the purchase requisition. In the second case, purchase order line general ledger fields default exactly as they do on a purchase requisition.

- [Material orders from an external vendor](#)

Specific information is held for storeroom items that are ordered from an external vendor. The purchase requisition line shown in parentheses, indicating that the purchase order general ledger information might have been copied from there.

### Material orders from an external vendor

Specific information is held for storeroom items that are ordered from an external vendor. The purchase requisition line shown in parentheses, indicating that the purchase order general ledger information might have been copied from there.

<b>Displayed fields</b>	GL Debit Account (GLDEBITACCT) ⇐ GL Debit Account field on purchase requisition line ⇐ GL Control Account field (not displayed) for storeroom location in the Inventory application.
	GL Credit Account (GLCREDITACCT) ⇐ GL Credit Account field on purchase requisition line ⇐ RBNI field for vendor in Companies ⇐ RBNI field for Company Type field (for vendor on purchase order line) on Company-Related Accounts window in the Chart of Accounts application.
<b>Database fields</b>	POLINE.GLDEBITACCT ⇐ (PRLINE.GLDEBITACCT) ⇐ INVCOST.CONTROLACC
	POLINE.GLCREDITACCT ⇐ (PRLINE.GLCREDITACCT) ⇐ COMPANIES.RBNIACC ⇐ COMPANYACCDEF.RBNIACC where TYPE = company type of the vendor

---

## Receiving application

The Receiving application is used to process receipts for materials.

- [External material receipts into a storeroom](#)  
Specific information is held for processing external receipts through the Materials tab in the Receiving application into a storeroom.
- [External material receipts issue on receipt](#)  
Specific information is held for processing external receipts through the Materials tab in the Receiving application.
- [Material receipts with an inspection required](#)  
You process a receipt, when an inspection of the item is required, through the Material Receipts tab in the Receiving application. The inspection status is set with the Inspection Required check box on the purchase order Lines in the Purchase Orders application.
- [Void receipts](#)  
You use the Select Receipts to Void action to reverse a receipt that is recorded in error. This inserts a transaction of ISSUETYPE=VOIDRECEIPT to the MATRECTRANS table. The related receipt record is reversed and balances and inventory costs are adjusted as necessary.

---

## External material receipts into a storeroom

Specific information is held for processing external receipts through the Materials tab in the Receiving application into a storeroom.

The date and time are used in the Received Date field to determine the financial period for the transaction. The Received Date field defaults to the system date and time.

The Loaded Cost column in the table window represents the cost of material, plus any taxes or standard services that have been added to the line.

---

### Primary transaction

When you save this information, a record is written to the MATRECTRANS table.

An example of receiving 20 bearings at \$0.50 each.

Source of GL account	Debit	Credit	Source of GL account
Purchase order line Debit account	10 x \$0.50 = \$5.00	20 x \$0.50 = \$10.00	Purchase order line Credit account

All cost entries and calculations are made in the base currency.

---

## External material receipts issue on receipt

Specific information is held for processing external receipts through the Materials tab in the Receiving application.

To do this process on the Material Receipts tab click New Row or Select Ordered Items.

The date and time are used in the Received Date field to determine the financial period for the transaction. The Received Date field defaults to the system date and time.

---

### Primary transaction

When you save this information, ISSUETYPE = RECEIPT is written to the MATRECTRANS table.

You use the same debit and credit amounts when inserting a purchase order or purchase requisition line.

---

### Secondary transaction

A record is written to the MATUSETRANS table. This record represents the issue of the item upon receipt. From an accounting perspective, it is the same transaction as in MATRECTRANS.

---

## Material receipts with an inspection required

You process a receipt, when an inspection of the item is required, through the Material Receipts tab in the Receiving application. The inspection status is set with the Inspection Required check box on the purchase order Lines in the Purchase Orders application.

---

### Purchase orders with receipt required

If you selected the Inspection Required check box, the Inspection Status field on the Material Receipts tab defaults to WINSP (Waiting for Inspection) upon receipt.

Use the Change Inspection Status action in the Receiving application to accept or reject these items.

## Change inspection status

In the following example, you have transferred eight items to your storeroom and returned two to the vendor. After you complete the transaction, the Material Receipts tab displays updated line item information.

The following table shows what general ledger transactions are written when you receive 10 copper tubings at \$0.50 each. Upon inspection, eight copper tubings are accepted and the remaining two copper tubings are rejected.

Transaction type	GL account source	Debit	Credit	GL account source
Receipt	Holding Location GL account	10 x \$0.50 = \$5.00	10 x \$0.50 = \$5.00	RBNI (Received But Not Invoiced) GL account from company application
Transfer to your Storeroom	The GL account of your Storeroom	8 x \$0.50 = \$4.00	8 x \$0.50 = \$4.00	Holding Location GL account
Return to Holding Location	Holding Location GL account	-2 x \$0.50 = - \$1.00	= -\$1.00 -2 x \$0.50 = - \$1.00	RBNI GL account from company application

## Void receipts

You use the Select Receipts to Void action to reverse a receipt that is recorded in error. This inserts a transaction of ISSUETYPE=VOIDRECEIPT to the MATRECTRANS table. The related receipt record is reversed and balances and inventory costs are adjusted as necessary.

Voided receipts are used for correction only and cannot be referenced on invoices.

## Shipment Receiving application

A shipment record is used to transfer a shipment between two storerooms when an intermediary, such as a shipper, is used. Shipment records are created using the Inventory Usage application and receipts are created against these records using the Shipment Receiving application.

The date and time are used in the Received Date field to determine the financial period for the transaction. The Received Date field defaults to the system date and time.

When you click Save, ISSUETYPE = SHIPRECEIPT is written to the MATRECTRANS table.

If you use standard cost, a potential secondary transaction can occur. For example, if you move the item from storeroom A to storeroom B, and the receipt price of the item differs from the standard price of the item in storeroom B. TRANSTYPE = STDRECADJ is written to the INVTRANS table.

The value of the transaction (that is, the LINECOST) is equal to the following equation:

[Receipt Quantity x (Receipt Price-Standard Price in Storeroom B)].

## Example

You create an inventory usage record and add a usage line where the item quantity is five and the unit cost is \$10. You want to transfer the item from the Central Storeroom at your Bedford site to the Central Storeroom at your Nashua site.

You change the status of the inventory record to SHIPPED and record the shipment details; that is, the carrier and so on. At this point, transactions of type SHIPTRANSFER are recorded in the MATRECTRANS table for the supplying storeroom.

At such time as the shipment is to be received at the destination storeroom you will use the Shipment Receiving application to record receipts against the shipment.

If you are receiving...	You enter...
A rotating item	One transaction for each received asset
A non-rotating item	One transaction for all received assets

Each of these transactions appears in the MATRECTRANS table as type SHIPRECEIPT and inspection status WASSET.

Table 1. Source of GL account for rotating item

GL account source	Debit	Credit	GL account source
Clearing account for your Bedford site	1*\$10=\$10	1*\$10=\$10	Inventory Control account for the Central storeroom at your Bedford site.
	1*\$10 = \$10	1*\$10 = \$10	
	1*\$10 = \$10	1*\$10 = \$10	
	1*\$10 = \$10	1*\$10 = \$10	
	1*\$10 = \$10	1*\$10 = \$10	

Table 2. Source of GL account for non-rotating item

GL account source	Debit	Credit	GL account source
Clearing account for your Bedford site	5*\$10 = \$50	5*\$10 = \$50	Inventory Control account for the Central storeroom at your Bedford site.

---

## Financial processes in the Invoices application

Although records might be created to establish GL accounts, no general ledger transactions occur until you approve the invoice. Upon invoice approval, many transactions can occur.

The date and time are used in the Entered Date field in the Invoices application to determine the financial period for transactions in this application. All transactions are in the base currency.

Processes that result in debit or credit transactions use decimal fields and amount (cost) fields. Minimize the effects of rounding in calculations by using the Database Configuration application to set the scale for these fields to six or more places. The scale is the number of places calculated and displayed after the decimal point.

- **[Invoice lines tab](#)**  
You can copy invoice line items from purchase order line items or enter them directly. If you copy an invoice line from a purchase order, the GL Debit Account field for that invoice line defaults to the purchase order line debit account. When you directly enter invoice line items, the invoice line GL Debit Account field defaults exactly as if inserting a purchase requisition line.
- **[Not charged to store](#)**  
You receive an invoice for two hours of computer repair at \$50 an hour. The invoice has no associated purchase order and it is not charged to store. In addition to the primary transaction, a transaction is written to the SERVRECTRANS table.
- **[Charged to store](#)**  
If the Charge to Store check box is selected, the charges are carried through to the rotating asset.
- **[Distribute costs window](#)**  
Default information on this window comes from the INVOICECOST table; where data results from inserting invoice line items. The GL Debit Account and GL Credit Account source fields are the same fields used when inserting an invoice line.
- **[Invoice approval](#)**  
In the Invoices application, the displayed general ledger fields acquire their values when you insert the invoice lines. When you approve an invoice, the general ledger field values in any application are not affected; however, at least one database transaction is created and possibly others.
- **[Invoice reversal](#)**  
You can cancel individual invoices that have an approved or paid status, without doing a return transaction. Reverse invoices can be used to remove erroneously entered invoices, and credit or debit memos.
- **[Invoice total transaction](#)**  
When you approve an invoice, during the primary transaction, TRANSTYPE=TOTAL is written to the INVOICETRANS table.
- **[Additional transactions for materials](#)**  
If the item is a material to be issued on receipt, any change in the item cost is accounted for by writing entries to both the MATRECTRANS and MATUSETRANS tables. The accounts default as if inserting a purchase requisition line. If the materials are charged to a work order, the actual materials cost is also updated.

---

## Invoice lines tab

You can copy invoice line items from purchase order line items or enter them directly. If you copy an invoice line from a purchase order, the GL Debit Account field for that invoice line defaults to the purchase order line debit account. When you directly enter invoice line items, the invoice line GL Debit Account field defaults exactly as if inserting a purchase requisition line.

The GL Credit field source is always the RBNI account for the vendor that you have specified in the Invoices application.

In the Database section, both the purchase order line and the purchase requisition line are shown in parentheses, indicating that you might have copied the invoice general ledger information from the purchase order.

Inserting invoice lines creates no general ledger transactions until you reach the invoice approval stage.

---

## Displayed fields

GL Debit Account (GLDEBITACCT) ⇐ GL Debit Account field on PO Lines tab ⇐ GL Debit Account field on PR Lines tab ⇐ GL Control Account field (not displayed) for storeroom location in the Inventory application.

GL Credit Account (GLCREDITACCT) ⇐ RBNI field in Companies for vendor ⇐ RBNI field for Company Type field (for vendor in Invoices application) on Company-Related Accounts window in the Chart of Accounts application.

---

## Database fields

INVOICECOST.GLDEBITACCT ⇐ (POLINE.GLDEBITACCT) ⇐ (PRLINE.GLDEBITACCT) ⇐ INVCOST.CONTROLACC

INVOICECOST.GLCREDITACCT ⇐ COMPANIES.RBNIACC ⇐ COMPANYACCDEF.APSUSPENSEACC (where TYPE = type of vendor company)

---

## Not charged to store

You receive an invoice for two hours of computer repair at \$50 an hour. The invoice has no associated purchase order and it is not charged to store. In addition to the primary transaction, a transaction is written to the SERVRECTRANS table.

Table 1. GL account source when invoice not charged to store

GL account source		Debit	Credit	GL account source
1	If issued to a work order, uses work order GL account	2 x \$50.00 = \$100.00	2 x \$50.00 = \$100.00	Company RBNI (Received But Not Invoiced) account
2	If issued to asset, uses Asset GL account Asset location of GL account			
3	If issued to a location and there is only one asset at location, uses asset GL account Location GL account			

Service for Item With No PO, if Charge to Store? = N.

Database fields	SERVRECTRANS.GLDEBITACCT ⇐ INVOICECOST.GLDEBITACCT ⇐ or, WORKORDER.GLACCOUNT, or, ASSET.GLACCOUNT, or, LOCATIONS.GLACCOUNT
	SERVRECTRANS.GLCREDITACCT ⇐ COMPANIES.RBNIACC ⇐ COMPANYACCDEF.RBNIACC (where TYPE = type of vendor company)

## Charged to store

If the Charge to Store check box is selected, the charges are carried through to the rotating asset.

You receive an invoice for two hours of computer repair at \$50 an hour. The invoice has no associated purchase order, and it is charged to store. In addition to the primary transaction, a transaction is written to SERVRECTRANS.

GL account source	Debit	Credit	GL account source
Asset rotating suspense account	2 x \$50.00 = \$100.00	2 x \$50.00 = \$100.00	Company RBNI account

Furthermore, when UPDATEINVENTORY = 1, the database inventory cost of the rotating asset (for example, the computer) is updated.

Service for Item With No PO, if Charge to Store? = Y

## Database fields

SERVRECTRANS.GLDEBITACCT ⇐

INVOICECOST.GLDEBITACCT ⇐

ASSET.ROTSUSPACCT ⇐

ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = INVRELACC and GROUPVALUE = ROTSUSPACCT)

SERVRECTRANS.GLCREDITACCT ⇐

COMPANIES.RBNIACC ⇐ COMPANYACCDEF.RBNIACC (where TYPE = type of vendor company)

## Distribute costs window

Default information on this window comes from the INVOICECOST table; where data results from inserting invoice line items. The GL Debit Account and GL Credit Account source fields are the same fields used when inserting an invoice line.

Using the Distribute Costs window creates no general ledger transactions until you reach the invoice approval stage.

## Displayed fields

GL Debit Account (GLDEBITACCT) ⇐ GL Debit Account field on invoices line.

GL Credit Account (GLCREDITACCT) ⇐ GL Credit Account field on invoices line ⇐ RBNI field in Companies for vendor ⇐ RBNI field for Company Type field (for vendor in Invoices) on Company-Related Accounts window in the Chart of Accounts application.

## Database fields

INVOICECOST.GLDEBITACCT (⇐ POLINE.GLDEBITACCT)(⇐ PRLINE.GLDEBITACCT)

INVOICECOST.GLCREDITACCT ⇐ COMPANIES.APSUSPENSEACC ⇐ COMPANYACCDEF.RBNIACC (where TYPE = type of vendor company)

## Example

Materials are purchased for a storeroom.

The following are the displayed fields:

GL Debit Account (GLDEBITACCT) ⇐ GL Debit Account field on purchase order line ⇐ GL Debit Account field on purchase requisition line ⇐ GL Control Account field (not displayed) for storeroom location in the Inventory application.

GL Credit Account (GLCREDITACCT) ⇐ RBNI field in Companies for vendor ⇐ RBNI field for Company Type field (for vendor in Invoices) in the Company-Related Accounts window in the Chart of Accounts application.

The following are the database fields:

INVOICECOST.GLDEBITACCT (⇐ POLINE.GLDEBITACCT) ⇐ (PRLINE.GLDEBITACCT) ⇐ INVCOST.CONTROLACC

INVOICECOST.GLCREDITACCT ⇐ COMPANIES.RBNIACC ⇐ COMPANYACCDEF.RBNIACC (where TYPE = type of vendor company)

Transactions Resulting From Distributing Costs

The actual general ledger transactions occur only at the time of invoice approval.

For Materials

MATRECTRANS.GLDEBITACCT ⇐ INVOICECOST.GLDEBITACCT ⇐ POLINE.GLDEBITACCT

MATRECTRANS.GLCREDITACCT ⇐ INVOICECOST.GLCREDITACCT ⇐ POLINE.GLCREDITACCT

## Invoice approval

In the Invoices application, the displayed general ledger fields acquire their values when you insert the invoice lines. When you approve an invoice, the general ledger field values in any application are not affected; however, at least one database transaction is created and possibly others.

The date and time in the Entered Date field is used in the Invoices application to determine the financial period for transactions in this application.

If a purchase order number for the invoiced item exists and the Buy Ahead field (not displayed, by default) in the Purchase Orders application is set to Buy Ahead, the exchange rate at invoice approval is the rate locked in with the vendor when you create the purchase order. Otherwise, if the Vendor Currency field in the Invoices application is populated, the exchange rate is the current active rate from the Exchange Rate table in the Currency Management application.

## Invoice reversal

You can cancel individual invoices that have an approved or paid status, without doing a return transaction. Reverse invoices can be used to remove erroneously entered invoices, and credit or debit memos.

You cannot reverse an invoice that was created with the Payment Scheduling or the Labor Reporting application.

The date and time in the G/L Posting Date field is used to determine the financial period for transactions in the Invoices application.

When the reverse invoice is created and its status is set to Pending Reversal (PENDREV); additionally, the invoice, invoice lines, and invoice line costs are copied from the original invoice. The original invoice number is stored in the ORIGINVOICENUM column. The reverse invoice number is stored in the REVINVOICENUM column of the original invoice.

When the reverse invoice is approved, the Invoices application reverses all the related records that were created with the original transaction, by setting opposite values. The status of the original invoice is set to REVERSED.

## Primary transaction

When you approve a reverse invoice, the TRANSTYPE = TOTAL is written to the INVOICETRANS table.

## Example

In this example, you approve a reverse invoice for the original invoice 20 bearings at \$0.50 each, plus tax of \$0.75.

Table 1. Source of GL account to reverse an invoice

GL account source	Debit	Credit	GL account source
Company RBNI Account	$(-20 \times \$0.50) + (-0.75) = -\$10.75$	$(-20 \times \$0.50) + (-0.75) = -\$10.75$	Company AP Suspense account

## Invoice total transaction

When you approve an invoice, during the primary transaction, TRANSTYPE=TOTAL is written to the INVOICETRANS table.

For example, an invoice is approved for 20 bearings at \$0.50 each, plus tax of \$0.75:

Table 1. GL account source to approve an invoice

GL account source	Debit	Credit	GL account source
Company RBNI account	$(20 \times \$0.50) + \$0.75 = \$10.75$	$(20 \times \$0.50) + \$0.75 = \$10.75$	Company AP suspense account

A secondary transaction moves the tax portion into a tax account. We include tax in the preceding example to emphasize that the line cost for the TOTAL transaction includes tax.

If the unit cost of the item is in a foreign currency, for example, Canadian dollars, the LINECOST is in the base currency, for example, US dollars. The approval date determines the exchange rate used at invoice approval. The enter date in the INVOICE table determines the financial period.

<b>Database fields</b>	INVOICETRANS.GLDEBITACCT $\Leftarrow$ COMPANIES.RBNIACC $\Leftarrow$ COMPANYACCDEF.RBNIACC (where TYPE = type of vendor company)
	INVOICETRANS.GLCREDITACCT $\Leftarrow$ COMPANIES.APSUSPENSEACC $\Leftarrow$ COMPANYACCDEF.APSUSPENSEACC (where TYPE = type of vendor company)

## Additional transactions

The following additional transactions can occur. These potential transactions are written to the INVOICETRANS, MATRECTRANS, and SERVRECTRANS tables. All transactions are in the base currency.

## Service transaction for each invoice line with no associated purchase order line

If the invoice contains a line for a service for which no purchase order line exists, an additional transaction is written to the SERVRECTRANS table. Because no associated purchase order exists, no receipt for that service exists. However, an entry to account is required for the receipt stage. Therefore, the debit account defaults as if you inserted a purchase order line (or a purchase requisition line).

## Additional transactions for materials

If the item is a material to be issued on receipt, any change in the item cost is accounted for by writing entries to both the MATRECTRANS and MATUSETRANS tables. The accounts default as if inserting a purchase requisition line. If the materials are charged to a work order, the actual materials cost is also updated.

## Example

You approve an invoice for 20 bearings at CAD3.30 each. The base currency is US dollars, and the exchange rate is currently CAD5.00 per USD1.00. At the point of receipt, the item price is only CAD3.00, and the exchange rate is CAD6.00 per USD1.00.

At receipt, the bearings are CAD3.00 = USD0.50 each.

At invoice approval, the bearings are CAD3.30 = USD0.66 each.

The following record, ISSUETYPE = INVOICE, is written to both the MATRECTRANS and MATUSETRANS tables.

Table 1. Source of GL account for MATRECTRANS and MATUSETRANS

GL account source	Debit	Credit	GL account source
Debit account established upon insertion of invoice line = PO line debit Account	$(\$0.66 - \$0.50) \times 20 = \$3.20$	$(\$0.66 - \$0.50) \times 20 = \$3.20$	PO line credit account = Company RBNI account

If Issue on Receipt? = Y

MATUSETRANS.GLDEBITACCT  $\Leftarrow$  INVOICECOST.GLDEBITACCT  $\Leftarrow$  POLINE.GLDEBITACCT

MATUSETRANS.GLCREDITACCT  $\Leftarrow$  INVOICECOST.GLCREDITACCT  $\Leftarrow$  POLINE.GLCREDITACCT

For Service

SERVRECTRANS.GLDEBITACCT  $\Leftarrow$  INVOICECOST.GLDEBITACCT  $\Leftarrow$  POLINE.GLDEBITACCT

SERVRECTRANS.GLCREDITACCT  $\Leftarrow$  INVOICECOST.GLCREDITACCT  $\Leftarrow$  POLINE.GLCREDITACCT

## Tax transactions

An invoice can include tax. If so, in addition to the transaction of TRANSTYPE = TOTAL, a transaction is written to the INVOICETRANS table with TRANSTYPE = TAX $n$ , where  $1 \leq n \leq 27$ . The value of  $n$  depends on which tax type you selected for the tax in the Chart of Accounts application.

## Pay tax to vendor example 1

Approve an invoice for 20 bearings at \$0.50 each, plus tax of \$0.75.

If the tax is of type Tax 1, the following tax transactions are written: TRANSTYPE = TAX1 to INVOICETRANS.

Table 1. Source of GL account for pay tax to vendor

GL account source	Debit	Credit	GL account source
Paid Tax GL account	\$0.75	\$0.75	Company RBNI account

## Pay tax to vendor example 2

Additionally, there is an option to add taxes to the cost of the item. When you choose this option and Pay Tax to Vendor is true, a single transaction of TRANSTYPE=TOTAL is written to the INVOICETRANS table. A tax type transaction is not written in this scenario.

If Tax Paid to Vendor (Pay Tax to Vendor? = Y) and if Tax is of Type Tax  $n$ , where  $1 \leq n \leq 27$

INVOICETRANS.GLDEBITACCT  $\Leftarrow$  INVOICE.TAXnGL  $\Leftarrow$  TAXTYPE.INCLUSIVEGL

INVOICETRANS.GLCREDITACCT  $\Leftarrow$  COMPANIES.RBNIACC  $\Leftarrow$  COMPANYACCDEF.RBNIACC (where TYPE = type of vendor company)

## Do not pay tax to vendor example 1

Approve an invoice for 20 bearings at \$0.50 each, plus tax of \$0.75.

If the tax is of type Tax 1, a tax transaction is written with TRANSTYPE = TAX1 to INVOICETRANS.

Table 2. Source of GL account for do not pay tax to vendor

GL account source	Debit	Credit	GL account source
Paid Tax GL Account	\$0.75	\$0.75	Unpaid Tax GL account

## Do not pay tax to vendor example 2

When you can add tax to items and Pay Tax to Vendor is false, two transactions are written to the INVOICETRANS table:

- TRANSTYPE=TAX $n$ , where  $1 \leq n \leq 27$
- TRANSTYPE=TOTAL

Approve an invoice for 20 bearings at \$0.50 each, plus tax of \$0.75.

If the tax is of type Tax 1, a tax transaction is written with TRANSTYPE = TAX1 to INVOICETRANS.

Table 3. Source of GL account for do not pay tax to vendor

GL account source	Debit	Credit	GL account source
Company RBNI account	\$0.75	\$0.75	Unpaid Tax GL account

If Tax Paid Directly to Authority (Pay Tax to Vendor? = N) and if Tax is of Type Tax  $n$ , where  $1 \leq n \leq 27$ .

INVOICETRANS.GLDEBITACCT  $\Leftarrow$  INVOICE.TAXnGL  $\Leftarrow$  TAXTYPE.EXCLUSIVEGL

INVOICETRANS.GLCREDITACCT  $\Leftarrow$  TAXTYPE.INCLUSIVEGL

## Cost variance transactions

If time lapses between receiving the item and approving the invoice, the cost associated with the invoice line might differ from the cost of the item at receipt.

Both the resulting transactions and the transaction tables to which they are written vary in accordance with several factors. Also, if you purchased the item for a storeroom, the variance based is accounted for on the source of the cost change, including the following potential sources:

- The cost on the invoice is different from the cost at receipt
- The exchange rate changes between the time of receipt and invoice approval

With any cost variance, a transaction is written to either MATRECTRANS or SERVRECTRANS, depending on whether the item is material or service. As with records written to PRLINE and POLINE, the source of the accounts varies, depending on the nature of the item and on the planned use for the item.

In addition, a currency variance and invoice cost variance transactions might be written to INVOICETRANS.

- **Variance for materials**  
If the invoice line is for materials, the total exchange rate gain or loss is calculated related to the line. This amount is combined with the total variance due to cost changes related to the same invoice line. One transaction is written for both currency variance and invoice cost variance to the MATRECTRANS table (and to the MATUSETRANS table, if set to Issue on Receipt on the purchase order line). Both the debit and credit accounts default as if you inserted a receipt line for a purchase order. In addition, if variances are tracked separate transactions can be written for each type of variance to the INVOICETRANS table.
- **Cost variance transaction case study 1**  
A transaction is written to the MATRECTRANS table or the INVOICETRANS table, or both, for the entire variance. The value of UPDATEINVENTORY in MAXVARS is 1, the default, and the quantity of the item on the invoice is less than or equal to the current balance of the item in the storeroom at the time of invoice approval.
- **Cost variance transaction case study 2**  
A transaction is written to the MATRECTRANS table or the INVOICETRANS table, or both, for the entire variance. The value of UPDATEINVENTORY in MAXVARS is 1, the default, and the quantity of the item on the invoice is greater than the current balance of the item in the storeroom at the time of invoice approval.
- **Cost variance transaction case study 3**  
A transaction is written to the MATRECTRANS table or the INVOICETRANS table, or both, for the entire variance. The value of UPDATEINVENTORY in MAXVARS is 0 and the average cost is not updated.
- **Variances for services**  
If the line item is a service, any changes are tracked to the item cost by writing an entry to the SERVRECTRANS table. The accounts default as if a purchase requisition line was being inserted. Furthermore, if the service is associated with a work order, the actual service cost is updated for the work order.
- **Service not charged to store**  
You receive an invoice for a service that required 2 hours at a rate of CAD3.30 per hour. The base currency is US dollars, and the exchange rate is currently CAD5.00 per USD1.00. At the point of receipt, the item price is only CAD3.00, and the exchange rate is CAD6.00 per USD1.00.
- **Service charged to store**  
The debit account for the transaction to the SERVRECTRANS table is the rotating suspense account of the asset that was serviced. Otherwise, this

transaction works exactly as if the invoice is for a service where the Charge to Store check box is clear.

## Variance for materials

If the invoice line is for materials, the total exchange rate gain or loss is calculated related to the line. This amount is combined with the total variance due to cost changes related to the same invoice line. One transaction is written for both currency variance and invoice cost variance to the MATRECTRANS table (and to the MATUSETRANS table, if set to Issue on Receipt on the purchase order line). Both the debit and credit accounts default as if you inserted a receipt line for a purchase order. In addition, if variances are tracked separate transactions can be written for each type of variance to the INVOICETRANS table.

If you purchased the item for inventory (not for issue on receipt), any cost variances are accounted for based on two determining factors:

- The quantity of an item on the invoice, relative to the current balance of the item in the storeroom at the time of invoice approval
- The value of UPDATEINVENTORY in MAXVARS

If many items are issued or transferred out since receipt, the current balance at invoice approval time might be less than the invoice quantity.

## Cost variance transaction case study 1

A transaction is written to the MATRECTRANS table or the INVOICETRANS table, or both, for the entire variance. The value of UPDATEINVENTORY in MAXVARS is 1, the default, and the quantity of the item on the invoice is less than or equal to the current balance of the item in the storeroom at the time of invoice approval.

UPDATEINVENTORY = 1 (the default) and Invoice Quantity  $\leq$  Current® Balance

For the items remaining in inventory, the average cost of the item is updated to reflect the per unit variance by writing a transaction of TRANSTYPE = INVOICE to the MATRECTRANS table for the amount in inventory.

In this example, you approve an invoice for 20 bearings at CAD3.30 each. The base currency is US dollars, and the exchange rate is currently CAD5.00 per USD1.00. At the point of receipt, the item price is only CAD3.00, and the exchange rate is CAD6.00 per USD1.00.

At receipt, the bearings are CAD3.00 = USD0.50 each.

At invoice approval, the bearings are CAD3.30 = USD0.66 each.

## Average cost change

Originally, 10 items were in the storeroom at \$0.50 each. Upon receipt, there are 30 items at \$0.50 each for a total value of \$15.00. Upon invoice approval, the value increases by \$3.20 to \$18.20. The average cost is \$18.20 divided by 30 = \$0.61.

If you capitalize this item, the average cost in the storeroom changes. If the item you capitalized has a zero cost in the storeroom before you approve the invoice, it has a positive cost after you approve the invoice.

Table 1. Source of GL account for invoice cost variance transaction

GL account source	Debit	Credit	GL account source
Debit account established upon insertion of invoice line = Purchase order line debit account	$(\$0.66 - \$0.50) \times 20$ = \$3.20	$(\$0.66 - \$0.50) \times 20$ = \$3.20	Purchase order line credit account = company RBNI account

## Cost variance transaction case study 2

A transaction is written to the MATRECTRANS table or the INVOICETRANS table, or both, for the entire variance. The value of UPDATEINVENTORY in MAXVARS is 1, the default, and the quantity of the item on the invoice is greater than the current balance of the item in the storeroom at the time of invoice approval.

UPDATEINVENTORY = 1 (the default) and Invoice Quantity > Current® Balance

For the items remaining in inventory, the average cost of the item is updated to reflect the per unit variance by writing a transaction of TRANSTYPE = INVOICE to the MATRECTRANS table for the amount in inventory.

A transaction of TRANSTYPE = INVCEVAR is written to the INVOICETRANS table for the items that you issued out of the storeroom. This transaction is written after you received the item, but before you approve the invoice.

If a change in the exchange rate caused any of the remaining variance, a transaction of TRANSTYPE = CURVAR is written to the INVOICETRANS table for the remainder of the currency variance.

For this example, assume that you already have 10 bearings currently in inventory. You receive 20 bearings into your inventory, when the exchange rate is CAD3.00 = USD0.50.

When the exchange rate changes to CAD3.00 = USD0.60, you issue all 10 of the items that were already in inventory plus four of the 20 bearings that you recently received.

When you receive the invoice for the 20 bearings, the exchange rate is CAD3.30 = USD0.66.

## Average cost change

Each of the 20 bearings you ordered is now worth \$0.16 more at invoice than at receipt. Of those 20 items, four have already been issued from the storeroom.

Instead of taking the \$3.20 ( $20 \times \$0.16 = \$3.20$ ) and allocating it among the 16 remaining items, which would create a \$0.20 increase per item, the average cost of the storeroom is maintained correctly by increasing the average cost of each item by \$0.16 to \$0.66.

Upon invoice approval, the 16 bearings remaining in the storeroom are accounted for by debiting the inventory control account and crediting the RBNI account by  $16 \times \$0.16 = \$2.56$ . Also, the invoice cost variance account is debited and the company RBNI account is credited  $4 \times \$0.16$  for the already issued four bearings.

Table 1. Source of GL account for average price change

GL account source	Debit	Credit	GL account source
Inventory Control Account	$16 \times \$0.16 = \$2.56$	$16 \times \$0.16 = \$2.56$	Company RBNI account

The remaining amount of  $\$3.20 - \$2.56 = \$0.64$  is allocated between the currency variance and invoice cost variance accounts through the following transactions that are written to the INVOICETRANS table.

If you capitalize this item, the average cost in the storeroom changes. If the capitalized item has a cost of \$0.00 in the storeroom before you approve the invoice, it has a positive cost after you approve the invoice.

## Currency variance transaction

Here, we must control for the cost variable. The cost on receipt was CAD3.00 = US\$0.50. If the cost at invoice had been CAD3.00, as opposed to CAD3.30, the cost per bearing at invoice would have been CAD3.00 = \$0.60. Four invoice items are no longer in the storeroom.

Table 2. Source of GL account for currency variance transaction

GL account source	Debit	Credit	GL account source
Currency variance account	$(\$0.60 - \$0.50) \times 4 = \$0.40$	$(\$0.60 - \$0.50) \times 4 = \$0.40$	Company RBNI account

If the item is capitalized, the credit account is the inventory control account and not the capital GL account.

## Invoice cost variance transaction

In this transaction, we must control the exchange rate variable. If the exchange rate at receipt is the same as the invoice exchange rate, the cost per bearing at receipt is CAD3.00 = US\$0.60 (not \$0.50). The cost at invoice was CAD3.30 = US\$0.66. Four items are no longer in the storeroom.

Variance accounts track cost variances by storeroom location, not by item.

Table 3. Source of GL account for invoice cost variance transaction

GL account source	Debit	Credit	GL account source
Invoice Cost Variance account of Storeroom	$(\$0.66 - \$0.60) \times 4 = \$0.24$	$(\$0.66 - \$0.60) \times 4 = \$0.24$	Company RBNI account

The \$0.64 variance for the four items in inventory consists of a \$0.40 currency variance and a \$0.24 cost variance.

Even if the item is capitalized, the credit account is the inventory control account, not the capital GL account.

## Cost variance transaction case study 3

A transaction is written to the MATRECTRANS table or the INVOICETRANS table, or both, for the entire variance. The value of UPDATEINVENTORY in MAXVARS is 0 and the average cost is not updated.

A change in the exchange rate causes TRANSTYPE = CURVAR to be written to the INVOICETRANS table for that portion of the total variance.

A change in the cost in the foreign currency causes TRANSTYPE = INVCEVAR to be written to the INVOICETRANS table for that portion of the total variance.

Both the preceding overview and the following example apply to both capitalized and non-capitalized items.

In this example, you approve an invoice for 20 bearings at CAD3.30 each. The base currency is US dollars, and the exchange rate is currently CAD5.00 per USD1.00. At the point of receipt, the item price is only CAD3.00, and the exchange rate is CAD6.00 per USD1.00.

At receipt, the bearings are CAD3.00 = US\$0.50 each.

At invoice approval, the bearings are CAD3.30 = US\$0.66 each.

## Currency variance transaction

The cost on receipt is CAD3.00 = US\$0.50. If the cost at invoice is CAD3.00, as opposed to CAD3.30, the cost per bearing at invoice is CAD3.00 = US\$0.60. The CURVAR transaction is written to the INVOICETRANS table.

Table 1. Source of GL account for currency variance transaction

GL account source	Debit	Credit	GL account source
Currency variance account	$(\$0.60 - \$0.50) \times 20 = \$2.00$	$(\$0.60 - \$0.50) \times 20 = \$2.00$	Inventory control account

Even if the item is a capitalized item, the credit account is the inventory control account, not the capital GL account.

## Invoice cost variance transaction

For this transaction, you control the exchange rate variable. If the exchange rate at receipt is the same as the invoice exchange rate, the cost per bearing at receipt is CAD3.00= USD0.60 (not USD0.50). The cost at invoice was CAD3.30= USD0.66. The INVCEVAR transaction is written to INVOICETRANS.

Variance accounts track cost variances by storeroom location, not by item.

Table 2. Source of GL account for invoice cost variance transaction

GL account source	Debit	Credit	GL account source
Invoice Cost Variance account of Storeroom	$(\$0.66 - \$0.60) \times 20 = \$1.20$	$(\$0.66 - \$0.60) \times 20 = \$1.20$	Inventory Control account

The \$3.20 variance for the 20 items on the invoice is made of a \$2.00 currency variance and a \$1.20 cost variance.

Even if the item is capitalized, the credit account is the inventory control account, not the capital GL account.

## Variances for services

If the line item is a service, any changes are tracked to the item cost by writing an entry to the SERVRECTRANS table. The accounts default as if a purchase requisition line was being inserted. Furthermore, if the service is associated with a work order, the actual service cost is updated for the work order.

## Service not charged to store

You receive an invoice for a service that required 2 hours at a rate of CAD3.30 per hour. The base currency is US dollars, and the exchange rate is currently CAD5.00 per USD1.00. At the point of receipt, the item price is only CAD3.00, and the exchange rate is CAD6.00 per USD1.00.

At receipt, the hourly rate is CAD3.00 = USD0.50.

If no exchange rate change occurs, the hourly rate at invoice approval is CAD3.30 = USD0.55. However, the exchange rate changed to CAD5.00 per USD1.00. Therefore, at invoice approval, the hourly rate is CAD3.30 = USD0.66.

The following transaction is written to the SERVRECTRANS table:

Table 1. Source of GL account for service not charged to store

GL account source	Debit	Credit	GL account source
1. If issued to a work order, uses work order GL account	$(\$66.00 - \$50.00) \times 2 = \$32.00$	$(\$66.00 - \$50.00) \times 2 = \$32.00$	Company RBNI account
2. If issued to asset, uses asset GL account			
3. If issued to asset, uses GL account of asset location			

## Service charged to store

The debit account for the transaction to the SERVRECTRANS table is the rotating suspense account of the asset that was serviced. Otherwise, this transaction works exactly as if the invoice is for a service where the Charge to Store check box is clear.

In addition, if UPDATEINVENTORY = 1, the database inventory cost of the rotating asset is updated.

## Transactions resulting from the distribute costs process

Recall the following conditions that determine distribute costs:

- The invoice line has a purchase order line number specified
- You received the line and distributed the costs to another GL account

At invoice approval, the corresponding entries to the GL account are made depending upon the invoice line item:

- If the invoice line item is a material, the transaction is written to the MATRECTRANS table.
- If the invoice line item is a service, the transaction is written to the SERVRECTRANS table.

The costs can be distributed for only material line items when you select the Issue on Receipt check box. At the approve invoices stage, consider any lines that the user inserts on the Distribute Costs window as new invoice lines that need the receipt transaction.

## Scenario

Suppose that originally, as a result of your receiving 20 bearings at \$0.50 each, the following transaction is written to the MATRECTRANS table.

Table 1. Source of GL account for service charged to store

GL account source	Debit	Credit	GL account source
1111-111-111 (Purchase order line debit account)	$20 \times \$0.50 = \$10.00$	$20 \times \$0.50 = \$10.00$	3333-333-333 (Purchase order line credit account)

Later, you decide that to charge 20% of the cost to account 2224-111-111, as, perhaps, two bearings went to a different location than planned.

Using the distribute costs process, you back out the invoice line corresponding to that receipt. On the Distribute Cost window, you distribute the cost. Upon invoice approval, the following transactions are written to the MATRECTRANS table. The account codes are the codes you entered on the Distribute Costs window.

Table 2. Source of GL account for MATRECTRANS table

GL account source	Debit	Credit	GL account source
1111-111-111 (Purchase order line debit account)	-\$10.00	-\$10.00	3333-333-333 (Purchase order line credit account)
1111-111-111 (Purchase order line debit account)	\$8.00	\$8.00	3333-333-333 (Purchase order line credit account)
2224-111-111 (Defaults as if receiving the item)	\$2.00	\$2.00	(Defaults as if receiving the item)

## Financial processes in the Resources module

Various financial processes occur in the Labour application.

- [Financial processes in the Labor application](#)  
Various financial processes occur in the Labor application.

## Financial processes in the Labor application

Various financial processes occur in the Labor application.

If the rate records associated with a labor are internal labor rates, they typically receive one set of default GL accounts. If they are external labor rates, they receive another set of default GL accounts.

Database Fields	Content
Database fields for internal labor rates	LABORCRAFTRATE.GLACCOUNT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = LABRESCODE and GROUPVALUE = 0) (Labor Resource field for Outside? = N on Labor Resource Codes window in the Chart of Accounts application) ⇐ direct entry (no default) LABORCRAFTRATE.CONTROLACC ⇐ LOCATIONS.INTLABREC (where the LOCATION = LABOR.WORKLOCATION and SITE=LABOR.WORKSITE)
Database fields for external labor rates	LABORCRAFTRATE.GLACCOUNT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = LABRESCODE and GROUPVALUE = 1) (Labor Resource field for Outside? = Y on Labor Resource Codes window in the Chart of Accounts application) ⇐ direct entry (no default) LABORCRAFTRATE.CONTROLACC ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = EXLABREC and GROUPVALUE = vendor name) (Control Account field for associated vendor field on External Labor Control Accounts window in the Chart of Accounts application) ⇐ direct entry (no default)

## Financial processes in the Service Desk module

Various financial processes occur in the Service Requests, Incidents, and Problems applications.

- [Financial processes in the Service Requests, Incidents, and Problems applications](#)  
Various GL account rules are used for starting and stopping the timer in the Service Requests, Incidents, or Problems applications.

## Financial processes in the Service Requests, Incidents, and Problems applications

Various GL account rules are used for starting and stopping the timer in the Service Requests, Incidents, or Problems applications.

- [Capturing time spent on a ticket](#)  
Start and stop the timer to capture the time spent on a ticket.

## Capturing time spent on a ticket

Start and stop the timer to capture the time spent on a ticket.

There are various GL account rules after you start the timer.

Displayed fields	GL Account (GLACCOUNT) ⇐ GL Control Account field (displayed), normal validation rules for GL accounts apply. GL Account (GLACCOUNT) ⇐ GL Control Account field (not displayed).
------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

The following table describes which GL account rules apply when the GL Control Account field is not shown on the ticket.

Table 1. GL account rules without general ledger control account field on ticket

If asset or location...	and the site and asset site are...	use the GL account...
not on the ticket	equal or not equal	from the Labor record of the user running the application as the LABTRANS (GL) default. If the GL account does not exist, the global ticket GL account is used as the LABTRANS (general ledger) default.
on ticket	not equal	the asset or location generates the LABTRANS (general ledger) record. If asset or location do not have an associated GL account, the GL account from the labor record of the user running the application is used as the LABTRANS (general ledger) default. If the labor record does not have a valid GL account, the global ticket GL account is used as the LABTRANS (general ledger) default.
both on ticket	equal	as determined by existing asset or location merging rules. If asset and location do not have associated GL accounts, the GL account from the labor record of the user running the application is used as the LABTRANS (general ledger) default. If the labor record does not have a valid GL account, the global ticket GL account is used as the LABTRANS (general ledger) default.

## Financial processes in the Work Orders module

Various financial processes occur in the Work Order Tracking, Quick Reporting, and Labor Reporting applications.

- [Financial processes in the Work Order Tracking application](#)  
Various financial processes occur in the Work Order Tracking application.
- [Financial processes in the Quick Reporting application](#)  
Various financial processes occur in the Quick Reporting application.
- [Financial process in the Labor Reporting application](#)  
Various financial processes occur in the Labor Reporting application.

## Financial processes in the Work Order Tracking application

Various financial processes occur in the Work Order Tracking application.

- [Report actual material use](#)  
The financial processes used in the tracking of actual quantities, locations, and cost for items used on an approved work order.
- [Report actual labor use](#)  
The financial processes used in the tracking of actual labor hours that were required to complete the work order.
- [Report actual tool use](#)  
The financial processes used in the tracking of actual quantities, hours, and rates for tools used on an approved work order.

## Report actual material use

The financial processes used in the tracking of actual quantities, locations, and cost for items used on an approved work order.

The date and time in the Actual Date field are used to determine the financial period for the transaction. The Actual Date field defaults to the system date and time.

After you enter and save material use information, a record is written, ISSUETYPE = ISSUE, to the MATUSETRANS table. The quantity is posted as a negative value.

### Example

Report use of 20 bearings (item type = BEARINGS), that costs \$0.20 per piece, on the Materials subtab on the Actuals tab in Work Order Tracking application.

Table 1. Source of GL account for report actual material use

Source of GL account	Debit	Credit	Source of GL account
1. Inventory GL account (item resource code)	-20 x \$0.20 = \$4.00	-20 x \$0.20 = \$4.00	Inventory control account
2. Work order GL account			

If the item is capitalized, the default credit account is the capital GL account, and the line cost is zero.

## If Issue Type field is set to RETURN

After you enter and save material use information, the ISSUETYPE = RETURN record is written to the MATUSETRANS table. The quantity is written as a positive value.

### Example

Report return of 20 bearings (item type = BEARINGS), that costs \$0.20 each, on the Materials subtab on the Actuals tab in the Work Order Tracking application.

Table 2. Source of GL account for report actual material use

Source of GL account	Debit	Credit	Source of GL account
1. Inventory GL account (item resource code)	20 x \$0.20 = - \$4.00	20 x \$0.20 = - \$4.00	Inventory control account
2. Work order GL account			

If the item is capitalized, the default debit account is the capital GL account and the line cost is zero.

The general ledger fields for actual material use that is reported or viewed in Work Orders application default just as they do when the usage is recorded or viewed in the Inventory application or the Issues and Transfers application.

## Report actual labor use

The financial processes used in the tracking of actual labor hours that were required to complete the work order.

At the transaction level, reporting actual labor use by labor code or craft works just as it does when using the Labor Reporting application to report labor use.

The date and time in the Actual Date field is used to determine the financial period for the transaction. The Actual Date field defaults to the system date and time.

The general ledger fields for actual labor use that is reported or viewed in the Work Orders application default just as they do when the usage is recorded or viewed in the Labor Reporting application.

## Report actual tool use

The financial processes used in the tracking of actual quantities, hours, and rates for tools used on an approved work order.

## Internal tools

You can enter a date and time to determine the financial period for the transaction. If you do not enter a date and time, it defaults to system date and time.

## Example

Table 1. Source of GL account for report actual tool use (internal tools)

Source of GL account	Debit	Credit	Source of GL account
1. Internal tools GL account (resource code)	2 x \$5.00 = \$10.00	2 x \$5.00 = \$10.00	Internal tools control account
2. Work order GL account			

<b>Displayed field</b>	GL Debit Account (GLDEBITACCT) ⇐  1. GL Account field in the Tool / Organization Details action of the Tools application ⇐ Internal Tool Resource Code field from the Resource Codes action in the Chart of Accounts application. 2. GL Account field in the Work Orders application. The general ledger fields for actual material use that is reported or viewed in the Work Orders application default just as they do when the usage is recorded or viewed in the Inventory application or the Issues and Transfers application.
	GL Credit Account (GLCREDITACCT) ⇐  Control Account field in the Tool / Organization Details action of the Tools application ⇐ Control Account field in the Organization Default Accounts action of the Chart of Accounts application

<b>Database fields</b>	TOOLTRANS.GLDEBITACCT ⇐  1. ITEMORGINFO.GLACCOUNT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = TOOLRESCODE and GROUPVALUE = 0) ⇐ direct entry (no default) 2. WORKORDER.GLACCOUNT ⇐ PM.GLACCOUNT or ASSET.GLACCOUNT or LOCATIONS.GLACCOUNT
	TOOLTRANS.GLCREDITACCT ⇐ ITEMORGINFO.CONTROLACC ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = TOOLREC and GROUPVALUE = TOOLREACCT) ⇐ direct entry (no default)

## External tools

Report external tool use the same as you report internal tool use. If the Outside check box of the tool is selected, the external tool resource code is used on the debit side, and the external tools control account, established by tool vendor, on the credit side.

After entering and saving the tool use information, a record is written to the TOOLTRANS table.

You can enter a date and time to determine the financial period for the transaction. If you do not enter a date and time, it defaults to system date and time.

## Example

Report the use of hoist for 2 hours, at \$7.00 an hour, belonging to a contractor, on the Tools subtab in the Actuals tab in the Work Order Tracking application.

Table 2. Source of GL account for report actual tool use (external tools)

Source of GL account		Debit	Credit	Source of GL account
1. External tools GL account (resource code)		2 x \$7.00 = \$14.00	2 x \$7.00 = \$14.00	External tools control account, for tool vendor
2. Work order GL account				
Displayed fields	GL Debit Account (GLDEBITACCT) ⇐  1. GL Account field in the Tool / Organization Details action of the Tools application ⇐ External Tool Resource Code field from the Resource Codes action in the Chart of Accounts application. 2. GL Account field in the Work Orders application. The general ledger fields for actual material use that is reported or viewed in the Work Orders application default just as they do when the usage is recorded or viewed in the Inventory application or the Issues and Transfers application.			
	GL Credit Account (GLCREDITACCT) ⇐  Control Account field in the Tool / Organization Details action of the Tools application ⇐ Tool Control Account field for the vendor in the Companies application.			
	TOOLTRANS.GLDEBITACCT ⇐  1. ITEMORGINFO.GLACCOUNT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = TOOLRESCODE and GROUPVALUE = 1 ⇐ direct entry (no default) 2. WORKORDER.GLACCOUNT ⇐ PM.GLACCOUNT or ASSET.GLACCOUNT or LOCATIONS.GLACCOUNT  TOOLTRANS.GLCREDITACCT ⇐ ITEMORGINFO.CONTROLACC ⇐ COMPANIES.TOOLCONTROLACCOUNT ⇐ direct entry (no default)			

## Financial processes in the Quick Reporting application

Various financial processes occur in the Quick Reporting application.

The GL Account field in this application populates just as it does in Work Order Tracking application.

In the Quick Reporting application, you can perform the following actions:

- Move or modify assets, or both
- Report actual labor use
- Report actual material use
- Report actual tool use

These processes are identical to the processes in the Work Order Tracking application.

## Financial process in the Labor Reporting application

Various financial processes occur in the Labor Reporting application.

You can report actual labor usage and see the transaction records of actual labor usage. You can also report this information in the Work Order Tracking application.

You can edit the GL Debit Account field and the GL Credit Account field when reporting labor usage. After you save your edits, the transaction is recorded and all fields become read-only.

- [Work types](#)  
The general ledger fields default in the same manner for all work types.
- [Report labor use](#)  
Describe the financial transactions in the Labor Reporting application that cause GL account transactions to be written.

## Work types

The general ledger fields default in the same manner for all work types.

There are three work types:

- NON-WORK (including Sick (SICK) and Vacation (VAC))
- OT-REF (overtime refused)
- WORK (including Travel (TRAV) and Waiting on Material (WMATL))

## Reporting work types

To report WORK, enter any one of the following items in the general ledger fields:

- Asset number
- General ledger debit account
- Operating location

- Work order number

If you enter the work order number, asset number, or operating location, a value defaults to the general ledger debit account field.

To report NON-WORK and OT-REF, you leave the following fields blank:

- General ledger debit account
- Work order
- Asset
- Operating location

If you do not specify a general ledger debit account, that field is remains blank.

## Displayed fields

---

GL Debit Account (GLDEBITACCT) ⇐

1. GL Account field (not displayed) in Labor ⇐ Labor Resource field (for Vendor = Null or for Vendor = Not Null) on Labor Resource Codes window in the Chart of Accounts application
2. GL Account field in the Work Orders application
3. GL Account field (not displayed) in the Asset window
4. GL Account field in the Locations window

GL Credit Account (GLCREDITACCT) ⇐

- Control Account field (not displayed) in Labor ⇐ Control Account field for Work Location on Internal Labor Control Accounts window in the Chart of Accounts application

Or

- GL Debit Account field from purchase order line on PO Lines window in the Purchase Orders application

## Database fields

---

LABTRANS.GLDEBITACCT ⇐

1. LABORCRAFTRATE.GLACCOUNT ⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = LABRESCODE and GROUPVALUE = 0 or GROUPVALUE = 1)
2. WORKORDER.GLACCOUNT
3. ASSET.GLACCOUNT
4. LOCATIONS.GLACCOUNT

LABTRANS.GLCREDITACCT ⇐ LABOR.CONTROLACC ⇐ LOCATIONS.INTLABREC

⇐ ACCOUNTDEFAULTS.GLDEFAULT (where DFLTGROUP = EXLABREC and GROUPVALUE = vendor name) or

If LABTRANS.PONUM is not null, LABTRANS.GLCREDITACCT ⇐ POLINE.DEBITGLACCT (where LABTRANS.PONUM = POLINE.PONUM and LABTRANS.POLINENUM = POLINE.POLINENUM)

## Report labor use

---

Describe the financial transactions in the Labor Reporting application that cause GL account transactions to be written.

## Report labor use for internal resources

---

The Labor Reporting application lets you report actual labor use and see the transaction records of previously reported actual labor use. You can also use the Work Order Tracking application. You can edit the GL Debit Account field and the GL Credit Account field when you report labor use before you save the record. After the transaction is recorded, all fields become read-only.

The general ledger fields default in the same manner for all three work types:

- NON-WORK (including SICK and VAC)
- OT-REF
- WORK (including TRAV and WMATL)

In order to report use of type WORK, enter any of the following items:

- A general ledger debit account
- A work order number
- An asset number
- An operating location

In the cases of NON-WORK and OT-REF, you can report usage without entering this data. If you do not enter a work order number, asset number, or location, the GL Debit Account field does not default to anything. In such cases, you enter a code in the GL Credit Account field.

## Primary transaction

---

When you save a record after reporting actual labor use, a record of type WORK is written to the LABTRANS table.

You can enter a date and time to determine the financial period for the transaction. If you do not enter a date and time, it defaults to system date and time.

## Example

Joe Jones works for 2 hours at a rate of \$15.00 per hour.

Table 1. Source of general ledger code for report labor use for internal resources

Source of GL account	Debit	Credit	Source of GL account
1. Internal labor GL account (resource code)	\$15.00 x 2 = \$30.00	\$15.00 x 2 = \$30.00	Internal labor control account of work location
2. Work order GL account			
3. Asset GL account			
4. Operating location GL account			

The table lists general ledger sources in order of priority. For example, the labor resource account code overrides any defined segment in the same position of the work order GL account, which, if present, overrides the asset GL account which overrides any segments in the same position from the GL account of the location.

## Report labor use for external resources

You report external labor usage similarly to how you report internal labor usage.

When you save a record after reporting actual labor use, a record of type WORK (or a synonym) is written to the LABTRANS table.

The date and time that you enter is used in the Daily Time table to determine the financial period for the transaction. If you do not enter a date and time it defaults to the system date and time.

## Example 1

Bill Smith works for 2 hours at a rate of \$15.00 per hour. A vendor provides Bill's services.

Table 2. Source of general ledger code for report labor use for external resources

Source of GL account	Debit	Credit	Source of GL account
1. External labor GL account (resource code)	\$15.00 x 2 = \$30.00	\$15.00 x 2 = \$30.00	External labor control account for the vendor
2. Work order GL account			
3. Asset GL account			
4. Operating location GL account			

## Example 2

Bill Smith works for 2 hours at a rate of \$15.00 per hour. A vendor provides Bill's services, but the following example has an outstanding purchase order for those services.

Table 3. Source of general ledger code for report labor use for external resources

Source of GL account	Debit	Credit	Source of GL account
1. External labor GL account (resource code)	\$15.00 x 2 = \$30.00	\$15.00 x 2 = \$30.00	Purchase order lines general ledger debit account.
2. Work order GL account			
3. Asset GL account			
4. Operating location GL account			

The table lists general ledger sources in order of priority. For example, the labor resource account code overrides any defined segment in the same position of the work order GL account, which overrides the asset GL account, if present, which overrides any segments in the same position from the GL account of the operating location.

The general ledger debit account of the purchase order for the external service order is assumed to be a temporary charge account; receiving the service in the Labor Reporting application clears the charge in the temporary account and charges the correct debit account.

## General ledger database columns

The table in this appendix lists the GL account columns found in user applications. It shows the application, table, and column name for each column. The table also indicates whether you must fully specify the GL account.

The GL account specification required (fully or partially) column indicates whether the general ledger database column, and its corresponding field on a tab, require a fully specified account, or whether a partially specified account is acceptable.

A fully specified account has an account code in each required component, for example, 6100-350-SAF. A partially specified account has placeholder characters for one or more account components, for example, 6100-???-SAF.

Table 1. General ledger database column definitions

## Implementing workflow processes

Workflow features let you automate repetitive business and record management processes. This provides a means for greater efficiency and accountability throughout your enterprise.

- [Workflow overview](#)  
You use the Workflow application to plan, design, build, test, implement, and manage workflow processes. Workflow provides a means of electronically reproducing business processes so that they can be applied to records.
- [Configuring for Workflow](#)  
Workflow applications require minimal configuration before you can create workflow processes.

## Workflow overview

You use the Workflow application to plan, design, build, test, implement, and manage workflow processes. Workflow provides a means of electronically reproducing business processes so that they can be applied to records.

With workflow, you can manage the movement of a record through a process from start to finish. You can instruct individuals to act on records, specify delegates when workers are unavailable, ensure that individuals act in a timely manner, and ensure that an audit trail exists for each record and process.

Workflow is an integrated part of the software. Workflow processes and their supporting records are at the system level in a multisite implementation. Workflow processes can be used for all organizations and sites. You can design processes or subprocesses that are specific to an organization or specific to a site, by using logical branching.

You can create a workflow process for any business object. Because all the applications are associated with product business objects and can run a customer Java™ class, you can build workflow processes for any application, including cloned and custom applications.

Workflow handles assignments in a flexible manner. You can specify assignee relationships for assignments to create groups of active assignments at run time. Assignees can receive notifications of assignments in their Workflow Inbox or in their email inbox, eliminating the need for users to search for their assignments. Workers or administrators can reassign workflow tasks, stop a process instance, and remove a record from the control of Workflow. You can specify at what point in a process you want email notifications to be generated. Delegates can be specified when workers are unavailable.

A workflow process can run a program, such as a batch file or an .exe file that is stored on a local server in the system directory. A workflow process for one type of record can start a process for another type of record. For example, a service request can launch a process for an incident. A process can contain subprocesses. For example, for different subcategories of records, or records from different sites. When a process requires user interaction, the product can direct a user to a specific application, to a tab, or to an action.

- [Applications that are used with Workflow](#)  
Workflow is used with other applications that directly or indirectly support its functionality.
- [Workflow design process](#)  
Workflow processes can be designed to incorporate the most effective ways of completing business tasks. You can evaluate your current practices and determine how you can improve or standardize them before you design workflow processes.

## Applications that are used with Workflow

Workflow is used with other applications that directly or indirectly support its functionality.

### Actions

Create and manage actions and action groups. Actions are associated with connection lines in a workflow process and are triggered by the routing that moves a record from one node to another.

### Communication Templates

Create and manage templates that the system uses when generating e-mail messages. Workflow uses communication templates for notifications.

### Escalations

Create and manage escalation processes. An *escalation* is a mechanism that can monitor time-sensitive records and key performance indicators, which can take actions or send notifications when a record reaches a defined escalation point. Workflow can use escalations with task assignments.

### Inbox/Assignments Setup

Configure the Workflow Inbox on the Start Center of a user.

### People

Create and manage records for individuals who are listed on records in any capacity. Workflow uses person records when generating assignments and notifications.

### Person Groups

Create and manage records for groups of individuals. Workflow uses person group records when generating assignments and notifications.

#### **Roles**

Create and manage records for roles. All roles resolve to a person, a person group, or an e-mail address. All workflow assignments and notifications are made to roles.

#### **Workflow Administration**

View and modify assignments and active instances of workflow processes.

#### **Workflow Designer**

Create, view, and modify workflow processes.

#### **Workflow Inbox**

View and respond to workflow assignments. A workflow process routes assignments to users' inboxes.

---

## Workflow design process

Workflow processes can be designed to incorporate the most effective ways of completing business tasks. You can evaluate your current practices and determine how you can improve or standardize them before you design workflow processes.

When you create a workflow process, the product directs records through paths that you specify. When you design a process, be sure to consider what can happen at each decision point and include all the paths that a record can take. You could begin your workflow implementation with simple processes. You can always build in more complexity in a later revision.

To design optimum workflow processes, consider the following guidelines:

- Generic processes require less maintenance than highly specific ones. For example, you could modify roles that resolve to an individual more frequently than roles that resolve to a person group.
- When designing processes, consider when you want the product to generate notifications. The product can generate notifications when the following events occur in a process:
  - A record reaches a decision point (node)
  - A record follows a specific path (connection line) in a process
  - Task assignments are made
- When designing processes, consider how you want to handle null values. A process could reach a decision point that evaluates data on the record and that data could be missing from the record.
- When a record takes the negative path, you can design the record so that it can be modified to take the positive path. You could also design the record to exit the process permanently.
- If a record can go through a process again after it has been rejected, you can define a limit to the number of times a record can repeat the process.
- Try to avoid having separate groups of nodes and connection lines that perform the same function at different points in a process. It is more efficient to reuse the same code through looping or through creating a subprocess.
- Simple processes involving a limited number of nodes are easier to troubleshoot and maintain. If the number of nodes in your process grows too large, you could break down the process into subprocesses.
- When writing Structured Query Language (SQL) statements, consider how the SQL syntax affects how the product interprets the statements. The following examples demonstrate the use of the colon in SQL statements:
  - ASSETNUM - (without a colon) Instructs the product to go to the database for the asset record
  - ASSETNUM - (with a colon) Instructs the product to use the asset record in memory (the record currently on the window)
- [Business process analyses](#)  
Your business practices encompass how you manage your enterprise. You can start the analyses of your processes by collecting information about your enterprise. This information helps you to determine the types of processes that you could automate.
- [Workflow tool palette buttons](#)  
Workflow tool palette buttons provide visual indications of workflow application support and workflow process control. You use these icons to route workflow assignments and to complete workflow assignments.
- [Elements of workflow processes](#)  
You use workflow processes to create steps to guide records for your business processes. You use numerous elements when creating your workflow processes to achieve the business goals set out for your enterprise.
- [Examples of workflow processes](#)  
You can use the Workflow application to manage records used in various business processes. The examples provided are basic because of the limited number of nodes that can be displayed.

---

## Business process analyses

Your business practices encompass how you manage your enterprise. You can start the analyses of your processes by collecting information about your enterprise. This information helps you to determine the types of processes that you could automate.

---

## Enterprise analysis

Gather the following enterprise information to use when designing your workflow processes:

- If you have an organizational chart, review your organizational chart to see how your enterprise is organized.
- If your enterprise is multinational, list the languages that are required for your workflow processes.
- Collect the business process flows that document the business units of your organization. If there are different process flows for the same organizations at various locations, gather those process flows. Compare the business practices at locations to find out if the differences are significant.
- Review the standard operating procedures, such as the International Organization for Standardization (ISO) 9000 quality management or the ISO 14000 procedures.
- Review the regulatory requirements for your industry and how they affect your business processes.

- Review the policies that define who is responsible for creating budgets.
- Review the policies that define financial approval limits and list the individuals who have the authority to approve spending.
- Research the types of records at your enterprise that require approval.
- Review the policies that define the levels of approval that are required for each type of record.

## Implementation analysis

---

Gather the following implementation information for use when designing your workflow processes:

- Determine the number of organizations and sites that exist for your enterprise. You create workflow processes at the system level. Find out if there are separate processes or subprocesses for different organizations or sites.
- Find out if you use the Integration Framework to integrate with any external systems.
- Determine if any Maximo® product options have been purchased.
- Research the applications that your enterprise has implemented.
- Determine the types of records for which you use the software.
- Find out if the system has been configured to generate records, such as inventory reorder records, preventive maintenance work orders, and scheduled payment invoices.
- Determine if your implementation uses Start Centers that do not include the Workflow Inbox. If users cannot access the Inbox, you can design your workflow processes to send e-mail messages to notify users.
- [Process analysis](#)  
Information you collect about your processes can be formatted into a flowchart. A flowchart can help you to identify reusable elements, the beginning and the end of record life cycles, and the parts of the life cycle that can be managed by a workflow process.
- [Workflow processes and user responsibilities](#)  
Workflow processes identify the people who create and who manage a record throughout its life cycle. Workflow processes also identify the types of records that are used.

## Process analysis

---

Information you collect about your processes can be formatted into a flowchart. A flowchart can help you to identify reusable elements, the beginning and the end of record life cycles, and the parts of the life cycle that can be managed by a workflow process.

You could diagram your business process on paper, on a blackboard, or using a graphics software program to create a flowchart. Writing or diagramming a business practice helps you to analyze it. It also provides you with a map of your process flows that you can use when you create a workflow process. Your goal is to produce a detailed diagram that shows all of the routes that a record can take through your enterprise during its life cycle.

Your research must include the following information:

- The names of the people who interact with records during a process
- The processes that are used to manage specific records
- The records that enter the process, and where the records go when they exit the process
- The records that are managed during a process
- The length of time it takes for a record to go through a process
- The parts of your current process that are working well and should be kept
- The parts of your current process that are not working well and should be changed or removed

As you document your business process, make note of trouble spots, such as undocumented procedures, or different ways to complete the same task. Address these issues and refine your business processes before you create and implement a workflow process.

## Workflow processes and user responsibilities

---

Workflow processes identify the people who create and who manage a record throughout its life cycle. Workflow processes also identify the types of records that are used.

In workflow processes, assignments are made to roles that represent either a single user or a group of people. As you generate a list of persons associated with each process, consider whether you can create person groups for people with similar job responsibilities, levels of authority, and security clearances.

To help you to identify the people, the roles, and the records that are involved in the workflow processes that you create, compile the following information:

- Decide how people are going to be notified of workflow assignments. Users who are going to be assigned tasks must have user records.
- Generate a list of the people who must be notified of the progress of a record. The product can send e-mail messages to notify specific users. It is more efficient to create person records for all individuals who receive notifications.
- Identify the personnel who work on shifts.
- Identify supervisors on person records for escalations and notifications.
- Identify contract labor personnel if they are required to interact with a record in a workflow process. Identify which contract workers have both person records and labor records.
- Specify the level of security that applies to individuals in different roles in your enterprise. Decide which applications and which actions personnel in each security group are allowed to view. When you design your security groups and workflow processes, you must ensure that users in a particular role have the security permissions they need to perform their assigned tasks.

## Workflow tool palette buttons

---

Workflow tool palette buttons provide visual indications of workflow application support and workflow process control. You use these icons to route workflow assignments and to complete workflow assignments.

When you add workflow support to an application, a Route button is added to the application toolbar. Two icons exist for the Route toolbar button, to indicate whether a record is being used in a workflow process. You can customize the Route buttons. If multiple processes exist for an application, you can create different buttons for each process.

Table 1. Route buttons

Icon	File name	Function
	nav_icon_route.gif	Indicates that the application supports workflow. You can click the icon to route the current record into a process.
	nav_icon_route_active.gif	Indicates that the current record is under the control of one or more workflow processes. You can click this toolbar button to perform one of the following actions: <ul style="list-style-type: none"><li>Complete a workflow assignment.</li><li>Route the record into another workflow process.</li></ul>

## Standards for graphic files

When you create customized images to use as toolbar buttons, create pairs of icons for each process.

The following standards are required for toolbar button images:

- Images must be Graphics Interchange Format (GIF) files. Use the GIF format for a transparent background for the icon image.
- Image resolution must be 72 DPI.
- Image height for toolbar icons is 17 pixels. The width of the icon can vary from 12 to 26 pixels.
- Copy the images for toolbar buttons to the following directory: <product directory>\applications\maximo\maximouiweb\webmodule\webclient\images

## Elements of workflow processes

You use workflow processes to create steps to guide records for your business processes. You use numerous elements when creating your workflow processes to achieve the business goals set out for your enterprise.

- Process nodes**  
A node is a graphical element that represents a point in your business process. Nodes are added at specific business process junctures to denote the entry of a record into the business process.
- Connection lines**  
All nodes in a workflow process, except for the start nodes and the stop nodes, must be connected to two other nodes. You can draw positive and negative types of connections between nodes.
- Person records**  
You use the People application to create, to modify, to view, and to delete records for individuals. The People application stores information about individuals, such as users, laborers, asset owners, and supervisors who receive workflow notifications.
- Person groups and workflow assignments**  
You use Person Groups to specify that a group member for a specific organization or site must be used when making workflow assignments. Workflow assignments are made to roles.
- Roles and role records**  
You use the Roles application to create role records. A role is a function within a business. A role can represent a specific job title (such as a department manager), an assigned duty (such as a watch officer), a class file, and a data set.
- Communication templates**  
You use Communication Templates to create and to manage templates that generate email messages about the status of workflow records.
- Notifications**  
You use the Workflow Designer application to create notifications. A notification is an email message that is generated by the progress of a record through a workflow process.
- Escalations and action groups**  
You use Escalations to create escalation records. You can use escalations to escalate workflow assignments before they time out in the Inbox for the recipient.
- Escalation points**  
An escalation point defines the attributes of a record that trigger an action. You can define one or more escalation points for an escalation and specify one or more actions and notifications for each escalation point.
- Actions and action records**  
Workflow processes use actions to move records through a process and to trigger events, such as status changes. You define actions in the Actions application and then you reuse them in other workflow processes that you create.
- Action types**  
When you create an action record, you specify the action type to help determine what kind of action to take when the action is encountered in a process.
- Record routing**  
Activating a workflow process indicates that the process is ready to have records routed through it. Before you activate a record, consider whether you want records to be routed into a process manually or automatically.
- Domains for status synonyms**  
If your business processes for record approvals or for status changes involve multiple steps for each approval or status change, you can create synonym statuses that model those processes.

## Process nodes

A node is a graphical element that represents a point in your business process. Nodes are added at specific business process junctures to denote the entry of a record into the business process.

You can drag nodes from the palette onto the canvas. You can add any number of nodes to a process. If a process exceeds 50 - 100 nodes, consider breaking the process into subprocesses to simplify management and maintenance.

As you drag each node onto the canvas, a name and a number are assigned to the node. The node name describes the type of node. The number indicates the order in which the node was added to the canvas. You can modify the name of a node when you configure the node properties.

Whenever possible, give nodes easy to understand labels. You can view node titles in the workflow map.

All nodes have properties, except for the start node and for the stop node. You configure nodes by modifying the properties to match your business requirements. You specify properties for a node in the Properties window for the node. Each node must be configured individually. You can configure nodes at any point while you build a process, but as a best practice, configure nodes as you add them to the canvas.

The Workflow Designer application includes the types of nodes that can represent various points in your business process. A node can be any of the following types:

Table 1. Types of nodes

Node	Description
 Start node	Indicates the point when a record starts a workflow process. When you create a process, a single start node displays on the canvas. Each process can have only one start node. You cannot delete start nodes.
 Condition node	Indicates an evaluation of the record, based on data in the record. Use a condition node to enable a true evaluation or a false evaluation of the record, and then direct the record based on that evaluation. When a condition node is generated, it evaluates the record based on the Structured Query Language (SQL) statement defined in the properties for the node. The record is then routed to either the positive connection line or to the negative connection line exiting the node. You can use the SQL Expression Builder tool, accessed from the Workflow Configuration > Escalations application, to create an SQL statement.
 Interaction node	Provides an option for a user interaction with a record. Use interaction nodes to guide a user through a structured interaction with a record. A process can have one or more interaction nodes. You do not have to include interaction nodes in a process. A manual input node precedes an interaction node. If an interaction node leads to an application not related to the object on the process record, place a stop node after the interaction node. The original process shuts down as the new record displays.
 Manual input node	Indicates a need for user input because there are multiple directions that a record can take in a process. Use a manual input node to have the assignee decide what happens next. When a manual input node is generated, a window displays. The manual input window contains a menu of options for routing the record. When the assignee selects an option, any actions or notifications associated with the option are triggered.
 Subprocess node	Indicates that a separate workflow process is contained within another workflow process. Use a subprocess node to break down a complicated business process into smaller, self-contained units. For example, you could have a subprocess that handles records in different sites, or that handles different classes of work orders. When the record encounters a stop node within a subprocess, the stop node is returned to the main process. The stop node is returned at the same point where it left the process and on the same type of routing line on which it finished.
 Task node	Indicates when a user is to be given an Inbox assignment. The user has two choices. For example, the user can either approve a record or reject a record. Use task nodes when your business process requires that a user evaluate a record. Create a task assignment that routes the record to one or more individuals. Workflow comes to a stop at a task node until the assigned user has routed the record.
 Wait node	Indicates that the progress of a record through a process pauses until a required condition is met. Use a wait node to create a reaction to a database event, such as a status change, or a record update. A process can have one or more wait nodes. You do not need to include wait nodes in a process. A wait node cannot precede a node that requires user interaction, such as an interaction node or a manual input node.
 Stop node	Marks the end of a workflow process. That is, the point where a record leaves control of the process. When you create a process, a single stop node is placed on the canvas. Use the stop node tool in the palette to place additional stop nodes on the canvas.

## Connection lines

All nodes in a workflow process, except for the start nodes and the stop nodes, must be connected to two other nodes. You can draw positive and negative types of connections between nodes.

### Positive connections

A solid black line on the canvas represents a positive connection. A positive connection indicates a positive outcome. For example, an action was performed, a record was approved, or a record met the condition specified by the node. Use the Connect Nodes tool  to draw a positive line between nodes.

### Negative connections

A dashed red line on the canvas represents a negative connection. A negative connection indicates a negative outcome. For example, a record was canceled, a record was rejected, or a record did not meet the condition specified by the node. Use the Negative Connection tool  to draw a negative line between nodes.

## Types of nodes and guidelines for connection lines

The following table describes the types of nodes and lists the guidelines for the connection lines that you can draw between one node and another node:

Table 1. Node guidelines

Type of node	Description	Lines permitted entering a node	Lines permitted or required exiting a node
--------------	-------------	---------------------------------	--------------------------------------------

Type of node	Description	Lines permitted entering a node	Lines permitted or required exiting a node
Start node 	Indicates the point when a record starts a workflow process.	None.	One positive line is required.
Condition node 	Indicates an evaluation of the record, based on data in the record.	One or more positive lines; one or more negative lines.	One positive line and one negative line are required.
Interaction node 	Provides an option for a user interaction with a record.	One or more positive lines; one or more negative lines.	One positive line is permitted.
Manual input node 	Indicates a need for user input because there are multiple directions that a record can take in a process.	One or more positive lines; one or more negative lines.	More than one positive line is required. Negative connections exiting the node are not allowed.
Subprocess node 	Indicates that a separate workflow process is contained within another workflow process.	One or more positive lines; one or more negative lines.	One positive line and one negative line are required.
Task node 	Indicates when a user is to be given an Inbox assignment.	One or more positive lines; one or more negative lines.	One positive line is required; one negative line is allowed.
Wait node 	Indicates that the progress of a record through a process pauses until a required condition is met.	One or more positive lines; one or more negative lines.	One positive line is required.
Stop node 	Marks the end of a workflow process. That is, the point where a record leaves control of the process.	One or more positive lines; one or more negative lines.	None.

## Person records

You use the People application to create, to modify, to view, and to delete records for individuals. The People application stores information about individuals, such as users, laborers, asset owners, and supervisors who receive workflow notifications.

A person record is a record for an individual whose name could appear as a text field value. Workflow assignments are made to roles. All roles resolve to a person, to a person group, or to an e-mail address.

The name of a person is used as the text field value in the **Reported By** field or in the **Affected Person** field on a service request, in the **Supervisor** field on a labor record, or in a **Ship To** field or **Bill To Attention** field on a purchasing record.

You must create a person record for any individual who is assigned tasks as part of a workflow process. When you create records in the Labor application and in the Users application, you must create a person record. Person records might have to be created for other individuals who do not have records in the Labor application or in the Users application.

Person records that you create for use as part of workflow processes must contain values in the following fields:

### Supervisor

The person who oversees or manages the individual. This information is used for escalations.

### Primary Email

The email address where notifications are sent.

### Primary Calendar

The work calendar that the individual follows. This information is used when determining assignments and escalations.

### Primary Shift

The shift that the individual works. This information is used when determining assignments and escalations.

### Workflow Email Notification

The circumstances when the individual must receive email notifications for task assignments. The default value is PROCESS.

### Workflow Delegate

The person identifier of the individual designated to receive assignments when the primary individual is unavailable for an extended period (for example, on vacation or on sick leave)

### Delegate From and Delegate To

The time period when workflow processes must route assignment to the delegate. If these fields are empty, all workflow assignments are routed to the delegate.

For complete information on People, see the help for [People](#).

## Person groups and workflow assignments

You use Person Groups to specify that a group member for a specific organization or site must be used when making workflow assignments. Workflow assignments are made to roles.

Different workers can perform the same role on different shifts. Creating person groups for roles such as "supervisor" or "safety engineer" simplifies a workflow process. Creating person groups also reduces the need for revisions as individuals move in and out of roles.

Workflow assignments are based on entries in the person group role record. If the Broadcast check box is selected on the role record, the task is assigned to all members of the person group. If the check box has not been selected, the product goes through the following steps to determine the appropriate role for the task:

- The product checks for a person record with appropriate entries in the Calendar and Shift fields for the assignment, verifying the group members in the order specified by the Sequence field. If no sequence values are specified, the assignment is made to the first group member with an appropriate entry in the Calendar and Shift fields. The search logic depends on whether the workflow process is for an application at the site, the organization, or the system level.
  - If the application is at the site level, the first check is for person records where the value in the Use for Site field matches the site of the record in the workflow process. The next check is for person records where the value in the Use for Organization field matches the Site of the record in the workflow process. The third check is for person records where there is no value in either the Use for Site field or the Use for Organization field.
  - If the application is at the organization level, the product checks for person records where the value in the Use for Organization field matches the organization of the record in the workflow process. The next check is for person records where there is no value in either the Use for Site field or the Use for Organization field.
  - If the application is at the system level, the product checks for person records where there is no value in either the Use for Site field or the Use for Organization field.
- If there is no person whose Calendar and Shift entries match the assignment, the product checks for a person record who is listed in the Site Default field. (This field is optional; you can specify a single site default per site.)
- If no site default is specified, the product checks for a person record who is checked in the Organization Default field. (This field is optional; you can specify only a single organization default per organization.)
- If no organization default is specified, the Group Default person is assigned. By default, the first person added to a person group becomes the group default, but you can modify this setting.

For complete information on Person Groups, see [Person Groups](#).

---

## Roles and role records

You use the Roles application to create role records. A role is a function within a business. A role can represent a specific job title (such as a department manager), an assigned duty (such as a watch officer), a class file, and a data set.

Workflow Inbox assignments and workflow notifications are always made to roles. All role records point to one or more person identifiers. Role records can also point to a table and column in the database that represent a person. When a role is encountered in a workflow process, it resolves the role to a person group or to an individual person record.

You use roles when you create and configure the following workflow elements:

- Communication templates (recipients)
- Escalations
- Negative connection lines (notifications)
- Positive connection lines (notifications)
- Manual Input nodes (notifications)
- Task nodes (assignments and notifications)
- Wait nodes (notifications)

By using role records instead of person records for assignments and notifications, you can create generic workflow processes that require less maintenance as individuals move in and out of different roles within your company.

For complete information on Roles, see [Roles](#).

---

## Communication templates

You use Communication Templates to create and to manage templates that generate email messages about the status of workflow records.

When you create a communication template, you can specify the following information:

- The business object that the template can be used for
- The applications where the template can be used
- The address that the email must be sent from
- The address that replies must be sent to
- The subject line of the message
- The body of the message
- One or more recipients of the message. You can send messages to roles, persons, person groups, and email addresses. You can specify whether each recipient must also receive a carbon copy (CC) or blind carbon copy (BCC) of the message.
- Documents to include as attachments when the message is generated

You can use substitution variables when you create the subject line and the body of your message. The last memo substitution variable ensures that the last memo saved to the database displays in the list of memos. The current memo substitution variable ensures that the memo is available immediately. When an email is generated by using that template, it replaces the substitution variables from the template with the corresponding values from the record.

For complete information about Communication Templates, see the help for [Communication Templates](#).

---

## Notifications

You use the Workflow Designer application to create notifications. A notification is an email message that is generated by the progress of a record through a workflow process.

The Workflow Designer application uses communication templates for notifications. You use the Communication Templates application to create and to manage the templates.

When you create communication templates for workflow notifications, you specify roles as the recipients rather than persons or person groups. Many individuals come into contact with a record as it moves through its life cycle. Often these individuals need to know about the progress of a record. You can design your workflow process to generate notifications as required by your business process. Notifications can be made through email or through a pager, providing that your paging system supports email.

You can configure the following workflow components to generate notifications:

- Escalations
- Negative connection lines
- Positive connection lines
- Manual input nodes
- Task nodes
- Wait nodes

You cannot modify a communication template in the Workflow Designer application. You must create separate templates for your notification requirements.

---

## Escalations and action groups

You use Escalations to create escalation records. You can use escalations to escalate workflow assignments before they time out in the Inbox for the recipient.

When you assign specific steps in a workflow process to employees, those assignments display in their Inbox. If the assignments are not completed promptly, they time out in the Inboxes for the recipients. When this event happens, you can use escalations to assign the tasks to other people. Escalations help to get tasks completed on time and help to prevent work backlogs.

An action group is a type of action record that includes multiple actions and a sequence to use when performing the actions. Escalations are always associated with action groups.

You can associate an action group with an escalation in either of the following ways:

- You can create action groups using the Actions application and then click Detail Menu next to the Action Group field on the Actions sub tab to associate the action group with the escalation.
- You can create action groups in the Escalations application by clicking New Row on the Actions sub tab. When you create an action group in the Escalations application, the action group receives a generated name. The actions receive assigned sequence numbers. The sequence numbers are based on the order in which you add the actions to the group.

For complete information on Escalations, see the help for [Escalations](#).

---

## Escalation points

An escalation point defines the attributes of a record that trigger an action. You can define one or more escalation points for an escalation and specify one or more actions and notifications for each escalation point.

You can create the following categories of escalation points:

- Elapsed time since a past event - Compares the current date and time to the specified field that represents an event in the past. You can select from a list of DATETIME fields on the record (for example, a Start Date on a workflow assignment, an Actual Start date on a work order, or a Status Date on a record that includes status).
- Time until a future event - Compares the current date and time to the specified field that represents an event in the future (for example, a Renewal Date on a contract, a Due Date on an invoice, or a Target Finish date on a work order).
- Condition - Condition without a time measurement. If you want to trigger the actions and notifications of an escalation based on a condition that does not have a time measurement, you can specify the condition in the Escalation Point Condition field. You also can use the Condition field to specify that the escalation point must be applied to only the subset of records specified by the condition

---

## Actions and action records

Workflow processes use actions to move records through a process and to trigger events, such as status changes. You define actions in the Actions application and then you reuse them in other workflow processes that you create.

You use actions when you create and configure the following Workflow elements:

- Escalations
- Negative connection lines

- Positive connection lines

For complete information on the Actions application, see [Actions associated with escalation points](#).

## Action types

When you create an action record, you specify the action type to help determine what kind of action to take when the action is encountered in a process.

An action can be one of the following types:

### APPACTION

Used to specify that an application action be initiated. For this type of action, there must be values in the Object and Value fields. When creating an APPACTION type action, you can specify one of the following actions if it is available for the specified object:

- Apply SLA - Apply the specified service level agreement.
- Create Change - Create a change work order.
- Create Incident - Create an incident ticket.
- Create Problem - Create a problem ticket.
- Create Release - Create a release work order.
- Create SR - Create a service request ticket.
- Create WO - Create a work order.
- WF Accept - Workflow auto-accept. Accepts the record and routes it to the positive path in the workflow process.
- WF Escalate - Escalate the record in the workflow process and reassigns the assignment to its escalation role.
- WF Initiate - Initiate® a workflow process. This option requires a value in the Parameter/Attribute field.
- WF Reject - Workflow auto-reject. Rejects the record and routes it to the negative path in the workflow process.

### CHANGESTATUS

Used to specify that the status of a record changes. There must be a value in the Object field and a status in the Value field for this type of action.

### CUSTOM

Used to specify that a custom class file should run. There must be a value in the Object field and the name and path of a class file in the Value field for this type of action.

### EXECUTABLE

Used to specify that a program on the server should run. For this type of action, the name of a program file must be in the Value field.

### GROUP

Used to specify that the system should run the sequence of actions that you specify in the Members table window.

### SETVALUE

Used to specify that the system should set the value of a specified field. For this type of action, values are required in the Object, Value, and Parameter/Attribute fields.

## Record routing

Activating a workflow process indicates that the process is ready to have records routed through it. Before you activate a record, consider whether you want records to be routed into a process manually or automatically.

A record can enter a workflow process by any of the following methods:

- When you click the Route button on the toolbar.
- When you select the Route Workflow action.
- When you create and save a record, the record is routed into the workflow process. You can set one process per object to initiate automatically.
- You can set workflow options in the Organizations application. These options specify that generated records must be routed into a particular workflow process. You can specify a workflow process to manage the following records:
  - Work orders that are generated from a preventive maintenance record
  - Purchase requisitions that are generated through the inventory reorder process
  - Purchase orders that are generated through the inventory reorder process
  - Work orders that are generated when a purchase order for a rotating asset is approved
- A record can be routed from one workflow process to another in any of the following ways:
  - With an interaction node
  - With a subprocess node
  - With a WFINITIAE action specified on a connection line leaving a node
- A record can be automatically routed into a process with an escalation action.

## Domains for status synonyms

If your business processes for record approvals or for status changes involve multiple steps for each approval or status change, you can create synonym statuses that model those processes.

For example, your business process requires that three people review a record before it is considered approved. There is a single status for waiting for approval and a single status for approved. You can create synonym statuses of waiting for approval that represent each of the preliminary approvals before the record is considered approved.

You add synonym values to a value list in the Domains application in your nonproduction environment. Import the changes to your production environment.

---

## Examples of workflow processes

You can use the Workflow application to manage records used in various business processes. The examples provided are basic because of the limited number of nodes that can be displayed.

The examples illustrate some of the capabilities of the Workflow application and must not be used in a production environment. The product demonstration database includes workflow processes that display simple processes.

- [Example of a purchase requisition business process](#)

You can create a workflow process to handle a purchase requisition. When you create a purchase requisition, your supervisor must approve it.

- [Example of a service request business process](#)

A workflow process can be created to handle service requests. An enterprise uses the software for service desk functions. The enterprise has designed a workflow process that guides a service desk agent through the initial steps of the record management process.

- [Example of a work order business process](#)

A workflow process can be created to handle a work order. An enterprise has configured the system to route all new preventive maintenance work orders that are generated through the preventive maintenance work order generation cron task into a workflow process.

---

## Example of a purchase requisition business process

You can create a workflow process to handle a purchase requisition. When you create a purchase requisition, your supervisor must approve it.

When an approved purchase requisition reaches the purchasing department, a purchasing agent evaluates the record, and then performs one of the following steps:

- Rejects the requisition
- Creates a request for quotation to receive bids for the purchase
- Creates a purchase order from the requisition

The record then exits the workflow process for the purchase requisition.

For example, you can create a requisition such that if the total is less than \$500, the requisition is routed to the purchasing department. If the requisition total exceeds \$500, the requisition requires the approval of the department manager before it can be routed to the purchasing department. If the requisition total exceeds \$1,000, the requisition requires the approval of a vice president before it can be routed to the purchasing department. If the requisition total exceeds \$5,000, the requisition requires the approval of the chief financial officer before it can be routed to the purchasing department.

The diagram that follows illustrates one way that you might map the preceding scenario. The nodes and the connection lines in this example are arranged so that they are easy to see at a glance, but they can be arranged differently. You could add or remove stop nodes, and the workflow process would still illustrate the same business process.

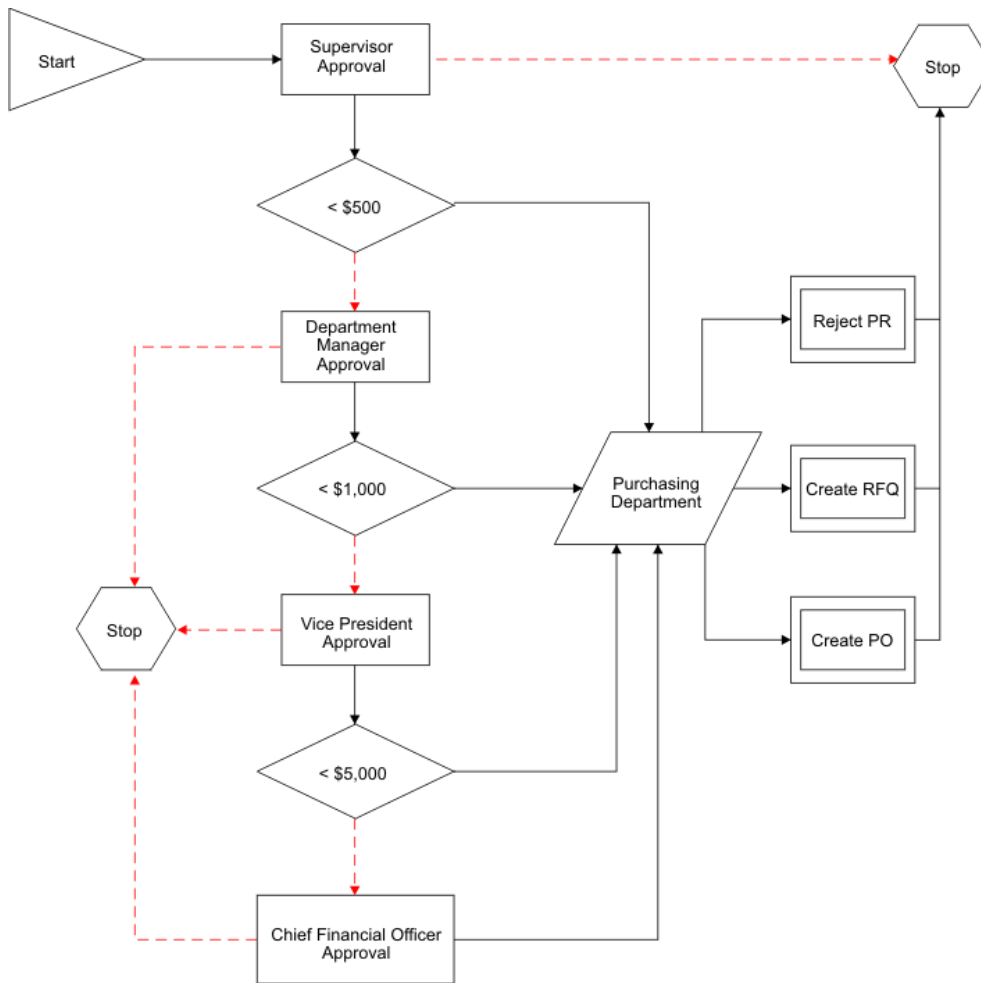

Figure 1. Example of a purchase requisition workflow process

## Example of a service request business process

A workflow process can be created to handle service requests. An enterprise uses the software for service desk functions. The enterprise has designed a workflow process that guides a service desk agent through the initial steps of the record management process.

When a service desk agent takes an incoming telephone call, the agent creates a service request ticket to record the interaction. The enterprise requires the agent to record the name of the caller and telephone number. The agent also must type a short description of the service request. For example, a request for information, maintenance, and a classification for the service request. Depending on the type of service request, the agent also might type information about the asset or the location.

When the agent saves the service request ticket, the product starts the service request workflow process. The Manual Input window opens with the following options:

- I must type additional information regarding this service request.
- I must type information about tickets or work orders related to this service request.
- I must make an entry in the Work Log or Communications Log.
- I have completed data entry for this ticket.

If the agent requests to type more information, either the Service Request tab, the Related Records tab, or the Log tab display, depending on which option the agent selected. When the agent indicates the completion of data entry for a service request, the product evaluates the data on the record.

If the agent has not provided asset or location data, the Manual Input window displays the following options:

- Close ticket - informational call
- Close ticket - unauthorized caller
- Close ticket - misdirected call
- Take no action

If an asset or a location is specified on the record, the Manual Input window opens with the following options:

- Take Ownership of ticket (**Take Ownership** action)
- Assign Ownership of ticket (**Assign Ownership** action)
- Create Incident record (**Create Incident** action)
- Create Problem record (**Create Problem** action)

- Create Change work order for an IT asset. (**Create Change** action)
- Create Work Order for a non-IT asset. (**Create Work Order** action)
- Take no action on this ticket.

The following diagram illustrates one way that the preceding scenario might be mapped.

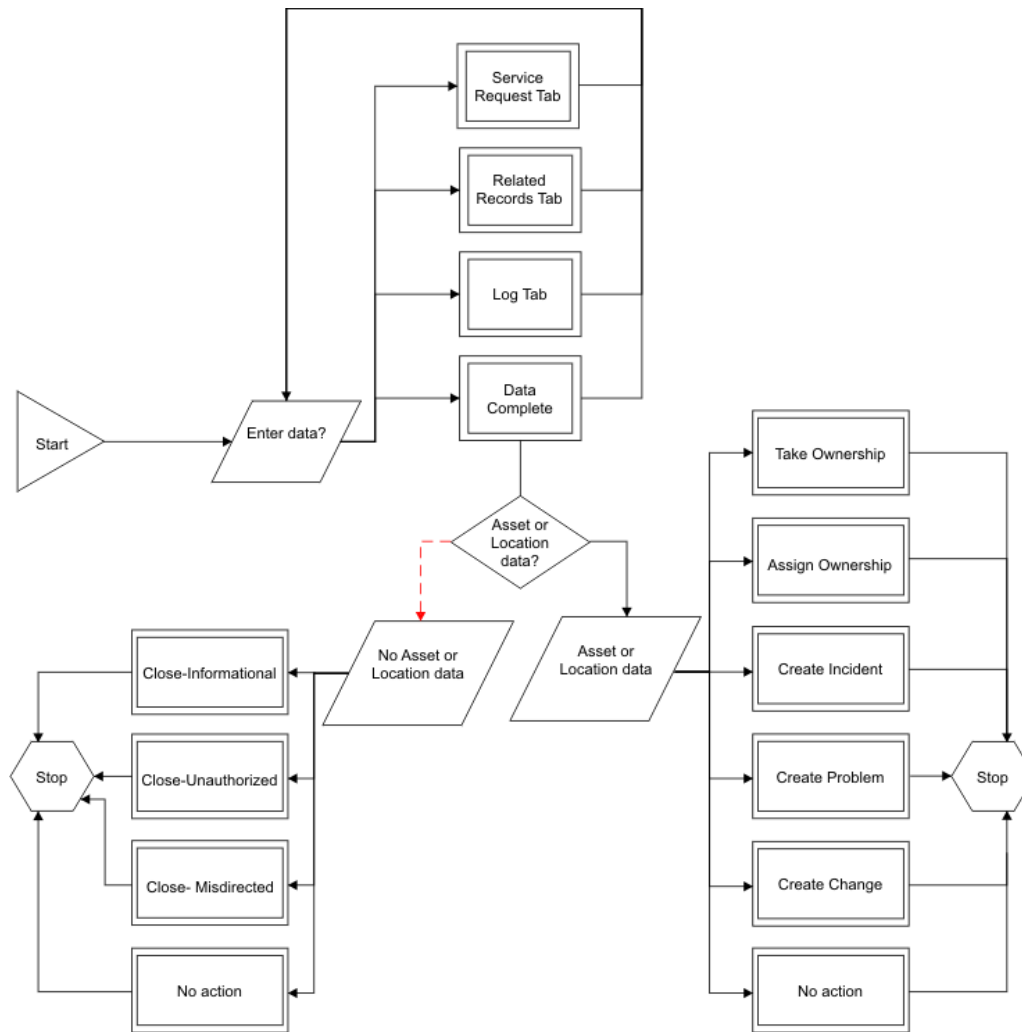

Figure 1. Sample Service Request Workflow

## Example of a work order business process

A workflow process can be created to handle a work order. An enterprise has configured the system to route all new preventive maintenance work orders that are generated through the preventive maintenance work order generation cron task into a workflow process.

The first step is to evaluate the priority of the work order, as follows:

- If the preventive maintenance work order is high priority or has a null value in the Priority field, it is routed to a work planner for immediate review and approval.
- If the preventive maintenance work order has a low priority, it is routed to a Stop node and exits the process.

All preventive maintenance work orders then go through a financial approval process. Work orders with an estimated total cost of less than \$500 are automatically approved. The maintenance supervisor must review and approve work orders with an estimated total cost of more than \$500.

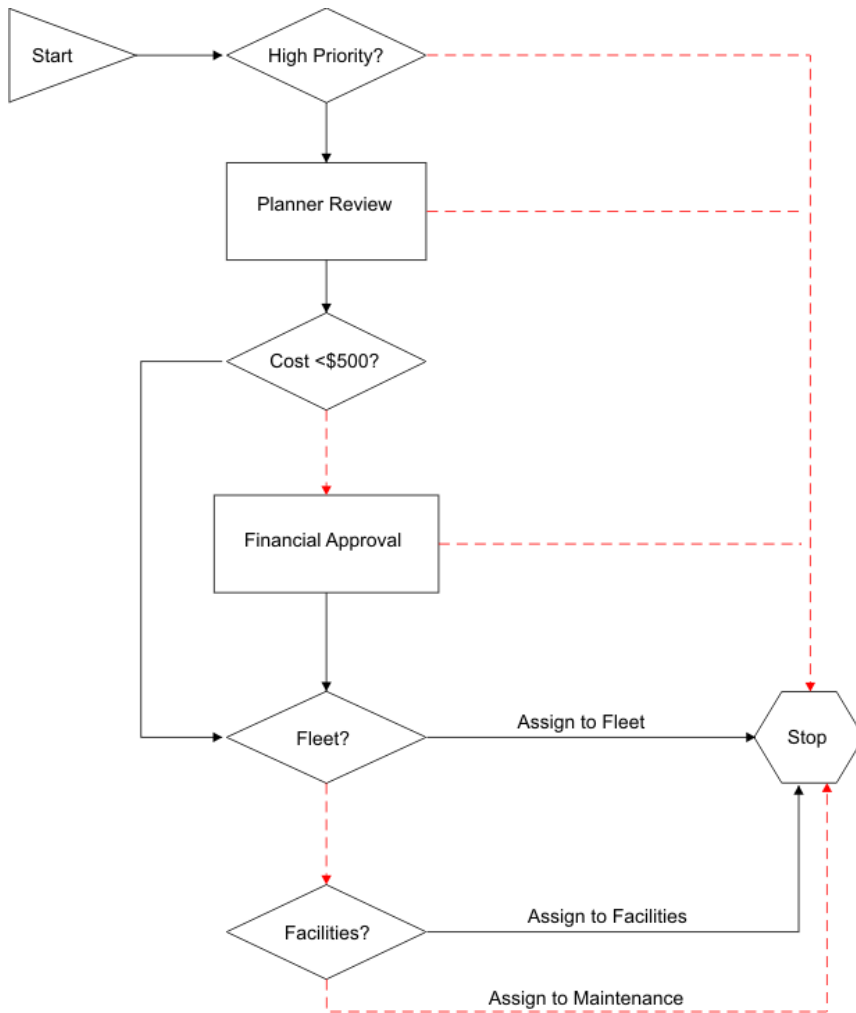

After a work order passes the financial approval process, it must be assigned to a work group, as follows:

- If the preventive maintenance work order is for a vehicle, the system assigns it to the fleet maintenance group.
- If the preventive maintenance work order is for a building or location, the system assigns it to the facilities maintenance group.
- The system assigns all other preventive maintenance work orders to the maintenance group.

After the system assigns the work order to a maintenance group, the work order exits the workflow process.

The following diagram illustrates one way that you might map the preceding scenario.

Figure 1. Example of a preventive maintenance work order workflow

## Configuring for Workflow

Workflow applications require minimal configuration before you can create workflow processes.

- [Configuration prerequisites](#)  
The Workflow Designer application requires a Java™ Virtual Machine (JVM) on the client workstation. If you do not have a JVM installed, the product cannot display the Workflow canvas.
- [Creating workflow processes](#)  
You can create workflow processes that reflect your business processes. A workflow process defines the actions and notifications that can occur at different points in a business process.
- [Testing workflow processes](#)  
You test your workflow processes in a test environment by routing a record through each possible path. Perform these tests before you export your processes to your production environment to ensure that each workflow process accurately reflects your business process.
- [Modifying workflow processes](#)  
Testing your workflow processes might reveal areas for improvement, or over time your processes might evolve due to changes in your business, increased efficiencies, and so on. You can add, modify, or delete process elements at any time until the process has been enabled. Once a process has been enabled, create a revision of the process if you want to modify it.
- [Integrating workflow processes](#)  
You use workflow processes to perform tasks, to execute actions, and to send notifications. After you create workflow processes, you can test them in an environment other than your working environment to fine-tune their behavior. After you test the processes, you can integrate them into your working environment.
- [Workflow/Inbox Assignments portlet](#)  
The Workflow Inbox/Assignments is one of the portlets that might appear on your Start Center. If your workplace has implemented the Workflow feature, a list of your task assignments displays in the Inbox.

## Configuration prerequisites

The Workflow Designer application requires a Java™ Virtual Machine (JVM) on the client workstation. If you do not have a JVM installed, the product cannot display the Workflow canvas.

To design and create workflow processes, you must be familiar with the following tools, processes, and concepts:

- The business processes for the enterprise
- Product applications
- Object structures and data relationships
- Structured query language (SQL) statements and syntax
- [Workflow administration](#)  
You use the Workflow Administration application to view and to manage active instances of workflow processes.
- [Security permissions for workflow processes](#)  
If you design workflow processes, you must belong to a security group with security permissions.
- [Synonym statuses](#)  
You can create synonym statuses if your business processes for record approvals or for status changes involve multiple steps for each approval or status change.
- [Stopping instances of workflow processes](#)  
When you route a record into a workflow process, an active instance of that process is created to manage that individual record. You can view and stop workflow processes for records for any Workflow-enabled application.
- [Test environment design](#)  
Workflow processes are automated and can be complex. For this reason, you can create a test environment where you design and test processes without affecting records in your production environment.

---

## Workflow administration

You use the Workflow Administration application to view and to manage active instances of workflow processes.

The Workflow Administration application contains a window that displays a row for each active instance of a workflow process. A record can show up multiple times if it is controlled by multiple workflow instances. You can see which version of a revised process was used to create each instance, the person identifier of the individual who routed each record into Workflow, and the date and time that the process was initiated.

The recordkey (for example, the work order number or the purchase order number) displays with the site identifier in the Owner Description field.

---

## Security permissions for workflow processes

If you design workflow processes, you must belong to a security group with security permissions.

Users are not automatically granted access to workflow actions. An administrator must use the Security Groups application to grant users security permissions to workflow actions. The workflow actions appear in the Security Groups application when you add workflow support to an application. You can grant users access to actions before you activate a process.

Additionally, you require security permissions for the following applications:

- Actions
- Communication Templates
- Escalations
- Inbox/Assignments Setup
- People
- Person Groups
- Roles
- Workflow Administration
- Workflow Designer
- Workflow Inbox (portlet)

If you or your group are responsible for testing workflow processes, you must have security permissions for other applications, depending on the processes that are being tested.

---

## Synonym statuses

You can create synonym statuses if your business processes for record approvals or for status changes involve multiple steps for each approval or status change.

For example, your business process might call for three different people to review a record before it is considered approved. There is a single status for waiting for approval and a single status for approved. You can create synonym statuses of waiting for approval that represent each of the preliminary approvals before the record is considered approved.

You use the Domains application to add synonym values to a value list. For more information about creating synonym statuses, see the Domains Help for this product.

---

## Stopping instances of workflow processes

When you route a record into a workflow process, an active instance of that process is created to manage that individual record. You can view and stop workflow processes for records for any Workflow-enabled application.

## Before you begin

---

The application associated with the workflow process record must be enabled for Workflow.

## About this task

---

When you stop a workflow process, you are only stopping the single instance of the workflow process that controls a particular record. To deactivate a workflow process, use the Workflow Designer application. When you stop a process instance, the following tasks are performed:

- The record is removed from the control of the workflow process.
- A transaction is written to the workflow history of the record. Workflow history remains with a record permanently, even after the record has left the control of Workflow.
- Specified notifications are sent to past assignees, current assignees, or both. You can use a communication template to create a notification, or type the subject, message, and role recipients manually.

## Procedure

---

1. To stop a workflow process, complete one of the following steps:
  - In a Workflow-enabled application, display the record you want to remove from Workflow. From the Select Action menu, choose Stop Workflow.
  - In the Workflow Administration application, select the active process that you want to stop. Click Stop Process on the assignment line.
2. Optional: Create an email notification. The system defaults to the WFSTOP communication template. You can use the WFSTOP communication template to create the notification. You can also manually specify the subject, message, and role recipients.
3. Click OK. The system stops the workflow process. The system also sends any notifications.

## Test environment design

---

Workflow processes are automated and can be complex. For this reason, you can create a test environment where you design and test processes without affecting records in your production environment.

Design your test environment so that it is a copy of your production environment. Your test database must include enough data and users so that you can thoroughly test each workflow process. You use the applications in the Integration module to migrate a workflow process from your test environment to your production environment.

## Creating workflow processes

---

You can create workflow processes that reflect your business processes. A workflow process defines the actions and notifications that can occur at different points in a business process.

## About this task

---

A workflow process consists of the header information for the record, the nodes, the connection lines, and the properties specified for the nodes and the connection lines.

## Procedure

---

1. On the toolbar of the Workflow Designer application, click New Process.
2. In the Process field, type a name for the process.
3. Optional: Type a description.
4. In the Object field, type a value or click Select Value and select an object.
5. Click Save Process.

## What to do next

---

You are now ready to use the canvas to add nodes and connection lines and to configure the properties of each of the elements of the process.

- [Specifying the properties of actions](#)  
You can specify the properties of an action. An action is an event that is triggered by the progress of a record through a workflow process.
- [Specifying the properties of condition nodes](#)  
A condition node indicates an evaluation of the record, based on data in the record. You use a condition node to have a true or false evaluation made on the record and then direct the progress of the record based on that evaluation.
- [Specifying the properties of interaction nodes](#)  
You use interaction nodes to specify the actions that occur in a workflow process between different applications.
- [Specifying the properties of manual input nodes](#)  
You use manual input nodes in a workflow process to designate options that users are presented with during a workflow process.

- [Specifying the properties of subprocess nodes](#)  
You can specify the properties for subprocess nodes. Subprocess nodes are processes that have been created to be used within a main workflow process.
- [Specifying the properties of task nodes](#)  
A task node indicates when a user has two choices, such as approving or to rejecting a record. You use task nodes when your business process requires you to evaluate the record. You also use task nodes when you want to create a task assignment that routes the record to one or more individuals.
- [Specifying the properties of wait nodes](#)  
You can specify the properties of wait nodes. Wait nodes specify that the process is halted until a specific event occurs.
- [Adding nodes and connections lines](#)  
You create a workflow process by inserting nodes and connection lines on a workflow canvas.
- [Setting a workflow process to automatically initiate](#)  
You can specify that when a user creates and saves a new record in an application, the record is automatically routed into a workflow process. Each object can have only a single process that is automatically initiated.
- [Setting processes to not auto-initiate](#)  
You can specify that when a record is created and saved in an application, the record is not routed into a workflow process. Each object can have only a single process that is initiated automatically.

---

## Specifying the properties of actions

You can specify the properties of an action. An action is an event that is triggered by the progress of a record through a workflow process.

### About this task

---

To trigger actions, you can configure the following workflow components:

- Negative connection lines
- Positive connection lines

### Procedure

---

1. From the List tab of the Workflow Designer application, select a process with properties to be modified.
2. In the Actions window of the Process tab, click Edit Properties.
3. In the Action field, specify a value.
4. In the Instruction field, type text to describe to the run-time user what specific action occurs for routing and manual inputs.
5. Click Condition Expression Builder.
6. Select the Custom Class check box to specify that a custom class file is used to evaluate the record.
7. In the Communication Template field, specify a value.
8. In the Send To field, specify a value.
9. In the Subject field, type the subject of the notification e-mail.
10. In the Message field, type the message of the notification e-mail.
11. Click OK and click Save Process.

---

## Specifying the properties of condition nodes

A condition node indicates an evaluation of the record, based on data in the record. You use a condition node to have a true or false evaluation made on the record and then direct the progress of the record based on that evaluation.

### About this task

---

When a condition node is encountered, the record is evaluated based on the Structured Query Language (SQL) statement defined in the node properties. The record is then routed to either the positive or the negative connection line exiting the node. Use the Condition Node  tool in the Workflow palette to place a new condition node on the canvas. A workflow process can have one or more condition nodes, but you do not have to include condition nodes in a process.

You can specify the following properties for condition nodes:

Title

Type or modify the node name and description.

Expression

Used to specify the SQL statement that tests one or more field values on the record. The product returns either a true result or a false result. You can define a simple expression or a complex expression, based on the needs of your business process. You can use substitution variables in the SQL expression. When the product encounters the condition node during a condition test, it substitutes values from the current record for the table and column information based upon the specified substitution variables. Use the Expression Builder to create your SQL expression.

Custom Class

Used to specify the custom class file that performs the condition test. Locate custom class files in the product directory.

---

### Procedure

1. From the List tab of the Workflow Designer application, select a process with properties to be modified.

2. From the Canvas tab, right-click the condition node and select Properties.
3. Optional: Type a description.
4. Click Condition Expression Builder.
5. Select the Custom Class check box.
6. Click OK and click Save Process.

---

## Specifying the properties of interaction nodes

You use interaction nodes to specify the actions that occur in a workflow process between different applications.

### About this task

---

Use the Interaction Nodes Properties window to specify the following properties for interaction nodes:

**Application**

Used to specify the application that displays.

**Tab**

Used to specify the tab that displays. Use the tab identifier from the application presentation file as the value for the tab name. You can view this information in Application Designer. Tab identifiers are not in the database. You must specify tab names manually.

**Action**

Used to specify an action that either displays or that is performed by the product. You can select from actions available by means of a toolbar button or from the Select Action menu.

**Relation**

Used to create an interaction that leads to another application. The information in the Relation field determines which record to display when the application opens.

**Process**

Used to specify an active workflow process for the specified application. The process starts on the current record upon arrival in the target application.

**Direction Title**

Used to specify the title of the message window that displays.

**Direction Body**

Used to specify the text of the instructions that displays in a message window.

The absence of a title or the absence of a body does not create a window.

---

### Procedure

1. From the List tab of the Workflow Designer application, select a process with properties to be modified.
2. From the Canvas tab, right-click the interaction node  and select Properties.
3. Optional: Type a description.
4. In the Application field, specify a value.
5. In the Tab Name field, type the tab identifier from the XML presentation file.
6. In the Action field, specify a value.
7. In the Relation field, specify a value.
8. In the Launch Process field, specify a value.
9. In the Directions Title field, type the title of the message window.
10. In the Directions Body field, type the instructions that the product displays in the message window.
11. Click OK and click Save Process.

---

## Specifying the properties of manual input nodes

You use manual input nodes in a workflow process to designate options that users are presented with during a workflow process.

### About this task

---

Use the Manual Input Properties window to specify the following properties for manual input nodes:

**Title**

Used to specify or modify the node name and the description.

**Display One**

Used to specify what the product does if a user has security permissions to only one specified option.

**Actions**

Displays actions associated with the connection lines that exit from the node. Add rows to the Actions window by drawing connections that exit the node. You can type a number in the Sequence column to specify the order in which options are presented to a user. The Instruction displays for each row in the

Manual Input window.

#### Notifications

Used to specify any notifications that the product generates if the record travels through a connection line that exits the node. You can use a communication template to create one or more notifications. You can also choose to specify the subject, message, and role recipients manually.

## Procedure

---

1. From the List tab of the Workflow Designer application, select a process with properties to be modified.
2. From the Canvas tab, right-click the manual input node  and select Properties.
3. Optional: Type a description.
4. Select the Display One check box to specify the action that occurs when a user has security permissions to one specified option.
5. In the Action field, specify a value.
6. In the Communication Template field, specify a value.
7. In the Send To field, specify a value.
8. In the Subject field, type the subject of the notification e-mail.
9. In the Message field, type the message of the notification e-mail.
10. Click OK and click Save Process.

## Specifying the properties of subprocess nodes

You can specify the properties for subprocess nodes. Subprocess nodes are processes that have been created to be used within a main workflow process.

### About this task

---

Use the Subprocess Properties window to specify the following properties for subprocess nodes:

#### Title

Used to specify or modify the node name and the description.

#### Subprocess

Used to type the name and the description of a workflow process record. The subprocess must meet the following criteria:

- The process must exist in the Workflow Designer application.
- The process must be associated with the same object as the main process.
- The process must be enabled, but not activated.

## Procedure

---

1. From the List tab of the Workflow Designer application, select a process with properties to be modified.
2. From the Canvas tab, right-click the subprocess node  and select Properties.
3. Optional: Type a description.
4. In the Subprocess field, specify a value.
5. Click OK and click Save Process.

## Specifying the properties of task nodes

A task node indicates when a user has two choices, such as approving or to rejecting a record. You use task nodes when your business process requires you to evaluate the record. You also use task nodes when you want to create a task assignment that routes the record to one or more individuals.

### About this task

---

Use the Task Node Properties window to specify the following properties for task nodes:

#### Title

Used to specify or modify the node name and the description.

#### Time Limit

Used to specify the time limit for the assignee to complete the task before it is escalated.

#### Application

Used to specify which application the product uses to display the assigned record. Typically, the object is associated with a single application. In some cases, such as in Quick Reporting and Work Order Tracking, an object can be associated with more than one application. It might, for example, represent a clone or even a new custom application on that table.

#### Display One

Used to specify whether a single option is displayed when the user has security permissions to only one option.

- If the check box is selected, the product displays the single option in the Complete Workflow Assignment window.

- If the check box is cleared, the product performs the action.

#### WF Task Type

Used to add another task to the workflow process.

#### Assignments

Used to specify one or more roles to receive the task assignment. Specify at least one assignment per task node. A task assignment can be designated to a role or to an assignee relationship.

#### Notifications

Used to specify the notifications that the system generates as a record leaves the node. You can use a communication template to create one or more notifications. Or, you can specify the subject, message, and role recipients manually.

#### Perform Accept Action

Used to specify how the system routes the record when the assignment is made to a group.

- When any assignment is accepted - Used to specify that the system needs only one positive action to route the record to the positive connection line.
- When all assignments are accepted - Used to specify that all assignees must select the positive action in order for the system to route the record to the positive connection line. If a single assignee selects the negative option, the system routes the record to the negative connection line.

## Procedure

1. From the List tab of the Workflow Designer application, select a process with properties to be modified.
2. From the Canvas tab, right-click the task node  and select Properties.
3. Optional: Type a description.
4. In the Application field, specify a value.
5. In the Time Limit field, specify the time limit for the assignee to complete the task before it is escalated.
6. Select the Display One check box to specify what the system might do if the user has security permissions to only one specified option.
7. In the Assignments section, click New Row, and specify values for each of the fields that display.
8. In the Notifications section, click New Row, and specify values for each of the fields that display.
9. In the Perform Accept Action field, select one of the following options to specify how the record is routed:
  - a. When any assignment is accepted.
  - b. When all assignments are accepted.
10. Click OK, and click Save Process.

## Specifying the properties of wait nodes

You can specify the properties of wait nodes. Wait nodes specify that the process is halted until a specific event occurs.

## About this task

You can specify the following properties for wait nodes:

#### Title

Used to specify or modify the node name and the description

#### Wait List

Used to specify one or more system events. The first event to occur triggers the record to resume its progress through the process. Event names consist of three or four lowercase words, delimited by periods. For example, maximo.workorder.update or maximo.po.statuschange.appr.

- The first word is always `maximo`.
- The second word is the name of the business object (MBO). For example, `po`.
- The third word is one of the following words:
  - `statuschange`. If the event is a change of status, the event name has a fourth part; either the name of a specific status, for example, `appr`, or `*` for any status change.
  - `update`

#### Notifications

Used to specify the notifications that the system should generate as a record leaves the node. You can use a communication template to create one or more notifications. You can also specify the subject, the message, and the role recipients manually.

## Procedure

1. From the List tab of the Workflow Designer application, select a process with properties to be modified.
2. From the Canvas tab, right-click the wait node  and select Properties.
3. Optional: Type a description.
4. In the Event field, type an event name.
5. In the Communication Template field, specify a value.
6. In the Send To field, specify a value.
7. In the Subject field, type the subject of the notification email.
8. In the Message field, type the message of the notification email.
9. Click OK and click Save Process.

---

## Adding nodes and connections lines

You create a workflow process by inserting nodes and connection lines on a workflow canvas.

### About this task

---

Each workflow process includes start nodes and stop nodes. Start nodes and stop nodes do not carry user-defined information. The other types of nodes carry user-defined actions.

### Procedure

---

1. Select one of the following options:

Options	Step
To create a workflow process	Click Create a Workflow Process.
To configure a process that is enabled and activated	Select the process you want to revise and click Create Revision.

2. To add a node, select one of the following options:

To Add a Node	Step
In the Canvas tab	On the Workflow Designer toolbar, select Move/Add Nodes and drag the node onto the canvas.
In the Process tab	Click New Node.

3. To edit the properties of the node, select one of the following options:

Option	Step
In the Canvas tab	Double click the node, and edit the properties in the Condition Node Properties window.
In the Process tab	Click the Edit Properties icon.

4. Repeat step 2 to place other types of nodes onto the canvas.
5. To reposition nodes, in the Canvas tab, drag the node you want to move.
6. On the Workflow designer toolbar, select one of the following connection tools to create connection lines between nodes:
  - a. Click Connect Nodes to add a positive connection line.
  - b. Click Connect Nodes with a Negative Action to add a negative connection line.
7. Click a node and drag the line to another node. Lines must travel from one node to another node. The lines indicate the path for records to follow in the workflow process. The type of lines and the number of lines you can draw from each node varies depending on the type of node.
8. Click Save Process.

### What to do next

---

After adding nodes and connection lines, the next step is to validate the process to ensure its structural integrity.

---

## Setting a workflow process to automatically initiate

You can specify that when a user creates and saves a new record in an application, the record is automatically routed into a workflow process. Each object can have only a single process that is automatically initiated.

### Before you begin

---

A process must be validated, enabled, and activated before you can set it to automatically initiate.

### About this task

---

This action only routes records created by users. Records that the product creates automatically (for example, through a PM cron task or through the inventory reorder function) cannot be automatically routed into a process through this method.

### Procedure

---

1. In the Workflow Designer application, display an activated process record.
2. Select the Set Process to Auto-Initiate action.

---

## Setting processes to not auto-initiate

You can specify that when a record is created and saved in an application, the record is not routed into a workflow process. Each object can have only a single process that is initiated automatically.

### Procedure

---

1. In the Workflow Designer application, select the activated process record that you want to set to not auto-initiate.

2. Select the Set Process to Not Auto-Initiate action.
3. Click Save Process.

---

## Testing workflow processes

You test your workflow processes in a test environment by routing a record through each possible path. Perform these tests before you export your processes to your production environment to ensure that each workflow process accurately reflects your business process.

1. [Workflow process testing](#)  
Design your test environment so that it is a copy of your production environment. Your test database must include enough data and users so that you can thoroughly test each workflow process.
2. [Validating workflow processes](#)  
You must validate workflow processes to verify the structural integrity of the process.
3. [Enabling workflow processes](#)  
Workflow process records are in a draft or a development stage until you enable the record. Enabling a process involves validating the structure of the process.
4. [Activating workflow processes](#)  
You activate workflow records before they can be routed into a workflow process.
5. [Disabling workflow processes](#)  
Disabling a process prevents new records from being routed into the workflow process. Disabling a process does not affect records that are under the control of the process.
6. [Viewing workflow history](#)  
For auditing purposes, a record is maintained of all records that are routed through a workflow process. You can view a list of all user-initiated actions in the workflow process, for example, routing a record into a workflow process, or completing an assignment.
7. [Viewing workflow assignments from a Workflow-enabled application](#)  
The Workflow Map shows a graphic of a workflow process, including its nodes and connection lines. The current location of the map in a process is highlighted by a box around the node. You can view the workflow assignments for a record from within a workflow-enabled application. You use the Workflow Map to see where your assignment falls in the context of the workflow process as a whole.
8. [Viewing a Workflow Map](#)  
The Workflow Map shows a graphic of a workflow process. You can use the Workflow Map to see where your assignment falls in the context of the process as a whole.

---

## Workflow process testing

Design your test environment so that it is a copy of your production environment. Your test database must include enough data and users so that you can thoroughly test each workflow process.

You use the applications in the Integration module to migrate a workflow process from your test environment to your production environment:

- Validate, enable, and activate each workflow process in a test environment that contains sufficient sample data to test the process. Set up your environment to include test users who can receive assignments and notifications.
- Route records through all possible paths in the process, including all possible paths through any subprocesses. You might create test plans to help you verify that you have tested all possible routes in a process.
- Verify that assignments appear in the Workflow Inbox for users, and that email notifications are being generated.
- Determine whether the process is complete, or whether additional steps must be added.
- Determine that you have configured the process to make the necessary assignments, notifications, and so forth, that are required by your business process. If you have not configured the process, you must modify the process.
- Make any necessary additions, modifications, or deletions and retest the process.
- Use the integration applications to export your tested processes from your test environment to your production environment.

**Next topic:** [Validating workflow processes](#)

---

## Validating workflow processes

You must validate workflow processes to verify the structural integrity of the process.

---

### Before you begin

If you are validating a process that includes subprocesses, you must validate the subprocess records before you validate the main process.

---

### Procedure

1. From the List tab of the Workflow Designer application, select the process record that you want to validate.
2. Select the Validate Process action. If the process fails validation, a window displays that lists the errors. If the process passes validation, a message displays in the navigation bar.
3. Click Save Process.

---

## What to do next

You are now ready to enable the workflow process. Enabling a process locks the process. To modify a process that has been locked, create a revision and make your changes to it.

**Previous topic:** [Workflow process testing](#)

**Next topic:** [Enabling workflow processes](#)

---

## Enabling workflow processes

Workflow process records are in a draft or a development stage until you enable the record. Enabling a process involves validating the structure of the process.

---

### About this task

After you enable a process record, the record is locked, and it is ready for use.

---

### Procedure

1. From the List tab of the Workflow Designer application, select the process record that you want to enable.
2. Select the Enable Process action.
3. Click Close and click Save Process.

---

## What to do next

To make a workflow process record ready to use as a main process, you must activate the process.

**Previous topic:** [Validating workflow processes](#)

**Next topic:** [Activating workflow processes](#)

---

## Activating workflow processes

You activate workflow records before they can be routed into a workflow process.

---

### About this task

When you activate a workflow process record, the following actions occur:

- The Workflow actions and buttons are added to the applications associated with the object if those applications do not support workflow yet.
- The Active check box is selected to indicate that the record is currently being used to manage records.
- When you activate a process revision, the previously active revision is deactivated. The product does not disable the revision because active instances of the process might exist.

---

### Procedure

1. From the List tab of the Workflow Designer application, select the process record that you want to activate.
2. Select the Activate Process action. If the applications associated with the object already support workflow, a message displays in the navigation bar stating that the process has been activated.
3. Click OK.

**Previous topic:** [Enabling workflow processes](#)

**Next topic:** [Disabling workflow processes](#)

---

## Disabling workflow processes

Disabling a process prevents new records from being routed into the workflow process. Disabling a process does not affect records that are under the control of the process.

---

### Before you begin

You must use the Workflow Designer application to stop any active instances of the process.

---

### About this task

After a record is routed through an enabled process, the process cannot be deleted because other records might be under the control of the process. When you enable a new process revision, the previous revision is automatically disabled.

## Procedure

---

1. From the List tab of the Workflow Designer application, display the record that you want to disable.
2. Select the Disable Process action.

**Previous topic:** [Activating workflow processes](#)

**Next topic:** [Viewing workflow history](#)

---

## Viewing workflow history

For auditing purposes, a record is maintained of all records that are routed through a workflow process. You can view a list of all user-initiated actions in the workflow process, for example, routing a record into a workflow process, or completing an assignment.

### About this task

---

When a record routes through more than one workflow process, the workflow history is sorted by process name, then by transaction date. To view workflow assignments, select the Workflow\_>..View Workflow History action.

### Results

---

Some transactions are performed automatically. The transactions that are performed automatically do not display even though they are recorded in the workflow history of the record in the database.

**Previous topic:** [Disabling workflow processes](#)

**Next topic:** [Viewing workflow assignments from a Workflow-enabled application](#)

---

## Viewing workflow assignments from a Workflow-enabled application

The Workflow Map shows a graphic of a workflow process, including its nodes and connection lines. The current location of the map in a process is highlighted by a box around the node. You can view the workflow assignments for a record from within a workflow-enabled application. You use the Workflow Map to see where your assignment falls in the context of the workflow process as a whole.

### About this task

---

From the View Workflow Assignments window, you can perform the following tasks:

- View a list of the active workflow assignments for the record
- View the workflow history for a record
- View the workflow map for any processes that are currently managing the record.

To view workflow assignments, select the Workflow\_>..View Workflow Assignments action.

**Previous topic:** [Viewing workflow history](#)

**Next topic:** [Viewing a Workflow Map](#)

---

## Viewing a Workflow Map

The Workflow Map shows a graphic of a workflow process. You can use the Workflow Map to see where your assignment falls in the context of the process as a whole.

### About this task

---

A workflow process consists of decision points, known as nodes, and connecting lines between the decision points. The nodes indicate points in a process where a decision is made, and the connection lines show the path that the record takes after a decision point. The current location of the map in the process is highlighted by a box around the node.

## Procedure

---

1. Select the Workflow\_>..Workflow Map action from any workflow-enabled application. You can also access the Workflow Map from the View Assignments window.
2. If multiple workflow processes for the application exist, select the process from the Process Name menu.
3. Click OK to close the workflow map.

**Previous topic:** [Viewing workflow assignments from a Workflow-enabled application](#)

---

## Modifying workflow processes

Testing your workflow processes might reveal areas for improvement, or over time your processes might evolve due to changes in your business, increased efficiencies, and so on. You can add, modify, or delete process elements at any time until the process has been enabled. Once a process has been enabled, create a revision of the process if you want to modify it.

- [Revising a process](#)  
If you want to modify a process after it is enabled and locked, you must create a revision of the process. A revision of the process is required because other records might be under the control of this process.
- [Synchronizing active workflow processes](#)  
A workflow process can include one or more subprocesses. When you modify a subprocess, you must update the main process so that it uses the revised subprocess. This process is known as synchronization.
- [Viewing synchronized processes](#)  
You can view the name and the revision number of each subprocess associated with a main workflow process.
- [Adding workflow support to applications](#)  
Workflow actions or buttons are not included with any of the applications when you install them. You can add the workflow actions and buttons to an application without activating a process. For example, you can make the actions and buttons visible for user training. You can also create customized toolbar buttons before activating a process.
- [Adding toolbar buttons for active workflow processes](#)  
If multiple active processes exist for an object, you can use a single toolbar button for all active workflow processes.
- [Modifying toolbar buttons for active workflow processes](#)  
You can modify the toolbar buttons that are associated with an application at any time during the design process, or after a process activates.
- [Deleting workflow processes](#)  
Depending upon your security permissions and whether records have been marked for deletion, you can delete records from both active and inactive workflow processes.

---

## Revising a process

If you want to modify a process after it is enabled and locked, you must create a revision of the process. A revision of the process is required because other records might be under the control of this process.

---

### About this task

You also can create a revision of a process that is not yet activated or enabled. Creating a revision does not deactivate or disable an activated or enabled process record. However, when you activate a new process revision, the previous revision is deactivated.

---

### Procedure

1. In the Workflow Designer application, display the enabled process record.
2. On the toolbar, click Create Process Revision.
3. Make any necessary modifications to the process.
4. Click Save Process.

---

### What to do next

You must validate, enable, and activate a process revision before it can be used to process records.

---

## Synchronizing active workflow processes

A workflow process can include one or more subprocesses. When you modify a subprocess, you must update the main process so that it uses the revised subprocess. This process is known as synchronization.

---

### Before you begin

You must enable the subprocess revisions before you can synchronize a workflow process.

---

### Procedure

1. In the Workflow Designer application, select the main process record that you want to update.
2. Select the Resynchronize an Active Process action.
3. Click Save Process.

---

## Viewing synchronized processes

You can view the name and the revision number of each subprocess associated with a main workflow process.

## Before you begin

---

The main workflow process record must be activated before you can perform this action.

## Procedure

---

1. From the List tab of the Workflow Designer application, select the process record that you want to view.
2. Select the View Synchronized Processes action.
3. Click OK.

---

## Adding workflow support to applications

Workflow actions or buttons are not included with any of the applications when you install them. You can add the workflow actions and buttons to an application without activating a process. For example, you can make the actions and buttons visible for user training. You can also create customized toolbar buttons before activating a process.

## Before you begin

---

Users are not automatically granted access to workflow actions. An administrator must grant users security permissions to workflow actions in the Security Groups application. The workflow actions appear in the Security Groups application after you add workflow support to an application. You can grant users access to actions before you activate a process.

## About this task

---

When you add workflow support to applications, the product performs the following tasks:

- Adds the Add a Route button to the application toolbar. To customize this button, click Edit Workflow Go Buttons.
- Adds the following workflow-related actions to the Select Action menu for an application:
  - Route Workflow
  - Stop Workflow
  - View Workflow History
  - View Workflow Assignments
  - View Workflow Map
  - Workflow Help
- Supplies the workflow options to all users in security groups with access to the target application.

The Add Workflow to Applications action does not validate, enable, or activate processes.

## Procedure

---

1. From the List tab of the Workflow Designer application, select the process record to which you want to apply workflow.
2. From the Select Action menu, select Add Workflow to Applications.
3. Save your changes.

## Results

---

The Add Workflow Support to Applications window displays. If an application does not support Workflow, the Add Support checkbox displays. You can clear the Add Support checkbox for an application if you do not want to add workflow support to it.

---

## Adding toolbar buttons for active workflow processes

If multiple active processes exist for an object, you can use a single toolbar button for all active workflow processes.

## About this task

---

The Start Workflow window displays a menu of active processes from which to select. You can also add your own toolbar buttons for different active processes. If you exceed the number of icons that can fit on the toolbar, an arrow displays to indicate that a menu of options exists.

## Procedure

---

1. In the Workflow Designer application, select a process record.
2. Select the Edit Workflow GO Buttons action.
3. Insert a row.
4. Specify the application where the workflow process is initiated or routed.

5. Optional: Specify the name of the workflow process.  
If no process is specified, the user is prompted to select from active processes for the application or object.
6. Specify a sequence value for the order of the Go Buttons.
7. Add a description that acts as a tooltip for the button.
8. Specify the name of the graphic file to use for the toolbar icon.  
For example, specify nav\_icon\_route.gif.
9. Specify the path and name of the graphic file to use for the toolbar icon when the process is active.  
For example, specify nav\_icon\_route\_active.gif.
10. Click OK and then save the process.

---

## Modifying toolbar buttons for active workflow processes

You can modify the toolbar buttons that are associated with an application at any time during the design process, or after a process activates.

Modify toolbar buttons for active processes in the same way that you add buttons for active processes. For more information about modifying buttons, see [Adding toolbar buttons for active workflow processes](#).

---

## Deleting workflow processes

Depending upon your security permissions and whether records have been marked for deletion, you can delete records from both active and inactive workflow processes.

- [Setting security permissions for record deletion](#)  
You can give specific groups of users security permissions that allow them to delete records from active workflows.
- [Deleting inactive workflow process records](#)  
Process records can be deleted if the process has not been activated or enabled, and no records have been routed through the process.
- [Marking workflow process records for deletion](#)  
You can identify records that can be deleted when you create a workflow process. Records that have been marked can be deleted once the workflows they are part of have stopped.

---

## Setting security permissions for record deletion

You can give specific groups of users security permissions that allow them to delete records from active workflows.

---

### Procedure

1. In the Security Groups application, select the security group on the List tab.
2. On the Applications tab, select the Workflow Designer application record.
3. In the Options for Workflow Designer table, select Grant Access for the following options:
  - a. Allow deletion of records
  - b. Disallow deletions
4. Once you have saved the security group, log out and log in to ensure the security settings are applied.

---

## Deleting inactive workflow process records

Process records can be deleted if the process has not been activated or enabled, and no records have been routed through the process.

---

### About this task

---

### Procedure

1. In the Workflow Designer application, display the process record to delete.
2. Select the Delete Process action.
3. Click Yes to confirm the deletion.

---

## Marking workflow process records for deletion

You can identify records that can be deleted when you create a workflow process. Records that have been marked can be deleted once the workflows they are part of have stopped.

## About this task

---

This action can be performed only by users with the appropriate security permissions.

## Procedure

---

1. In the Workflow Designer application, select or create a workflow.
2. Select the Allow deletion of records action.

## Integrating workflow processes

---

You use workflow processes to perform tasks, to execute actions, and to send notifications. After you create workflow processes, you can test them in an environment other than your working environment to fine-tune their behavior. After you test the processes, you can integrate them into your working environment.

## Before you begin

---

The supporting data must be in place before you can integrate the workflow processes.

- [Exporting workflow actions](#)  
When you export workflow actions, you create a query to select records. The export performs the standard outbound processing for the selected interface on the result set of the query.
- [Exporting workflow communication templates](#)  
When you export workflow communication templates, you create a query to select records. The export performs the standard outbound processing for the selected interface on the result set of the query.
- [Exporting workflow roles](#)  
When you export workflow roles, you create a query to select records. The export performs the standard outbound processing for the selected interface on the result set of the query.
- [Manipulating workflow supporting data](#)  
After exporting the workflow supporting data, you must manipulate the data to import it properly. You change the data to ensure that the data is imported from and to the correct places in your system, and to ensure that the commands within the data are set to perform the correct procedures.
- [Importing workflow supporting data](#)  
The Integration Framework can import a workflow process and its supporting data (including actions, roles, and communication templates).
- [Exporting workflow processes](#)  
You can export the workflow processes that you have created.
- [Manipulating workflow processes](#)  
After you export a workflow process, you must manipulate it to import it properly. You manipulate or change the process to ensure that the data is imported from and to the correct places in your system. You also manipulate it to ensure that the commands within the processes are set to perform the correct procedures.
- [Importing workflow processes](#)  
You use the integration framework to import a workflow process and its supporting data, such as actions, roles, and communication templates.

## Exporting workflow actions

---

When you export workflow actions, you create a query to select records. The export performs the standard outbound processing for the selected interface on the result set of the query.

## About this task

---

If the standard processing runs classes or rules that exclude or that modify records or fields, you might need to create and use a new integration point that does not filter or modify records.

To export data, enable the applicable external system and interface. You do not have to enable the outbound event listener.

## Procedure

---

1. From the List tab of the External Systems application, select the system where you want to export a data file. EXTSYS1 is a default system that you can use to export workflow supporting data. You can create as many external systems as you need.
2. Click the Outbound Interfaces tab and select MXACTIONInterface.
3. Click Data Export.
4. In the Integration Point field of the Data Export window, type the name of the corresponding integration point.
5. Optional: In the Export Condition field, type a Structured Query Language (SQL) query statement. The query must be against the primary (top-level) Maximo® business object (MBO) in the integration object.
  - a. To export all workflow-related actions, your query might read: `action in (select action from wfaction)`
  - b. To export actions related to a single workflow process, your query might read: `action in (select action from wfaction where processname = 'name' and processrev = 'rev')` To avoid processing problems due to the size of the XML transaction, use the Export Condition field to filter out unnecessary records.
6. Click OK.

---

## Exporting workflow communication templates

When you export workflow communication templates, you create a query to select records. The export performs the standard outbound processing for the selected interface on the result set of the query.

### About this task

If the standard processing runs classes or rules that exclude or that modify records or fields, you might need to create and use a new integration point that does not filter or modify records.

To export data, you enable the applicable external system and interface. You do not have to enable the outbound event listener.

### Procedure

1. From the List tab of the External Systems application, select the system where you want to export a data file. EXTSYS1 is a default system to where you can export workflow supporting data. You can create as many external systems as you need.
2. Click the Outbound Interfaces tab and select the MXCTEMPLATEInterface that you want to export.
3. Click Data Export.
4. In the Integration Point field of the Data Export window, type the name of the corresponding integration point.
5. Optional: In the Export Condition field, type a Structured Query Language (SQL) query. The query must be against the primary (top-level) Maximo® business object (MBO) in the integration object.
  - a. To export all workflow-related communication templates, your query might read: `templateid in (select templateid from wfassignment)`
  - b. To export communication templates related to a single workflow process, your query might read: `templateid in (select templateid from wfassignment where processname = 'name' and processrev = 'rev')` To avoid processing problems due to the size of the transaction, use the Export Condition field to filter out unnecessary records.
6. Click OK.

---

## Exporting workflow roles

When you export workflow roles, you create a query to select records. The export performs the standard outbound processing for the selected interface on the result set of the query.

### About this task

If the standard processing runs classes or rules that exclude or that modify records or fields, you might need to create and use a new integration point that does not filter or modify records.

To export data, you must enable the applicable external system and interface. You do not have to enable the outbound event listener.

### Procedure

1. From the List tab of the External Systems application, select the system where you want to export a data file. EXTSYS1 is a default system to where you can export workflow supporting data. You can create as many external systems as you need.
2. Click the Outbound Interfaces tab and select the MXMAXROLEInterface that you want to export.
3. Click Data Export.
4. In the Integration Point field of the Data Export window, type the name of the corresponding integration point.
5. Optional: In the Export Condition field, type a Structured Query Language (SQL) query. The query must be against the primary (top-level) Maximo® business object (MBO) in the integration object.
  - a. To export all workflow-related roles, your query might read: `maxrole in (select roleid from wfassignment)`
  - b. To export roles related to a single workflow process, your query might read: `maxrole in (select roleid from wfassignment where processname = 'name' and processrev = 'rev')` To avoid processing problems due to the size of the transaction, use the Export Condition field to filter out unnecessary records.
6. Click OK.

---

## Manipulating workflow supporting data

After exporting the workflow supporting data, you must manipulate the data to import it properly. You change the data to ensure that the data is imported from and to the correct places in your system, and to ensure that the commands within the data are set to perform the correct procedures.

### Procedure

1. Open the file that you exported from your test environment, such as mxaction. If you have not modified the INTGLOBALDIR, the path for the file is: `<drive_letter>:\<bea_folder>\user_projects\domains\mydomain\xmfiles`
2. Locate the tag `<SenderID>`. Modify the data within the tag to be from EXTSYS1 to read: `<SenderID>EXTSYS1</SenderID>`.
3. Locate the tag `<RecipientID>`. Modify the data within the tag to be from MX, or from the VARVALUE specified in the MAXVARS table for VARNAME MXSYSID by modifying it to read: `<RecipientID>MX</RecipientID>`.

4. Search the document to locate the parent tags, such as `COMMTTEMPLATE`, `MAXROLE`, and `ACTION`. Replace these tags with `<COMMTTEMPLATE action = "">`, `<ACTION action = "">`, and `<MAXROLE action = "">`. Adding the `action = ""` command tells the system to add or to replace this action.
5. Save the file and place it in the folder of your working environment: `<drive_letter>:\<bea_folder>\user_projects\domains\mydomain\load\xml`

---

## Importing workflow supporting data

The Integration Framework can import a workflow process and its supporting data (including actions, roles, and communication templates).

---

### Before you begin

Your environment must be configured before you can import workflow supporting data. The Data Import feature is available only for interfaces of the Notify operation type within an adapter.

To import data, the data must be in an Extensible Markup Language (XML) file. The format of the data must be the same as the format of the table that corresponds to the interface.

---

### About this task

You can import data to build and test your process in a test environment, then you use the integration framework to export the process to your production environment.

---

### Procedure

1. From the List tab of the External Systems application, select the system where you want to import workflow supporting data. EXTSYS1 is a default system that you can use to import workflow supporting data.
2. Select the Data Import action.
3. In the Data Import window, select XML File.
4. In the Server Directory field, specify the location of the file. The default location of the file is: `<global directory location>\load\xml`.
5. In the File Name field, specify the name of the file.
6. Click Import.

---

## Exporting workflow processes

You can export the workflow processes that you have created.

---

### Before you begin

You must first create your workflow processes and test them.

---

### Procedure

1. From the List tab of the External Systems application, select the system where you want to export a data file. EXTSYS1 is a predefined destination where you can export workflow data. The System tab opens with all fields populated. You can create as many external systems as you need.
2. Click the Outbound Interfaces tab and select the interface that you want to export, MXWFInterface
3. Click Data Export.
4. In the Data Export window, choose one of the following options:
  - a. To export all workflow processes, click OK. All workflow processes are exported in a single XML file.
  - b. To restrict the output, and export only certain processes, add a Structured Query Language where clause in the Export Condition field. For example, to export only the first revision of the WOSTATUS process, type `PROCESSNAME='WOSTATUS' AND PROCESSREV='1'`.
5. Click OK. The workflow processes are exported to a single XML file.

---

### What to do next

You can now integrate the workflow processes into your working environment.

---

## Manipulating workflow processes

After you export a workflow process, you must manipulate it to import it properly. You manipulate or change the process to ensure that the data is imported from and to the correct places in your system. You also manipulate it to ensure that the commands within the processes are set to perform the correct procedures.

---

### Procedure

1. Open the file that you exported from your test environment. If you have not modified the `INTGLOBALDIR`, the path for the file is: `<global directory>:\xmlfiles`
2. Locate the tag `<SenderID>`. Modify the data within the tag to be from EXTSYS1 to read: `<SenderID>EXTSYS1</SenderID>`.

3. Locate the tag `<RecipientID>`. Modify the data within the tag to be from MX. You can also modify the data within the tag from the VARVALUE specified in the MAXVARS table for VARNAME MXSYSID, as follows: `<RecipientID>MX</RecipientID>`.
4. Search the XML document to locate the `<WFPROCESS>` and replace with `<WFPROCESS> action = "" Adding the action = ""` command tells the product to add or to replace this action.
5. Save the file and place it in the folder of your working environment: `<global directory location>\load\xml`.

---

## Importing workflow processes

You use the integration framework to import a workflow process and its supporting data, such as actions, roles, and communication templates.

### Before you begin

---

Your environment must be configured before you can import workflow processes. The Data Import feature is available only for interfaces of the Notify operation type within an adapter. For more information about configuring your environment, refer to the system administrator guide. For every workflow process that you import, you must add workflow support to the associated applications after you activate the workflow process.

To import data, the data must be in an Extensible Markup Language (XML) file. The format of the data must be the same as the format of the table that corresponds to the interface.

If your workflow process has subprocesses, you must activate the parent and child processes, and then resynchronize the processes. Also, you must import any subprocesses to your workflow process before you import the workflow process.

### About this task

---

When you import a workflow process, you build and test your process in a test environment. After you test your process, you use the integration framework to export the process to your production environment.

### Procedure

---

1. From the List tab of the External Systems application, select the system that you want to import a data file to. EXTSYS1 is a default system to which you can import workflow processes.
2. Select the Data Import action.
3. In the Data Import window, select XML File.
4. In the Server Directory field, specify the location of the file. The default location of the file is: `<global directory location>\load\xml`.
5. In the File Name field, specify the name of the file.
6. Click Import.

---

## Workflow/Inbox Assignments portlet

The Workflow Inbox/Assignments is one of the portlets that might appear on your Start Center. If your workplace has implemented the Workflow feature, a list of your task assignments displays in the Inbox.

A task assignment is a record that is routed to you for action, based on the information contained in a workflow process. The number of records in Inbox/Assignments displays in the top left corner of the portlet.

You use the Workflow Inbox to review assignments, to route assignments, and to complete assignments. You must complete the assignments before a record can move to the next step in a workflow process.

- [Configuring the Workflow Inbox](#)  
You use the Workflow Inbox to review, to route, and to complete your task assignments. A task assignment is a record that is routed to you for action, based on the information contained in a workflow process. Records that are listed in your Workflow Inbox are assigned to you.
- [Configuring administrator email notifications](#)  
The administrator can receive email notifications about workflow errors to help resolve issues more quickly.
- [Reassigning workflow assignments](#)  
You use the Workflow Administration application to reassign workflow task assignments. Sometimes, a workflow task that has been assigned to an individual or to a group must be reassigned to someone else.
- [Sending reassignment notifications](#)  
You can notify a person or a group of a workflow task reassignment.
- [Completing workflow assignments](#)  
You can complete workflow assignments to complete a task and to route the task to the next assignee. You can view and edit memos that are entered by individuals who have previously reviewed the record or assignment. You can also write memos to task assignees.
- [Deleting assignments](#)  
You can delete task assignments if a task node has more than one assignment and you want to make a particular task assignment inactive.

---

## Configuring the Workflow Inbox

You use the Workflow Inbox to review, to route, and to complete your task assignments. A task assignment is a record that is routed to you for action, based on the information contained in a workflow process. Records that are listed in your Workflow Inbox are assigned to you.

## Before you begin

---

You must have security permissions to configure the portlets that display on your Start Center, including configuring the Workflow Inbox.

## About this task

---

The description that displays in the Inbox portlet is the description of the step from the workflow process, not the description of the record. For example, the description for a purchase order task might be "Supervisor approval."

## Procedure

---

1. Click Edit Portlet (pencil icon) in the Inbox/Assignments header to display the Inbox/Assignments Setup application.
2. You can perform the following actions in the Inbox/Assignments Setup application:
  - Change the display name of the portlet
  - Indicate how many rows to display in the portlet
  - Select the columns that are displayed in the portlet and modify their descriptions
  - Indicate the order that the columns are displayed by entering a value in the Order column
3. Click Finished.

## What to do next

---

You must complete the assignment in your Workflow Inbox before the record can move to the next step in the workflow process.

## Configuring administrator email notifications

---

The administrator can receive email notifications about workflow errors to help resolve issues more quickly.

## Procedure

---

1. In the System Properties application, filter to select the mxe.workflow.admin property.
2. In the Global Value field, specify your email address.
3. Save your changes and click Live Refresh.

## Reassigning workflow assignments

---

You use the Workflow Administration application to reassign workflow task assignments. Sometimes, a workflow task that has been assigned to an individual or to a group must be reassigned to someone else.

## Procedure

---

1. From the View Active Assignments window of the Workflow Administration application, click View/Modify Active Assignments.
2. Click Reassign Assignment to reassign assignments.
3. In the Person field of the Reassign window, type a person ID.
4. Click OK to close the Reassign window, then click OK.

## Sending reassignment notifications

---

You can notify a person or a group of a workflow task reassignment.

## Procedure

---

1. In the Reassign window, click New Row.
2. In the Send To field, specify the identifier for a person or click Detail Menu... Select Value and choose a person record from the list.
3. In the Subject field, type a subject for the e-mail message.
4. In the Message field, type the text of the e-mail message.
5. Click OK to close the Reassign window, then click OK.

## Completing workflow assignments

---

You can complete workflow assignments to complete a task and to route the task to the next assignee. You can view and edit memos that are entered by individuals who have previously reviewed the record or assignment. You can also write memos to task assignees.

## Procedure

---

1. Perform one of the following actions:
  - In the workflow inbox, select Route.
  - In a Workflow-enabled application, click Route Workflow.
  - In the Workflow window, click Complete an Assignment.
2. Select an action.
3. In the Memo field, enter a memo value.
4. Click Reassign, to assign the task to another individual.
5. Click OK.

## Results

---

The task is placed in the workflow inbox of the assigned person. The memo that you entered is added to the record workflow history. The next person in the process flow can view your memo in the Earlier Memos table window

---

## Deleting assignments

You can delete task assignments if a task node has more than one assignment and you want to make a particular task assignment inactive.

### About this task

---

All task nodes must have at least one task assignment. You cannot delete the last active assignment for a given task.

Deleting an assignment changes the status of the task assignment record to inactive.

## Procedure

---

1. If necessary, use the table filter to locate a process instance.
2. In the Processes table window, click View/Modify Active Assignments.
3. To delete an assignment, click Delete Assignment. The status of the task assignment is changed to inactive. The assignment record is removed from the View Active Assignments window.
4. Click OK to close the window.

---

## Integrating data with external applications

The integration framework helps you to integrate application data with other applications, either within your enterprise or with external systems. The framework includes predefined content that enables integration with a number of business objects, and a tool kit that you can use to extend predefined integration content and to develop new integration points. Features that allow enablement of message providers are included in the integration framework. The framework provides an abstraction of the message queuing features. In this way, the product is independent of the model for the underlying messages, such as JMS or Apache Kafka.

- [Integration framework overview](#)  
As the system administrator for the Maximo® Manage Integration Framework, you can enable the secure sharing of data between Maximo Manage and an external system or application. Integration components, which you can configure to fit your integration needs, are included in your Maximo Manage system.
- [Architecture](#)  
The integration framework architecture includes the data, transport, communication, and security components required to exchange information between separate applications and systems.
- [Integration by using Apache Kafka](#)  
You can integrate with the Apache Kafka messaging platform to publish and consume messages asynchronously from the Kafka platform. Kafka can be configured as an external message provider that accepts and stores outbound and inbound messages.
- [Enabling data export and import through message queues](#)  
Before you use the integration framework to exchange data with an external application, you configure some components that are needed for inbound and outbound communication. You configure system properties, end points, publishing channels and integration controls, external systems, message queues, and cron tasks. You might need to make other configurations to export and import data.
- [Configuring Java Message Service \(JMS\) servers](#)  
If you use Java™ Messaging Service (JMS) to integrate data, you can deploy one or more server bundles with a Liberty server that supports JMS messaging.
- [Integration components](#)  
Depending on the scope and requirements of your implementation, you can create new components or copy, modify, or extend most of the predefined components.
- [Integration data processing](#)  
You can configure integration components in different ways to meet your integration requirements. You can integrate with multiple external applications, and each application requires a different integration approach that is based on the integration support that is provided by that application.
- [Configuring the integration framework](#)  
Setting up the integration framework includes configuring related system properties, queues, and security. Implementing integration scenarios requires a knowledge of configuring queues and knowledge of J2EE and product security support.
- [Exporting and importing file-based data](#)  
The integration administrator can initiate export and import data from within the External Systems application to support, for example, integrating data using files. The import process includes the ability to preview a data load from a file to validate the data prior to saving it to the database. The import process also includes an option to manage errors that result from file loading in the same file format as the imported file

- [Federated MBO integration](#)  
Maximo Manage supports the sharing of data between Maximo Manage and external systems in several ways.
- [Integration APIs](#)  
The integration framework supports the use of REST (Representational State Transfer) application programming interface (API), and the sharing of lifecycle data between applications based on Open Services for Lifecycle Collaboration (OSLC) integration.
- [Integration queries](#)  
The integration framework supports queries from external systems. You can execute a query for object structures and enterprise services by using HTTP, REST APIs, or a Simple Object Access Protocol (SOAP) request in a web service. Queries can be in the form of XML messages or REST API JSON.
- [Interface tables](#)  
Interface tables are an option for integration with systems that use database tables to exchange data. This integration option applies only to enterprise services and publish channels and is always processed asynchronously, by using JMS queues.
- [Integration modules](#)  
An integration module provides a mechanism for a process management product to invoke an external operational management product. You can configure an integration module to automate logical management operations, such as software deployment, by using an operational management product.
- [Launch in Context feature](#)  
You use the Launch in Context application to create and modify launch entry records which open an external application in the same or a different browser session. You can open applications independently or as part of an application integration scenario.
- [Integrating with Workday Connector](#)  
You can integrate IBM® Maximo Manage and Workday Human Capital Management (HCM) to synchronize your HCM data and integrate IBM Maximo Manage and Workday Financial to synchronize your financial data. By completing an integration with Workday Connector, you can synchronize data between systems and access more accurate cost and time reporting information.
- [Envizi ESG Suite and TRIRIGA Application Suite Connectors](#)  
IBM TRIRIGA® Application Suite and IBM Maximo Application Suite customers have access to a collection of predefined integrations between each other and IBM Envizi ESG Suite.
- [Integration reference information](#)  
Reference information includes a guide to the XML structures and schemas used by the integration framework, the system properties you can set, and predefined collaboration switches provided with applications.

---

## Integration framework overview

As the system administrator for the Maximo® Manage Integration Framework, you can enable the secure sharing of data between Maximo Manage and an external system or application. Integration components, which you can configure to fit your integration needs, are included in your Maximo Manage system.

The integration framework includes the following components and features:

- Predefined integration content
- Applications to create and configure integration components
- Support for multiple communication modes including web services, Java™ Message Service (JMS) messaging, Apache Kafka messaging, and hyper text transfer protocol (HTTP).
- Support for different data formats, including database interface tables, XML and JavaScript Object Notation (JSON) messages, and flat files such as comma-separated text files
- Event-based, batch, program-initiated, and user-initiated processing and context-based launch of external applications
- Support for integration to operational management products (OMPs)
- Support for clustered environments
- Support for interacting with applications that support the Open Services for Lifecycle Collaboration (OSLC) integration specification. The integration framework can enable an application to be an OSLC consumer application that can integrate with an external application that has implemented OSLC provider capabilities.
- REST API support for the standard services of the integration framework. The Maximo Manage business objects form the resources for the REST API.
- Use of API keys for all machine-to-machine integrations. Generate the API key in the Administration Work Center.

The integration framework provides multiple options for sending and receiving data. Evaluate which approach is the most efficient for your requirements when you are planning an integration. Some typical integration scenarios include:

- Load files with legacy data during an implementation.
- Synchronize master data between a product application and an external ERP application.
- Use web services to enable real-time querying of product application data by an external application.
- Call an external application to validate data that is entered in a product application.

If you want to import a large number of records from an external source, import the data in batch files or use interface tables. This approach separates the data so that multiple messages are processed as separate transactions. You can also use REST APIs to import and export data in JSON, XML, or CSV format. With a single transaction that processes synchronously, such as a web service call, limit the number of messages in a single transaction to ensure that the transaction processes in an acceptable length of time. When you are planning an integration, evaluate which integration option is most appropriate for your requirements.

Predefined integration content includes support for a number of business objects and insert, update, and delete functions on these business objects is enabled. When you use predefined content, there are certain limitations that can affect your implementation. If business rules exist within the business object that do not allow a function, for example the delete function, the function is not available for integration. In addition to support for insert, update and delete operations, the product applications support other functions that are available as actions. Predefined integration content does not support all the actions that are available. In most cases, the Change Status action is supported through integration.

---

## Architecture

The integration framework architecture includes the data, transport, communication, and security components required to exchange information between separate applications and systems.

- [Integration framework components](#)  
The framework for data exchange includes components and tools that you can use to implement different types of integration scenarios.
- [Message provider enablement](#)  
The Integration Framework includes features that allow enablement of message providers. The framework provides an abstraction of the message queuing features. In this way, the product is independent of the model for the underlying messages, such as JMS or Apache Kafka.
- [Framework for operational management product integration](#)  
Process management products can integrate with operational management products in an automated mode using integration modules. Process management products can use the launch in context feature to integrate with operational management products in an assisted mode.
- [Framework for user interface integration](#)  
You can configure the integration framework to open a window in an external application and provide data to include in the context of that window.

## Integration framework components

The framework for data exchange includes components and tools that you can use to implement different types of integration scenarios.

### Components

The framework includes predefined integration components and applications you can use to configure components. The main components are described in the following table.

Table 1. Integration framework data exchange components

Component	Description
Object structures	An object structure is the common data layer that the integration framework components use for outbound and inbound application message processing. An object structure consists of one or more related business objects that define the content of an XML or JSON message (schema). For JSON messages, you can configure message templates to filter which data from the related business objects is included in the message.
Business objects	Application business objects are available as Representational State Transfer (REST) resources for queries and updates by using the REST API component of the integration framework.
Publish channels	A publish channel is used for sending asynchronous messages through a message queue to an external system. Publish channel messages can be initiated via an event or through the Data Export feature.
Invocation channels	Invocation channels are used for sending synchronous messages to an external system and processing the response content. The channel supports the implementation of processing logic and mapping of the request and the response. An invocation channel also allows for response data to be used to update business objects and be displayed to application users.
Enterprise services	An enterprise service is a pipeline for querying and importing data from an external system. An enterprise service can process data synchronously (without a queue) or asynchronously (with a queue). Enterprise services can use multiple protocols, such as web services and HTTP.
External systems	An external system is defined for the external application that you plan to integrate with. The external system identifies the communication protocol to use and which enterprise services, publish channels and message queues to implement for that external system.
Handlers and endpoints	A handler and its associated endpoint routes outbound messages to an external system. The combination of a handler and its endpoint specify the transport protocol, such as HTTP or web service, and provide the communication data required to reach the destination, such as a URL. You configure endpoints for the handler that you use.
Web services	You can deploy integration framework services, such as enterprise or object structure services, as web services that external systems can invoke.
Data import and export	You can load data from either XML files or flat files, such as a comma-separated text file or a CSV file. You can import and export data in the JSON format. You can initiate data import and export from a product application and you can schedule a batch process to perform an import as a background process. You can export one or more records to a file using a Publish Channel, where filter conditions can be applied to control the content of the data that is exported.
Content	The integration framework provides predefined content that includes object structures, corresponding enterprise services and publish channels, an external system, and predefined handlers that support different communication protocols.
API keys	You use API keys to enable a machine-to-machine integration for an external client. When an API key is assigned to the external client, the external client can access and interact with data in the Maximo® Manage system.

### Processing

As integration messages flow in and out, the framework provides options, such as Java™ classes, XSL mapping and processing rules, to provide message transformation logic and business rules to meet your integration requirements.

### Communication

The integration framework can facilitate asynchronous or synchronous data exchange. Asynchronous messages are processed through the message queues. The queues can process messages in order of priority (sequential processing), or in a multi-threaded manner (continuous processing). Synchronous messages that require a response to the sender are not processed through the JMS queues and require a direct connection between the integration framework and the external application.

When integrating with multiple external applications, you can configure different channels and services to use different communication protocols, including HTTP, web services, and message queue messaging, based on the capabilities of each individual external application.

### Security

The integration framework uses the product support for J2EE authentication security so that you can configure for Enterprise Java Beans (EJBs), web services, and HTTP. You can configure authorization security for applications, objects, and standard service methods.

You can specify security that enables only the logged-in user to create an API key. To limit the creation of API keys to the logged-in user, specify 1 for the `mxe.apikeyforloggedinuser` system property.

---

## Message provider enablement

The Integration Framework includes features that allow enablement of message providers. The framework provides an abstraction of the message queuing features. In this way, the product is independent of the model for the underlying messages, such as JMS or Apache Kafka.

The Integration Framework provides a client for JMS and Kafka. A factory implementation for these supported messaging models is registered. Each factory provides a concrete implementation of the clients for the message consumer, producer, and browser.

Updates to the framework provide a higher-level abstraction of the existing JMS features. Existing JMS support and configuration remain unchanged. Any existing JMS configuration in the Integration Framework is the same if the same JMS messaging provider and application server are used.

---

## Framework for operational management product integration

Process management products can integrate with operational management products in an automated mode using integration modules. Process management products can use the launch in context feature to integrate with operational management products in an assisted mode.

The process management product provides an action Java™ class that initiates the call to an integration module, and subsequently the operational management product. The process management product then processes the response from the operational management product.

A logical management operation defines the action that the process management product takes on the operational management product. The logical management operation identifies the following properties:

- The name and description of the action that it supports
- Whether processing is synchronous or asynchronous
- The input (source) and output (target) objects and fields for the transaction

The integration module provides a mechanism for a process management product to call an external operational management product. When it is started by a process management product, the integration module uses data provided by the process management product to assist in calling the operational management product service. The integration module can also return any response data to the process management product.

Operational management products provide services that integration modules can call to initiate operational management product actions.

---

## Framework for user interface integration

You can configure the integration framework to open a window in an external application and provide data to include in the context of that window.

You can configure a console URL for any application with a web-based console, and you can configure URLs for consoles that use Java™ Web Start. You cannot use a launch entry to open applications that are not enabled for the web. You can configure a launch point from any product application. You can provide access to launch points as actions, as hyperlinks, and in application buttons.

You can use the same approach to open a product application window from an external application.

---

## Integration by using Apache Kafka

You can integrate with the Apache Kafka messaging platform to publish and consume messages asynchronously from the Kafka platform. Kafka can be configured as an external message provider that accepts and stores outbound and inbound messages.

---

## Introduction to Kafka integration

The product provides the Kafka messaging client that supports consuming, producing, and browsing Kafka topics. To use Kafka features in the product, you must obtain and configure a Kafka server instance of the provider. You can choose any Kafka provider that is compatible with the Kafka 2.8.x client libraries.

The Kafka provider manages the topics and the corresponding partitions and storage that persist the integration messages. The integration framework provides the Kafka client framework to read, write, and browse messages in Kafka topics.

The integration framework uses the point-to-point delivery of Kafka messages. Thus, all Kafka topics are used by the integration framework as a messaging queue. Only one consumer group per topic is used to consume messages. A separate consumer group is used for browsing. However, one other consumer group per topic is available for browsing topics.

The integration framework uses only messaging features of Kafka and does not use any of the Kafka streaming features.

The integration framework supports asynchronous message processing that uses Kafka providers similarly to the way that the integration framework uses JMS. Kafka topics persist messages to a data store for outbound publish or notification channel messages and inbound enterprise service messages. In both cases,

sequential and continuous message processing is supported.

## Maximo Manage components for Kafka message queues

The following Maximo® Manage components support using Kafka as a message queue:

- Maximo Manage cron tasks for consuming messages from the queues.
- The integration framework for file loading, and the interface table cron task and servlet that write, or produce, messages to queues.
- External Systems application configuration to support registration of the Kafka provider and queue processing.
- Maximo Manage REST API for Kafka that enables browsing messages in the queue. Kafka messages cannot be deleted from Maximo Manage. It is better to leverage the Message Reprocessing application to remove Kafka messages, which in effect just skips the message for the next one.

## Differences between JMS queue processing and Kafka queue processing

If you are considering changing from using JMS queues to using Kafka queues for message processing, though the processing features in Kafka are similar, be aware of some differences. Many of the following differences are discussed in more detail in other topics in the Kafka content.

- In Maximo Manage, a Kafka message type is always byte and not text. JMS messages can be text or byte.
- A Kafka message is always compressed.
- The Kafka message size limit is configured in the *mxs.kafka.messagesize* system property in Maximo Manage. Set its value in bytes to match the value that is used on the Kafka server for Maximo Manage.
- Kafka messages are not deleted when they are processed. They are removed from the queue after the configured retention time is exceeded.
- Continuous message consumption is managed by Maximo Manage cron tasks and not by message-driven beans (MDBs).
- The Maximo Manage REST API is used for browsing messages in a queue.
- [Specifying Kafka providers for message processing](#)  
You can specify Kafka as a messaging provider to asynchronously process outbound and inbound integration framework messages. The integration framework supplies a Kafka client.
- [Registering Kafka topics as Maximo Manage queues](#)  
To exchange message data and contents with Kafka, you register Kafka topics as Maximo Manage message queues.
- [Configuration of the Kafka cron task](#)  
You configure an instance of the Kafka cron task for each of your Kafka queues. The cron task consumes Kafka messages based on the schedule that you specify. All message consumption is controlled by the Kafka cron task.
- [Message processing by using a Kafka provider](#)  
With a Kafka messaging provider, you can process outbound messages sequentially and inbound messages sequentially or continuously. In general, Kafka message processing is similar to JMS message processing.
- [Sample REST API requests for browsing Kafka queues](#)  
You can browse message content in a Kafka queue by using a REST API that the product provides. Browse message content to analyze it or to troubleshoot processing.

## Specifying Kafka providers for message processing

You can specify Kafka as a messaging provider to asynchronously process outbound and inbound integration framework messages. The integration framework supplies a Kafka client.

## Before you begin

Obtain and configure a Kafka provider that is compatible with the Kafka 2.8 libraries.

## About this task

Kafka refers to a *topic* as a category or feed name to which records are published. Because of the way that the integration framework works with Kafka, topics are referred to as messaging queues.

Only one Kafka provider instance per deployment is supported.

## Procedure

1. In the External Systems application, add or select the external system and then select Add/Modify Message Providers to open the Message Hub Provider dialog box.
2. Insert a row and add a Kafka provider name.  
The provider type is specified as KAFKA.
3. Specify values for the following properties. The SASL\_MECHANISM and SECURITY\_PROTOCOL properties are optional.

Option	Description
<b>SASL_MECHANISM</b>	The mechanism that implements the Simple Authentication and Security Layer (SASL) authentication and security framework. The allowed value is PLAIN. If no value is specified, the value of PLAIN is used.
<b>SECURITY_PROTOCOL</b>	The protocol that ensures secure data sharing. Allowed values are SASL_SSL, SSL, PLAINTEXT, or SASL_PLAINTEXT. If no value is specified, the default value of SASL_SSL is used.
<b>BOOTSTRAPSERVERS</b>	A comma-separated list of server URLs that host your Kafka instance. Include the port specification. For example, specify <i>brokerurl1,brokerurl2</i> . You can use quotation marks if needed.

Option	Description
<b>PASSWORD</b>	If you specify the security protocol as either SASL_SSL or SASL_PLAINTEXT, specify an authentication password.
<b>USERNAME</b>	The username for your password.

4. Save your changes.

## What to do next

- Register the Kafka topics as Maximo® Manage queues in the External Systems application.
- For continuous inbound queues, you do not need to set any error queues. The error table acts as the error queue.
- Configure one or more cron tasks to poll your queues and process the queue messages.
- For continuous queues, configure one or more error cron tasks to process the messages from the error table.

## Registering Kafka topics as Maximo Manage queues

To exchange message data and contents with Kafka, you register Kafka topics as Maximo® Manage message queues.

### Before you begin

Before you can register Kafka topics as product queues, take the following steps:

- Create the topics on the Kafka server.
- Configure a message provider of Kafka type in the External Systems application.

### Procedure

1. Select Add/Modify Queues in the External Systems application and add a queue.
2. Specify the Kafka provider and topic name. Specify the message direction and whether the queue is sequential or continuous.  
All outbound queues are sequential queues. You specify a queue as continuous by leaving the Sequential check box deselected and specify a queue as outbound by leaving the Inbound check box deselected.  
Note: No separate error queue is needed for continuous queue processing. Error messages are written to the error tables as it was done in Maximo Manage earlier. There is a new error processing cron task called KAFKAERROR. You should configure an instance of the KAFKAERROR cron task for each continuous queue. It is responsible for processing messages from the error table in a continuous way. The Kafka cron task just moves to the next offset and continues processing remaining messages from the Kafka continuous queue.
3. Specify the email address of the user who receives notices when errors occur in the queue. This value is used instead of the email value that is specified in system properties.
4. In the Maximum Retry Count field, specify the maximum number of reprocessing attempts after an initial error and before a message is put in a Hold status and moved to a configured error queue.
5. Save your changes.

## What to do next

For each queue, add an instance of the Kafka cron task to periodically poll the queue for messages and process them.

## Configuration of the Kafka cron task

You configure an instance of the Kafka cron task for each of your Kafka queues. The cron task consumes Kafka messages based on the schedule that you specify. All message consumption is controlled by the Kafka cron task.

### Kafka cron task setup

The Kafka cron task consumes messages according to whether the queue is sequential or continuous. In the Cron Task Setup application, add one or more instances of the Kafka cron task. Define the cron task schedule, administrative user to notify about problems, whether the cron is active, and whether to keep history. For each instance, specify values for the following properties:

Property	Description	Default
TOPIC	The name of the Kafka topic. This value is required.	None
MESSAGEHUB	The name of the Kafka provider that is registered in the product. This value is required.	None

Property	Description	Default
MESSAGEPROCESSOR	The message processor. The same message processor is used for JMS processing. This value is optional. If no value is specified, the default values are used.	Inbound psdi.iface.jms.QueueToMaximoProcessor Outbound psdi.iface.jms.QueueToDestManagerProcessor Notification com.ibm.tivoli.maximo.notification.NotificationMessageProcessor
PARTITION	A cron task is a specific Kafka consumer instance. The specific numeric partition that is assigned to the cron task creates a Kafka consumer that has that partition. When external systems send messages to the Maximo® Manage application, Kafka partitions can potentially be used for scaling. You can define cron tasks, which are Kafka consumers, by using preassigned partitions during setup time.	None

## KAFKAERROR cron task setup

The KAFKAERROR cron task is responsible for processing messages from the error table in a continuous way. It should be set up only for continuous Kafka queues.

Property	Description	Default
TOPIC	The name of the Kafka topic. This value is required.	None
MESSAGEPROCESSOR	The message processor. The same message processor is used for JMS processing. This value is optional. If no value is specified, the default values are used.	Inbound psdi.iface.jms.QueueToMaximoProcessor Outbound psdi.iface.jms.QueueToDestManagerProcessor Notification com.ibm.tivoli.maximo.notification.NotificationMessageProcessor

- [Guidelines for Kafka cron task configuration](#)  
For the Kafka cron task, it is important that you configure it using these guidelines.

## Guidelines for Kafka cron task configuration

For the Kafka cron task, it is important that you configure it using these guidelines.

- Maximo® Manage does not use Kafka topics for error management of continuous queues. The error table, maxinterror is used for error handling. To enable the process of error message reprocessing for continuous queues, you must setup an instance of the KAFKAERROR cron task for each continuous queue. Error processing for sequential queues remains unchanged.
- It is important to setup partitions for continuous queues to facilitate parallel processing. For each partition, ensure that you have only one Kafka cron task instance.  
For example, if a continuous queue has three partitions, you must have three instances of the Kafka cron task. Each of the Kafka cron task instances must be set with a unique partition number set in the PARTITION parameter. Typically, partitions follow a zero-based numeric sequence, that is, a three-partition Kafka task has 0,1, and 2 numbered partitions.

Follow the same method for sequential queues as well. However, for sequential queues, since only one partition exists, you must set the PARTITION parameter to 0.

- If you are using Maximo Application Suite 8.9 or earlier versions, set the mxe.int.kafkapolltimeout property to 5000 for better message consumption performance. The default value is set to 5000 for the mxe.int.kafkapolltimeout property starting from Maximo Application Suite 8.10 onwards.
- If a Kafka cron task stops processing messages for a long period, stop the cron task. Delete and re-create the cron task by using a different name to resolve the issue.
- The Kafka cron task uses Maximo Manage users for message processing. If the user is inaccessible for some reason, the Kafka cron task is unable to create the user information for the Maximo user. In this scenario, the cron task cannot pull messages from Kafka, but it continues to run, that is, the lastruntimeStamp is updated according to the frequency. Look for the following message in the log:  
"Default userinfo for integration user is null ... will not attempt to get any message from Kafka topic."

In such cases, check the Maximo Manage User application and the loginblock table to see whether the user is disabled or invalid or blocked. You might have to delete or restart the Kafka cron task.

## Message processing by using a Kafka provider

With a Kafka messaging provider, you can process outbound messages sequentially and inbound messages sequentially or continuously. In general, Kafka message processing is similar to JMS message processing.

## Kafka message processing

Kafka message processing tracks processed messages by maintaining an *offset* value that represents the sequential order in which messages are received by Kafka topics. The offset value indicates the next message to be processed. After a message is processed in Kafka, the offset is now beyond that processed message, and the message is never processed again.

The processed message is not deleted from the queue. It remains in the queue until the configured expiration time for the message is met.

Maximo® Manage provides an application to help you to reprocess messages that have errors. See [more information about error processing](#).

## Message size limits

You configure a message size limit on the Kafka server. When you configure this limit, consider the size of your transactions, including the size of integrated attachments. Large message size can have a negative performance impact on the reading and writing of messages in the queue.

In Maximo Manage, you can add the `mxe.kafka.messagesize` system property for the maximum message size that can be processed. Configure the property to match the message size, in bytes, that you set on the Kafka server. The default setting is 10 MB.

## Kafka write timeouts

In Maximo Manage, Kafka write actions wait for acknowledgment from the Kafka brokers. You can control the write timeout for the Kafka producer by using the `mxe.kafka.waittimeforack` property. The measurement unit is in milliseconds.

## Outbound sequential message processing

The integration framework uses Kafka topics as outbound, sequential message queues. When a message is sent from the integration framework, it is routed to your Kafka provider, where it is hosted as a JSON message in a predefined topic. Although publish channels can send messages in XML or JSON format, the product wraps them as JSON formatted messages and writes them to the Kafka topic. An outbound message uses the structure that is shown in the following code example:

```
{
 "interfacetype": "MAXIMO",
 "INTERFACE": "MXPRInterface",
 "payload": "<xml/json message>",
 "SENDER": "MX",
 "destination": "<external system name>",
 "destjndiname": "<kafka topic name>",
 "compressed": "1",
 "MEAMessageID": "<providername>~<topic>~<partition>~<offset>",
 "mimetype": "application/xml"
}
```

The payload property contains the payload that is sent to the endpoint. The entire Kafka message is compressed at the time of storage inside the Kafka partitions. In the Kafka partitions, messages are stored in a strict timestamp order. The position of the message in the partition is given a sequential ID number that is known as a message *offset*. Although Kafka topics can be partitioned, sequentially processed topics must be in a single partition.

After the message is written to the Kafka topic, it is processed by the associated Kafka cron task that you configure in the Cron Task Setup application for each topic. Processing occurs according to the external system and endpoint that are configured for the channel.

## Inbound sequential processing

Inbound message processing can be sequential or continuous. Inbound sequential processing is similar to outbound sequential processing and requires the same types of configuration, including an instance of the Kafka cron task.

The structure of a sequential inbound message is shown in the following example:

```
{
 "interfacetype": "MAXIMO",
 "SENDER": "testkafka",
 "destination": "testkafka",
 "USER": "wilson",
 "MEAMessageID": "...",
 "INTERFACE": "MXASSETInterface",
 "payload": "{\"assetnum\":\"AZ163\",\"siteid\":\"BEDFORD\"}",
 "mimetype": "application/json",
 "destjndiname": "anamitrtestcont"
}
```

Configure sequential queues with a single partition and no more than one cron task instance to consume messages from the queue.

See [more information about error processing](#).

## Inbound continuous queue processing and scaling

Inbound continuous message processing with Kafka is similar to JMS message processing, however, there are differences in scaling and in error processing.

In general, and unlike sequential queues, continuous queue processing does not stop processing when a message has an error. Messages with errors are written to the error table and processed from the error table by the KAFKAERROR cron task instance for the respective queue.

A single Kafka queue can be scaled as *multithreaded*, or as having multiple consumers of messages, by defining more partitions for the queue. Each partition represents a separate consumer, and each partition requires its own cron task instance to support message consumption for the partition. To scale processing, configure multiple partitions. The number of cron task instances must match the number of partitions.

See [more information](#) about error processing of messages in continuous inbound queues and configuring a redelivery delay.

- **Error processing with an Apache Kafka provider**  
When messages have errors during processing in Kafka, you can reprocess them or mark them to be deleted after they expire from Kafka.
- **Expired message cleanup**  
You can configure a cron task to remove messages that have expired in the Kafka topic from Maximo Manage. Kafka does not provide a way to delete messages from the server.
- **Managing Kafka offset values in Maximo Manage**  
Offset values are managed by Kafka. Queue processing in Maximo Manage attempts to keep the Maximo Manage offset values synchronized with the corresponding Kafka offset values for a queue.

---

## Error processing with an Apache Kafka provider

When messages have errors during processing in Kafka, you can reprocess them or mark them to be deleted after they expire from Kafka.

---

### Error processing of messages in sequential queues

Sequential queues do not use an error queue because only one message is in error at any time. A message in error prevents the messages behind it in the queue from processing. However, an error does not prevent new messages from being added to the queue. Kafka retains both processed and unprocessed messages in the queue, based on the retention time that is set in Kafka.

In Kafka, pay attention to the Kafka retention time. For example, if you set it to 48 hours, a message goes in error late Friday evening. Other messages stack up behind the error message. If the error message is not managed until Monday morning, the error message and other unprocessed messages might expire before messages resume processing.

Messages that are in error and expired in Kafka can be reprocessed in the Message Reprocessing application.

If messages are in a queue but are not being processed, which happens if the cron task is not active, messages can expire. Because the messages did not process with an error, they are not available in the Message Reprocessing application and are not recoverable.

If you have messages in error that you do not want to reprocess, mark the messages for deletion in the Message Reprocessing application.

---

### Error processing of messages in continuous inbound queues

A message that is in error in a continuous queue is written to the end of the queue so that it reprocesses. The number of times that an errored message can be reprocessed is determined by the value of the Maximum Retry Count field for this external system.

For continuous inbound error processing, you must set up an instance of the KAFKAERROR cron task for that continuous queue. This cron task processes the messages from the maxinterror table in Maximo® Application Suite.

Note: After attempting the "maximum retry count" times, the error message is set on HOLD status. This gets skipped by the KAFKAERROR cron task in favor of the next message in the error table. If you want to fix the message and retry, use the Message Reprocessing application to edit the message and change the message status to "RETRY" for the KAFKAERROR cron task to process it in the next iteration. If you do not want to process the error message anymore, mark the message for deletion in the Message Reprocessing application.

---

### Configuration of a redelivery delay for continuous queues

An administrator can configure a redelivery delay that is in effect when a retry count is specified for a continuous queue. When a redelivery delay is specified in the mxe.int.kafkaredeldelay property, the cron task for the queue does not rewrite a message to the end of the Kafka queue until after the delay time.

For example, if the delay is set to 30 seconds, the cron task for the continuous queue pauses for 30 seconds before it rewrites the message with errors to the end of the queue. The delay allows other messages to be processed in the queue, some of which can contain objects that are needed to successfully process the message that had errors. The drawback of using this mechanism is that the delay slows down the processor because it delays the cron task from continued processing.

To implement a redelivery delay, create the mxe.int.kafkaredeldelay property in the System Properties application and set a delay time in seconds.

---

## Expired message cleanup

You can configure a cron task to remove messages that have expired in the Kafka topic from Maximo® Manage. Kafka does not provide a way to delete messages from the server.

---

### KafkaErrorsCleanup cron task

When a message is older than the retention time that you configure on the server, Kafka expires the message. Maximo Manage cron tasks cannot process expired message from the queue, and if any of the expired messages didn't process because of errors, they remain in the Message Reprocessing application.

The KafkaErrorsCleanup cron task can be configured to clean up the Kafka expired messages that meet the following conditions:

- The message must be older than the retention time in hours that is specified when you add a message queue for a publish channel, enterprise service, or notification channel. The integration administrator should set this time to match the retention time that is specified when the topic is registered in Kafka.
- The message must be marked for deletion in the product or already processed. Topics that are already processed are no longer visible in the Message Reprocessing application, but they are deleted by the cleanup cron task.

Messages that have a status of Hold or Retry are not deleted by the cron task. The integration administrator can try to reprocess those messages manually from the Message Reprocessing application or mark the message for deletion and run the cron task.

## Managing Kafka offset values in Maximo Manage

Offset values are managed by Kafka. Queue processing in Maximo® Manage attempts to keep the Maximo Manage offset values synchronized with the corresponding Kafka offset values for a queue.

Maximo Manage maintains these offset values in the MAXKAFKAOFFSET table, so that for messages with errors, processing of duplicate messages is prevented.

Values might not be synchronized if you delete and re-create Kafka queues, such as while you are working in a development environment. The offset values also might not be synchronized if you use a command line or user interface tool in Kafka to reset the Kafka consumer offset for the Maximo Manage consumer group. You must update Maximo Manage to reflect these types of changes.

### Procedure

1. In Maximo Manage, stop the cron task for the consumer.  
The name of the cron task instance is the client ID of the Kafka consumer.
2. Delete the Kafka queue.  
The queue name is the name of the consumer group.
3. Take one of the following steps:

Condition	Action
<b>A Kafka queue was deleted in Kafka</b>	In the MAXKAFKAOFFSET table of Maximo Manage, delete the row that corresponds to the Kafka offset value for the deleted Kafka queue. You delete the row either in the database or by creating an object structure and deleting the row by using a REST client, such as Postman. Each queue partition is associated with one row.
<b>An offset value was changed in Kafka by using Kafka tooling or scripting</b>	In the MAXKAFKAOFFSET table of Maximo Manage, set the offsets to the same values.

4. Create the Kafka queue.
5. Restart the Kafka server.
6. Restart the cron task for the consumer.

## Sample REST API requests for browsing Kafka queues

You can browse message content in a Kafka queue by using a REST API that the product provides. Browse message content to analyze it or to troubleshoot processing.

When you browse a Kafka queue, you see messages that are unprocessed and messages that are processed but not yet expired from Kafka. In a continuous queue, you might see multiple iterations of a message if the message encountered an error during processing.

To make a REST request, you need a browser session or another API tool.

### Sample REST API requests

Sample formats of the REST requests are shown in the following examples:

Providing the hostname, port, Kafka provider, and topic name

```
http://localhost:7001/maximo/oslc/browsemsgshub/Kafka Provider Name/Kafka Topic Name?&lean=1
```

Showing all records or showing records from the offset point on forward by using the all parameter

```
http://localhost:7001/maximo/oslc/browsemsgshub/Kafka Provider Name/Kafka Topic Name?all=1
```

To show all records and ignore the offset value, set the all parameter to 1, as shown previously.

To show all messages from the offset point on forward, set the all parameter to 0.

Limiting the content in the response by using the pageSize parameter

```
http://localhost:7001/maximo/oslc/browsemsgshub/Kafka Provider Name/Kafka Topic Name?oslc.pageSize=100
```

Limiting the content in the response and identifying the partition by using the pageSize parameter

```
http://localhost:7001/maximo/oslc/browsemsgshub/Kafka Provider Name/Kafka Topic Name?oslc.pageSize=100&partition=0
```

Limiting the content in the response, identifying the partition and requests on the second page of data by using the pageSize parameter

```
http://localhost:7001/maximo/oslc/browsemsgshub/Kafka Provider Name/Kafka Topic Name?oslc.pageSize=100&partition=0&pageno=2
```

---

## Enabling data export and import through message queues

Before you use the integration framework to exchange data with an external application, you configure some components that are needed for inbound and outbound communication. You configure system properties, end points, publishing channels and integration controls, external systems, message queues, and cron tasks. You might need to make other configurations to export and import data.

If you are using JMS message queues, you obtain them from a JMS provider, such as IBM® MQ. If you are using Kafka message queues, you obtain a Kafka provider and configure the connection to it.

If you are using JMS message queues, you can use a JMS version 1.1 compliant provider, such as IBM MQ or the Maximo® Application Suite built-in JMS provider from WebSphere® Application Server Liberty. If you are using Kafka message queues, obtain a Kafka provider and configure the connection to it.

Note: Delete messages for all types of JMS queues through Message Reprocessing. However, if your system admin uses the Delete Selected Messages or Delete All Messages option to delete messages, ensure that the JMS crontask for that queue is shut down before deleting the message. Other tasks include understanding the object structures and child components for message content, setting up optional message templates, and setting up API keys if you use machine-to-machine integration.

---

### Procedure

1. Obtain and configure the messaging queue provider.
  2. Register either the JMS queue or the Kafka topics in Maximo Manage.
  3. Create an external system.
  4. Register the JMS queues or the Kafka topics with the external system.
  5. Configure the external system for sequential or continuous processing.
  6. For JMS processing, register the queues and connection factories in the `server.xml` file for Maximo Manage in WebSphere Application Server Liberty.  
If you are already using a supported JMS provider, use the same JNDI name as the JNDI name that you use in Maximo Manage. For more information about configuring the `server.xml` file, see [Enabling JMS messaging for Liberty](#) in the WebSphere Application Server Liberty documentation.
- [Configuring system properties for JMS queues](#)  
Before you enable the integration framework, modify the default settings for integration properties to settings that are appropriate to your environment.
  - [Activating the cron task for JMS queues](#)  
For asynchronous processing, integration messages are placed in JMS queues. Cron tasks poll the JMS queues at frequent intervals and then process messages that are found in the queues.
  - [Exporting data to a test file](#)  
To validate that outbound processing is correctly configured and enabled, run a test export.
  - [Importing data from a test file](#)  
To validate that inbound processing is correctly configured and enabled, run a test import.

---

## Configuring system properties for JMS queues

Before you enable the integration framework, modify the default settings for integration properties to settings that are appropriate to your environment.

---

### Procedure

1. In the System Properties application, filter for the integration properties by specifying the filter `mxe.int` in the Property Name field.
2. Select the `mxe.int.dfltuser` property and verify that the user account that is specified is a valid system user account. Modify the property value if necessary.  
The property specifies the default login ID that is used for all integration transactions that are processed by an inbound JMS queue.
3. Optional: Configure the `mxe.int.globaldir` property to specify a global directory to hold integration-related files. The product must have access to the global directory.  
For example, you use a file-based endpoint that does not specify a file location. The file that is generated by the endpoint is placed in a default directory in the global directory.

---

## Activating the cron task for JMS queues

For asynchronous processing, integration messages are placed in JMS queues. Cron tasks poll the JMS queues at frequent intervals and then process messages that are found in the queues.

---

### Procedure

1. In the Cron Task Setup application, search for the JMSQSEQCONSUMER cron task.
2. Verify that the cron task is configured to poll both the SEQQIN and the SEQQOUT queues.
3. Set the Active check box for each queue.
4. Click Save.
5. Click the Reload Request action.

---

## Exporting data to a test file

To validate that outbound processing is correctly configured and enabled, run a test export.

### About this task

---

To test outbound processing, this task uses the data export feature to export a person record to a file. The task uses the following predefined integration components:

- External system: EXTSYS1
- Publish channel: MXPERSONInterface, which uses the MXPERSON object structure
- Endpoint: MXXMLFILE

### Procedure

---

1. In the Systems tab, ensure that the Enabled check box is selected for the EXTSYS1 external system.
2. In the Publish Channels tab, filter for the MXPERSONInterface publish channel.
3. In the Details section for the MXPERSONInterface publish channel, specify MXXMLFILE in the End Point field.
4. Click Data Export.
5. In the Data Export window, specify 1 in the Count field to limit the export to just one record.

### Results

---

If a location is not specified in the FILEDIR property, the XML file is exported to the location that you specified in the mx.int.globaldir property.

---

## Importing data from a test file

To validate that inbound processing is correctly configured and enabled, run a test import.

### Procedure

---

1. Open the test file that you exported in a text editor and perform the following modifications:
  - a. Change the <PublishMXPERSON> tag to <SyncMXPERSON> to change the operation for inbound processing.
  - b. Add a suffix to the LASTNAME value, such as LASTNAME\_TEST, to make it easy to verify the change when you import the test file.
  - c. Save the file.
2. On the System tab of the External Systems application, ensure that the Enabled check box is selected for the EXTSYS1 external system.
3. On the Enterprise Services tab, filter for the MXPERSONInterface enterprise service.
4. Select the MXPERSONInterface row, and clear Use Continuous Queue.
5. Click Save.
6. Select the MXPERSONInterface row and click Data Import.
7. In the Data Import window, specify the following values:
  - a. Select the XML file option.
  - b. In the Specify Import File field, navigate to the modified test file and select it.
8. Click OK.
9. In the People application, filter for the test record and verify that the value in the Last Name field includes the suffix that you added.
10. Delete the suffix to restore the record to its original value and click Save.

---

## Configuring Java Message Service (JMS) servers

If you use Java™ Messaging Service (JMS) to integrate data, you can deploy one or more server bundles with a Liberty server that supports JMS messaging.

- [Configuring JMS servers for Maximo Manage](#)  
To add a JMS server bundle, you specify `standalonejms` for the server bundle type when Maximo Manage is deployed.
- [Scaling JMS servers](#)  
By default, the server bundle for JMS servers is a single pod or server bundle in Maximo Manage. You can add server bundles if you need them.

---

## Configuring JMS servers for Maximo Manage

To add a JMS server bundle, you specify `standalonejms` for the server bundle type when Maximo® Manage is deployed.

### About this task

---

This configuration creates a single-pod Liberty JMS server.

By default, ephemeral storage for the JMS server uses the /jmsstore directory in the container. Generally, users require persistent storage for messaging. To provide persistent storage, provision a persistent storage volume for Maximo Application Suite. Then, configure a persistent volume claim for the JMS bundle when you deploy the application. You can specify a different directory for the JMS storage while setting server configuration through the additional server configuration parameters for the bundle.

## Procedure

1. Log in to Maximo Application Suite as a system administrator.
2. From Suite administration, select Workspaces from the side navigation menu and then select the Manage tile.
3. On the Manage workspace details page, click Actions, and select Update configuration.
4. In the Server bundles row, click the edit icon.
5. In the Server bundles section, if the System managed checkbox is selected, clear it. Click Add bundle.
6. In the Name column, enter a name for the bundle, such as jmsserver.
7. In the Type column, select *standalonejms*.
8. To configure the queues, complete the following steps:
  - a. In the Additional properties column for your JMS server bundle, click View.
  - b. Optional: Set a different route subdomain.
  - c. In the Additional server config section, use XML to specify both the default queues and the custom queues that you want to add. This step adds the default queues and two custom queues:

```
<?xml version="1.0" encoding="UTF-8"?>
<server description="new server">
 <messagingEngine>
 <fileStore path="/jmsstore"/>
 <queue
 id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc.manage_deploy_t.configure_jms_server_2_sqoutbd" maintainStrictOrder="true" maxMessageDepth="100000" failedDeliveryPolicy="KEEP_TRYING"
 maxRedeliveryCount="-1"/>
 <queue
 id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc.manage_deploy_t.configure_jms_server_2_sqinbd" maintainStrictOrder="true" maxMessageDepth="200000" failedDeliveryPolicy="KEEP_TRYING"
 maxRedeliveryCount="-1"/>
 <queue
 id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc.manage_deploy_t.configure_jms_server_2_cqinerrbd" maxMessageDepth="100000" failedDeliveryPolicy="KEEP_TRYING"/>
 <queue
 id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc.manage_deploy_t.configure_jms_server_2_cqinbd" maxMessageDepth="100000" exceptionDestination="cqinerrbd"/>
 <queue
 id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc.manage_deploy_t.configure_jms_server_2_notferrbd" maxMessageDepth="100000" failedDeliveryPolicy="KEEP_TRYING"/>
 <queue
 id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc.manage_deploy_t.configure_jms_server_2_notfbd" maxMessageDepth="100000" exceptionDestination="notferrbd"/>
 <queue
 id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc.manage_deploy_t.configure_jms_server_2_custsqoutbd" maintainStrictOrder="true" maxMessageDepth="100000" failedDeliveryPolicy="KEEP_TRYING"
 maxRedeliveryCount="-1"/>
 <queue
 id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc.manage_deploy_t.configure_jms_server_2_custsqinbd" maintainStrictOrder="true" maxMessageDepth="200000" failedDeliveryPolicy="KEEP_TRYING"
 maxRedeliveryCount="-1"/>
 </messagingEngine>
</server>
```

Note: The fileStore path can be modified to use a different directory to store JMS messages. If you are using persistent volumes, make sure that the fileStore path is configured correctly under the persistent volume directory. For example, if your persistent volume is mounted on directory /nfs, then the fileStore path might be /nfs/jmsstore.

- d. Click Save to save the additional server bundle properties.
9. If you have a single server (all) bundle or for the mea bundle, to prepare the other Maximo Manage server bundles for the JMS queues, complete the following steps:
    - a. In the Additional properties column for the server bundle, click View.
    - b. In the Additional server config section, specify features for both the default queues and the custom queues that you want to add, as shown in the following example:

```
<?xml version='1.0' encoding='UTF-8'?>
<server description="new server">
 <featureManager>
 <feature>jndi-1.0</feature>
 <feature>wasJmsClient-2.0</feature>
 <feature>jmsMdb-3.2</feature>
 <feature>mdb-3.2</feature>
 </featureManager>
 <jmsQueueConnectionFactory jndiName="jms/maximo/int/cf/intcf" connectionManagerRef="mifjmsconfact">
 <properties.wasJms remoteServerAddress="<InstancesId>-<workspaceId>-<serverbundlename>.mas-<instanceId>-manage.svc:7276:BootstrapBasicMessaging"/></jmsQueueConnectionFactory>
 <connectionManager
 id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc.manage_deploy_t.configure_jms_server_2_mifjmsconfact" maxPoolSize="20"/>
 <jmsQueue jndiName="jms/maximo/int/queues/sqout"><properties.wasJms queueName="sqoutbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/sqin"><properties.wasJms queueName="sqinbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/cqin"><properties.wasJms queueName="cqinbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/cqinerr"><properties.wasJms queueName="cqinerrbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/notf"><properties.wasJms queueName="notfbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/notferr"><properties.wasJms queueName="notferrbd"/></jmsQueue>
```

```

 <jmsQueue jndiName="jms/maximo/int/queues/custsqout"><properties.wasJms queueName="custsqoutbd"/>
 </jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/custsqin"><properties.wasJms queueName="custsqinbd"/></jmsQueue>
 <jmsActivationSpec
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
r_2_maximo-all/mboejb/JMSContQueueProcessor-1" maxEndpoints="5"><properties.wasJms
destinationLookup="jms/maximo/int/queues/cqin" maxConcurrency="5" maxBatchSize="20"
connectionFactoryLookup="jms/maximo/int/cf/intcf"/></jmsActivationSpec>
 <jmsActivationSpec
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
r_2_maximo-all/mboejb/JMSContQueueProcessor-2" maxEndpoints="1"><properties.wasJms
destinationLookup="jms/maximo/int/queues/cqinerr" maxConcurrency="1" maxBatchSize="20"
connectionFactoryLookup="jms/maximo/int/cf/intcf"/></jmsActivationSpec>
</server>

```

10. If you have report, cron, or UI bundles, complete the following steps for each of them:

- In the Additional properties column for the server bundle, click View.
- In the Additional server config section, specify features for both the default queues and the custom queues that you want to add, as shown in the following example:

```

<?xml version='1.0' encoding='UTF-8'?>
<server description="new server">
 <featureManager>
 <feature>jndi-1.0</feature>
 <feature>wasJmsClient-2.0</feature>
 <feature>jmsMdb-3.2</feature>
 <feature>mdb-3.2</feature>
 </featureManager>
 <jmsQueueConnectionFactory jndiName="jms/maximo/int/cf/intcf" connectionManagerRef="mifjmsconfact">
 <properties.wasJms remoteServerAddress="<InstancesId>-<workspaceId>-<serverbundlename>.mas-<instanceId>-
manage.svc:7276:BootstrapBasicMessaging"/></jmsQueueConnectionFactory>
 <connectionManager
id=" _home_markdown_jenkins_workspace Transform in SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
r_2_mifjmsconfact" maxPoolSize="20"/>
 <jmsQueue jndiName="jms/maximo/int/queues/sqout"><properties.wasJms queueName="sqoutbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/sqin"><properties.wasJms queueName="sqinbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/cqin"><properties.wasJms queueName="cqinbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/cqinerr"><properties.wasJms queueName="cqinerrbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/notf"><properties.wasJms queueName="notfbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/notferr"><properties.wasJms queueName="notferrbd"/></jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/custsqout"><properties.wasJms queueName="custsqoutbd"/>
 </jmsQueue>
 <jmsQueue jndiName="jms/maximo/int/queues/custsqin"><properties.wasJms queueName="custsqinbd"/></jmsQueue>
 </server>

```

For steps 9 and 10:

The queueName values must match the queue names that you specified in step 8.c. Also, the difference between all bundles or mea bundle XML versus the report, cron, UI bundles XML is that the second category does not have the jmsActivationSpec lines.

When you enter the connection properties, supply the following variables:

```

<InstanceId>
 Name of your Maximo Application Suite instance.
<workspaceId>
 Name of your workspace.
<serverbundlename>
 Name of your JMS server bundle, for example, jmsserver.

```

Note: Your *remoteServerAddress* must be in the following format:

```
remoteServerAddress="<InstancesId>-<workspaceId>-<serverbundlename>.mas-<InstanceId>-
manage.svc:7276:BootstrapBasicMessaging"
```

For example:

```
remoteServerAddress="mngrel84-masdev-jmsserver.mas-mngrel84-manage.svc:7276:BootstrapBasicMessaging"
```

- Click Save again to save the additional server bundle properties.
- After you complete the workspace updates, activate the changes.

## What to do next

After you configure the stand-alone JMS servers, you can log in to Maximo Manage and configure your JMS queues. For more information, see [JMS queue configuration](#).

## Scaling JMS servers

By default, the server bundle for JMS servers is a single pod or server bundle in Maximo® Manage. You can add server bundles if you need them.

You can select one of the following options to add JMS server bundles:

- Complete the following steps to create more instances of the standalonejms server bundle and the mea server bundle:
  - Create another instance of the standalonejms server bundle.

2. Create the same set of queues that existed in your first server bundle.
  3. Create another instance of the mea server bundle that uses the new standalonejms server bundle.
- You can then configure an external system to use either of the mea cluster URLs to send the messages, which distributes the processing load across multiple servers.
- You can add more mea server instances for the same standalonejms server. This process effectively creates message-driven beans (MDB) that can consume messages in parallel from the JMS server.

---

## Integration components

Depending on the scope and requirements of your implementation, you can create new components or copy, modify, or extend most of the predefined components.

Duplicating an integration component and modifying the copy has several advantages. The copy of an integration component becomes a user-defined entity, and modification restrictions that apply to the predefined component do not apply to the copy. The original version of the component is unchanged. To avoid modifying a component while it is being used for transaction processing, perform all modifications in administrator mode.

- **[Object structures](#)**  
An object structure is the common data layer that the integration framework components use for outbound and inbound application message processing. An object structure consists of one or more related business objects that define the content of an XML or JSON message (schema).
- **[Publishing channels and services](#)**  
Channels and services reference an object structure for their message content and enable the synchronous and asynchronous exchange of data with external systems. Outbound messages are processed by publishing channels and invocation channels. Inbound messages are processed by object structure services, enterprise services, and standard services.
- **[Endpoints and handlers](#)**  
An endpoint and its associated handler route outbound messages to an external system. The combination of an endpoint and handler specify the transport protocol to use or web service, and provide the communication data required to reach the destination, such as a URL.
- **[Web services](#)**  
External systems can use integration framework web services to send messages or queries to the Maximo® database. You can use an integration framework service as the source for a web service and then deploy this service to communicate with external systems.
- **[Configuring an external system](#)**  
You can configure the external system that the integration framework communicates with. You can configure external systems for external applications inside or outside your enterprise.
- **[API keys application](#)**  
You use API keys to enable an inbound machine-to-machine integration for an external client. API keys can be used by the OSLC and REST APIs and also can be used as part of the Manage integration framework.
- **[Predefined integration content](#)**  
The integration framework provides predefined integration content, including object structures, enterprise services, and publish channels that support exporting data to external systems importing data from external system or exporting data to them.

---

## Object structures

An object structure is the common data layer that the integration framework components use for outbound and inbound application message processing. An object structure consists of one or more related business objects that define the content of an XML or JSON message (schema).

An object structure provides the message content for channels and services and enables application-based import and export. In addition, an object structure, on its own, can be called as a service, supporting the Create, Update, Delete, Sync, and Query operations.

Note: Use the object structures that are provided with your Manage system whenever possible, instead of creating a new or duplicate object structure. If the outbound integration messages are in the JSON format, you can modify which data is shared from that object structure by creating a message template for the object structure.

- **[Identification of object structure data](#)**  
If you are adding or modifying object structures, identification of the data to include requires some understanding of the applications and their associated objects. Review the data model of an application to determine which objects, database tables, and views contain the data to transfer to and from an external system.
- **[Alternate keys](#)**  
Inbound message processing relies on the key field(s) of an object to find an existing record in the system to support updates and deletes. The default processing relies on the primary key to retrieve existing records. Sometimes a primary key is unknown to an external application and an alternate key (known by the external system) is defined to support the updating and deleting of records by the external system.
- **[Object fields](#)**  
The integration framework and the external system exchange a subset of the data columns in the objects within the object structure. Subject to certain restrictions, you can control the content of the object fields within the message by including persistent and nonpersistent columns of individual objects.
- **[Interface table and flat file considerations](#)**  
If you use an object structure for exchanging data with interface tables or flat files, you must ensure that the object structure does not contain duplicate column names.
- **[Modification of a predefined object structure](#)**  
There are certain restrictions if you modify a predefined object structure.
- **[Configuring an object structure](#)**  
You can create new object structures and during that process you can generate schema files, include or exclude fields, and resolve alias conflicts. You can also specify inbound setting restrictions, set advanced configuration properties, configure application authorization, and configure message templates for outbound integration messages.
- **[Message templates that specify outbound data](#)**  
Message templates are an additional option for editing the structure of an outbound message. You use message templates to limit which data from the

associated object structure is included in the message.

---

## Identification of object structure data

If you are adding or modifying object structures, identification of the data to include requires some understanding of the applications and their associated objects. Review the data model of an application to determine which objects, database tables, and views contain the data to transfer to and from an external system.

You must find out which objects populate the database tables. Generally, a one-to-one relationship exists between an object and a database table. However, in some cases, multiple objects write data to a single table.

When an object structure contains multiple objects, the object structure is arranged as a hierarchy, with a root object (the top or main object) and child objects. An object structure can support any number of levels of objects in its hierarchy. If you create or modify object structures, you must specify a valid parent-child relationship for all objects under the top level of the hierarchy and you cannot reference the same object more than once in the same branch of the hierarchy. When you create an object structure, start by adding the main (top-level) object. You can then add more objects as child objects of the parent object.

For example, there is a predefined object structure for exchanging data in the person object with an external system. If no predefined object structure existed, to create one, you determine that the data that you require resides in the PERSON, PHONE, EMAIL, and SMS tables. The database tables have the same name as the corresponding objects. Include these objects in the object structure that you create. The name of the object structure must begin with an alphabetic character.

Typically, the objects in an object structure include all the persistent columns of the objects and exclude all nonpersistent columns. A persistent column is a data field that an object uses to write data to a database table as part of its processing. A nonpersistent column is a temporary data field that an object uses for calculations or temporary storage.

Learn more about object structures and their relationships in the Object Structures and Database Configuration applications. To see information about various object structures for Work Centers, open the Object Structures application and filter the object structure names by entering `mxaapi` in the Object Structure field. In Work Centers, the queries for the various object structures control the information that is visible in containers such as the columns and tabs.

---

## Alternate keys

Inbound message processing relies on the key field(s) of an object to find an existing record in the system to support updates and deletes. The default processing relies on the primary key to retrieve existing records. Sometimes a primary key is unknown to an external application and an alternate key (known by the external system) is defined to support the updating and deleting of records by the external system.

An inbound message normally uses the primary key of an object to look up and process records that already exist in the system. However, sometimes a primary key is an internally-generated value that is not available to the external system. In such cases, you can define an alternate key for an object and the external system passes the alternate key field(s) that the integration framework uses, instead of the primary key fields, to retrieve the data for that object.

You can specify an alternate key for an object either at object level or at object structure level. If you specify an alternate key at object level, all object structures that include the object use the same alternate key. If you specify an alternate key at the object structure level, you can use different object structures to specify a different alternate key for each external data source that the object uses. You define the index that make up an alternate key for an object in the Database Configuration application. After you create the index, you can select it as an alternate key for the object.

During inbound processing, the integration framework processes the alternate key and primary key in the following order:

- Processes the alternate key of the object structure, if one is configured.
- Processes the alternate key of the object, if one is configured and an alternate key is not configured for the object structure.
- Uses the object primary key if an alternate key is not configured for either the object structure or the object.

After you specify an alternate key, inbound messages can fail if you change or drop the alternate key index.

---

## Object fields

The integration framework and the external system exchange a subset of the data columns in the objects within the object structure. Subject to certain restrictions, you can control the content of the object fields within the message by including persistent and nonpersistent columns of individual objects.

A business object can have many fields, most of which may not be necessary for an integration scenario. When you configure an object structure, you can select which fields to include in integration messages and improve the performance of message transfer between applications. By default, the objects in an object structure include all the persistent columns of the objects. A persistent column is a data field that an object uses to write data to a database table as part of its processing. To control the content size, you can exclude persistent columns that you are not exchanging with external applications. Only the included persistent columns are part of the XML or JSON message for outbound messages. For inbound messages, only the object columns that are included in the object structure are updated. Do not exclude any column that is part of a primary or alternate key.

An object structure excludes most nonpersistent columns in the component objects. A nonpersistent column is a temporary data field that an object uses for calculations or temporary storage. You can include additional nonpersistent columns in the object structure. For example, objects that contain the persistent column DESCRIPTION also contain the nonpersistent column DESCRIPTION\_LONGDESCRIPTION. Most predefined object structures include this nonpersistent column because many integration scenarios require long description fields. If this field is not included, it is not part of the integration messages. If you change the message content of an object structure that is being used for an interface table, the interface table must be regenerated to reflect the updated content of the object structure.

---

## Interface table and flat file considerations

If you use an object structure for exchanging data with interface tables or flat files, you must ensure that the object structure does not contain duplicate column names.

You must select the Flat Supported check box for any object structure that you intend to use for interface table or flat file integration scenarios. When this option is set, messages are checked to ensure that every column for every object in the object structure has a unique name. If duplicate column names exist, you can create an alias field name for one of the duplicate names. Modifying the alias ensures that all column names are unique and the system can generate the interface table or flat file without errors. Interface tables require that all columns that are included in the corresponding object have an alias name of 18 or fewer characters.

---

## Modification of a predefined object structure

There are certain restrictions if you modify a predefined object structure.

You can add objects to a predefined object structure, but you cannot delete predefined objects from the object structure. To avoid this restriction, you can copy the predefined object structure to create a user-defined object structure, and delete objects from the copy. You can also use a message template to filter which data from the objects is included in JSON outbound messages. Do not delete or edit an object structure that is for a primary Manage API. These object structures are included in your Manage system.

You can include and exclude persistent and nonpersistent columns, subject to the standard validations that apply during integration processing. Outbound messages include the columns for objects that you add to an object structure. Test inbound messages to ensure that any columns that you added are processed successfully. If the additional object columns are not processed successfully, add an object structure processing class to handle the inbound processing.

If you use the object structure in interface tables or flat files, check for column duplications. If you use interface tables, regenerate the table for every enterprise service or publish channel that uses the modified object structure.

---

## Configuring an object structure

You can create new object structures and during that process you can generate schema files, include or exclude fields, and resolve alias conflicts. You can also specify inbound setting restrictions, set advanced configuration properties, configure application authorization, and configure message templates for outbound integration messages.

- [Creating object structures](#)  
When you create an object structure, you define a group of related objects to be part of an integration message that you exchange with external applications. You can identify data fields for each business object that determines the content of integration messages.
- [Configuring an alternate key](#)  
To configure an alternate key, create a unique index in the Database Configuration application and reference this index as the alternate key for an object structure or for a specific object.
- [Including nonpersistent fields in the object structure](#)  
You can include nonpersistent field data in an integration message. By default, the business object nonpersistent fields are excluded from the object structure definition. Business objects use nonpersistent fields for calculations or for temporary storage of data.
- [Excluding persistent fields from the object structure](#)  
You can exclude persistent field data that you do not want to map to an integration message. By default, the business object persistent fields are included in the object structure definition. Business objects use persistent fields to write processing data to a database.
- [Resolving alias conflicts](#)  
An object structure that contains multiple objects and supports flat files or interface tables, cannot have duplicate field names for any of the fields in its objects. You must resolve any field name (alias) conflicts before you can generate interface tables and flat file records.
- [Setting restrictions on fields for inbound messages](#)  
Standard integration processing sets the values in object fields with the corresponding values from an inbound message. You can set a field as restricted if you do not want the value to be updated by inbound messages, for example for a field with an internal ID or where a processing class provides the logic to set the field.
- [Setting advanced configurations for an object structure](#)  
You can set advanced configurations for an object structure to change some default processing behavior for integration messages. Advanced configurations include configuring how key fields are processed for child objects, whether an event on a child object activates a corresponding event on the parent object, and whether auto-generated data is deleted.

---

## Creating object structures

When you create an object structure, you define a group of related objects to be part of an integration message that you exchange with external applications. You can identify data fields for each business object that determines the content of integration messages.

---

### About this task

During the configuration, you can define the Java™ classes, if needed, that process inbound and outbound messages. You also can define an application that provides authorization rules for the integration messages processed through the object structure. If the object structure is intended for querying only and you do not want to use it for updating, select the Query Only option. If the main object in the object structure has a relationship to itself as a child object, set the Self Reference option.

---

### Procedure

1. In the Object Structures application, click New Object Structure.
2. In the Object Structure field, specify an object structure identifier.
3. Optional: If you are using the object structure for query operations, select the Query Only check box.
4. Optional: If you are using interface tables or flat files to exchange data between the integration framework and an external system, select the Support Flat File Structure check box.
5. In the Consumed By field, specify the module that uses the object structure.

Option	Description
<b>INTEGRATION</b>	Integration framework
<b>MIGRATIONMGR</b>	Migration manager
<b>REPORTING</b>	Reporting
<b>OSLC</b>	OSLC

6. In the Source Objects table window, click New Row.
7. Enter values in the following fields to create a business object hierarchy:
  - Object
  - Parent Object
  - Reporting Description
  - Relationship
  - Object Order
8. Click Save Object Structure.

## What to do next

If the Alias Conflict check box is selected on the object structure record, you can add or modify an alias to correct the duplicated field names in your source objects. You can also specify the persistent and nonpersistent fields that you want to exclude and include from the object structure.

## Configuring an alternate key

To configure an alternate key, create a unique index in the Database Configuration application and reference this index as the alternate key for an object structure or for a specific object.

## About this task

If you set the alternate key at the object level, the key applies to all uses of the object in any object structure. If you set the alternate key within the object structure, the key applies to the object only when it is accessed through the selected object structure.

## Procedure

1. Identify the field(s) of an object to use as the alternate key.
2. Select the object in the Database Configuration application.
3. Create a unique index for the field(s) in the Indexes tab.
4. Specify this index in the Alternative Key field in one of the following tabs:
  - a. In the Object tab of the Database Configuration application if you want to apply the alternate key to the object for all external data sources.
  - b. In the Object Structures tab of the Database Configuration application if you want to apply the alternate key to this specific usage of the object.

## Including nonpersistent fields in the object structure

You can include nonpersistent field data in an integration message. By default, the business object nonpersistent fields are excluded from the object structure definition. Business objects use nonpersistent fields for calculations or for temporary storage of data.

## Before you begin

If you want to change a predefined object structure, make a duplicate of that object structure to create a user-defined version that is suitable for modification.

## Procedure

1. In the Object Structures application, select the object structure that you want to update.
2. Select the business object that contains the nonpersistent field that you want to include.
3. From the Select Action menu, select Exclude/Include Fields.
4. Click the Non-Persistent Fields tab to display the nonpersistent fields in the business object.
5. Specify whether you want the nonpersistent field to be included or excluded.

Option	Included
<b>Include the field</b>	Selected
<b>Exclude the field</b>	Cleared

6. Click OK.

## What to do next

---

You can generate schema files and view the XML structures of an object structure web service.

---

## Excluding persistent fields from the object structure

You can exclude persistent field data that you do not want to map to an integration message. By default, the business object persistent fields are included in the object structure definition. Business objects use persistent fields to write processing data to a database.

---

### About this task

You cannot exclude a field that is part of a primary key. If you exclude a persistent field from a predefined object structure, the associated object might not function properly during inbound message processing. Test your inbound messages to ensure that an excluded persistent field does not impact the object processing.

---

### Procedure

1. In the Object Structures application, select the object structure that you want to update.
2. Select the business object that contains the persistent field that you want to exclude.
3. From the Select Action menu, select Exclude/Include Fields.
4. Click the Persistent Fields tab to display the persistent fields in the business object.
5. Specify whether you want the persistent field to be excluded or included.

Option	Excluded
Exclude the field	Selected
Include the field	Cleared

6. Click OK.

---

### What to do next

You can generate schema files and view the XML structures of an object structure web service.

---

## Resolving alias conflicts

An object structure that contains multiple objects and supports flat files or interface tables, cannot have duplicate field names for any of the fields in its objects. You must resolve any field name (alias) conflicts before you can generate interface tables and flat file records.

---

### About this task

If an alias conflict exists, the Alias Conflict check box is selected on the object structure record. You can change an alias only if the Support Flat File Structure check box is selected on the record, indicating that the data is processed using interface tables or flat files.

---

### Procedure

1. When an alias conflict exists, select a business object in the Source Objects table.
2. Select the Add/Modify Alias action.  
If a duplicate alias exists for a field, the corresponding Duplicate check box is selected.
3. To update a duplicate alias:
  - a. Click View Details for the duplicate alias.
  - b. Specify a new value in the ALIASNAME field.
  - c. Click OK.

---

### What to do next

After you resolve all alias conflicts, you can generate interface tables and flat file records. If you use interface tables, you must regenerate all tables that use the updated object structure. To regenerate interface tables, select the Create Interface Tables action in the External Systems application.

---

## Setting restrictions on fields for inbound messages

Standard integration processing sets the values in object fields with the corresponding values from an inbound message. You can set a field as restricted if you do not want the value to be updated by inbound messages, for example for a field with an internal ID or where a processing class provides the logic to set the field.

---

### Procedure

1. In the Object Structures application, select the Inbound Setting Restrictions action.
2. In the Inbound Setting Restrictions window, select the object that you want to apply setting restrictions to.  
The Inbound Setting Restrictions table refreshes with a list of the fields that are configured for the selected object.

3. Select the Restricted check box for any field that you do not want to be updated with values in inbound messages.
4. You can select the Override check box to remove the restrictions set for a field.  
You cannot override the restriction set on some fields, for example for a field with a system-generated ID.
5. Click OK to close the dialog box.

---

## Setting advanced configurations for an object structure

You can set advanced configurations for an object structure to change some default processing behavior for integration messages. Advanced configurations include configuring how key fields are processed for child objects, whether an event on a child object activates a corresponding event on the parent object, and whether auto-generated data is deleted.

### Procedure

---

1. Select the Advanced Configuration action.
2. Deselect the Exclude Parent Key Attributes check box for any object where you want these attributes to be included for child objects.  
When checked (the default), key fields that exist in a child object are not included in the section of the message for the child object if the same field is part of the key of the parent object. If you deselect this option, key fields for a child object are always included and the field is included in both the child object section of the message and the parent object section.
3. Select the Skip Key Update check box if you want to disable updates of primary keys.
4. Deselect the Delete Auto-generated Data check box for any object where you want to retain this data.  
When checked (the default), integration processing always deletes any child-level data that is automatically created by the business object logic when the parent object is created. If you deselect this option, any additional data that is auto-generated is retained.
5. Check the Propagate Event option for any object where you want an event on a child object to trigger an event on the main object.  
When you configure a publish channel to send messages based on an object event, the event listener is configured for the main object of the object structure. In some cases, an update to a child object does not trigger an event on the main object and no message is initiated. Check this option if you want an update to the child object to trigger an event to the main object without updating the main object. If a child object includes logic that triggers an event to its parent object, you cannot enable or disable it with this configuration.

---

## Message templates that specify outbound data

Message templates are an additional option for editing the structure of an outbound message. You use message templates to limit which data from the associated object structure is included in the message.

When you create the message template, you associate it with an object structure. A single object structure can have multiple message templates. You configure message templates on the Message Templates subtab on the Integration tab of the Administration Work Center.

After you add a message template, select it and then select the object and data from the object that you want to include in messages. Hover on a field to see information about various properties of the field, such as length and description.

---

## Publishing channels and services

Channels and services reference an object structure for their message content and enable the synchronous and asynchronous exchange of data with external systems. Outbound messages are processed by publishing channels and invocation channels. Inbound messages are processed by object structure services, enterprise services, and standard services.

- **[Publish channels](#)**  
A publish channel is used for sending asynchronous messages through a queue to an external system. Publish channel messages can be initiated via an event or through the Data Export feature.
- **[Invocation channels](#)**  
Invocation channels define the processing logic and mapping of inbound and outbound data, which enables the integration framework to call external applications and process responses. No predefined invocation channels are provided.
- **[Object structure services](#)**  
When you configure an object structure, no additional configuration is necessary to make it available as a service or a REST resource.
- **[Enterprise services](#)**  
An enterprise service is a pipeline for querying external data and importing data from an external system. An enterprise service can process data synchronously (without a queue) or asynchronously (with a queue). Enterprise services can use multiple protocols, such as web services and HTTP.
- **[Standard services](#)**  
A standard service is based on an annotated method in an application. A standard service is specific to the method annotated for an object and is not reusable for other objects. You can deploy a standard service as a web service. You can access a standard service by using the REST API.

---

## Publish channels

A publish channel is used for sending asynchronous messages through a queue to an external system. Publish channel messages can be initiated via an event or through the Data Export feature.

The integration framework includes predefined publish channels or you can configure new publish channels. When configuring a publish channel, you must associate it with an object structure, and, optionally, enable an event listener.

You must also configure the publish channel with an external system to determine where the message is delivered to and configure an endpoint that routes the message to the specified external system.

You can also configure processing rules, Java™ processing classes, or XSL mapping to customize transaction processing of the publish channel.

- [Creating publish channels](#)  
You can create a publish channel record to send integration messages to an external system. Messages are based on an associated object structure.
- [Enabling publish channel listeners](#)  
You enable an event listener on a publish channel to monitor for processing activity on the associated publish channel objects. Publish channel processing is initiated when an event occurs on the main object of the associated object structure.

---

## Creating publish channels

You can create a publish channel record to send integration messages to an external system. Messages are based on an associated object structure.

---

### Before you begin

Before you create and configure a publish channel, use the Object Structures application to configure the object structure that you intend to associate with the publish channel.

---

### Procedure

1. In the Publish Channels application, click New Publish Channel.
2. Specify a name for the publish channel.
3. In the Object Structure field, specify the object structure to use with the publish channel.  
The Object Structure Sub-Records section refreshes with details of the objects that are contained in this object structure.
4. Optional: To restrict publish channel events to the main object of the object structure, select Skip Different Object Types.  
This option can help to avoid publishing errors when there are multiple objects associated with an object structure.
5. Optional: To send messages in JSON format, select the Publish JSON checkbox.  
Publish channels send messages in XML format by default.
6. Optional: If you intend to use an interface table as the data source, specify its name in the Interface Table field.  
The object structure must be configured to support flat files to be used with interface tables
7. Optional: If you intend to customize outbound processing logic, specify the paths for the Java™ Classes and the XSL style sheet in the following fields:
  - a. Processing Class
  - b. User Exit Class
  - c. XSL Map
  - d. Event Filter ClassAny Java classes you specify must be part of the application EAR file. An XSL file can be within the EAR file or located on an accessible file system.
8. Optional: Configure processing rules for the publish channel. Prevent the publish channel from processing business object-based rules by clearing the Retain Objects checkbox.
9. Save the publish channel.

---

### What to do next

You can enable a publish channel listener to direct the integration framework to build and process the selected publish channel. You can also use the External Systems application to associate the publish channel with an external system and identify an endpoint for delivering messages from the publish channel.

---

## Enabling publish channel listeners

You enable an event listener on a publish channel to monitor for processing activity on the associated publish channel objects. Publish channel processing is initiated when an event occurs on the main object of the associated object structure.

---

### Procedure

1. In the Publish Channels application, select the publish channel that you want to configure with an event listener.
2. Select the Enable Event Listener action.
3. Click OK to enable the publish channel listener.  
The details for the publish channel refresh and the Event Listener check box is now selected.

---

### What to do next

Select Disable Event Listener action if you want to disable the event listener at any time..

## Invocation channels

Invocation channels define the processing logic and mapping of inbound and outbound data, which enables the integration framework to call external applications and process responses. No predefined invocation channels are provided.

- **[Creating invocation channels](#)**  
You can create an invocation channel record to send outbound data from an object structure to an external system and to process responses from the external system.
- **[Configuring an action to call an invocation channel](#)**  
The integration framework provides a default action class that you can configure as a system action. By providing this action class, you can configure a user interface control, an escalation, or a workflow to invoke an external service using an invocation channel.
- **[Invoking an external system from an application](#)**  
After configuring an action class to invoke an external system (via an invocation channel), you can configure a button in an application to trigger the invocation action. You can also extend the action class to display the results of the transaction in an application dialog box.

## Creating invocation channels

You can create an invocation channel record to send outbound data from an object structure to an external system and to process responses from the external system.

### Before you begin

You must include the defined processing class, user exit class, and XSL mapping files in the application EAR file. You also must define an XSL mapping filename path that is accessible by the application server.

### Procedure

1. In the Invocation Channels application, click New Invocation Channel.
2. In the Invocation Channel field, specify an invocation channel identifier.
3. Enter values in the following fields:
  - Adapter
  - Endpoint
4. Optional: If this invocation channel processes responses from an external application, select the Process Response check box.
5. In the Service Request Configuration table window, enter values in the following fields:

Option	Description
<b>Request Object Structure</b>	The object structure that is used to define the content for outbound data processing.
<b>Request Processing Class</b>	The Java™ class file that is used when the invocation channel requires predefined outbound processing logic.
<b>Request User Exit</b>	The class file that the invocation channel uses to customize the predefined outbound processing logic
<b>Request XSL File</b>	The XSL file that is used to customize predefined outbound invocation channel mapping.

6. Optional: If you selected the Process Response check box, enter values in the following fields in the Service Response Configuration table window:

Option	Description
<b>Response Object Structure</b>	The object structure that is used to define the content for the response.
<b>Response Processing Class</b>	The Java class file that is used when the invocation channel requires predefined inbound processing logic for the response.
<b>Response User Exit Class</b>	The class file that the invocation channel uses to customize the predefined inbound processing logic for the response.
<b>Response XSL File</b>	The XSL file that is used to customize predefined inbound invocation channel mapping for the response.

7. Click Save Invocation Channel.

### What to do next

You can view the XML schema of the object structure using a URL with the following format:  
`http://localhost:port/meaweb/schema/service/object_structure_name`

## Configuring an action to call an invocation channel

The integration framework provides a default action class that you can configure as a system action. By providing this action class, you can configure a user interface control, an escalation, or a workflow to invoke an external service using an invocation channel.

### Procedure

1. Create an invocation channel in the Invocation Channels application.
2. Create an action in the Actions application.
3. Specify an object for the action.  
This object must be the same as the main object of the request object structure of the invocation channel and the main object of the application, workflow, or escalation that invokes the action.
4. Specify Custom Class in the Type field.

5. Specify the name of the custom class in the Variable field.  
You can use the name of the default class provided for this purpose, `psdi.iface.action.InvokeCustomClass`, or an alternative class name if you created your own custom class to invoke an external system.
6. Specify values in the Parameters/Attributes field.  
Specify the values in the following order, and separate each value with a comma:
  - a. Required: The name of the invocation channel to use.  
The value must be precisely the same as the name of the invocation channel.
  - b. Optional: The name of the relationship to use if the main object of the response object structure is different from the main object of the request object structure in the invocation channel. If the response object is the same as the request object, no relationship is required.
  - c. Optional: If you specified a relationship, specify the action to apply. The default action is Add, which creates records. To update existing records, specify Change as the action. If the request and response object structures are the same, the objects are updated if updated fields are mapped into the response object structure.
7. Specify whether to apply the action to all applications, to workflows, or applications.
8. Save the action.

---

## What to do next

Associate an application, workflow, or escalation with the action. The main object is passed to the action class and then to the object structure of the invocation channel to form the request XML.

---

## Invoking an external system from an application

After configuring an action class to invoke an external system (via an invocation channel), you can configure a button in an application to trigger the invocation action. You can also extend the action class to display the results of the transaction in an application dialog box.

---

## Before you begin

You must create an invocation channel and an action class before you add the invocation action to an application. If you intend to show the results of the invocation, create a Results (dialog) window in advance.

---

## Procedure

1. Open the application in the Application Designer application.  
The main object for this application must be same as the main object for the invocation channel and the action that you intend to call from the application.
2. Add a Button Group control to the workspace from the Control Palette.  
The Button Group control automatically adds a Pushbutton control to the workspace.
3. Click Properties to open the Pushbutton Properties window.
4. Specify a name for the button in the Value field, for example `Invoke External System`.
5. Specify the Control ID for the Results window in the Target ID field.
6. Specify a method in the Value field that calls the invocation channel and redirects the results to the Results window.  
For example:

```
InvokeChannelCache.getInstance().getInvokeChannel(channelName)
.invoke(metadata, mbo, mbo.getMboSet(rel), action, null);
```

Where:

- The `channelName` value is the name of the invocation channel.
- The `mbo` value is the name of the object.
- The `rel` value is the name of the relationship (if applicable).
- The `action` value is Add.

---

## Object structure services

When you configure an object structure, no additional configuration is necessary to make it available as a service or a REST resource.

---

## Enterprise services

An enterprise service is a pipeline for querying external data and importing data from an external system. An enterprise service can process data synchronously (without a queue) or asynchronously (with a queue). Enterprise services can use multiple protocols, such as web services and HTTP.

An enterprise service has data processing layers that transform data and apply business processing rules to data before the it reaches the target objects. When the inbound message reaches the object structure layer, the XML message must be in the format of the object structure schema. The integration framework can then can process the message successfully.

You can configure an enterprise service to implement the following transaction processing:

- Processing rules

- User exit Java™ processing class
- Enterprise service processing class
- XSL mapping

The gateway is the entry point for enterprise service messages, excluding those that are delivered directly from an external queue to the integration queue. For some integration scenarios, it can be useful to configure gateway properties, for example if properties such as system IDs are provided within the XML message rather than in the header information. You can configure an interpreter Java class to change the external system ID, the enterprise service ID, or other JMS message header properties that are provided in an inbound message. Alternatively, you can configure gateway properties in the Enterprise Services application.

- [Configuring an enterprise service](#)

When you create an enterprise service, you associate it with an object structure. You can also configure gateway properties that are added to the header information of inbound messages.

## Configuring an enterprise service

When you create an enterprise service, you associate it with an object structure. You can also configure gateway properties that are added to the header information of inbound messages.

- [Creating an enterprise service](#)

You can create an enterprise service record to receive inbound data from an external system. On the enterprise service, you can identify the data transformation and processing rules that the integration framework uses to receive inbound data from an external system.

- [Configuring additional object structures for an enterprise service](#)

An enterprise service must be associated with a primary object structure. You can add additional object structures to an enterprise service to support updating additional data that is not included in the primary object structure of the enterprise service. Based on the defined processing order, the enterprise service processes additional object structures before it processes its primary object structure.

- [Adding gateway properties to an enterprise service](#)

The gateway is the entry point for enterprise service messages, excluding those that are delivered directly from an external queue to the integration queue. An interpreter Java™ class can be implemented that can change the external system (SENDER) or the enterprise service (INTERFACE) and can set other JMS header properties as needed. In the Enterprise Services application, you can set gateway properties either as hard-coded values or by specifying XML tags.

## Creating an enterprise service

You can create an enterprise service record to receive inbound data from an external system. On the enterprise service, you can identify the data transformation and processing rules that the integration framework uses to receive inbound data from an external system.

## Before you begin

Before you create and configure an enterprise service, use the Object Structures application to configure the object structure that you associate with the enterprise service.

## About this task

When the Use External Schema check box is selected, the Split Tag, External Schema File, and External Schema Element fields are editable. The external schema values identify the schema location and external root element name.

## Procedure

1. In the Enterprise Services application, click New Enterprise Service.
2. In the Enterprise Service field, specify an enterprise service identifier.
3. Enter a values in the following fields:
  - Object Structure
  - Adapter
4. Optional: Enter values in the following fields:

Option	Description
<b>Operation</b>	Determines how the Enterprise Service processes data. For example, you can synchronize objects or create new objects. You can also update, delete, or query existing objects.
<b>Multiplication Control</b>	Determines the cross-reference control that the enterprise service uses to multiply an inbound message for multiple organizations or sites.
<b>Interface Table</b>	Reflects the content of the enterprise service object structures.
<b>Split Tag</b>	Identifies whether the received message contains multiple instances of a document. For example, a single message can contain ten purchase orders. The split process handles each of these instances individually. The application writes multiple files to the inbound queue. The syntax that you use to identify these node values should have a fully qualified XPATH expression.

5. Optional: To use an external schema, select the Use External Schema check box.
6. Optional: You can customize inbound enterprise service processing logic by completing the following steps:
  - a. In the Processing Class field, enter a class value if the enterprise service requires predefined inbound processing logic.
  - b. In the User Exit Class field, enter a class value the enterprise service uses to customize the predefined inbound processing logic.

- c. In the XSL Map field, enter a value to customize the predefined inbound enterprise service mapping.
7. Click Save Enterprise Service.

## What to do next

---

You can use the External Systems application to associate the enterprise service with an external system.

## Configuring additional object structures for an enterprise service

---

An enterprise service must be associated with a primary object structure. You can add additional object structures to an enterprise service to support updating additional data that is not included in the primary object structure of the enterprise service. Based on the defined processing order, the enterprise service processes additional object structures before it processes its primary object structure.

### Procedure

---

1. In the Enterprise Services application, display the service for which you want to add an object structure.
2. Select the Add/Modify Additional Object Structure action and click New Row.
3. Enter values in the following fields:
  - Object Structure
  - Processing Order
4. Optional: You can customize inbound enterprise service processing logic by completing the following steps:
  - a. In the Processing Class field, enter a class value if the enterprise service requires predefined inbound processing logic.
  - b. In the User Exit Class field, enter a class value the enterprise service uses to customize the predefined inbound processing logic.
  - c. In the XSL Map field, enter a value to customize the predefined inbound enterprise service mapping.
  - d. In the Multiplication Control field, enter a value to define the cross-reference control that the enterprise service uses to multiply an inbound message for multiple organizations or sites.
5. Click OK.

## Adding gateway properties to an enterprise service

---

The gateway is the entry point for enterprise service messages, excluding those that are delivered directly from an external queue to the integration queue. An interpreter Java™ class can be implemented that can change the external system (SENDER) or the enterprise service (INTERFACE) and can set other JMS header properties as needed. In the Enterprise Services application, you can set gateway properties either as hard-coded values or by specifying XML tags.

### Before you begin

---

Review the following points about the settings in the Gateway Properties before you configure the gateway properties:

- If you select the XML Tag check box and leave the Value field null, the gateway uses the name of the root element in the XML message as the value for the corresponding property.
- If you select the XML Tag check box and enter a tag name in the Value field, the gateway uses the value for that tag as the value for the corresponding property.
- If the tag appears multiple times in the XML message, the adapter uses the value of the first occurrence of the tag. If you clear the XML Tag check box and enter a data value in the Value field, the gateway uses that data as the value for the corresponding property.

### Procedure

---

1. In the Enterprise Services application, display the service for which you want to add a gateway property.
2. Select the Gateway Properties action.
3. In the Gateway Properties for Enterprise Service table window, click New Row.
4. In the Property field, specify the name of the property that you want to include in the message.
5. In the Value field, type the data that you want to use as the value of the property.
6. Optional: Specify whether you want to use the XML root element as the value of the corresponding property.

Option	XML Tag
Use the XML root element	Selected
Do not use the XML root element	Cleared

7. Click OK.

## Standard services

---

A standard service is based on an annotated method in an application. A standard service is specific to the method annotated for an object and is not reusable for other objects. You can deploy a standard service as a web service. You can access a standard service by using the REST API.

A standard service is a service that an application provides for performing a specific operation on an object. Standard services are available only for methods that are properly annotated within the service. The service schemas that are generated for standard services are used only by the corresponding actions.

---

## Endpoints and handlers

An endpoint and its associated handler route outbound messages to an external system. The combination of an endpoint and handler specify the transport protocol to use or web service, and provide the communication data required to reach the destination, such as a URL.

For data export using a publish channel, the cron task for the outbound queue invokes the handler. For a data export using an invocation channel, the invocation channel invokes the handler directly. The handler uses the metadata properties of the message to determine the external system for a publish channel transaction and any override values configured for the endpoint properties. The handler then sends the data to the destination that is specified by the endpoint associated with the handler. A single handler can have multiple endpoints, and each endpoint can contain different parameters.

Endpoints and handlers are used for outbound integration only. However, the interface table endpoint and handler also support the creation of interface tables, which are needed for inbound integration.

Endpoints provide the execution parameter values that the handler uses to perform its function. The metadata included with the endpoint definition, together with the outbound integration message, are used by the handler at the time of execution. Some handlers have predefined endpoints. These can be modified or new endpoints configured using the End Points application. The following table lists predefined endpoints.

Endpoint	Handler	Description
MXFLATFILE	FLATFILE	Writes outbound integration messages in a flat file format to a specified directory location.
MXIFACETABLE	IFACETABLE	Writes outbound integration messages to interface tables.
MXXMLFILE	XMLFILE	Writes outbound integration messages in an XML file format to a specified directory location.
MXCMDLINE	CMDLINE	Implements the CMDLINE handler. Takes a command and endpoint as input and uses the SSH protocol to invoke the command on the target system and return the results.

A number of predefined handlers are provided. For several of these handlers, corresponding endpoint definitions have been configured. The endpoint definition provides the metadata values for the handler parameters, such as a directory name for the FLATFILE handler.

- [Configuring an endpoint](#)  
In the End Points application, you can create an endpoint that specifies how outbound transactions are delivered and the handler that routes them.
- [Predefined endpoint handlers and properties](#)  
Predefined handlers are provided that you can associate with an endpoint. Learn more about the handlers and how to configure their properties. Additionally, you can create and register custom handlers when needed.
- [Configuring OAuth access](#)  
If you want to use an OAuth authentication service to provide secure delegated access to Maximo® Manage data, you can configure OAuth access for the HTTP handler and the WEBSERVICE-JAX-WS handler.

---

## Configuring an endpoint

In the End Points application, you can create an endpoint that specifies how outbound transactions are delivered and the handler that routes them.

- [Creating endpoints](#)  
You create an endpoint to identify a target location and the transport mechanism that the integration framework uses to publish data or to start a service.
- [Adding a handler to an endpoint](#)  
You can add a handler to an endpoint record to specify how to route outbound data to a specific endpoint location. You can also add a handler to define the data format that is used in the data transfers. When you create a handler, you must identify the specific Java™ class file that contains the processing logic that you need for data transfers.
- [Writing custom handlers](#)  
You can write a custom handler and associate it with an endpoint, for example to support communication with an FTP server.

---

## Creating endpoints

You create an endpoint to identify a target location and the transport mechanism that the integration framework uses to publish data or to start a service.

---

### Procedure

1. In the End Points application, add an endpoint and specify an identifier for it.
2. In the Handler field, select a value.  
The handler's endpoint properties are displayed and the Consumed By field displays the information that is associated with the specified endpoint handler.
3. In the Properties for End Point window, configure values for the endpoint properties that you need.
  - a. If you configure a Password property, add an encrypted value to specify that the endpoint needs more security for storage and display.
  - b. Optional: Select the Allow Override checkbox to identify properties that can be overwritten.  
Select this checkbox when you use an invocation channel processing class.
4. Optional: Test the endpoint by selecting Test, selecting a local test file, and selecting Test again.
5. Save the endpoint.

---

### What to do next

You can add a handler to specify how to route outbound data to a specific endpoint location in a specific format. You can use the endpoint in the following integration framework applications:

- External Systems
- Publish Channels
- Invocation Channels
- Integration Modules
- Logical Management Operations

---

## Adding a handler to an endpoint

You can add a handler to an endpoint record to specify how to route outbound data to a specific endpoint location. You can also add a handler to define the data format that is used in the data transfers. When you create a handler, you must identify the specific Java™ class file that contains the processing logic that you need for data transfers.

### About this task

---

You cannot modify or delete a predefined handler.

### Procedure

---

1. In the End Points application, select the endpoint that you want to update with handler information.
2. Select the Add/Modify Handlers action.
3. Click New Row.
4. Enter values in the following fields:
  - Handler
  - Handler Class Name
  - Consumed By
5. Click OK.

---

## Writing custom handlers

You can write a custom handler and associate it with an endpoint, for example to support communication with an FTP server.

### Procedure

---

1. To write a custom handler, implement the RouterHandler interface.
2. Specify the following method to return a list of properties that the handler uses to send data to the endpoint:

```
getParameter()
```

The method returns a list of RouterPropsInfo objects. The isCrypto attribute in the RouterPropsInfo object indicates whether to encrypt the property value while storing data. For password properties, the value of this attribute is True.

3. Specify the following method to send data to the specified endpoint:

```
sendData(Map metaData, byte[] data, Map destinationMap)
```

The method returns the following information:

- Metadata provides information about the external system and the interface.
- Data is the XML data.
- DestinationMap specifies the endpoint.

---

## Predefined endpoint handlers and properties

Predefined handlers are provided that you can associate with an endpoint. Learn more about the handlers and how to configure their properties. Additionally, you can create and register custom handlers when needed.

- [Enterprise bean handler](#)  
The Enterprise Java™ Bean (EJB) handler is a Java component that consists of enterprise bean clients. The handler publishes a set of properties that a client uses to communicate with and deliver an integration message to a target client. The target client can run on the local application server or on a remote application server.
- [Flat file handler](#)  
The FLATFILE handler converts an outbound integration message into a flat file and writes it to a directory that has a configurable location. Flat files contain ASCII data in the form of rows and columns. Each line of text constitutes one row, and a separator character separates each column in the row. The FLATFILE handler encodes outbound flat files in the standard UTF-8 format.
- [Kafka handler and properties](#)  
You can configure an endpoint to use the Kafka handler to send exchange inbound or outbound messages to with the object storage for your Kafka provider.
- [HTTP handler](#)  
The HTTP handler is a Java component that consists of properties. The handler delivers an outbound integration message to a URL by using HTTP or HTTPS protocols. The HTTP handler also evaluates the response code received from the external system.

- [S3 handler and properties](#)  
You can configure an endpoint to use a Simple Storage Service (S3) handler to exchange inbound or outbound messages with an S3 object storage provider.
- [IFACETABLE handler](#)  
The IFACETABLE handler consists of several properties. This handler writes an outbound integration message to an interface table in a local or remote database. There are no Java exit classes for this handler.
- [JMS handler](#)  
The JMS handler delivers outbound integration messages to a JMS-compliant messaging system that supports a JMS queue or topic.
- [Web service handler](#)  
The web service handler is a Java client that can invoke any document-literal web service that is WS-I BP 1.1 compliant. The outbound integration message forms the payload (SOAP body) and the handler provides the SOAP headers and envelope. This handler operates independent of the container.
- [Web service handler \(JAX-WS\)](#)  
The WEBSERVICE-JAX-WS handler is a Java client that can invoke any document-literal web service that is WS-I BP 1.1 compliant. The outbound integration message forms the payload (SOAP body) and the handler provides the SOAP headers and envelope.
- [XML file handler](#)  
The XML file handler is a Java component that writes an outbound integration message into a file in XML format.
- [Command line handler](#)  
The CMDLINE handler takes a command and an endpoint as input. The CMDLINE handler uses the SSH protocol to run the command on the target system and return the results.

---

## Enterprise bean handler

The Enterprise Java™ Bean (EJB) handler is a Java component that consists of enterprise bean clients. The handler publishes a set of properties that a client uses to communicate with and deliver an integration message to a target client. The target client can run on the local application server or on a remote application server.

To establish a connection, the remote Java class and the home Java class must be available in the class path of the handler. If the client is on a remote application server that is different from the handler application server, the client jar file reference must be in the class path of the handler. The handler picks up the context factory class name from the local application server when the enterprise bean client is on a remote application server that is the same as the handler application server.

---

## CONTEXTFACTORY property

This required property specifies a J2EE context factory class name. The documentation for your application server contains the name of the default context factory to use.

---

## EJBEXIT property

This optional property is used for customization and specifies the fully qualified name of a custom Java class that implements the EJBExit interface.

If you do not specify a value for this property, the DefaultEJBExit interface is executed and attempts to resolve the enterprise bean method signature and parameters.

If the enterprise bean client has its own method signature and parameters, create a Java class that contains your version of the EJBExit interface and implementations of the following methods:

```
public Class[] getClassParams()
```

The getClassParams() method returns the method signature in the form of an array of Java classes.

```
public Object[] getObjectParams(byte[] data, String interfaceName, Map String, ? metaData) throws MXException
```

The getObjectParams() method returns the parameters of the enterprise bean business method in the form of an array of Java objects.

```
public void responseOk(Object response) throws MXException
```

The responseOk() method is called after a successful enterprise bean invocation.

```
public void responseError(Exception e) throws MXException
```

The responseError() method is called with the originating exception as a parameter if an error is encountered during enterprise bean invocation.

The following code illustrates what your implementation of getClassParams() looks like when the enterprise bean client has a business method with a byte array and a string:

```
Class[] classParams = {byte[].class, String.class};
return classParams;
```

The following code illustrates what your implementation of getObjectParams() looks like when the enterprise bean client has a business method with a byte array and a string:

```
byte[] data = ...;
String ifaceType = ...;

Object[] objParams = {data,ifaceType};
return objParams;
```

Complete one of the following actions to identify the location of the package structure for the EJBExit class file:

- Place the class in the Java package structure in the applications/maximo/businessobjects/classes directory.

- Modify the mboweb\webmodule\META-INF\MANIFEST.MF class path to include the package structure.
- Rebuild the application EAR file and include the EJBExit class file.

## JNDIName property

---

This required property specifies the name by which the enterprise bean client is registered in the Java Naming and Directory Interface (JNDI) tree on the application server. The filename is ibm-ejb-jar-bnd.xml and the property is set to

```
<ejbBindings
xmi:id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mif.doc_gp_intfrmwk_r_ejb_handler_Session_enterpr
iseservice_Bnd"
 jndiName="ejb/maximo/remote/enterpriseservice">
 <enterpriseBean xmi:type="ejb:Session"
 href="#_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mif.doc_gp_intfrmwk_META-INF_ejb-
jar.xml_Session_enterpriseservice"/>
</ejbBindings>
```

## METHODNAME property

---

This required property specifies the public business method that is exposed by the enterprise bean client that is invoked by this handler.

## PROVIDERURL property

---

This required property specifies the URL of the target application server on which the enterprise bean is running. The system then maps to the java.naming.provider.url property and creates the InitialContext object.

If the handler and the target enterprise bean are running on the same application server instance, do not specify this property because it defaults to the local server URL.

## USERNAME and PASSWORD properties

---

The user name and password properties correspond to the java.naming.security.principal (USERNAME) and java.naming.security.credentials (PASSWORD) properties that are used to create the InitialContext object.

## Flat file handler

---

The FLATFILE handler converts an outbound integration message into a flat file and writes it to a directory that has a configurable location. Flat files contain ASCII data in the form of rows and columns. Each line of text constitutes one row, and a separator character separates each column in the row. The FLATFILE handler encodes outbound flat files in the standard UTF-8 format.

The FLATFILE handler can be used only with publish channels, not invocation channels. The object structure associated with the publish channel must be configured to support flat files. You must resolve all alias conflicts for the object structure and format the XML message according to the object structure schema before writing the message to a flat file.

## Naming conventions

---

File names require the following format.

externalsystemname\_publishchannelname\_uniqueidentifier.dat

- externalsystemname is the identifier of the system (the value of MAXVARS.MXSYSID).
- publishchannelname is the name of the publish channel.
- uniqueidentifier is a number based on current system time.

The following example file name indicates that the file goes to the external system EXTSYS1 and was published through the MXASSETInterface publish channel:

EXTSYS1\_MXASSETInterface\_10971102668641498.dat

The first two lines of the file contain header information. The first line has the following format:

```
externalsystemname <separator>
publish channel name <separator> [action] <separator> langcode
```

The second line of the file contains the names of the columns, separated by the separator character. The column names are the same as the names in the corresponding interface table.

## Flat file format

---

If the data in the flat file contains the flat file delimiter character, the data adds the text qualifier, which is " (quotation marks). If the data contains quotation marks, the handler escapes the quotation marks. You cannot use quotation marks as the delimiter character.

The following example data uses a comma (,) as a delimiter. The INVOICEDISC value, (Rotating Custom Item, No 71), contains a comma. When the flat file is written, the INVOICEDISC value is enclosed in quotation marks.

```
EXTSYS1,MXINVOICEInterface,Add
INVOICENUM,INVOICEDESC,PONUM,VENDOR,CONTACT,PAYMENTTERMS
1071,"Rotating Custom Item, No 71",1000,A0001,,
```

The following example data uses a comma (,) as a delimiter. The INVOICEDESC value (Rotating "Custom" Item No 71) contains double quotation marks. When the flat file is written, double quotation marks in INVOICEDESC data ends with quotation marks, and the entire string is wrapped in quotation marks.

```
EXTSYS1,MXINVOICEInterface,Add
INVOICENUM,INVOICEDESC,PONUM,VENDOR,CONTACT,PAYMENTTERMS
1071,"Rotating ""Custom"" Item No 71",1000,A0001,,
```

The following example data uses a comma (,) as a delimiter. The INVOICEDESC data (Rotating "Custom" Item, No. 71) contains the delimiter character and double quotation marks. When the flat file is written, the INVOICEDESC value appears in the code.

```
EXTSYS1,MXINVOICEInterface,Add
INVOICENUM,INVOICEDESC,PONUM,VENDOR,CONTACT,PAYMENTTERMS
1071,"Rotating ""Custom"" Item, No. 71",1000,A0001,,
```

## Flat file properties

The FLATFILEDIR property is an optional property that specifies the location of flat files on a server. The location must exist on the server where the JMS CRON task for the outbound queue is running, or on an accessible shared network drive. The default value points to the global directory. To specify a location for the global directory, configure the mx.int.globaldir property in the System Properties application.

In a multitenancy environment, the FLATFILEDIR property is required and is made available by the system provider.

The FLATFILESEP property is a required property that specifies the character that separates the columns in each row.

## Kafka handler and properties

You can configure an endpoint to use the Kafka handler to send exchange inbound or outbound messages to with the object storage for your Kafka provider.

Configure these Kafka handler properties for an endpoint in the End Points application:

Topic

The identifier of the inbound or outbound queue.

Bootstrapservers

The comma-separated list of servers that host your Kafka instance. Include the port specification.

Password

The password for authenticating to your Kafka instance. You can specify whether the value is encrypted.

Username

The User ID for authenticating to your Kafka instance.

## HTTP handler

The HTTP handler is a Java™ component that consists of properties. The handler delivers an outbound integration message to a URL by using HTTP or HTTPS protocols. The HTTP handler also evaluates the response code received from the external system.

## HTTPEXIT property

This optional property is used for customization and specifies the fully qualified name of a Java class that interprets the HTTP response. This property also helps implement the code that is required for an external system to interpret the HTTP response.

Tip: You also can configure HTTP handler exits by using automation scripts. For more information about configuring with a script, see [Defining an HTTP handler using a script](#).

The Java class must be available in the application EAR file and must be in the class path of the handler.

Table 1. Property values

Property	Value
Java class	DefaultHTTPExit.java
Package	psdi.iface.router
HTTPEXIT property	psdi.iface.router.DefaultHTTPExit

If you do not specify a value for this property, the DefaultHTTPExit exit class is executed and implements the psdi.iface.router.HTTPExit interface. The Java class has the following key methods:

Table 2. Key methods for the Java class

Method	Signature	Description
--------	-----------	-------------

Method	Signature	Description
processResponseData()	<code>public void processResponseData(int responseCode, String responseMsg, byte[] msgBodyData) throws MXException</code>	<p>The default implementation compares the response code from the external system to a range of valid codes (values 200 through 299). If the response code falls outside that range, the system assumes that the message was not delivered to the external system. An exception occurs and the message remains in the queue.</p> <p>If you need additional processing for a specific implementation, extend the default implementation and override the processResponseData () method. As an alternative, you can implement the psdi.iface.router.HTTPExit interface. If the response that is received from the external system does not pass the validation in this class, the overriding method must issue an exception.</p> <p>If you do not define a value for this property, the default implementation of HTTPExit is run.</p>
getURLProperties()	<code>public Map String, String getURLProperties(Map String, ? metaData, byte[] data, Map String, MaxEndPointProp Info httpInfo)</code>	Returns the map of URL properties that are added to the URL in the form <code>url?prop1=value1&amp;...</code> . The default implementation returns a null value.
getHeaderProperties()	<code>public Map String, String getHeaderProperties(Map String, ? metaData, byte[] data, Map String, MaxEndPointProp Info httpInfo)</code>	Returns a map of the HTTP header properties for the request. The default implementation returns a null value unless a header property map is associated with the metadata map that has the HEADERPROPS key.
transformPayloadToFormData()	<code>public Map String, String transformPayloadToFormData(Map String, ? metaData, byte[] data, Map String, MaxEndPointProp Info destinationMap)</code>	Converts the XML payload to data. The default implementation returns a null value.

You can use the following methods to control the exception if an error occurs. If you create a script that includes one of these methods, select the Allow invoking methods check box so that the script processor can invoke the script functions that map to these methods.

Table 3. Methods for exception customization

Method	Description
urlProps()	Adds query parameters to a configured URL. The psdi.iface.router.ScriptHTTPRequest interface implements the request object.
getUrl()	Sets the URL for the HTTP call.
headerProps()	Sets the request headers for the HTTP call.
processResponse()	Processes the HTTP response. The psdi.iface.router.ScriptHTTPResp interface implements the response object.

## CONNECTTIMEOUT property

This optional property specifies the connection timeout value in milliseconds.

## READTIMEOUT property

This optional property specifies the read timeout value in milliseconds.

## HTTPMETHOD property

This required property specifies a valid HTTP method that is executed by the endpoint. Valid HTTP methods are GET, POST, PUT, PATCH, and DELETE.

## HTTPHEADER property

This optional property can add a comma-separated list of names and values to the header section of HTTP messages. The list includes name and value information in the format of Headername1:Headervalue1, Headername2:Headervalue2. If no value is provided in the property, custom code can inject the values into the transaction context during invocation channel processing.

## URL property

This optional property specifies a valid URL to which XML data can be posted or where an HTTP GET operation can be performed.

## USERNAME and PASSWORD properties

If the URL requests basic authentication, these properties specify the required values. Both values are MIME encoded and are passed to the URL.

## OAUTHCIENT property

This optional property specifies the primary key for the MAXOAUTHCIENT object, which is used to configure OAuth for access to external services.

---

## S3 handler and properties

You can configure an endpoint to use a Simple Storage Service (S3) handler to exchange inbound or outbound messages with an S3 object storage provider.

IBM Cloud® Object Storage is one provider of Cloud Object Storage.

Configure the following S3 handler properties for an endpoint in the End Points application:

### URL

The URL of the S3 provider.

### Bucketname

The name of the container for objects that you store in S3 storage.

### Secretkey

The secret access key that you use to sign the HTTP requests that you make to S3. You must authenticate your request with both the access key ID and the secret access key.

### Accesskey

The access key ID that you use to sign the HTTP requests that you make to S3. You must authenticate your request with both the access key ID and the secret access key.

### Datareader

The property that specifies the class that is used to read files from S3. The default that is set for this property implements the data reader feature that is included in the application, which applies to most cases.

---

## Related information

- [Documentation for IBM Cloud Object Storage](#)

---

## IFACETABLE handler

The IFACETABLE handler consists of several properties. This handler writes an outbound integration message to an interface table in a local or remote database. There are no Java™ exit classes for this handler.

Only publish channels can use the IFACETABLE handler. Invocation channels cannot use this handler.

---

## ISREMOTE property

This required property is a Boolean value that specifies whether interface tables are available in the local database or in a remote database. A value of 0 (false) indicates that the interface tables are available in the local database in the system schema. You do not have to enter any other handler properties. In the predefined MAXIFACETABLE handler, the value of this property is 0. A value of 1 (true) indicates the interface tables are in a remote database. If necessary, specify values for all the handler properties.

---

## DRIVER property

This property specifies the JDBC driver to connect to a remote database that contains the interface tables. This property applies only when the value of the ISREMOTE property is 1.

---

## URL property

This property specifies the JDBC URL and applies only when the value of the ISREMOTE property is 1. The following example contains the location, port number, and database name:

```
jdbc:db2://hostname:port/maximodb
```

---

## USERNAME and PASSWORD properties

If access to the remote database requires a user name and password, these properties specify those values. These properties apply only when the value of the ISREMOTE property is 1.

---

## JMS handler

The JMS handler delivers outbound integration messages to a JMS-compliant messaging system that supports a JMS queue or topic.

The messaging models have the following characteristics:

- Point-to-point messaging (one to one): A sender generates messages and places them in a queue. Only one receiver can obtain the message from the queue.
- Publish-subscribe (one to many): A publisher generates messages and places them in a topic. Multiple subscribers can retrieve messages from the topic.

The messaging system represents a queue or topic that is available on the local application server, on a remote application server, or on a remote dedicated queuing system such as IBM® WebSphere® MQ. To use this handler, enable the messaging systems by using JMS. The messaging system is distinct from the

standard internal queues that reside on the local application server.

## CONFACTORYJNDINAME property

---

This required property specifies a Java™ object that is used to create connections to a JMS provider. Before the system can connect to a queue or topic, it must obtain a reference to a connection factory.

## DESTINATIONTYPE property

---

This optional property specifies the JMS destination type; queue or topic. The following table lists the DESTINATIONTYPE options and their associated values.

Destination	Value
Topic	javax.jms.Topic
Queue	javax.jms.Queue

## DESTJNDINAME property

---

This required property specifies the name by which the JMS queue or topic is registered in the application server Java Naming and Directory Interface (JNDI) tree.

## CONTEXTFACTORY property

---

This property specifies the initial context factory class name. The property is not required when the JMS handler is communicating with a JMS provider that shares the same initial context factory as the application server of the handler. When the handler and the JMS provider share an application server, they share the initial context factory class. The context property value is required when the handler and the JMS provider do not share an application server.

## ISCOMPRESS property

---

This required property specifies whether the message is compressed before it is placed into a queue or topic. Compression is an optimization technique that delivers smaller messages to a queue or topic. The following table lists the ISCOMPRESS options and their associated values.

Option	Value
Do not compress data	0
Compress data	1

Compressed messages must be extracted after they are received. Extract the messages by creating the appropriate JMS receiver or subscriber component and placing Java decompression logic within the receiver or subscriber. Use the standard Java Inflater() class that is part of the java.util.zip package. The default compression uses the standard Java Deflator() class.

## ISTEXT property

---

This optional property specifies whether the JMS handler will deliver messages to another queue in text format.

Option	Value
Deliver messages in default (bytes) format	0
Deliver messages in text format	1

## JMSEXIT property

---

In a multitenancy environment, customization by using Java classes can be implemented only by the system provider and may not be supported in your environment.

This optional property is used for customization and specifies the fully qualified name of a Java class that runs the JMSExit interface. The Java class must implement the getMessageProperties() method that is defined in the JMSExit interface. The Java class must be in the class path for the application server or in the application EAR file.

You can use this option change or add properties in the JMS message. If this property does not contain a value, the header attributes for the message are not changed when the message is delivered to the external queue or topic.

## PROVIDERURL property

---

This required property specifies a local or remote URL where the JMS provider can be accessed. If the target JMS provider is local to the application server of the handler, the property is not required.

## PROVIDERUSER and PROVIDERPASSWORD properties

---

These properties are used for the JMS provider authentication. The properties map to the connectionFactory.createConnection(provideruser,providerpassword) API in JMS.

## USERNAME and PASSWORD properties

---

These properties correspond to the `java.naming.security.principal` (USERNAME) and `java.naming.security.credentials` (PASSWORD) properties used for creating the `InitialContext` object.

---

## Web service handler

The web service handler is a Java™ client that can invoke any document-literal web service that is WS-I BP 1.1 compliant. The outbound integration message forms the payload (SOAP body) and the handler provides the SOAP headers and envelope. This handler operates independent of the container.

This web service handler supports an early implementation of web services and is provided to maintain backwards compatability with existing web services. If you are implementing new web services, configure them to use the web service handler for JAX-WS.

---

## MEP property

This optional property specifies the message exchange pattern for the web service. The property supports the following values. If you do not provide a value, the default value, the `sendreceive` value is used.

Value	Web Service Operation Type
<code>sendreceive</code>	Request and response
<code>sendrobust</code>	Request with void or fault response
<code>fireandforget</code>	Request only, no response, or fault

---

## ENDPOINTURL property

This required property specifies a valid web service URL on which to invoke a web service. You can use the `WSEXIT` class to override the value specified via the user interface just before the web service is invoked.

---

## SERVICENAME property

This required property specifies the name of the web service deployed in the URL.

---

## SOAPACTION property

This optional property specifies the value of the SOAPAction HTTP header to be used when invoking the web service. The default value is an empty string. To set a value for the property, view the WSDL file for a web service to determine the action and specify this value. You can use the `WSEXIT` class to override the value specified in the user interface before you invoke the web service.

---

## SOAPVERSION property

This optional property specifies the version of the SOAP specification used during web service call. Valid values are `SOAP11` and `SOAP12`.

---

## HTTPVERSION property

This optional property specifies the version of the HTTP protocol for web service invocations. The valid values are `HTTP/1.0` and `HTTP/1.1`. If you do not provide a value, the system uses the default value, `HTTP/1.1`.

---

## HTTPCONNTIMEOUT property

This optional property specifies the connection timeout value in milliseconds. The default value for this property is 60000 milliseconds.

---

## HTTPREADTIMEOUT property

This optional property specifies the read timeout value in milliseconds. The default value for this property is 60000 milliseconds.

---

## USERNAME and PASSWORD properties

If the specified web service is secured (if HTTP basic authentication is enabled), specify a user name and password.

---

## WSEXIT property

In a multitenancy environment, customization by using Java classes can be implemented only by the system provider and may not be supported in your environment.

This optional property is used for customization. It specifies the fully qualified name of a custom Java class that implements the `psdi.iface.router.WSExit` interface. The property defines the following methods:

The `responseOk()` method is called after a successful invocation of the external web service.

```
public void responseError(Exception e) throws MXException
```

If an error occurs when the web service is called, the `responseError()` method is called with the originating exception as a parameter.

The default implementation of the WSExit interface is `psdi.iface.router.DefaultWSExit`.

---

## Web service handler (JAX-WS)

The WEBSERVICE-JAX-WS handler is a Java™ client that can invoke any document-literal web service that is WS-I BP 1.1 compliant. The outbound integration message forms the payload (SOAP body) and the handler provides the SOAP headers and envelope.

This web service handler supports the implementation of web services for Maximo® Manage 8.3 and later. If you are implementing new web services, configure them to use this web service handler.

---

### MEP property

This optional property specifies the message exchange pattern for the web service. The property supports the following values. If you do not provide a value, the default sendreceive value is used.

Value	Web Service Operation Type
sendreceive	Request and response
sendrobust	Request with void or fault response
fireandforget	Request only, no response, or fault

---

### ENABLEAPPCONTEXT property

Set this property to 1 (true) when implementing support for WS-\* policies.

---

### ENDPOINTURL property

This required property specifies a valid web service URL on which to invoke a web service. You can use the WSEXIT class to override the value specified via the user interface just before the web service is invoked.

---

### SERVICENAME property

This required property specifies the name of the target web service that the handler invokes.

---

### SOAPACTION property

This optional property specifies the value of the SOAPAction HTTP header to be used when invoking the web service. The default value is an empty string. To set a value for the property, view the WSDL file for a web service to determine the action and specify this value. You can use the WSEXIT class to override the value specified in the user interface before you invoke the web service.

---

### SOAPVERSION property

This optional property specifies the version of the SOAP specification used during web service call. Valid values are SOAP11 and SOAP12.

---

### HTTPCONNTIMEOUT property

This optional property specifies the connection timeout value in milliseconds. The default value for this property is 60000 milliseconds.

---

### HTTPREADTIMEOUT property

This optional property specifies the read timeout value in milliseconds. The default value for this property is 60000 milliseconds.

---

### HTTPHEADER property

This optional property can add a comma-separated list of names and values to the header section of HTTP messages. The list includes name and value information in the format of Headervalue1:Headervalue1, Headervalue2:Headervalue2. If no value is provided in the property, custom code can inject the values into the transaction context during invocation channel processing.

---

### USERNAME and PASSWORD properties

If the specified web service is secured (if HTTP basic authentication is enabled), specify a user name and password.

---

### WSEXIT property

Tip: You also can configure SOAP endpoint exits by using automation scripts.

This optional property is used for customization. It specifies the fully qualified name of a custom Java class that implements the `psdi.iface.router.WSExit` interface. The property defines the following methods:

The `responseOk()` method is called after a successful invocation of the external web service.

```
public void responseError(Exception e) throws MXException
```

If an error occurs when the web service is called, the `responseError()` method is called with the originating exception as a parameter.

The default implementation of the `WSExit` interface is `psdi.iface.router.DefaultWSExit`.

---

## CFGXMLPATH property

This property is obsolete. Do not use it.

---

## OAUTHCLIENT property

This optional property specifies the primary key for the `MAXOAUTHCLIENT` object, which is used to configure OAuth for access to external services.

---

## XML file handler

The XML file handler is a Java™ component that writes an outbound integration message into a file in XML format.

---

## FILEDIR property

This optional property specifies where the handler creates the XML files. The default value is `mxe.int.globaldir/xmlfiles`. The file location must be accessible by the JMS CRON task for the outbound queue for publish channel messages. For Invocation Channel messages, the file location must be accessible by any Maximo® Manage servers where an invocation channel can be initiated.

---

## PRETTYPRINT property

This required property specifies whether the handler formats the XML file. The valid values are 0 and 1. A value of 1 prompts the handler to pretty print format the xml file. Publish channel, invocation channel, and invocation API file names have the following formats:

```
externalsystemname_publishchannelname_uniqueidentifier.xml
```

```
invocationchannelname_uniqueidentifier.xml
```

- `externalsystemname` is the identifier of the system (the value of `MAXEXTSYSTEM.EXTSYSNAME`).
- `publishchannelname` is the name of the publish channel.
- `uniqueidentifier` is a number based on current system time.

For example, the file name `MX_MXASSETInterface_10971102668641398.xml` indicates that the file was generated to send data to the external system `EXTSYS1`. The file name also indicates that the file contains the `MXASSETInterface` publish channel.

---

## Command line handler

The `CMDLINE` handler takes a command and an endpoint as input. The `CMDLINE` handler uses the SSH protocol to run the command on the target system and return the results.

A metadata parameter is passed during a system invocation when the handler is called. The parameter is a map that contains the name of the endpoint that represents the target system. The caller can target any system at run time and pass the endpoint to the command handler. The caller uses whatever configuration the endpoint has at the time of the invocation.

---

## CMDLINE handler properties

The `CMDLINE` handler has the following properties:

- `CMDTIMEOUT` – The timeout value for command execution
- `CONNTIMEOUT` – The timeout value for the connection
- `USERNAME` – The user name for the connection
- `PASSWORD` – The password for corresponding user name
- `HOST` – The host name of target where command is run
- `PORTNO` – The port number of target where the command is run
- `IGNORESETUPERR` – A boolean value that indicates whether to ignore an error running the setup command
- `RETRYINTERVAL` – The time to wait between retrying a command
- `MAXRETRY` – The number of attempts to run a command before returning an exception
- `SSHEXIT` – The Java™ exit class that can be implemented to customize processing of the handler

---

## Command data parameters

The data parameter is a byte array representation of an XML document. The data parameter contains the following information:

- The tags that correspond to the setup command
- The working directory
- The command to run
- Any substitution parameters

## Available tags

The following tags are available:

- CLWORKINGDIR – A directory to change (`cd`) to on the remote system before the command is run.
- CLSETUPCMD – A setup command to be run before the main command. Use this tag for any environmental setup that must occur on the remote system before the main command is issued.
- CLCMDPATTERN - A string that defines the pattern of the command to be run. The format of this pattern is similar to the `java.text.MessageFormat` class. An example is `ls -l {0}`, where `{0}` represents a parameter that is substituted.
- CLSUB0 - The value to substitute into positions that are marked by `{0}` in the CLCMDPATTERN.
- CLSUB1- The value to substitute into positions that are marked by `{1}` in the CLCMDPATTERN.
- CLSUBn - The value to substitute into positions that are marked by `{n}` in the CLCMDPATTERN. A CLSUBn tag must correspond to each substitution position in the CLCMDPATTERN tag.

## Command results

The return byte array representation of an XML document contains the results of the command. The XML document contains tags that correspond to the return value, STDOUT and STDERR.

The following tags are available:

- CLRETURNCODE – The return code from the remote command.
- CLRESPONSEOUT – The data that is returned by the remote command in STDOUT tag.
- CLRESPONSEERR – The data that is returned by the remote command in STDERR tag.

## Configuring OAuth access

If you want to use an OAuth authentication service to provide secure delegated access to Maximo® Manage data, you can configure OAuth access for the HTTP handler and the WEBSERVICE-JAX-WS handler.

## Before you begin

Details for the OAuth client access are stored in the MAXOAUTHCLIENT object.

Administrators must grant the appropriate authorizations to the MAXOAUTHCLIENT object structure by using the Security Groups application.

Because most OAuth handshakes are done over TLS, the Manage truststore must also be updated with the CA trust chain of the OAuth provider.

## About this task

Maximo Manage supports the OAuth 2.0 client credentials grant type. Using this flow, Maximo Manage sends a client ID and client secret to the URL of the OAuth provider for authentication and receives an access token.

The date and time that the access token is created are stored in the MAXOAUTHCLIENT object. The OAuth provider specifies an expiration interval for the access token, and the token expires at the end of that interval. After expiration, a new token is generated when a new authentication request occurs.

There are two options for adding or modifying OAuth clients:

- You can add or modify clients in the End Points application.
- You can add or modify clients by using a REST API call.

## Adding or modifying OAuth clients in the End Points application

In the End Points application, you can add OAuth clients or update existing clients.

### Procedure

1. In the End Points application, from the More Actions menu, select Add/Modify OAuth Clients.
2. In the Add/Modify OAuth Clients window, click New Row.
3. In the Details section on the Add/Modify OAuth Clients window, enter the details for the OAuth connection, as shown in the following table.

Option	Description
Client Name	Unique identifier of the OAuth client.
Client ID	Maximo Manage client ID that is registered with the OAuth provider.
Grant Type	Grant type for exchange. The default is <code>client_credentials</code> .
Token URL	URL of the OAuth provider, which is used to exchange the client ID with the access token.

Option	Description
<b>Client Secret</b>	Maximo Manage client secret that is registered with the OAuth provider. The clientsecret is encrypted in the Manage database. Because the table is backed up in cache, do not perform offline updates to the table.
<b>Scope</b>	Scope that specifies the permissions that are granted for the access token request. This field is optional.
<b>Refresh Token</b>	Token to support grant types that use a refresh token. Maximo Manage 8.3 does not support this attribute.

The following fields on the Add/Modify OAuth Clients window are read-only fields:

- The Expiry field displays the expiration interval in seconds for the access token.
- The Creation date field displays the date and time that the access token was created.

4. Click OK.

## Adding or modifying OAuth clients by using a REST API

The HTTP handler and the WEBSERVICE-JAX-WS handler include an oauthclient property. To add a client by using a REST API call, you must specify the value for the clientname attribute in the oauthclient property.

### Procedure

To configure the OAuth client for token exchange, you can send a REST API call that specifies values from the MXAPIOAUTHCLIENT object structure, as shown in the following example:

```
POST /oslc/os/mxapioauthclient?lean=1&ctx=ccrypto=1
{
 "clientname": "{user-defined name for the client}",
 "clientid": "{ID that is provided by the OAuth provider}",
 "clientsecret": "{secret that is provided by the OAuth provider}",
 "scope": "{optional scope}",
 "tokenurl": "{token URL that is provided by the OAuth provider}"
}
```

## Web services

External systems can use integration framework web services to send messages or queries to the Maximo® database. You can use an integration framework service as the source for a web service and then deploy this service to communicate with external systems.

The web services are based on the Java™ API for XML Web Services (JAX-WS). In earlier releases, the integration framework also supported AXIS2 web services but these web services are no longer supported. During an upgrade, any existing AXIS2 web services are automatically converted to JAX-WS web services.

In the WebSphere® Application Server Liberty environment, you can use Simple Object Access Protocol (SOAP) 1.1 and SOAP 1.2 with the JAX-WS as a transport protocol in the same web service instance.

- [Web service sources](#)  
The source of a web service can be an object structure service, a standard service, or an enterprise service.
- [Implementing SOAP 1.1 and 1.2 with JAX-WS web services](#)  
You can use SOAP (SOAP) 1.1 and SOAP 1.2 with the JAX-WS (Java API for XML Web Services) endpoint handler to exchange messages in a WebSphere Application Server Liberty environment.
- [Web service deployment options](#)  
After you create a web service, you have a choice of deployment options. If you deploy a web service to the product web service container, the deployment is automatic. If you deploy a web service to an application server web service container, the deployment is manual.
- [Web service deployment actions](#)  
When you deploy a web service, a number of events occur, including the generation of the XML schema and the web services description language (WSDL) file for the web service.
- [Schema generation](#)  
You can generate the schema and view the XML for any web service in the Web Services Library application. You can also regenerate the schema to ensure that the schema is updated to reflect any changes that you make to the service.
- [Generation of a Web Services Description Language file](#)  
A WSDL file is generated during the deployment of a web service. The WSDL file describes the web service, provides its location, and specifies the operations that the service makes available.
- [UDDI registration](#)  
You can register deployed web services in a UDDI registry. UDDI is an XML-based registry for publishing and locating WSDL files that describe web service applications.
- [Creating and deploying web services](#)  
You can create a web service based on any object structure service, standard service, or enterprise service that is defined for the system. You then deploy the web service to the product web service container or to the application web service container.
- [Web service interactions overview](#)  
An interaction can start a web service and send data to it from an application. The interaction can then display data returned from the web service and save this data to the application database.

## Web service sources

The source of a web service can be an object structure service, a standard service, or an enterprise service.

## Object structure services

---

You can create an object structure web service from a predefined or a user-defined object structure service. Object structure web services support create, update, delete, sync, and query operations. Create and query operations also support responses. The response to the create operation can be based on the primary or alternate key of the primary object that is defined in the object structure. The response to the query operation is provided in the XML schema format of the object structure.

## Standard services

---

You can create a standard web service from methods that are annotated in application services. To use methods as web services, annotated methods, such as the `ChangeStatus` method, must exist within an application. A single standard web service is created for each application service and all annotated methods within the service are the web service operations. The input and output parameters of the methods are associated with the input and output parameters for the standard web service.

## Enterprise services

---

You can create an enterprise web service from a predefined or a user-defined enterprise service. Enterprise web services support additional exit processing, business rules, and transformations. A service exists for each operation that is contained in an enterprise service record (one service per operation). With the exit processing layer, you can map an external schema XML to the object structure XML for both the invocation and the response. Enterprise web services provide response content for the create and query operations that are processed in the queue. The enterprise service definition has a `ProcessResponse` flag that indicates whether the service supports a response.

- [JMS queue settings for enterprise web services](#)

Enterprise web services can use the Java™ Message Service (JMS) queue to process XML messages, or you can specify that the service bypasses the JMS queue.

---

## JMS queue settings for enterprise web services

Enterprise web services can use the Java™ Message Service (JMS) queue to process XML messages, or you can specify that the service bypasses the JMS queue.

JMS queue-based processing provides asynchronous message processing. For enterprise services that support synchronous processes, you must specify non-queue-based message processing. The integration framework processes XML messages from external applications based on the queue settings that are defined for the enterprise web service:

### Queue-based message processing

A queue-based enterprise web service processes XML messages and writes these messages into the configured, inbound JMS queue. When the message is moved into the JMS queue, the external application is released from the invocation. The integration framework processes the messages and saves them in the Maximo® database.

An enterprise web service cannot use the JMS queue if the service includes create or query operations that require a response to the external application.

### Non-queue-based message processing

A non-queue-based enterprise web service processes messages from the integration framework to the object processing layer and saves information, when applicable, to the Maximo database. After the enterprise web service completes message processing, the integration framework sends a response to the external application. You must specify non-queue-based processing if the enterprise web service supports query or create operations that require a response to the external application.

---

## Implementing SOAP 1.1 and 1.2 with JAX-WS web services

You can use SOAP (SOAP) 1.1 and SOAP 1.2 with the JAX-WS (Java™ API for XML Web Services) endpoint handler to exchange messages in a WebSphere® Application Server Liberty environment.

## About this task

---

In the Liberty environment, you can use one or both versions of SOAP as a transport protocol in the same web service instance.

To implement SOAP with JAX-WS web services, you must modify the XML files for **mea** server bundles and for server bundles with the type **a11** since the **a11** bundle also includes **mea**. The following files must be configured:

- `web_oidc.xml`
- `web.xml`
- `webservices.xml`

To customize the XML files, create a file set that replicates the Manage file structure and configure the replicated XML files. Then, add the updated file set to a compressed archive file, copy the archive to a location that is accessible to Maximo® Manage, and configure the application to include the customization archive when it is redeployed. For more information, see [Customizing the application](#).

## Procedure

---

1. In Liberty, in the `servers.xml` file, locate the `<featureManager>` element and ensure that its `<feature>` element is `webProfile-8.0`.
2. To modify the XML files for server bundles of type **mea**, complete the following steps:

- a. Navigate to the following location in the file system for your customization archive and open the web.xml file in a text editor:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-mea\meaweb\webmodule\WEB-INF\web.xml
```

- b. Review the root element and ensure the version attribute that is used is 3.1 or later, but earlier than 4.x.  
c. Ensure that the servlet class is `psdi.iface.webservices.JAXWSWebServiceProvider` and that the `psdi.iface.webservices.WASJAXWSWebServiceProvider` servlet class is commented out because it is not used with Liberty. Ensure that all references to the WASJAXWSWebServiceProvider class in the file are replaced with JAXWSWebServiceProvider class. Save any changes.  
d. Navigate to the following location in the file system for your customization archive and open the web\_oidc.xml file in a text editor:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-mea\meaweb\webmodule\WEB-INF\web_oidc.xml
```

- e. Review the root element and ensure the version attribute that is used is 3.1 or later, but earlier than 4.x.  
f. Ensure that the servlet class is `psdi.iface.webservices.JAXWSWebServiceProvider` and that the `psdi.iface.webservices.WASJAXWSWebServiceProvider` servlet class is commented out because it is not used with Liberty. Ensure that all references to the WASJAXWSWebServiceProvider class in the file are replaced with JAXWSWebServiceProvider class. Save any changes.  
g. Navigate to the following location and open the webservices.xml file in a text editor:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-mea\meaweb\webmodule\WEB-INF\webservices.xml
```

- h. Select from the following options to update the webservices.xml file:

Option	Description
To use SOAP 1.1	In the <wsdl-file> element, specify <code>wsprovider11.wsdl</code> as the value and save the file.
To use SOAP 1.2	In the <wsdl-file> element, specify <code>wsprovider12.wsdl</code> as the value and save the file.
To use both protocols in the same endpoint	In the <wsdl-file> element, specify <code>wsprovider12.wsdl</code> as the value and save the file. Then, in the System Properties application, set the global value of the <code>mx.int.supportsbothsoapversion</code> system property to 1.

Save any changes.

3. To modify the XML files for server bundles of type **all**, complete the following steps:

- a. Navigate to the following location in the file system for your customization archive and open the web.xml file in a text editor:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\meaweb\webmodule\WEB-INF\web.xml
```

- b. Review the root element and ensure the version attribute that is used is 3.1 or later, but earlier than 4.x.  
c. Ensure that the servlet class is `psdi.iface.webservices.JAXWSWebServiceProvider` and that the `psdi.iface.webservices.WASJAXWSWebServiceProvider` servlet class is commented out because it is not used with Liberty. Ensure that all references to the WASJAXWSWebServiceProvider class in the file are replaced with JAXWSWebServiceProvider class. Save any changes.  
d. Navigate to the following location in the file system for your customization archive and open the web\_oidc.xml file in a text editor:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\meaweb\webmodule\WEB-INF\web_oidc.xml
```

- e. Review the root element and ensure the version attribute that is used is 3.1 or later, but earlier than 4.x.  
f. Ensure that the servlet class is `psdi.iface.webservices.JAXWSWebServiceProvider` and that the `psdi.iface.webservices.WASJAXWSWebServiceProvider` servlet class is commented out because it is not used with Liberty. Ensure that all references to the WASJAXWSWebServiceProvider class in the file are replaced with JAXWSWebServiceProvider class. Save any changes.  
g. Navigate to the following location and open the webservices.xml file in a text editor:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\meaweb\webmodule\WEB-INF\webservices.xml
```

- h. Select from the following options to update the webservices.xml file:

Option	Description
To use SOAP 1.1	In the <wsdl-file> element, specify <code>wsprovider11.wsdl</code> as the value and save the file.
To use SOAP 1.2	In the <wsdl-file> element, specify <code>wsprovider12.wsdl</code> as the value and save the file.
To use both protocols in the same endpoint	In the <wsdl-file> element, specify <code>wsprovider12.wsdl</code> as the value and save the file. Then, in the System Properties application, set the global value of the <code>mx.int.supportsbothsoapversion</code> system property to 1.

Save any changes.

## What to do next

After you configure the XML files, add them to a compressed archive file, copy the archive to a location that is accessible to Maximo Manage, and configure the application to include the customization archive when it is redeployed.

## Web service deployment options

After you create a web service, you have a choice of deployment options. If you deploy a web service to the product web service container, the deployment is automatic. If you deploy a web service to an application server web service container, the deployment is manual.

You can deploy web services to one container type only. You cannot deploy some web services to a product web service container and deploy other web services to an application server web service container. Deployment to the web service container for the product is the quicker option, because the deployment is automatic. This type of deployment does not require redeployment of the Maximo® EAR files or a restart of the application server.

To invoke a web service on the application server, you must deploy the service to the application server web service container. Integration with an application server can provide a web service with access to additional services, such as enhanced security policies. If you choose this type of deployment, the information is added to the `deplmodule.dar` file. You must then add this file to the application server deployment directory, rebuild the EAR files, and restart the application server.

You can convert existing web services that are deployed to the product web service container to redeploy them to the application server web service container.

---

## Web service deployment actions

When you deploy a web service, a number of events occur, including the generation of the XML schema and the web services description language (WSDL) file for the web service.

When you deploy a web service, the following events occur:

- The XML schema is made available for a new web service or the schema is regenerated for an existing web service.
- The WSDL file is made available for the service interface.
- The web service is deployed for the selected service.
- If Universal Description Discovery and Integration (UDDI) registry properties are configured, the web service is registered in the UDDI registry.

The deployed web service is available at the following URL:

**`http://hostname:port/meaweb/services/web service name`**

- **`host:port/meaweb`** is the value of the integration web application URL property.
- **`web service name`** is the name of the service for which the web service is deployed.

The list of deployed web services is available in the Web Services Library application.

---

## Schema generation

You can generate the schema and view the XML for any web service in the Web Services Library application. You can also regenerate the schema to ensure that the schema is updated to reflect any changes that you make to the service.

A web service data structure is based on its associated object structure (for object structure services and enterprise services) or method signature (for standard web services). The web service data structure is provided in a standard XML representation, as a schema. This schema is used to create the WSDL file for the service.

If you change the data structure that is associated with a web service, regenerate the schema to update its schema and the WSDL file. The following changes to the data dictionary change the object structure:

- Adding new fields to a table
- Changing the type of a field
- Dropping fields from a table
- Changing a field from optional to required

The XML does not contain fields that are marked for exclusion in the object structure.

Before you deploy a web service, you must generate the schema to provide updated schema information to the WSDL file. When you generate a schema, input elements are displayed in the XML Data window and output elements are displayed in the Response XML window.

To access a generated schema, you can use a URL.

Enterprise service and object structure schemas

Use a URL that is similar to the following example in which MXSR is the object structure name that is associated with the service:

**`http://localhost:port/meaweb/schema/service/MXSR`**

For compatibility with version 7.5, URLs that are similar to the following example are still supported:

**`http://localhost:port/meaweb/schema/service/MXSRSERVICE.xsd`**

Standard service schemas

Use a URL that is similar to the following example in which ITEM is the name of the service.

**`http://localhost:port/meaweb/schema/service/ss/ITEM`**

For compatibility with version 7.5, URLs that are similar to the following example are still supported:

**`http://localhost:port/meaweb/schema/service/ss/ITEMSERVICE.xsd`**

If you set the **`mxe.int.resolveschema`** global property to true in the System Properties application, all include files are resolved. The entire schema content resides in a single file.

---

## Generation of a Web Services Description Language file

A WSDL file is generated during the deployment of a web service. The WSDL file describes the web service, provides its location, and specifies the operations that the service makes available.

The WSDL file specifies the XML structure of the input and output messages for the operation, based on the XML schema. The file also specifies the URL for the web service, and the operations that the web service makes available.

A client program needs the schema definitions and WSDL file to generate client stubs. The client program uses a programming language, such as Java™ or C#, to call the web service.

You can view a generated WSDL file in a browser at `http://localhost:port/meaweb/wsdl/service_name?wsdl`, where *service\_name* is the name of the service, such as MXASSET.

---

## UDDI registration

You can register deployed web services in a UDDI registry. UDDI is an XML-based registry for publishing and locating WSDL files that describe web service applications.

You can register deployed web services in a UDDI registry by configuring the following global properties in the System Properties application:

System property	Description
<code>mxe.int.uddipuburl</code>	UDDI registry publish URL
<code>mxe.int.uddiinurl</code>	UDDI registry inquiry URL
<code>mxe.int.uddiname</code>	UDDI registry user ID
<code>mxe.int.uddipassword</code>	UDDI registry password

If you specify values for the publish URL property and the inquiry URL property, the web service is registered in the UDDI registry. To bypass UDDI registration, do not specify any values for these properties. Only the model for the WSDL file is registered in the UDDI registry. The `businessEntity`, `businessService`, and `bindingTemplate` values are not registered. The UDDI registration entry contains the URL to the WSDL file.

---

## Creating and deploying web services

You can create a web service based on any object structure service, standard service, or enterprise service that is defined for the system. You then deploy the web service to the product web service container or to the application web service container.

- [Creating a web service](#)  
When you create a web service, an external system can send web-based messages and queries to the associated service without configuring additional communication protocols or services.
- [Deploying a web service to the product web service container](#)  
After you create a web service, you must deploy it before it can start processing XML messages. When you deploy a web service to the product web service container, the deployment process occurs automatically and does not require a server restart.
- [Deploying a web service to the application server web service container](#)  
A deployment file is generated when you deploy a web service to the application server web service container. You must rebuild the Maximo EAR file to include the deployment file and restart the application server to activate the web service.
- [Updating schema information](#)  
If you change the data structure of an integration service, update the schema information to the WSDL file to update the web service. If you do not regenerate the schema, the schema used by the web service can differ from the structure defined for the associated integration service.

---

## Creating a web service

When you create a web service, an external system can send web-based messages and queries to the associated service without configuring additional communication protocols or services.

---

## Before you begin

Perform the following checks to ensure that the service you want to use is available to create a web service:

- For an object structure service, verify that the Consumed By field is set to `INTEGRATION` in the Object Structures application.
- For a standard service, ensure that a method is annotated in the application service for each operation that you want to use in the web service. Only those methods that are properly annotated are accessible in the Web Services Library application.
- For an enterprise service, ensure that the service is associated with an external application in the External Systems application.

---

## Procedure

1. In the Web Services Library application, select the appropriate Create Web Service action.
2. Choose the service to use by selecting the corresponding Source Name check box.
3. Optional: In the Name field, specify an identifier for the web service.
4. For a web service that is based on an enterprise service, specify whether you want the web service to be queue-based or to bypass the JMS queue.
5. Click Create.

---

## What to do next

You must deploy the web service before you can use it to process inbound messages and queries. You can also generate the schema and view the XML structures of any selected web service.

---

## Deploying a web service to the product web service container

After you create a web service, you must deploy it before it can start processing XML messages. When you deploy a web service to the product web service container, the deployment process occurs automatically and does not require a server restart.

### Procedure

---

1. In the Web Services Library application, select the web service that you want to deploy.
2. Select the Deploy to Product Web Service Container, > Deploy Web Service action.
3. Click OK.

---

## Deploying a web service to the application server web service container

A deployment file is generated when you deploy a web service to the application server web service container. You must rebuild the Maximo® EAR file to include the deployment file and restart the application server to activate the web service.

### About this task

---

The deplmodule.dar deployment file is in the directory that is specified by the mx.e.int.globaldir system property.

### Procedure

---

1. In the Web Services Library application, select the web service that you want to deploy.
2. Select the Deploy to Application Server Web Service Container, > Generate Deployment File Entries action.  
This action generates an entry in the deployment file, deplmodule.dar.
3. Click OK.
4. Copy the deplmodule.dar file from the integration framework global directory to the product deployment directory.
5. In the deployment directory, build the maximo.ear file.
6. In the administrative console for the application server, deploy all web services in the deplmodule.dar file:
  - a. Stop the application server.
  - b. Redeploy the maximo.ear file.
  - c. Restart the application server.

---

## Updating schema information

If you change the data structure of an integration service, update the schema information to the WSDL file to update the web service. If you do not regenerate the schema, the schema used by the web service can differ from the structure defined for the associated integration service.

### Procedure

---

1. After modifying the data structure of a web service, click Generate Schema, WSDL, and View XML.  
If you do not regenerate the schema, the web service is not aware of changes that you make.
2. For web services that are deployed to the application server web service container, you can automate schema updates in the System Properties application.
  - a. Set the value of the mx.e.int.containerdeploy property to 1 to deploy web services to the application server web service container.
  - b. Set the value of the mx.e.int.wsdlincludeschema property to 1 to ensure that schema information is included as part of WSDL files.
  - c. Set the value of the mx.e.int.resolveschema property to 1 to ensure that the system resolves all included fields into a single file.
  - d. Set the value of the mx.e.int.wsdlcurrentschema property to 1 to provide up-to-date schema content as part of a WSDL file.

---

## Web service interactions overview

An interaction can start a web service and send data to it from an application. The interaction can then display data returned from the web service and save this data to the application database.

To implement interactions requires knowledge of:

- XML schemas
- Web services
- The integration framework
- Customizing applications and application user interfaces

An interaction can manage the following processes:

- Prepare a request for a web service.
- Invoke a web service from an application.
- Retrieve results from the web service in the form of a response.

- Display the results in an application.
- Optionally, apply the response data into the system database.
- Report any errors that occur during the request or response processes.

Two applications are provided to help you create and manage interactions:

- Create and configure interactions in the Create Interaction application.
- Review, modify, and delete interactions in the Interactions application.

After you create an interaction, users can perform the following tasks from the application user interface:

- Start the interaction.
- View and, if configured, change the parameters of the request to the web service.
- Invoke the web service by sending the request.
- Optionally, view data received from the web service and commit this data to the database.
- [Creating interactions](#)  
The Create Interactions wizard application guides you through all the steps required to create and configure an interaction. After you complete the wizard process and test the interaction, users can start working with it immediately with no requirement for additional configuration or deployment.

---

## Creating interactions

The Create Interactions wizard application guides you through all the steps required to create and configure an interaction. After you complete the wizard process and test the interaction, users can start working with it immediately with no requirement for additional configuration or deployment.

### Before you begin

---

Before you run the Create Interactions application, ensure that you have all the information required for the configuration. During the process, you must specify the web service, define the structure of messages, and map the data between the application and the web service.

A logging tool is provided to log configuration activity and maintain a log file of the items that are configured. To generate a detailed log of the configuration, in the Logging application, set the interaction logger to DEBUG mode.

### Procedure

---

1. To configure the web service for the interaction, in step 1 of the process:
  - a. Specify the URL for the WSDL file for the web service.
  - b. When the screen refreshes with information from the WSDL file, specify one port for the interaction.
  - c. Specify one operation for the interaction and check Process Response if you want the web service to return data to the application during the interaction.
2. Review the contents of the request to the web service in step 2, and modify the request object structure by removing any unnecessary elements.
3. Optional: Review the contents of the response from the web service in step 3, and modify the response object structure by removing any unnecessary elements.  
This step is included only if you checked the Process Response option in step 1.
4. To configure the application for the interactions, in step 4 of the process:
  - a. Specify the application that uses the interaction.
  - b. Configure the application binding for the interaction, including the main object, the signature option, the interaction mode, and the user interface components.
  - c. Specify the security groups that are authorized to initiate the interaction.
5. Configure the Request tab of the Interactions window in step 5, including specifying the fields that users can see and whether they can edit them.
6. Optional: Configure the Response tab of the Interactions window in step 6, including specifying the fields that users can see and whether they can edit them.  
This step is included only if you checked the Process Response option in step 1.
7. You can map information from the application to the web service in step 7. Mapped information is entered automatically into the request when users start the interaction.
8. Optional: You can map information from the web service to the application in step 8. If you check the Commit Response option, the mapped information is saved automatically to the database.
9. Review the configurations in the final step of the process.

### What to do next

---

To monitor the time it takes to execute the interaction, in the Logging application, set the integration logger to either INFO mode or DEBUG mode.

You can view the interaction and modify mapping information in the Interactions application. If you intend to modify an interaction, select the Deactivate Interaction action before you make any changes and reactivate it after you complete the modification.

---

## Configuring an external system

You can configure the external system that the integration framework communicates with. You can configure external systems for external applications inside or outside your enterprise.

You can configure an external system to use new or existing JMS queues and you can configure integration controls to support customization with processing rules.

If you copy a predefined external system, it copies the channels and services that are configured for it.

- [Creating an external system](#)  
You create an external system to exchange data with external applications. When you create an external system, the application copies the integration controls that are defined for the corresponding publish channels and enterprise services. You then can specify default control values that apply to a particular external system.
- [Enabling a publish channel](#)  
You must enable a publish channel that is associated to an external system before it can be used to publish event-based messages to an external system. By default, the publish channel records that are associated with an external system are disabled. A disabled publish channel prevents the external system from processing outbound integration framework messages.
- [Enabling an enterprise service](#)  
You must enable an enterprise service that is associated to an external system before it can be used to receive inbound external application data. By default, the enterprise service records that are associated with an external system are disabled. A disabled enterprise service prevents the external system from processing inbound external application messages.
- [Exporting data](#)  
To export a batch of message data to an external system, you can use the data export feature in the External Systems application. You can initiate the export process for each publish channel that is associated with an external system.
- [Exporting data in sequential batches](#)  
To export multiple batches of message data to an external system, you can use the Bulk Data Exports action in the External Systems application. When you use this feature, exports are processed in order based on the sequence that you specify for the publish channels.
- [Importing file-based data](#)  
You can use the data import feature to load data from either XML, JSON, or flat, delimited files to update the database. You can preview and validate the data prior to loading it and committing it to the database. You can choose to manage errors with the Message Reprocessing application or by extracting errors to a file format that is the same as the imported file format.
- [Importing data by using a REST API call](#)  
You can use the Get External Data option on the Enterprise Services tab in the External Systems application to import data from external sources using a REST API call.
- [Registering Kafka topics as Maximo Manage queues](#)  
To exchange message data and contents with Kafka, you register Kafka topics as Maximo® Manage message queues.
- [Adding JMS queues to an external system](#)  
You can use Java™ Message Service (JMS) or other queues to exchange enterprise service and publish channel data with an external application. When messages are received or sent, they are written to the queue. These messages remain in the queues until they are successfully processed or deleted.
- [Creating interface tables](#)  
You can create an interface table to integrate with external systems that use database tables for data exchange. Interface tables reflect the content of publish channel or enterprise service object structures. You must recreate existing tables when you change the definition of the corresponding object structure.
- [Working with integration controls](#)  
If integration channels or services contain processing rules or exit classes that are based on integration controls, the values of the integration controls can be configured for the external system. You can configure boolean, list, and value integration controls that you can incorporate in processing rules.

---

## Creating an external system

You create an external system to exchange data with external applications. When you create an external system, the application copies the integration controls that are defined for the corresponding publish channels and enterprise services. You then can specify default control values that apply to a particular external system.

---

## Before you begin

Before you create an external system, define the queues and endpoint that the external system uses.

---

## Procedure

1. In the External Systems application, click New External System.
2. In the System field, specify an external system identifier.
3. To send outbound messages, complete the following steps:
  - a. Select a value for the Outbound Sequential Queue field.
  - b. Select a value for the End Point field.The configured properties for the endpoint are displayed.
4. To receive inbound messages, complete the following steps:
  - a. Select a value for the Inbound Sequential Queue field.
  - b. Select a value for the Inbound Continuous Queue field.
5. Enable and save the external system.

---

## What to do next

Configure a message provider and a message queue. Enable at least one publish channel or enterprise service for message processing.

- [Specifying Kafka providers for message processing](#)  
You specify Kafka as a messaging provider to asynchronously process outbound integration framework messages. The integration framework supplies a Kafka client.
- [Enabling an external system](#)  
You can enable an external system after you configure the external system record and when you are ready to begin integration framework message processing.

---

## Specifying Kafka providers for message processing

You specify Kafka as a messaging provider to asynchronously process outbound integration framework messages. The integration framework supplies a Kafka client.

### Before you begin

---

Obtain and configure a Kafka provider that is compatible with the Kafka 1.1.1 libraries.

### About this task

---

Kafka refers to a *topic* as a category or feed name to which records are published. Because of the way that the integration framework works with Kafka, topics are referred to as messaging queues.

### Procedure

---

1. In the External Systems application, add or select the external system and then select Add/Modify Message Providers to open the Message Hub Provider dialog box.
2. Insert a row and add a Kafka provider name.  
The provider type is specified as KAFKA.
3. Specify values for the following properties. The SASL\_MECHANISM and SECURITY\_PROTOCOL properties are optional.

Option	Description
<b>SASL_MECHANISM</b>	The mechanism that implements the Simple Authentication and Security Layer (SASL) authentication and security framework. Allowed values are PLAIN, GSSAPI, SCRAM-SHA-256, and SCRAM-SHA-512. If no value is specified, the default value of PLAIN is used.
<b>SECURITY_PROTOCOL</b>	The protocol that ensures secure data sharing. Allowed values are SASL_SSL, SSL, PLAINTEXT, or SASL_PLAINTEXT. If no value is specified, the default value of SASL_SSL is used.
<b>BOOTSTRAPSERVERS</b>	A comma-separated list of server URLs that host your Kafka instance. Include the port specification. For example, specify <i>brokerurl1,brokerurl2</i> . You can use quotation marks if needed.
<b>PASSWORD</b>	If you specify the security protocol as either SASL_SSL or SASL_PLAINTEXT, specify an authentication password.
<b>USERNAME</b>	The username for your password.

4. Save your changes.

### What to do next

---

Register the Kafka topics as Maximo® queues in the External Systems application. Configure one or more cron tasks to poll your queues and process the queue messages.

---

## Enabling an external system

You can enable an external system after you configure the external system record and when you are ready to begin integration framework message processing.

### Before you begin

---

You must enable at least one publish channel or enterprise service before any message processing can occur.

### About this task

---

You also can disable an external system to stop all inbound and outbound message processing. If you disable an external system, only messages that are in the queues are processed. The integration framework does not accept inbound messages or send outbound messages. Additionally, you cannot use the external system data export and data import features.

### Procedure

---

1. In the External Systems application, select the system that you want to update.
2. Select the option to enable or disable the external system.
3. Save the external system.

---

## Enabling a publish channel

You must enable a publish channel that is associated to an external system before it can be used to publish event-based messages to an external system. By default, the publish channel records that are associated with an external system are disabled. A disabled publish channel prevents the external system from processing outbound integration framework messages.

## Procedure

---

1. In the External Systems application, select the system that you want to update.
2. On the Publish Channels tab, specify whether you want the publish channel to be enabled or disabled.

Option	Enabled
Enabled	Selected
Disabled	Cleared

3. Click Save External System.

- [Associating a publish channel with an external system](#)

You can associate a publish channel with an external system to send asset management object data to the external system. The channels that you create and associate to the external system contain the outbound message processing logic.

- [Selecting publish channels for the external system](#)

You can associate multiple publish channels with an external system to synchronize the asset management object data with the external application data. The channels that you create and associate to the external system contain the outbound message processing logic.

- [Adding an endpoint to a publish channel](#)

You can define the endpoint that a publish channel uses to determine where the outbound data is published. Endpoints identify a target location and the transport mechanism for outbound data publication. If you do not define an endpoint at the publish channel level, data is moved to the endpoint location that is defined at the external system level.

- [Importing file-based data](#)

You can use the data import feature to load data from either XML, JSON, or flat, delimited files to update the database. You can preview and validate the data prior to loading it and committing it to the database. You can choose to manage errors with the Message Reprocessing application or by extracting errors to a file format that is the same as the imported file format.

---

## Associating a publish channel with an external system

You can associate a publish channel with an external system to send asset management object data to the external system. The channels that you create and associate to the external system contain the outbound message processing logic.

### About this task

---

You can define the endpoint that the channel uses. If you do not define an endpoint at the publish channel level, data is moved to the endpoint location that is defined at the external system level. You also can enable the associated publish channel when you are ready to perform outbound integration framework message processing.

## Procedure

---

1. In the External Systems application, select the external system that you want to update.
2. On the Publish Channels tab, insert a row.
3. In the Publish Channel field, specify an identifier for the outbound interface of the external system.
4. Optional: In the Adapter field, specify an interface type.
5. Optional: In the End Point field, specify the end point that is used by the external system for outbound transactions.
6. Optional: Enable the publish channel to make it active.
7. Save your changes.

---

## Selecting publish channels for the external system

You can associate multiple publish channels with an external system to synchronize the asset management object data with the external application data. The channels that you create and associate to the external system contain the outbound message processing logic.

## Procedure

---

1. In the External Systems application, select the system that you want to update.
2. On the Publish Channels tab, click Select Channel.
3. Choose one or more publish channels by selecting the corresponding Publish Channel check boxes.
4. Click OK.
5. Click Save External System.

### What to do next

---

You can define the endpoints that the channels use. If you do not define an endpoint at the publish channel level, data is moved to the endpoint location that is defined at the external system level. You must enable the associated publish channels before you can perform integration framework message processing.

---

## Adding an endpoint to a publish channel

You can define the endpoint that a publish channel uses to determine where the outbound data is published. Endpoints identify a target location and the transport mechanism for outbound data publication. If you do not define an endpoint at the publish channel level, data is moved to the endpoint location that is defined at the external system level.

## Before you begin

You must associate a publish channel to an external system.

## Procedure

1. In the External Systems application, select the external system that you want to update.
2. On the Publish Channels tab, select the publish channel for which you want to add an endpoint.
3. In the End Point field, specify a value.
4. Click Save External System.

## What to do next

You can enable the associated publish channel when you are ready to perform outbound integration framework message processing.

## Importing file-based data

You can use the data import feature to load data from either XML, JSON, or flat, delimited files to update the database. You can preview and validate the data prior to loading it and committing it to the database. You can choose to manage errors with the Message Reprocessing application or by extracting errors to a file format that is the same as the imported file format.

## Before you begin

Before data can be imported, if you plan to import data from a flat file, such as a .csv file, the enterprise service object structure must support flat file structures. Ensure that the Support Flat File Structure check box is selected on the associated object structure record in the Object Structures application. You also must enable both the external system and the enterprise service before you can import data.

## About this task

The data import process can use a predefined or user-defined enterprise service.

## Procedure

1. In the External Systems application, display the external system that contains the enterprise service from which you want to import data.
2. On the Enterprise Services tab, select the enterprise service from which you want to import data.
3. Click Data Import.
4. Optional: Select the Import Preview check box to examine the data before importing and committing the data to the database.  
Use the preview option to sample data records. This feature is not intended to support a large file containing hundreds of records. Processing synchronously processes the file to the business objects and returns any error messages encountered, without committing any updates to the database.
5. Specify the type of file that you want to use for the file import.

Option	Description
<b>XML file</b>	Imported data is in XML format.
<b>Flat file</b>	Imported data is in a delimited flat file. If necessary, modify the Delimiter and Text Qualifier values.
<b>JSON file</b>	Imported data is in JSON format.

6. In the Specify Import File field, enter the file name path the imported file uses for identification and storage.
7. Select the File-based Error Management check box if you want to manage any errors you encounter through a file in the same format as the file being imported. This option is an alternative to managing errors with the Message Reprocessing application
8. Click OK to begin the import data process.

## What to do next

When the data import is executed, the file that is selected for import is formed into multiple messages and dropped into the inbound queue that is configured for the enterprise service and its corresponding external system. The messages are then processed from the inbound queue to the application objects for updating. The processing of messages from an inbound queue requires the enablement of the related cron task when the sequential queue is used or the enablement of Message Driven Beans for the continuous queue. If errors occur when processing a file, you can manage and view the data import messages that are flagged with an error in the Message Reprocessing application.

## Enabling an enterprise service

You must enable an enterprise service that is associated to an external system before it can be used to receive inbound external application data. By default, the enterprise service records that are associated with an external system are disabled. A disabled enterprise service prevents the external system from processing inbound external application messages.

## Procedure

---

1. In the External Systems application, display the system that you want to update.
2. On the Enterprise Services tab, specify whether you want the enterprise service to be enabled or disabled.
3. Save your changes.

- [Associating an enterprise service with an external system](#)

You can associate an enterprise service with an external system to synchronize inbound external application data with asset management objects. The services that you create and associate to the external system contain the inbound message processing logic.

- [Selecting enterprise services for the external system](#)

You can associate multiple enterprise services with an external system to synchronize inbound external application data with asset management objects. The services that you create and associate to the external system contain the inbound message processing logic.

- [Selecting an enterprise service queue type](#)

You can specify whether the enterprise service that you associate to the external system receives data from the continuous or sequential queue. The queue selection you make for the enterprise service determines how the Java™ Message Service (JMS) queue processes inbound messages.

---

## Associating an enterprise service with an external system

You can associate an enterprise service with an external system to synchronize inbound external application data with asset management objects. The services that you create and associate to the external system contain the inbound message processing logic.

### About this task

---

You can specify whether the associated enterprise services receive data from the sequential or continuous queue. You also can enable the associated enterprise service when you are ready to perform inbound integration framework message processing.

## Procedure

---

1. In the Enterprise Systems application, display the system that you want to update.
2. On the Enterprise Services tab, click New Row.
3. In the Enterprise Service field, enter a value.
4. Specify whether you want the enterprise service to be enabled or disabled.
5. Specify whether you want the service messages to receive data from the continuous or sequential queue.
6. Save your changes.

---

## Selecting enterprise services for the external system

You can associate multiple enterprise services with an external system to synchronize inbound external application data with asset management objects. The services that you create and associate to the external system contain the inbound message processing logic.

## Procedure

---

1. In the External Systems application, display the system that you want to update.
2. On the Enterprise Services tab, click Select Service.
3. Choose one or more enterprise services by selecting the corresponding Enterprise Service check boxes.
4. Click OK.
5. Save your changes.

### What to do next

---

You must enable the associated enterprise services before you can perform integration framework message processing. You also can specify whether the associated enterprise services receive data from the sequential or continuous queues.

---

## Selecting an enterprise service queue type

You can specify whether the enterprise service that you associate to the external system receives data from the continuous or sequential queue. The queue selection you make for the enterprise service determines how the Java™ Message Service (JMS) queue processes inbound messages.

### Before you begin

---

You must associate an enterprise service to an external system.

### About this task

---

The continuous queue continues to process messages that are in the queue even when message processing results in an error. Conversely, the sequential queue stops processing messages that are in the queue until the processing error is cleared. A sequential queue also processes messages on a strict first-in-first-out basis.

## Procedure

---

1. In the External Systems application, select the external system that you want to update.
2. On the Enterprise Services tab, select the enterprise service for which you want to select a queue.
3. Specify whether you want the service messages to receive data from the continuous or sequential queue.
4. Save your changes.

## What to do next

---

You can enable the associated enterprise service when you are ready to perform inbound integration framework message processing.

## Exporting data

To export a batch of message data to an external system, you can use the data export feature in the External Systems application. You can initiate the export process for each publish channel that is associated with an external system.

## Before you begin

---

You must configure an endpoint to the data destination.

In addition to configuring an endpoint, you must enable both the external system and the publish channel before you can export data. The data for export must either be in an XML, JSON, or delimited flat file format that conforms to the object structure schema. A delimited flat file, such as comma separated, is a flattened version of the object structure schema format.

## Procedure

---

1. In the External Systems application, click the Publish Channels tab and select the publish channel that you want to export.
2. In the End Point field, specify the destination for the outbound data.
3. Click Data Export to specify more criteria for the data export. Enter selections in one or more of the following fields.
  - a. In the Export Condition field, specify a SQL query to select records for export.  
For example, specify `assetnum like '11%' and siteid='BEDFORD'` to export all asset records that start with 11 and are in the Bedford site.  
The query must be specified on the primary or top-level object in the publish channel object structure.  
  
The query can affect the size of the exported message. The export process performs the standard outbound processing on the result set of the query for the selected publish channel.
  - b. In the Export Order By field, specify one or more fields by which records are sorted on export.  
You can specify ASC or DESC order.  
For example, specify `assetnum DESC` to order the exported data by descending asset ID.  
The ORDER BY statement must apply to the primary, or top-level, object in the integration object.
  - c. In the Export Count field, specify a value to limit the number of records in the export file.  
If the result of the query contains more records than the number you specify, those records are not included in the exported data.
4. To break up the data and store it in the queue as separate files, specify a value in the Batch Size field.  
If the number of records is larger than the batch size that you specify, the export data is split into a transaction with multiple files and stored separately.
5. Click OK to begin exporting the data.

## Results

---

When the data is exported, it is formed into a message and dropped into the outbound queue that is configured for the publish channel and its corresponding external system. Then, the message is processed from the outbound queue to the configured endpoint. If an error occurs when delivering a message to the endpoint, you can manage and view the data export messages that are flagged with an error in the Message Reprocessing application.

## Exporting data in sequential batches

To export multiple batches of message data to an external system, you can use the Bulk Data Exports action in the External Systems application. When you use this feature, exports are processed in order based on the sequence that you specify for the publish channels.

## Before you begin

---

Before you set up bulk data exports, complete the following tasks:

- Configure an endpoint to the data destination.
- Configure and enable the external system.
- Configure the publish channels for the export.

## About this task

Data is exported sequentially based on the order of the publish channels that you specify in the Bulk Data Exports window.

Data is processed using a cron task instance in the BULKEXPORT cron task. If no cron task instance exists for the external system, a cron task instance that matches the name of the external system for exporting the data is automatically generated. If the cron task instance already exists for the external system, it is activated when you click Process.

When a cron task is active, the In Process check box is selected. No other process for this external system can be started when the cron task is active. Only one export can occur at a time.

When all data in a publish channel is processed, the data is committed. If you have multiple batches in a publish channel, data is committed only after all batches are processed.

If an error occurs for any publish channel, processing is stopped, and an error message is displayed. No data for that channel is committed until the error is corrected. You can correct the error and click Process to restart the process. When you click Process, the publish channel that has the error is reprocessed, and processing continues with the next channel in the sequence. Data is not reprocessed for the publish channels that were successfully committed before the error occurred.

When the cron task is completed, it is automatically deactivated.

Table 1. Buttons in the Bulk Data Export window

Button	Function
Save	Saves any changes that you made in the Bulk Data Exports window.
Cancel	Closes the Bulk Data Exports window but does not save your changes. To save changes, click Save before you click Cancel.
Refresh	Reloads the Bulk Data Exports window and updates the fields to display the status of the data export process.
Reset	Restarts the bulk data export process for all the publish channels that are included in this external system.
Process	Starts the bulk data export process.

## Procedure

1. In the External Systems application, locate and open the external system that you want to use.
2. On the System tab, in the Outbound Sequential Queue field, specify a destination for the outbound data.
3. From the More Actions menu, select Bulk Data Exports.
4. For the publish channels that you want to export, add rows sequentially in the order that you want to process the data and enter details for the export in the following fields:

Option	Description
<b>Sequence</b>	Enter a number to specify the order in which to process the publish channel data. If you add sequence numbers in increments of ten, it is easy to insert additional publish channels if the need arises at a later date. For example, if you have sequence numbers 10 and 20, and later you want to export a publish channel between those two rows, you can add a sequence number of 15.
<b>Publish Channel</b>	Specify the publish channel to use for the export.
<b>Batch Size</b>	Optional. Specify the number of records to include in each JMS message for the selected publish channel. For example, if you have 100 messages and specify a batch size of 50, the result is 2 JMS messages. If the number of records is larger than the batch size that you specify, the export data is split into a transaction that has multiple files that are stored separately. Even though the records are processed in multiple batches, only one commit occurs for the entire publish channel.
<b>Export Condition</b>	Optional. Specify an SQL query to select records for export. For example, specify <code>assetnum like '11%'</code> and <code>siteid='BEDFORD'</code> to export all asset records that start with 11 and are in the Bedford site. The query must be specified on the primary or top-level object in the publish channel object structure.
<b>Export Order By</b>	Optional. Specify one or more fields by which to sort records that you export. You can specify <code>ASC</code> for ascending order or <code>DESC</code> for descending order. For example, specify <code>assetnum DESC</code> to order the exported data by descending asset ID. The <code>ORDER BY</code> statement must apply to the primary or top-level object in the integration object.
<b>Error Message</b>	If an error occurs during the export process, this field displays an error message.
<b>Enabled</b>	Select this field in the table row to enable the publish channel.
<b>Processed</b>	If this publish channel was processed, this field displays a check mark.
<b>User Defined</b>	Indicates whether you created the publish channel or it was predefined in the application.

5. Click Save.
6. Click Cancel to close the window.
7. From the More Actions menu, select Bulk Data Export.
8. To export the data, click Process.

## Importing file-based data

You can use the data import feature to load data from either XML, JSON, or flat, delimited files to update the database. You can preview and validate the data prior to loading it and committing it to the database. You can choose to manage errors with the Message Reprocessing application or by extracting errors to a file format that is the same as the imported file format.

## Before you begin

Before data can be imported, if you plan to import data from a flat file, such as a .csv file, the enterprise service object structure must support flat file structures. Ensure that the Support Flat File Structure check box is selected on the associated object structure record in the Object Structures application. You also must enable both the external system and the enterprise service before you can import data.

## About this task

The data import process can use a predefined or user-defined enterprise service.

## Procedure

1. In the External Systems application, display the external system that contains the enterprise service from which you want to import data.
2. On the Enterprise Services tab, select the enterprise service from which you want to import data.
3. Click Data Import.
4. Optional: Select the Import Preview check box to examine the data before importing and committing the data to the database.  
Use the preview option to sample data records. This feature is not intended to support a large file containing hundreds of records. Processing synchronously processes the file to the business objects and returns any error messages encountered, without committing any updates to the database.
5. Specify the type of file that you want to use for the file import.

Option	Description
<b>XML file</b>	Imported data is in XML format.
<b>Flat file</b>	Imported data is in a delimited flat file. If necessary, modify the Delimiter and Text Qualifier values.
<b>JSON file</b>	Imported data is in JSON format.

6. In the Specify Import File field, enter the file name path the imported file uses for identification and storage.
7. Select the File-based Error Management check box if you want to manage any errors you encounter through a file in the same format as the file being imported. This option is an alternative to managing errors with the Message Reprocessing application
8. Click OK to begin the import data process.

## What to do next

When the data import is executed, the file that is selected for import is formed into multiple messages and dropped into the inbound queue that is configured for the enterprise service and its corresponding external system. The messages are then processed from the inbound queue to the application objects for updating. The processing of messages from an inbound queue requires the enablement of the related cron task when the sequential queue is used or the enablement of Message Driven Beans for the continuous queue. If errors occur when processing a file, you can manage and view the data import messages that are flagged with an error in the Message Reprocessing application.

## Importing data by using a REST API call

You can use the Get External Data option on the Enterprise Services tab in the External Systems application to import data from external sources using a REST API call.

## Before you begin

Before you import external data, you must complete the following tasks:

- Configure and enable the external system.
- Configure an inbound queue for the external system.
- Configure an endpoint for the import.
- Configure the enterprise services for the import.

## About this task

When you complete the following procedure, the REST API that you specify is called, and data is imported into Maximo® Manage. The process runs in the background as a cron task that uses the endpoint that you specify. When the response is received, data is split into individual transactions and stored in the queue. Data is processed based on either the JMS or Kafka queue that you specify for the external system.

## Procedure

1. In the External Systems application, select the external system to use for importing data.
2. On the Enterprise Services tab, select the enterprise service to use for importing data.
3. Click Get External Data.
4. In the Get External Data window, enter the following information for importing your data:

Option	Description
<b>Select Data Type</b>	Select either JSON or XML.
<b>End Point</b>	Select the endpoint for your REST API call.
<b>Queue based</b>	If your import is queue-based, select the checkbox.

5. Click OK.

## Registering Kafka topics as Maximo Manage queues

To exchange message data and contents with Kafka, you register Kafka topics as Maximo® Manage message queues.

## Before you begin

Before you can register Kafka topics as product queues, take the following steps:

- Create the topics on the Kafka server.
- Configure a message provider of Kafka type in the External Systems application.

## Procedure

1. Select Add/Modify Queues in the External Systems application and add a queue.
2. Specify the Kafka provider and topic name. Specify the message direction and whether the queue is sequential or continuous.  
All outbound queues are sequential queues. You specify a queue as continuous by leaving the Sequential check box deselected and specify a queue as outbound by leaving the Inbound check box deselected.  
Note: No separate error queue is needed for continuous queue processing. Error messages are written to the error tables as it was done in Maximo Manage earlier. There is a new error processing cron task called KAFKAERROR. You should configure an instance of the KAFKAERROR cron task for each continuous queue. It is responsible for processing messages from the error table in a continuous way. The Kafka cron task just moves to the next offset and continues processing remaining messages from the Kafka continuous queue.
3. Specify the email address of the user who receives notices when errors occur in the queue. This value is used instead of the email value that is specified in system properties.
4. In the Maximum Retry Count field, specify the maximum number of reprocessing attempts after an initial error and before a message is put in a Hold status and moved to a configured error queue.
5. Save your changes.

## What to do next

For each queue, add an instance of the Kafka cron task to periodically poll the queue for messages and process them.

## Adding JMS queues to an external system

You can use Java™ Message Service (JMS) or other queues to exchange enterprise service and publish channel data with an external application. When messages are received or sent, they are written to the queue. These messages remain in the queues until they are successfully processed or deleted.

## Before you begin

Before you can add a queue to an external system, you must create the queue on the application server. If you add a sequential queue, you must set up a cron task to periodically poll the queue for messages.

## About this task

Each external system can have its own inbound and outbound queues, or you can configure multiple systems to share queues. You can either add your own user-defined message queues, or modify the existing queues when the predefined inbound and outbound message queues do not meet your needs.

## Procedure

1. In the External Systems application, select the system for which you want to add a JMS queue.
2. Select the Add/Modify Queues action and add a row.
3. Enter values in the following fields:

Option	Description
<b>Queue JNDI Name</b>	The name of the JMS queue.
<b>Queue Connection Factory</b>	The connection factory that is used for accessing the queue. For a JMS queue, the default value is jms/mro/int/queues/sqin.
<b>Maximum Try Count</b>	The number of times a message is reprocessed after an initial error and before it is written to the error log and an e-mail notification is sent to the system administrator.

4. Optional: Enter values in the following fields:

Option	Description
<b>Initial Context Factory</b>	The class used to connect to the JMS queue server.
<b>Provider URL</b>	The URL of the JMS queue server.
<b>User ID</b>	The user ID that is used to access the new queue.
<b>Password</b>	The password that is use to access the queue.
<b>E-mail Address</b>	The e-mail address of a user who receives notices when transaction errors occur in the queue. This value is typically the e-mail address of a system administrator.

5. Optional: If the queue delivers inbound messages and functions as a continuous queue, clear the Sequential check box.
6. Optional: If the queue delivers outbound messages, clear the Inbound check box.
7. Click OK.
8. On the System tab, enter values in the following fields as required:

- Outbound Sequential Queue for the sequential queue for outbound messages.
  - Inbound Sequential Queue for the sequential queue for inbound messages.
  - Inbound Continuous Queue for the continuous queue for inbound messages.
9. Save your changes.

---

## Creating interface tables

You can create an interface table to integrate with external systems that use database tables for data exchange. Interface tables reflect the content of publish channel or enterprise service object structures. You must recreate existing tables when you change the definition of the corresponding object structure.

### Before you begin

You cannot recreate an interface table when unprocessed messages for that interface table exist in the MXIN\_INTER\_TRANS queue table. If you do not back up data before you recreate an interface table, the system loses the data. Ensure that alias conflicts are resolved and the Support Flat File Structure check boxes are selected on the associated object structure records in the Object Structures application.

### About this task

The Create Interface Table dialog box displays the interface tables that are associated with publish channels and enterprise services that have the following characteristics:

- Registered to the selected external system.
- Interface table name is not null.
- Corresponding object structure supports a flat file representation.

### Procedure

1. In the External Systems application, select the Create Interface Tables action.
2. In the Create Interface Tables dialog box, select the interface table that you want update and create.
3. Enter a value in the End Point field.
4. Optional: Select the Rename Existing check box to create a copy of the selected interface table.  
The asset management system stores copy of the interface table and adds a BAK suffix to its name.
5. Click Create.
6. Click OK to create the table or Cancel to stop the process.  
Depending on the number of interface tables you are creating, this process can take some time.
7. Click OK to close the Create Interface Tables dialog box.

---

## Working with integration controls

If integration channels or services contain processing rules or exit classes that are based on integration controls, the values of the integration controls can be configured for the external system. You can configure boolean, list, and value integration controls that you can incorporate in processing rules.

- **[Setting up a Boolean control](#)**  
You can set up a Boolean control on an external system when you need a control that specifies a value of true or false. You also can add specific organization-level and site-level values to a Boolean control. A publish channel or an enterprise service can use this Boolean control in its processing rule evaluations. The true or false value that you assign to the control in the external system determines whether an enterprise service or a publish channel applies a processing rule.
- **[Setting up a cross-reference control](#)**  
You can set up a cross-reference control when you need a control that replaces one value with another. A cross-reference control can map a value in the asset management system to a value in the external system.
- **[Setting up a list control](#)**  
You create a list type integration control when you need a control that contains a list of values. You also can add specific organization-level and site-level values to a list control. A publish channel or an enterprise service can use this list control in its processing rule evaluations. The value that you assign to the control in the external system determines whether an enterprise service or a publish channel applies a processing rule.
- **[Setting up a value control](#)**  
You can set a value type integration control on an external system when you need a control that contains a single value. You also can add specific organization-level and site-level values to a value control. A publish channel or an enterprise service can use this value control in its processing rule evaluations. The value that you assign to the control in the external system determines whether the processing rule is applied.
- **[Overriding values for a cross-reference control](#)**  
You can set up a cross-reference control to override values for sites and organizations. You can choose to override the cross-reference values that were previously defined at the enterprise service or publish channel level. The value override can be configured according to each external system to maintain valid asset management system and external system mappings.
- **[Overriding values for a list control](#)**  
You can set up a list control to override values for sites and organizations. You can choose to override the list control values that were previously defined in the enterprise service or publish channel level. The rule could skip the processing of the transaction when the data field value does not match any of the overwritten list control values.

---

## Setting up a Boolean control

You can set up a Boolean control on an external system when you need a control that specifies a value of true or false. You also can add specific organization-level and site-level values to a Boolean control. A publish channel or an enterprise service can use this Boolean control in its processing rule evaluations. The true or false value that you assign to the control in the external system determines whether an enterprise service or a publish channel applies a processing rule.

## Before you begin

---

The boolean value that you assign to a control must already exist in the control definition in the Publish Channels or Enterprise Services application. If that definition points to a domain, any organization-level or site-level values that you assign must exist in that domain.

## Procedure

---

1. In the External Systems application, display the system that you want to update.
2. Select the Set Up Integration Controls action.
3. Select the boolean control that you want to update.
4. Click New Row.
5. Perform one of the following actions:
  - Enter a value in the Organization field.
  - Enter a value in the Site field.
6. Specify whether you want the Boolean control to have a default value of true or false.

Option	Default True
True value	Selected
False value	Cleared

7. Click OK to close the Boolean Control dialog box.
8. Click OK to close the Set Up Integration Controls dialog box.

---

## Setting up a cross-reference control

You can set up a cross-reference control when you need a control that replaces one value with another. A cross-reference control can map a value in the asset management system to a value in the external system.

## Before you begin

---

The value that you assign for translation must first exist in the control definition in the Publish Channels or Enterprise Services application. If that definition points to a domain, the organization-level or site-level values that you assign must exist in that domain.

## Procedure

---

1. In the External Systems application, display the system that you want to update.
2. Select the Setup Integration Controls action.
3. Select the cross-reference control that you want to update.
4. Click New Row.
5. In the Maximo Value field, enter the application value that the asset management system converts to or from an external system value.
6. In the External Value field, enter the external system value the asset management system converts to or from the Maximo value.
7. Click OK to close the Cross-Reference Control dialog box.
8. Click OK to close the Setup Integration Controls dialog box.

---

## Setting up a list control

You create a list type integration control when you need a control that contains a list of values. You also can add specific organization-level and site-level values to a list control. A publish channel or an enterprise service can use this list control in its processing rule evaluations. The value that you assign to the control in the external system determines whether an enterprise service or a publish channel applies a processing rule.

## Before you begin

---

The values that you add to a list control must already exist in the control definition in the Publish Channels or Enterprise Services application. If that definition points to a domain, the organization-level or site-level values that you assign must exist in that domain.

## Procedure

---

1. In the External Systems application, display the system that you want to update.
2. Select the Set Up Integration Controls action.
3. Select the list control that you want to update.
4. Click New Row.
5. In the Value field, enter a value that exists in the domain.
6. Click OK to close the List Control dialog box.
7. Click OK to close the Set Up Integration Controls dialog box.

---

## Setting up a value control

You can set a value type integration control on an external system when you need a control that contains a single value. You also can add specific organization-level and site-level values to a value control. A publish channel or an enterprise service can use this value control in its processing rule evaluations. The value that you assign to the control in the external system determines whether the processing rule is applied.

### Before you begin

---

The value that you assign first must exist in the control definition in the Publish Channels or Enterprise Services application. If that definition points to a domain, the organization-level or site-level values that you assign must exist in that domain.

### Procedure

---

1. In the External Systems application, display the system that you want to update.
2. Select the Set Up Integration Controls action.
3. Select the value control that you want to update.
4. Click New Row.
5. Perform one of the following actions:
  - Enter a value in the Organization field.
  - Enter a value in the Site field.
6. In the Value field, enter a value that exists in the domain.
7. Click OK to close the Value Control dialog box.
8. Click OK to close the Set Up Integration Controls dialog box.

---

## Overriding values for a cross-reference control

You can set up a cross-reference control to override values for sites and organizations. You can choose to override the cross-reference values that were previously defined at the enterprise service or publish channel level. The value override can be configured according to each external system to maintain valid asset management system and external system mappings.

### Before you begin

---

The value that you use for translation must first exist in the cross-reference control definition in the Publish Channels or Enterprise Services application. If that definition points to a domain, the organization-level or site-level values that you assign must exist in that domain.

### About this task

---

If you use synonyms, enter the external value as the control value, not the internal application value.

### Procedure

---

1. In the External Systems application, display the system that you want to update.
2. Select the Setup Integration Controls action.
3. Select the cross-reference control that you want to update.
4. Click Override.  
The Override Values for Cross-Reference Control dialog box displays any organization-level and site-level values that exist for the control.
5. Click New Row.
6. Perform one of the following actions:
  - Enter a value in the Organization field.
  - Enter a value in the Site field.
7. In the Values for Organization/Site table window, click New Row.
8. Enter the values in the Default Value and External Value fields.  
To use the control as a multiplication control, enter multiple records that have the same external value and different organization or site values.
9. Click OK to close the Override Values for Cross-Reference Control dialog box.
10. Click OK to close the Cross-Reference Control dialog box .
11. Click OK to close the Set Up Integration Controls dialog box .

### Example

---

Five external systems are configured to exchange data with the integration framework. Four of these external systems use the same site values, but one site value differs. A cross-reference control that performs the translation between the four mismatched values and the asset management system value can be overwritten at an external system level. The value override can be configured to translate the remaining mismatched external system site value to an asset management system storeroom value.

A cross-reference control in an enterprise service can translate the external system site value `EX001` to an asset management system site `MX001`. An override cross-reference control in external system can override the predefined `EX001` value and use an `EX002` value in its value translation.

---

## Overriding values for a list control

You can set up a list control to override values for sites and organizations. You can choose to override the list control values that were previously defined in the enterprise service or publish channel level. The rule could skip the processing of the transaction when the data field value does not match any of the overwritten list control values.

### Before you begin

---

The value that you assign first must exist in the control definition in the Publish Channels or Enterprise Services application. If that definition points to a domain, the organization-level or site-level values that you assign must exist in that domain.

### About this task

---

You must use a period (.) as the decimal placeholder when you enter decimals as a control value, regardless of the locale settings of the application server or database. Numbers to the left of the placeholder are not formatted. This format applies to inbound and outbound data. For example, \$1,738,593.64 must be specified as 1738593.64.

### Procedure

---

1. In the External Systems application, display the system that you want to update.
2. Select the Set Up Integration Controls action.
3. Select the list control that you want to update.
4. Click Override.  
The Override Values for List Control dialog box displays any organization-level and site-level values that exist for the control.
5. Click New Row.
6. Perform one of the following actions:
  - Enter a value in the Organization field.
  - Enter a value in the Site field.
7. In the Values for Organization/Site table window, click New Row.
8. Enter a value in the Value field.  
If you use synonyms, enter an external value, not the internal application value.
9. Click OK to close the Override Values for List Control dialog box.
10. Click OK to close the Cross-Reference Control dialog box .
11. Click OK to close the Set Up Integration Controls dialog box .

### Example

---

Work orders are sent to an external system based on their statuses. The processing rule that is defined on the enterprise service or publish channel can check the status of a work order against a list control that contains two status values: `APPR` (approved) or `COMPLETE`. This list override can be configured to evaluate two different work order status values: `WAPPR` (waiting on approval) or `WSCH` (waiting to be scheduled). If the status of a work order does not match the overwritten list control values, the work order transaction is not sent to the external system.

---

## API keys application

You use API keys to enable an inbound machine-to-machine integration for an external client. API keys can be used by the OSLC and REST APIs and also can be used as part of the Manage integration framework.

In a machine-to-machine integration, an external machine interacts with Manage data in the Manage system without the use of a browser. API keys are a native form of authentication that do not require an external repository for password storage.

By default, all API keys are encrypted at storage. This setting is controlled by the `mxe.secureapikey` property.

### Adding API keys for REST APIs

---

When an API key is assigned to the external client, the external client can access and interact with data in the Manage system by using the API key as an `apikey` query parameter or an `apikey` request header in REST API calls. REST API calls that use an API key do not create a persistent server connection, and the API key must be part of all REST API requests that the external client makes.

For more information and to use an API key, on the API Keys subtab of the Integration tab of the Administration Work Center, from the Action menu, select API documentation. Select Authorize to use your API key.

To use an API key, go to Integration > API Keys application from the menu.

### Using externally created API keys

---

You can use externally created API keys as an API key in Maximo® Manage. Create this type of API key by using the `MXAPIAPIKEY` REST API and providing your generated API key by using the "apikey" json property, as shown in the following code:

```
POST /oslc/os/mxapiapikey
{
 "apikey": "<outside generated apikey>",
 "expiration": -1
}
```

## Security access

---

As the system administrator, you must synchronize Manage users for the external clients before API keys are created for those clients. The permissions that are associated with the API key are determined by the permissions for the associated user. You can create and configure API keys on the API Keys subtab of the Integration tab of the Administration Work Center. You can create and configure API keys from the API Keys application under Integration.

You also can specify security that enables only the logged-in user to create an API key. To limit the creation of API keys to the logged-in user, go to the System Properties application and filter for the `mxe.apikeyforloggedinuser` property. In the Global Value field, specify 1 and save the record. Select Live Refresh to apply the value immediately.

To disable access to the Manage system for an external client, you can delete the associated API key, but the external client might still access the Manage system by using another configured authentication system. If an API key is compromised, delete the key and create another key for that user.

- [Searching for API keys](#)  
You can search for API keys in the API Keys application.
- [Sorting API keys](#)  
You can sort API keys in the API Keys application.
- [Adding API keys](#)  
When an API key is assigned to the external client, the external client can access and interact with data in the Manage system. The interaction happens by using the API key as an `apikey` query parameter or an `apikey` request header in REST API calls. REST API calls that use an API key do not create a persistent server connection, and the API key must be part of all REST API requests that the external client makes.
- [Copying API keys](#)  
It is possible to copy an API key value for your use.
- [Deleting API keys](#)  
You can delete an API key if necessary.
- [Changing the layout](#)  
You can switch between a tile and a tabular layout for the APIs you create.

---

## Searching for API keys

You can search for API keys in the API Keys application.

### Procedure

---

In the API Keys application, specify a string in the Search field.  
The search results are displayed based on your search string.

---

## Sorting API keys

You can sort API keys in the API Keys application.

### Procedure

---

In the API Keys application, select a sort criteria from the list.  
The API keys are sorted according to the criteria you select.  
Tip: Use the up or down arrow to sort in ascending or descending order.

---

## Adding API keys

When an API key is assigned to the external client, the external client can access and interact with data in the Manage system. The interaction happens by using the API key as an `apikey` query parameter or an `apikey` request header in REST API calls. REST API calls that use an API key do not create a persistent server connection, and the API key must be part of all REST API requests that the external client makes.

### Procedure

---

1. In the API Keys application, click Add API key +.
2. In the Add API key dialog, select the user the API key is for, in the User field.
3. Specify the token expiry in minutes period using the + and - controls.
4. Click Create.  
You can see the API key that you created in the API Keys page.

---

## Copying API keys

It is possible to copy an API key value for your use.

### Procedure

---

In the API Keys application, click Copy key for the API key whose value you want to copy.  
A notification is displayed stating that the key is copied to the clipboard.

---

## Deleting API keys

You can delete an API key if necessary.

### Procedure

---

In the API Keys application, click the Delete icon to delete the API you want to remove.

---

## Changing the layout

You can switch between a tile and a tabular layout for the APIs you create.

### Procedure

---

Select the list or the grid icon to toggle between APIs displayed in a table or APIs displayed as tiles.

- [Managing columns](#)  
You can add or remove columns to the tabular layout of the existing API keys.
- [Viewing APIs with filters](#)  
In the tabular layout of the API Keys page, you can use filters to customize the list displayed and hover over a row to view the copy and delete options.

---

## Managing columns

You can add or remove columns to the tabular layout of the existing API keys.

### Procedure

---

1. In the tabular view of the API Keys page, click the Column Selection icon.
2. Click Manage columns and in the Select value dialog, select the columns that you want to see from the list.
3. Click OK to see the table updated with your column selection.

---

## Viewing APIs with filters

In the tabular layout of the API Keys page, you can use filters to customize the list displayed and hover over a row to view the copy and delete options.

### Procedure

---

Click the Filters icon to see the available filters.

Note: If you add columns using Manage columns, you can see those column headings as filters.  
The list of API keys in the table is displayed according to the filters that you select.

---

## Predefined integration content

The integration framework provides predefined integration content, including object structures, enterprise services, and publish channels that support exporting data to external systems importing data from external system or exporting data to them.

In some cases, only the object structure is provided without a related publish channel or enterprise service. The integration framework, by design, provides support for inserting, updating, deleting and querying data according the business rules defined in the business objects within the object structure. It does not provide all

the functionality that is available through the applications, including those that are available from actions or the processing button on the screen. Some object structures may provide support for some actions or the processing button on the screen.

Some object structures that are provided with your product are the definition of REST APIs that are also provided with your product. For a module-based list of the product REST APIs and related object structures, log in to your product system, and then go to the following URL: *Your product URL*/maximo/maximomodules.jsp

- **[Master data objects](#)**  
The integration framework provides a selection of predefined integration content for master data, which generally consists of accounting, people, storeroom, labor, classification, and vendor data.
- **[Item and inventory objects](#)**  
The integration framework provides a selection of predefined integration content for item and inventory objects, such as service items, tool items, inventory vendors, and issues.
- **[Documents objects](#)**  
The integration framework provides a selection of predefined integration content for documents, such as purchasing records, invoices, and work order records.
- **[Transaction interface objects](#)**  
The integration framework provides a selection of predefined integration content for transaction interface objects, such as receipts, general ledger transactions, labor time reporting, and meter readings.
- **[System objects](#)**  
System objects are MBOs that are generally used for application or metadata configuration. Updating data using system objects may require specific post-processing activities, for example, reconfiguring the database.
- **[Data loading order](#)**  
When you use the integration framework to load multiple sets of data into the application database, you must maintain the dependencies so that the data is loaded correctly. Use the following sequence of predefined object structures as a guide to determine the order in which you load the data.

---

## Master data objects

The integration framework provides a selection of predefined integration content for master data, which generally consists of accounting, people, storeroom, labor, classification, and vendor data.

- **[Asset object](#)**  
The MXASSET object structure allows for bidirectional synchronization of asset information, including attributes that define meters.
- **[Chart of Account object](#)**  
The MXCOA object structure allows for bidirectional synchronization of chart of accounts data.
- **[Classification item object](#)**  
The MXCLASSIFICATION object structure allows for bidirectional synchronization of classifications, including Class Use With, Class Specs, and Class Spec Use With.
- **[Craft object](#)**  
The MXCRAFT object structure allows for bidirectional synchronization of craft information. Craft information includes crafts, craft skills and craft rates.
- **[Financial project object](#)**  
The MXPROJ object structure allows for bidirectional synchronization of financial project information. This object structure synchronizes individual tasks and projects as separate messages. It does not synchronize a project and all its child tasks in a single message.
- **[General ledger \(GL\) component object](#)**  
The MXGLCOMP object structure allows for inbound synchronization of GL components.
- **[Labor object](#)**  
The MXLABOR object structure allows for bidirectional synchronization of labor information, including person and labor craft rates.
- **[Person object](#)**  
The MXPERSON object structure allows for bidirectional synchronization of person information, including phone, email, and SMS data.
- **[Person/user object](#)**  
The MXPERUSER object structure allows for bidirectional synchronization of person/user information. This object structure supports status changes.
- **[Storeroom location object](#)**  
The MXSTORELOC object structure allows for bidirectional synchronization of storeroom, labor, and courier locations.
- **[Vendor \(Companies\) master object Structure object](#)**  
The MXVENDORMSTR object structure allows for bidirectional synchronization of vendor master data.
- **[Vendor \(Companies\) object](#)**  
The MXVENDOR object structure allows bidirectional synchronization of organization-level vendor data, including contacts.

---

## Asset object

The MXASSET object structure allows for bidirectional synchronization of asset information, including attributes that define meters.

---

### Purpose

The MXASSET object structure synchronizes individual assets, but not the asset hierarchy as a whole. It supports the addition and update of meters tied to an asset, but not the update of meter reading values. Inbound processing of ASSETMETER is restricted to attributes that define the meter, not meter reading values or other information pertaining to meter readings.

---

### Prerequisite

You must synchronize applicable operating locations, storerooms, meters, and items before loading assets.

The MBO relationship used to retrieve the ASSETMETER MBO is different from the MBO relationship used in the Assets application. Therefore, the changed attribute in the XML (outbound processing) is not set for any values from this MBO.

This object structure does not support status changes or asset movement. A standard service for assets is provided to support moving assets that reside in operating locations. The standard service, Asset, provides an operation, `assetmoveSingleAsset`, to support this functionality.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutAssetProcess - Populates the Hierarchypath field if a classification is associated with the asset.
Publish Channel	MXASSETInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxAssetProcess - If the Hierarchypath is provided, the processing class populates the corresponding classtructureid field of the asset, which creates the association of the classification with the asset.
Enterprise Service	MXASSETInterface
Processing Rules	None
Integration Controls	None

## Chart of Account object

The MXCOA object structure allows for bidirectional synchronization of chart of accounts data.

## Prerequisite

You must load general ledger components before loading the chart of accounts. There is no predefined publish channel for this object structure.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	None
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxCOAProcess - Can process as a combination of delimited segments or as individual components that are part of the GLACCOUNT datatype definition.
Enterprise Service	MXCOAInterface
Processing Rules	None
Integration Controls	None

## Examples of inbound processing

Processing as a combination of delimited segment is available for XML and interface tables. You can specify the general ledger account this way in all object structures.

```
<GLACCOUNT>
 <VALUE>6400-2-10</VALUE>
</GLACCOUNT>
```

The object structure validates each segment, then creates the chart of account record in database with the following values:

- GLACCOUNT=6400-2-10

- GLCOMP01=6400
- GLCOMP02=2
- GLCOMP03=10

You can also process the object as individual components that are part of the GLACCOUNT datatype definition.

```
<GLACCOUNT>
<GLCOMP glorder="0">6400</GLCOMP>
<GLCOMP glorder="1">2</GLCOMP>
<GLCOMP glorder="2">10</GLCOMP>
</GLACCOUNT>
```

The object structure validates the components and creates the account, using the delimiter defined in the GLCONFIGURE table for each segment. This option is available for XML only.

## Classification item object

The MXCLASSIFICATION object structure allows for bidirectional synchronization of classifications, including Class Use With, Class Specs, and Class Spec Use With.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	MXCLASSInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxClassificationProcess - Processing logic to find classification and parent using Hierarchypath. Because the system allows duplicate classifications (hierarchypaths), an exception is generated when attempting to update a classification if duplicates exist.
Enterprise Service	MXCLASSInterface
Processing Rules	None
Integration Controls	None

## Craft object

The MXCRAFT object structure allows for bidirectional synchronization of craft information. Craft information includes crafts, craft skills and craft rates.

## Prerequisite

If the craft references a skill or contracts, that information must exist prior to loading crafts.

A craft can have a standard rate, a rate for each skill level for the craft, or different rates for each contract that provides the craft, with an optional skill-level rate for each contract.

The CRAFT and CRAFTSKILL records have a STANDARDRATE field for the hourly rate for each craft or skill associated with the craft.

The CRAFTRATE record specifies rates for vendors that supply the craft and, optionally, different rates for each combination of skill, craft, and vendor.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	MXCRAFTInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	None
Enterprise Service	MXCRAFTInterface
Processing Rules	None
Integration Controls	None

## Financial project object

The MXPROJ object structure allows for bidirectional synchronization of financial project information. This object structure synchronizes individual tasks and projects as separate messages. It does not synchronize a project and all its child tasks in a single message.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	MXPROJInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	None
Enterprise Service	MXPROJInterface
Processing Rules	None
Integration Controls	None

## General ledger (GL) component object

The MXGLCOMP object structure allows for inbound synchronization of GL components.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	None
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	None
Enterprise Service	MXGLCOMPInterface
Processing Rules	None
Integration Controls	None

## Labor object

The MXLABOR object structure allows for bidirectional synchronization of labor information, including person and labor craft rates.

## Prerequisite

You must synchronize any associated craft, work location, or storeroom location before loading labor. Each person record can have only one labor record.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutLaborProcess - Processing logic disabled.
Publish Channel	MXLABORInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxLaborProcess - Supports status changes. Sets the ORGID for LaborCraftRate MBO from the parent MBO. Also sets the PERSONID on the PERSON record, based on the PERSONID in the LABOR record
Enterprise Service	MXLABORInterface
Processing Rules	None
Integration Controls	None

## Person object

The MXPERSO object structure allows for bidirectional synchronization of person information, including phone, email, and SMS data.

## Purpose

This object structure supports synchronizing individual person data. It does not support updating availability information for a person record. The object structure also supports status changes.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	MXPERSOInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxPersonProcess - Requires that data for all child objects (PHONE, EMAIL, SMS) must be provided with every person update. Due to a lack of a unique key on these objects, the logic always deletes all of the child objects and adds them again. If a person has three email records in the system and a person message is received with two email records, the email record not included in the person message will be deleted. The object structure supports status changes.
Enterprise Service	MXPERSOInterface
Processing Rules	None
Integration Controls	None

## Person/user object

The MXPERUSER object structure allows for bidirectional synchronization of person/user information. This object structure supports status changes.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	MXPERUSERInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxPersonUserProcess - Processing is required to save the person data prior to saving of the user data. This object structure supports status changes.
Enterprise Service	MXPERSUSERInterface
Processing Rules	None
Integration Controls	None

## Storeroom location object

The MXSTORELOC object structure allows for bidirectional synchronization of storeroom, labor, and courier locations.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutLocProcess - provides filtering to send only storeroom, courier, or labor locations.
Publish Channel	MXSTORELOCInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxLocProcess - provides filtering to accept only storeroom, courier, or labor locations.
Enterprise Service	MXSTORELOCInterface
Processing Rules	None
Integration Controls	None

## Vendor (Companies) master object Structure object

The MXVENDORMSTR object structure allows for bidirectional synchronization of vendor master data.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	MXVENDORMSTRInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	None
Enterprise Service	MXVENDORMSTRInterface
Processing Rules	None
Integration Controls	None

## Vendor (Companies) object

The MXVENDOR object structure allows bidirectional synchronization of organization-level vendor data, including contacts.

### Prerequisite

To enable this object structure to create the company master record, select the Automatically Add Companies to Company Master option for the set associated with the organization to which the vendor record is being added. The MXVENDOR object structure supports status changes.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	MXVENDORInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxComProcess - Provides logic to support creating the company master record.
Enterprise Service	MXVENDORInterface
Processing Rules	None
Integration Controls	None

## Item and inventory objects

The integration framework provides a selection of predefined integration content for item and inventory objects, such as service items, tool items, inventory vendors, and issues.

- [Item object](#)  
The MXITEM object structure allows for bidirectional synchronization of item data, including conversions, item specs and conditions. This object structure supports status changes.
- [Service item object](#)  
The MXSERVITEM object structure allows for bidirectional synchronization of service item data. The main object of the object structure, SERVICEITEMS, is a nonpersistent object.
- [Tool item object](#)  
The MXTOOLITEM object structure allows for bidirectional synchronization of tool item data, including tool item specs.
- [Inventory object](#)  
The MXINVENTORY object structure allows for bidirectional synchronization of inventory (item-storeroom) data, including inventory costs.
- [Inventory balance object](#)  
The MXINVBAL object structure allows for bidirectional synchronization of inventory balance data. The balance change information in this object structure is for the lowest level (BIN or LOT) within the application.
- [Item vendor object](#)  
The MXINVVENDOR object structure allows for bidirectional synchronization of vendor-item data.
- [Inventory reservations object](#)  
The MXINVRES object structure provides for the bidirectional synchronization of inventory (storeroom) reservations. This object structure does not process direct issue reservation records created by the system.
- [Inventory issues object](#)  
The MXINVISSUE object structure provides for the bidirectional synchronization of inventory (storeroom) issues and returns.

## Item object

The MXITEM object structure allows for bidirectional synchronization of item data, including conversions, item specs and conditions. This object structure supports status changes.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutItemProcess - Filter to not set tool or service items. Supports retrieval of the hierarchypath for the classtructureid of the item.
Publish Channel	MXITEMInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxItemProcess - If the inbound transaction is an item update and the capitalized flag of the item has changed, a method is called to change the capitalized status of the item. If the item type is not ITEM or a valid synonym. Supports status changes.
Enterprise Service	MXITEMInterface
Processing Rules	None
Integration Controls	None

## Service item object

The MXSERVITEM object structure allows for bidirectional synchronization of service item data. The main object of the object structure, SERVICEITEMS, is a nonpersistent object.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	None
Publish Channel	MXSERVITEMInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	None
Enterprise Service	MXSERVITEMInterface
Processing Rules	None
Integration Controls	None

## Tool item object

The MXTOOLITEM object structure allows for bidirectional synchronization of tool item data, including tool item specs.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutToolItemProcess - Supports retrieval of the hierarchypath for the classtructureid of the item.
Publish Channel	MXTOOLITEMInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the predefined values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxToolItemProcess - If the inbound transaction is an item update and the capitalized flag of the item has changed, a method is called to change the capitalized status of the item.
Enterprise Service	MXTTOOLITEMInterface
Processing Rules	None
Integration Controls	None

---

## Inventory object

The MXINVENTORY object structure allows for bidirectional synchronization of inventory (item-storeroom) data, including inventory costs.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutInvProcess - Sets the value of the ITEMTYPE field from the ITEM object.
Publish Channel	MXINVENTORYInterface
Processing Rules	SKIPINVENTORY - Skips the record if its ITEMTYPE is in the SKIPITEMTYPE integration control.
Integration Controls	SKIPITEMTYPE

## Inbound Integration Processing

---

The following table shows the predefined values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxInvProcess - Supports status changes.
Enterprise Service	MXINVENTORYInterface
Processing Rules	None
Integration Controls	None

---

## Inventory balance object

The MXINVBAL object structure allows for bidirectional synchronization of inventory balance data. The balance change information in this object structure is for the lowest level (BIN or LOT) within the application.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutInvBalancesProcess - Sets the value of the ITEMTYPE field from the ITEM object.
Publish Channel	MXINVBALInterface
Processing Rules	SKIPINVBALITM - Skips the record if its ITEMTYPE is in the SKIPITEMTYPE integration control.
Integration Controls	SKIPITEMTYPE

## Inbound Integration Processing

---

The following table shows the predefined values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxInvBalancesProcess - The inbound inventory balance object structure internally calls the current balance adjustment method, and this creates a CURBALADJ financial transaction in INVTRANS.
Enterprise Service	MXINVBALInterface MXINVBALQInterface - A second enterprise service that is configured for operation query.
Processing Rules	None
Integration Controls	None

---

## Item vendor object

The MXINVVENDOR object structure allows for bidirectional synchronization of vendor-item data.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutInvVendorProcess -Sets the value of the ITEMTYPE field from the ITEM object and set the value of the CURRENCYCODE from the vendor (companies) object.
Publish Channel	MXINVVENDORInterface
Processing Rules	INVVITEMTYPE - Skips the record if its ITEMTYPE is in the ITEMYPEFORINV integration control.
Integration Controls	ITEMYPEFORINV

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxInvVendorProcess - If the inbound message contains a currency code and that code differs from the vendor's currency code, an error is reported.
Enterprise Service	MXINVENDORInterface
Processing Rules	None
Integration Controls	None

## Inventory reservations object

The MXINVRES object structure provides for thebidirectional synchronization of inventory (storeroom) reservations. This object structure does not process direct issue reservation records created by the system.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutRSVProcess - Skips reservations that are for direct issues.
Publish Channel	MXINVRESInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	None
Enterprise Service	MXINVRESInterface
Processing Rules	None
Integration Controls	None

## Inventory issues object

The MXINVISSUE object structure provides for the bidirectional synchronization of inventory (storeroom) issues and returns.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	MoutISUPProcess - Skips reservations that are for direct issues.

Predefined integration components	Value and description
Publish Channel	MXINVISSUEInterface - Filters out direct issues from MATUSETRANS (PONUM is not null and ISSUETYPE is ISSUE or RETURN) because they are handled by the receipts (MXRECEIPTInterface) object structure. Filters out variance transactions that are written to MATUSETRANS by the invoice approval process.
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	MaxISUPProcess - If the action provided is not an Add action, then an exception is generated. Validates ISSUETYPE to ensure that it is ISSUE, RETURN, or null. If it is any other value, an error is reported. If it is null, the value is set to ISSUE by default.
Enterprise Service	MXINVISSUEInterface
Processing Rules	None
Integration Controls	None

## Documents objects

The integration framework provides a selection of predefined integration content for documents, such as purchasing records, invoices, and work order records.

- [The STATUSIFACE field and processing](#)  
All purchasing and work order documents have a status. The STATUSIFACE field identifies whether related transactions contain new or updated records, or status changes only.
- [Purchase contracts object](#)  
The MXPC object structure allows for bidirectional synchronization of exporting purchase contract information. This object structure currently only supports the purchase contracts types of blanket and price.
- [Purchase requisitions object](#)  
The MXPR object structure allows for bidirectional synchronization of exporting purchase requisition information and supports status changes.
- [Purchase order object](#)  
The MXPO object structure allows for bidirectional synchronization of exporting purchase order information and supports status changes.
- [Invoice object](#)  
The MXINVOICE object structure allows for bidirectional synchronization of exporting invoice information and supports status changes.
- [Outbound processing rules for work order interfaces](#)  
Unlike purchasing document interfaces, work order document interfaces do not have a STATUSIFACE field and do not send status change notifications. A work order document interface is first sent out when the status of a work order changes to WOSTART and on every subsequent update, regardless of the status of the work order.
- [Work order object](#)  
The MXWO object structure allows for bidirectional synchronization of exporting work order information and supports status changes.
- [Work order detail object](#)  
The MXWODETAIL object structure allows for bidirectional synchronization of exporting work order information, including planned material, labor, service, and tools.
- [Work order hierarchy object](#)  
The MXWOHIER object structure allows for bidirectional synchronization of exporting work order information, including child work orders, and also supports status changes. The system first sends out a work order when it reaches the status in the WOSTART control, then on all updates thereafter. The entire work order document is always sent.

## The STATUSIFACE field and processing

All purchasing and work order documents have a status. The STATUSIFACE field identifies whether related transactions contain new or updated records, or status changes only.

In general, the field STATUSIFACE applies to all object structure subrecords that are created from stateful MBOs, which are MBOs that have a STATUS field and support status change actions. The STATUSIFACE field is provided as a nonpersistent field to those objects where integration supports a status change.

## The STATUSIFACE field and outbound processing

While processing an object structure subrecord that has been created from a stateful MBO, the outbound integration processing looks for a STATUS field in the MBO and a STATUSIFACE field in the corresponding object structure subrecord. If both fields exist, the processing sets the value of the STATUSIFACE field to the value of the changed attribute for the corresponding STATUS field. A value of 0 indicates that the status was not changed. A value of 1 indicates that the status was changed.

This processing applies only to event-generated outbound messages, not to messages exported via the data export feature or through a programmatic invocation.

## The STATUSIFACE field and inbound processing

When processing an object structure where the primary (top) MBO is stateful, the inbound processing looks for a STATUSIFACE field on the corresponding object structure subrecord to determine if the inbound message is to be processed as both a document update and a status change, or as a status change only.

The following table describes inbound processing using object structures with a stateful primary (top) MBO. It does not apply to any stateful MBO that is included as a child object in an object structure.

Table 1. Actions taken during inbound processing of the STATUSIFACE field

Value of STATUSIFACE	Document exists in the database	Document does not exist in the database
Not provided, or 0	<ul style="list-style-type: none"><li>Updates the document in the database</li><li>If the status of the inbound document is different from the status in the database, updates the status in the database</li></ul>	<ul style="list-style-type: none"><li>Adds the document to the database</li><li>Sets the status in the database to the status of the inbound message</li></ul>
1	Updates the status in the database	Error

## Purchase contracts object

The MXPC object structure allows for bidirectional synchronization of exporting purchase contract information. This object structure currently only supports the purchase contracts types of blanket and price.

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. Purchase contracts object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	MoutPCProcess - Skips reservations that are for direct issues.
Publish channel	MXPCInterface - Uses processing rules so that the complete purchase contract document is sent only for a status change.
Processing rules	<ol style="list-style-type: none"><li>SKIPPC - Skips the sending of the document if both of the following conditions are true:<ul style="list-style-type: none"><li>The document has not been sent out before.</li><li>The new status is not listed in the PCSEND control.</li></ul></li><li>SKIPPCUPDATE - Skips the sending of the document when updated but no status change.</li><li>SETSTATUSIFACE - Sets the value of the STATUSIFACE field to 0 (false) for all status values except those listed in the PCSEND control.</li><li>CHECKSTATUS - Sends only the purchase contract header data if status changes and the new status is not in the PCSEND control. (In this case, the full document was previously sent and this is sending only the status change notification).</li></ol>
Integration controls	PCSEND

## Inbound integration processing

The following table shows the preconfigured values used in inbound integration processing.

Table 2. Purchase contracts object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	MaxPCProcess - Supports status changes. Creates a new revision when the purchase contract already exists and the revision does not. Only supports contract types of blanket and price.
Publish channel	MXPCInterface
Processing rules	None
Integration controls	None

## Purchase requisitions object

The MXPR object structure allows for bidirectional synchronization of exporting purchase requisition information and supports status changes.

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. Purchase requisitions object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functionality	None
Publish channel	MXPRIInterface – Uses the processing rules. The complete purchase request document is sent only for status changes.
Processing rRules	<ol style="list-style-type: none"> <li>1. SKIPPR - Skips the sending of the document if both of the following conditions are true: <ul style="list-style-type: none"> <li>• The document has not been sent out before.</li> <li>• The new status is not listed in the PRSEND control.</li> </ul> </li> <li>2. SKIPPRUPDATE - Skips the sending of the document when updated but the status is not changed.</li> <li>3. SETSTATUSIFACE - Sets the value of the STATUSIFACE field to 0 (false) for all status values except those listed in the PRSEND control.</li> <li>4. CHECKSTATUS - Sends only the purchase requisition header data if status changes and the new status is not in the PRSEND control. (In this case, the full document was previously sent and this is sending only the status change notification).</li> </ol>
Integration controls	PRSEND

## Inbound integration processing

The following table shows the preconfigured values used in inbound integration processing.

Table 2. Purchase requisitions object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	MaxPRProcess – Supports status changes. If the current status of the purchase requisition is approved, to support updates the processing class will change the status back to waiting for approval, perform updates and then return the status to what is identified in the XML message.
Publish channel	MXPRIInterface
Processing rules	None
Integration controls	None

## Purchase order object

The MXPO object structure allows for bidirectional synchronization of exporting purchase order information and supports status changes.

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. Purchase order object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functionality	None
Publish channel	MXPOInterface - Uses processing rules, the complete purchase order document is only sent only for status changes.
Processing rules	<ol style="list-style-type: none"> <li>1. SKIPPO - Skips the sending of the document if both of the following conditions are true: <ul style="list-style-type: none"> <li>• The document has not been sent out before.</li> <li>• The new status is not listed in the POSEND control.</li> </ul> </li> <li>2. SKIPPOUPDATE - Skips the sending of the document when updated but the status is not changed.</li> <li>3. SETSTATUSIFACE - Sets the value of the STATUSIFACE field to 0 (false) for all status values except those listed in the POSEND control.</li> <li>4. CHECKSTATUS - Sends only the purchase order header data if status changes and the new status is not in the POSEND control. (In this case the full document was previously sent and this is sending only the status change notification).</li> </ol>
Integration controls	POSEND

## Inbound integration processing

The following table shows the preconfigured values used in inbound integration processing.

Table 2. Purchase order object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	<p>MaxPOProcess - supports status changes.</p> <p>If the current status of the purchase order is approved, to support updates, the processing class changes the status back to waiting for approval, performs the updates, and then returns the status to what is identified in the XML message.</p>

Predefined integration components	Value and description
Publish channel	MXPOInterface
Processing rules	None
Integration controls	None

## Invoice object

The MXINVOICE object structure allows for bidirectional synchronization of exporting invoice information and supports status changes.

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. Invoice object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functionality	None
Publish channel	MXINVOICEInterface - Uses processing rules, the complete invoice document is sent only for status changes.
Processing rules	<ol style="list-style-type: none"> <li>1. SKIPINVOICE - Skips the sending of the document if both of the following conditions are true: <ul style="list-style-type: none"> <li>• The document has not been sent out before.</li> <li>• The new status is not listed in the IVSEND control.</li> </ul> </li> <li>2. SKIPINVIOCEUPDATE - Skips the sending of the document when updated but the status is not changed.</li> <li>3. SETSTATUSIFACE - Sets the value of the STATUSIFACE field to 0 (false) for all status values except those listed in the IVSEND control.</li> <li>4. CHECKSTATUS – Sends only the invoice header data if the status changes and the new status is not in the IVSEND control. (In this case the full document was previously sent and this is sending only the status change notification).</li> </ol>
Integration controls	IVSEND

## Inbound integration processing

The following table shows the preconfigured values used in inbound integration processing.

Table 2. Invoice object predefined components for inbound integration processing

Predefined integration components	Value and description
-----------------------------------	-----------------------

Predefined integration components	Value and description
Object structure processing class functionality	<p>The inbound processing creates and updates INVOICECOST lines only if one of the following conditions is met:</p> <ul style="list-style-type: none"> <li>• The invoice line does not reference a purchase order line.</li> <li>• The corresponding purchase order line does not have a distribution.</li> <li>• The purchase order line does not reference a storeroom.</li> </ul> <p>In all other cases, the inbound processing ignores INVOICECOST information when creating or updating the invoice.</p> <p>If the inbound message provides INVOICETERMS, the inbound processing deletes the old terms and adds the new ones.</p> <p>Users can optionally specify a price variance in the PRICEVAR field on each invoice line, if invoice matching is done in the external system and price variances determined in the external system are sent to create variance transactions to update work orders and storerooms. In order to process these variances, a value must exist for OWNERSYSID in the inbound invoice, and it cannot be the same as the value of MAXVARS.MXSYSID.</p> <p>Users can optionally specify a price variance in the PRICEVAR field on each invoice line, if invoice matching is done in the external system and price variances determined in the external system are sent to create variance transactions to update work orders and storerooms. In order to process these variances, a value must exist for OWNERSYSID in the inbound invoice, and it cannot be the same as the value of MAXVARS.MXSYSID.</p> <p>The IVMATCH collaboration switch requires the following values:</p> <ul style="list-style-type: none"> <li>• OWNER1SYSID value is always "THISMX".</li> <li>• OWNER2SYSID value is the value of INVOICE.OWNERSYSID.</li> </ul> <p>If the evaluation is false, line level invoice variances are ignored in the invoice processing.</p> <p>The following are the typical scenarios for using the invoice interface:</p> <ul style="list-style-type: none"> <li>• Invoice Matching in the system (AP Outbound): Invoices received from third parties, either electronically or manually, are processed by the system; that is, they are matched against receipts, if applicable, and then approved. Alternately, payment schedules created in the system will result in approved invoices being created based on the schedule. These approved invoices result in a payment advice being sent to an external AP system. The process of matching also results in accounting entries being posted to the general ledger.</li> <li>• Invoice Matching in external system (Variances Inbound): The system does not do the invoicing, but accepts matched invoices from external systems and applies any variances back to the respective work orders, storerooms, and so on. The accounting entries related to the accounts payable and/or variances must be recorded in the external system; they will not be sent out.</li> </ul> <p>The primary intent of this interface is to provide the system with any variance information necessary for updating the work order costs.</p>
Publish channel	MXINVOICEInterface
Processing rules	None
Integration controls	None

The following table shows an example of possible INVOICE.OWNERSYSID values, the evaluation that is generated, and the default result of the evaluation.

Table 3. Evaluation example

Value of INVOICE.OWNERSYSID	Evaluation	Result (default)
Null	OWNER1SYSID="THISMX" and OWNER2SYSID="THISMX"	False
MXSYSID	OWNER1SYSID="THISMX" and OWNER2SYSID="THISMX"	False
EXTSYSID	OWNER1SYSID="THISMX" and OWNER2SYSID="EXT"	True
Any other value	OWNER1SYSID="THISMX" and OWNER2SYSID="EXT"	True

## Outbound processing rules for work order interfaces

Unlike purchasing document interfaces, work order document interfaces do not have a STATUSIFACE field and do not send status change notifications. A work order document interface is first sent out when the status of a work order changes to WOSTART and on every subsequent update, regardless of the status of the work order.

Users can configure the start value in the WOSTART control. Any status that you specify in the control is the value, not the MAXVALUE. If multiple synonym values exist for a status, list all applicable synonyms.

## Work order object

The MXWO object structure allows for bidirectional synchronization of exporting work order information and supports status changes.

### Purpose

The system first sends out a work order when it reaches the status in the WOSTART control, then on all updates thereafter. The entire work order document is always sent.

The work order interface contains all the information defined by system on the work order, but it does not provide additional information about projects or financial control data, equipment, and locations that is not part of the standard work order. If necessary, you can add the additional information via user fields.

The system treats work order tasks as work orders. Both have similar properties and they are stored in the same table. If a user creates a work order, adds tasks/child work orders to the work order, and then approves the work order, the Inherit Status Changes flag on the work order indicates whether approval of the work order also results in approval of all the tasks/child work orders of that particular work order. The default is Y, so when a work order is approved, any child tasks or work orders that inherit the parent's approval based on this flag are also approved.

The outbound event listener on the work order MBO receives multiple independent events, one for each work order, and they are processed and sent out independently. Therefore, a work order with three tasks and two child work orders results in six independent outbound work orders.

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. Work order object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functionality	None
Publish channel	MXWOInterface - Uses processing rules, the complete work order document is sent only for status changes.
Processing rules	SKIPWO – Skips the sending of the document if both of the following conditions are true: <ul style="list-style-type: none"><li>The document has not been sent out before.</li><li>The new status is not listed in the WOSTART control.</li></ul>
Integration controls	WOSTART

## Inbound integration processing

The following table shows the preconfigured values used in inbound integration processing.

Table 2. Work order object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	StatefulMicSetIn - Generic class that supports status changes.
Publish channel	MXWOInterface
Processing rules	None
Integration controls	None

## Work order detail object

The MXWODETAIL object structure allows for bidirectional synchronization of exporting work order information, including planned material, labor, service, and tools.

### Purpose

The system first sends out a work order when it reaches the status in the WOSTART control, then on all updates thereafter. The entire work order document is always sent.

The MBO relationship that is used to retrieve the reservation MBO (INVRESERVE) is different from the relationship that is used in the Work Order Tracking application. Therefore, the changed attribute in the XML is not set for any values from this MBO

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. Work order detail object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functionality	MoutWORSvProcess - Provides the code required to update the sendersysid column on the invreserve MBO.
Publish channel	MXWODETAILInterface - Uses processing rules, the complete work order document with plan information is sent only for status changes.
Processing rules	SKIPWO - Skips the sending of the document if both of the following conditions are true: <ul style="list-style-type: none"><li>The document has not been sent out before.</li><li>The new status is not listed in the WOSTART control.</li></ul>
Integration controls	WOSTART

## Inbound integration processing

The following table shows the predefined values used in inbound integration processing.

Table 2. Work order detail object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	None
Publish channel	None
Processing rules	None
Integration controls	None

## Work order hierarchy object

The MXWOHIER object structure allows for bidirectional synchronization of exporting work order information, including child work orders, and also supports status changes. The system first sends out a work order when it reaches the status in the WOSTART control, then on all updates thereafter. The entire work order document is always sent.

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. Work order hierarchy object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functionality	None
Publish channel	MXWOHierInterface - Contains an event filter class, WOHierarchyEventFilter, that prevents the child MBOs from being sent out when they are being sent out via a parent MBO (where both parent and child MBOs are initiated by the same event action).
Processing rules	SKIPWO - Skips the sending of the document if both of the following conditions are true: <ul style="list-style-type: none"><li>The document has not been sent out before.</li><li>The new status is not listed in the WOSTART control.</li></ul>
Integration controls	WOSTART

## Inbound integration processing

The following table shows the predefined values used in inbound integration processing.

Table 2. Work order hierarchy object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	MaxWOHierarchyProcess - Supports status changes and commit processing to support loading multiple related work orders in a single message.
Publish channel	MXWOHierInterface
Processing rules	None
Integration controls	None

## Transaction interface objects

The integration framework provides a selection of predefined integration content for transaction interface objects, such as receipts, general ledger transactions, labor time reporting, and meter readings.

- [Receipts object for materials and services](#)  
The MXRECEIPT object structure allows for bidirectional synchronization of purchase order receipt information for material and service receipts and it also supports status change when receipts require inspections. The object structure uses a nonpersistent object to support both material (MATRECTRANS) and service (SERVRECTRANS) receipts. For material line items, this object structure supports nonrotating items, and a separate object structure, MXRCVROTITM supports rotating items.
- [Material and rotating item receipt object](#)  
The MXRCVROTITM object structure allows for inbound synchronization of receipt information for rotating items.
- [General ledger \(GL\) object](#)  
The MXGLTXN object structure allows for outbound synchronization of GL transactions. This interface allows for the posting of site-level transactions to an external general ledger application for accounting reconciliation.
- [Labor time reporting object](#)  
The MXEMPACT object structure allows for posting site-level actual time reported in the system to external applications. The approved labor actuals are sent out and all inbound labor actuals are accepted regardless of status. The status of existing records are not updated when processing inbound transactions.
- [Meter reading object](#)  
The MXMETERDATA object structure allows inbound synchronization of meter reading data. This object structure supports only inbound processing. This

interface does not support the processing of meter readings for work order tasks.

## Receipts object for materials and services

The MXRECEIPT object structure allows for bidirectional synchronization of purchase order receipt information for material and service receipts and it also supports status change when receipts require inspections. The object structure uses a nonpersistent object to support both material (MATRECTRANS) and service (SERVRECTRANS) receipts. For material line items, this object structure supports nonrotating items, and a separate object structure, MXRCVROTITM supports rotating items.

### Purpose

In the outbound direction, this object structure processes purchase order receipts, transfers (movements against receipts or receipts against internal PO). It also processes returns (returns to vendors after receipt inspection, or returns to vendor after acceptance and goods movement from the location that holds the inspections).

For inbound receipts, the MXRECEIPT object structure supports Receipts, Inspections, Returns, and Voiding of a receipt. You do not have to specify whether an inbound receipt is a material receipt or a service receipt. The integration processing uses the POLINE to make the determination.

Sending a transaction for an Inspection or Void, requires that the processing can identify the previously receipted line item to apply the Inspection or Void against. Inbound transactions identify a prior receipt transaction already in Maximo® in two ways:

- In the payload, provide the RECEIPTREF property with the value of the MATRECTRANSID of the previous receipt transaction. The external application must obtain the MATRECTRANSID of that initial receipt transaction.
- In the payload, provide the ORGRCVEXTERNALREFID property with the value of the EXTERNALREFID of the previous receipt transaction. The external application must provide a unique EXTERNALREFID value on all receipt-related transactions. The Inspection or Void transaction must also provide the EXTERNALREFID of the initial receipt transaction in the ORGRCVEXTERNALREFID field of the payload. Using this approach gives the external application complete control of the ID values that are used on transactions, with a requirement that each EXTERNALREFID must be unique. When you provide EXTERNALREFID on your payload, you also need to provide a SOURCESYSID that represents the external application that is sending the transaction.

Note: Do not specify a RECEIPTREF or ORGRCVEXTERNALREFID value for Returns. Returns are processed independently of the corresponding receipt.

### Sample transactions

```
{
 "issuetype": "RECEIPT",
 "orgid": "EAGLENA",
 "siteid": "BEDFORD",
 "positeid": "BEDFORD",
 "ponum": "1126",
 "porevisionnum": 0,
 "polinenum": 1,
 "itemnum": "6I-2499",
 "itemsetid": "SET1",
 "tostoreloc": "CENTRAL",
 "receiptquantity": 5,
 "externalrefid": "1126r5",
 "sourcesysid": "xyz"
}
```

If the PO line for the receipt requires an inspection, the following transaction would be the inspection (qty 5 accepted). This example uses the EXTERNALREFID to find the original Receipt record.

```
{
 "issuetype": "RECEIPT",
 "orgid": "EAGLENA",
 "siteid": "BEDFORD",
 "positeid": "BEDFORD",
 "ponum": "1126",
 "porevisionnum": 0,
 "polinenum": 1,
 "itemnum": "6I-2499",
 "itemsetid": "SET1",
 "tostoreloc": "CENTRAL",
 "receiptquantity": 5,
 "externalrefid": "1126i5",
 "sourcesysid": "xyz",
 "acceptedqty": 5,
 "rejectqty": 0,
 "inspected": true,
 "orgrcvexternalrefid": "1126r5"
}
```

The following inspection is the same but uses the MATRECTRANSID in the RECEIPTREF field to find the original Receipt record.

```
{
 "issuetype": "RECEIPT",
 "orgid": "EAGLENA",
 "siteid": "BEDFORD",
 "positeid": "BEDFORD",
 "ponum": "1126",
 "receiptref": "1126r5",
 "inspected": true
}
```

```

 "porevisionnum": 0,
 "polinum": 1,
 "itemnum": "6I-2499",
 "itemsetid": "SET1",
 "tostoreloc": "CENTRAL",
 "receiptquantity": 5,
 "externalrefid": "1126i5",
 "sourcesysid": "xyz",
 "acceptedqty": 5,
 "rejectqty": 0,
 "inspected": true,
 "receiptref": 13428573 *
 }

```

\* 13428573 is the generated by Maximo MATRECTRANSID on the MATRECTRANS row for the initial receipt transaction.

Other data-mapping information:

All quantities must be positive and the sum of the accepted qty and reject qty must equal the receiptquantity.

For a Void transaction, it requires:

- issuetype of VOIDRECEIPT
- receiptquantity (must be negative)

## Outbound integration processing

The following table shows the predefined values that are used in outbound integration processing.

Table 1. Receipts object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functions	<p>MoutProcess - Processes receipts with issue type of RECEIPT or RETURN. If no issue type is specified, it is treated as RECEIPT.</p> <p>Processing for RECEIPT issue type and Inspection Required = N:</p> <p>Material and service receipts:</p> <ul style="list-style-type: none"> <li>• Uses inbound RECEIPTQUANTITY (for material receipts) or QTYTORECEIVE (for service receipts) to create the receipt.</li> <li>• Maps inbound REJECTEDQTY to the REJECTEDQTY field in the receipt.</li> <li>• Ignores any other quantities.</li> <li>• Does not look at the inbound INSPECTED field.</li> </ul> <p>Material receipts (MATRECTRANS records):</p> <ul style="list-style-type: none"> <li>• Sends out only RECEIPT and RETURN type records and TRANSFER type records containing a PONUM (not a storeroom transfer). Sends out new receipts only, not updates to existing receipts.</li> </ul> <p>Service receipts (SERVRECTRANS records):</p> <ul style="list-style-type: none"> <li>• Sends out RECEIPT and RETURN type records. Sends out new receipts and updates to existing receipts.</li> </ul>
Publish channel	MXRECEIPTInterface
Processing rules	<p>Service receipts:</p> <p>Sends out records when the status is equal to a value in the SERVRECSTAT control (default COMP). It occurs under the following conditions:</p> <ul style="list-style-type: none"> <li>• A record that does not require inspection is inserted.</li> <li>• An existing record is updated in database and the status field is changed to COMP.</li> </ul>
Integration controls	SERVRECSTAT control identifies all statuses at which the system sends out service receipt transactions. It can have multiple values. By default, the value is COMP.

## Inbound integration processing

The following table shows the preconfigured values that are used in inbound integration processing.

Table 2. Receipts object predefined components for inbound integration processing

Predefined integration components	Value and description
-----------------------------------	-----------------------

Predefined integration components	Value and description
Object structure processing class functions	<p>MaxRCVProcess -</p> <p>Processing for RECEIPT issue type and Inspection Required = Y:</p> <p>Material receipts:</p> <p>INSPECTED = N:</p> <ul style="list-style-type: none"> <li>• Uses only the inbound RECEIPTQUANTITY field to create the receipt; ignores accepted and rejected quantity values.</li> <li>• Creates a receipt with STATUS = WINS (waiting inspection) and quantity that is derived from RECEIPTQUANTITY.</li> </ul> <p>INSPECTED = Y:</p> <ul style="list-style-type: none"> <li>• Uses the inbound RECEIPTQUANTITY, ACCEPTEDQTY, and REJECTEDQTY fields to create the receipt.</li> <li>• Does not allow partial inspections or acceptances. RECEIPTQUANTITY must equal ACCEPTEDQTY + REJECTEDQTY.</li> <li>• Creates a receipt with STATUS = WASSET (if it is a rotating item) or COMP (all other items).</li> <li>• Depending on quantities specified, can create up to three transactions—one RECEIPT, one TRANSFER, and one RETURN.</li> </ul> <p>Service receipts:</p> <p>INSPECTED = N:</p> <ul style="list-style-type: none"> <li>• Uses the inbound AMTTORECEIVE (if POLINE order quantity is null) or QTYTORECEIVE (in other cases) to create a receipt; ignores all other quantity values.</li> <li>• Creates a receipt with STATUS = WINS (waiting inspection) and quantity that is derived from QTYTORECEIVE.</li> </ul> <p>INSPECTED = Y:</p> <ul style="list-style-type: none"> <li>• Uses the inbound QTYTORECEIVE, ACCEPTEDQTY, and REJECTEDQTY fields to create a receipt.</li> <li>• Does not allow partial inspections or acceptances. QTYTORECEIVE must equal ACCEPTEDQTY + REJECTEDQTY.</li> <li>• Creates a single transaction of type RECEIPT, with STATUS = COMP.</li> </ul> <p>Processing for RETURN issue type:</p> <p>Material and service receipts:</p> <ul style="list-style-type: none"> <li>• Accepts return transactions for a POLINE only if an earlier receipt exists for the same line; if Inspection Required = Y for the POLINE, the receipt was approved. Otherwise, it reports an error.</li> <li>• Uses only the inbound RECEIPTQUANTITY (for material receipts) or QTYTORECEIVE (for service receipts) field to create the receipt; ignores all other quantity values.</li> <li>• Creates a single transaction with issue type RETURN and the credit GL account as the RBNI account.</li> </ul>
Publish channel	MXRECEIPTInterface
Processing rules	None
Integration controls	None

## Material and rotating item receipt object

The MXRCVROTITM object structure allows for inbound synchronization of receipt information for rotating items.

### Purpose

This object structure supports inbound processing only.

You cannot specify a status for the receipt in the interface. The status is set by the business processing.

This interface differs from the MXRECEIPTInterface in that it processes material receipts exclusively and you can identify serialized rotating assets to be created for rotating item receipts.

You can receive rotating items with or without asset numbers. If you receive them without asset numbers, you must manually specify the asset numbers by using the Receive Rotating Items dialog box in the Purchasing Receiving application.

For rotating items, the number of inbound transactions is one more than the number of rotating items. One transaction exists for the total receipt quantity, and one transaction exists for each rotating item that is associated with the receipt. For example, for a receipt of 10 rotating items produces 11 transactions.

For inbound receipts, the MXRCVROTITM object structure supports Receipts, Inspections, Returns, and Voiding of a receipt.

When a transaction is sent for an Inspection or Void, it requires that the processing can identify the previously receipted line item to apply the Inspection or Void against. Inbound transactions identify a prior receipt transaction already in Maximo® in two ways:

- In the payload, provide the RECEIPTREF property with the value of the MATRECTRANSID of the previous receipt transaction. It requires the internal application to obtain the MATRECTRANSID of that initial receipt transaction.

- In the payload, provide the ORGRCVEXTERNALREFID property with the value of the EXTERNALREFID of the previous receipt transaction. It requires the external application to provide a unique EXTERNALREFID value on all receipt-related transactions. It also requires the Inspection or Void transaction to provide the EXTERNALREFID of the initial receipt transaction in the ORGRCVEXTERNALREFID field of the payload. Using this approach gives the external application complete control of the ID values that are used in transactions, with a requirement that each EXTERNALREFID must be unique. When you provide an EXTERNALREFID on your payload, you also need to provide a SOURCESYSID that represents the external application that is sending the transaction.

Note: Do not specify a RECEIPTREF or ORGRCVEXTERNALREFID value for Returns. Returns are processed independently of the corresponding receipt.

## Sample transactions

Receipt for a PO line (No inspection required)

```
{
 "issuetype": "RECEIPT",
 "orgid": "EAGLENA",
 "siteid": "BEDFORD",
 "positeid": "BEDFORD",
 "ponum": "1126",
 "porevisionnum": 0,
 "polinenum": 1,
 "itemnum": "D600",
 "itemsetid": "SET1",
 "tostoreloc": "CENTRAL",
 "receiptquantity": 2,
 "externalrefid": "1126r5",
 "sourcesysid": "xyz",
 "asset": [
 {
 "siteid": "BEDFORD",
 "assetnum": "DS1134-1"
 },
 {
 "siteid": "BEDFORD",
 "assetnum": "DS1134-2"
 }
]
}
```

Receipt for a PO line (inspection required)

```
{
 "issuetype": "RECEIPT",
 "orgid": "EAGLENA",
 "siteid": "BEDFORD",
 "positeid": "BEDFORD",
 "ponum": "1127",
 "porevisionnum": 0,
 "polinenum": 1,
 "itemnum": "D600",
 "itemsetid": "SET1",
 "tostoreloc": "CENTRAL",
 "receiptquantity": 2,
 "externalrefid": "1127r2",
 "sourcesysid": "xyz"
}
```

The PO line for the receipt requires an inspection and the following transaction is the inspection (qty 2 accepted). This example uses the EXTERNALREFID to find the original Receipt record.

```
{
 "issuetype": "RECEIPT",
 "orgid": "EAGLENA",
 "siteid": "BEDFORD",
 "positeid": "BEDFORD",
 "ponum": "1127",
 "porevisionnum": 0,
 "polinenum": 1,
 "itemnum": "D600",
 "itemsetid": "SET1",
 "tostoreloc": "CENTRAL",
 "receiptquantity": 2,
 "externalrefid": "1127i2",
 "sourcesysid": "xyz",
 "acceptedqty": 2,
 "rejectqty": 0,
 "inspected": true,
 "orgrcvexternalrefid": "1127r2",
 "asset": [
 {
 "siteid": "BEDFORD",
 "assetnum": "DS1134-1"
 },
 {
 "siteid": "BEDFORD",
 "assetnum": "DS1134-2"
 }
]
}
```

```
]
}
```

The following inspection is the same but uses the MATRECTRANSID in the RECEIPTREF field to find the original Receipt record.

```
{
 "issuetype": "RECEIPT",
 "orgid": "EAGLENA",
 "siteid": "BEDFORD",
 "positeid": "BEDFORD",
 "ponum": "1127",
 "porevisionnum": 0,
 "polinenum": 1,
 "itemnum": "D600",
 "itemsetid": "SET1",
 "tostoreloc": "CENTRAL",
 "receiptquantity": 2,
 "externalrefid": "1127i2",
 "sourcesysid": "xyz",
 "acceptedqty": 2,
 "rejectqty": 0,
 "inspected": true,
 "receiptref": 13428573 *
 "asset": [
 {
 "siteid": "BEDFORD",
 "assetnum": "DS1134-1"
 },
 {
 "siteid": "BEDFORD",
 "assetnum": "DS1134-2"
 }
]
}
```

\* 13428573 is the MATRECTRANSID generated by Maximo on the MATRECTRANS row for the initial receipt transaction.

Other data-mapping information:

All quantities must be positive and the sum of the acceptedqty and rejectqty must equal the receiptquantity.

For a Void transaction, it requires:

- issuetype of VOIDRECEIPT
- receiptquantity (must be negative)

## Outbound integration processing

The following table shows the predefined values that are used in outbound integration processing.

Table 1. Material and rotating item receipt object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functions	None
Publish channel	None
Processing rules	None
Integration controls	None

## Inbound integration processing

The following table shows the preconfigured values that are used in inbound integration processing.

Table 2. Material and rotating item receipt object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functions	<p>MaxRcvRotItmMProcess - Reports an error if the purchase order line being processed has LINETYPE = SERVICE or STDSERVICE.</p> <p>Processing is the same as the inbound integration point processing class functionality for material receipts that use the MXRECEIPTInterface, with the following more processing:</p> <ul style="list-style-type: none"><li>• Receipts: If the line item is a rotating item and Inspection Required = N, or INSPECTED = Y, the processing checks for asset information that corresponds to the item provided in the interface. If the information is available, the processing validates the number of asset records to ensure it equals the RECEIPTQTY or ACCEPTEDEQTY (whichever applies). If it does, invokes the receiving functionality and creates asset as required.</li><li>• Returns: If the item being returned is a rotating item, ignores any asset information.</li></ul> <p>In the system, the return of a rotating type item does not affect the assets that are created by the original receipt. The asset records remain unchanged; only the item balances are updated (if applicable).</p>
Publish channel	MXRCVROITMInterface
Processing rules	None

Predefined integration components	Value and description
Integration controls	None

## General ledger (GL) object

The MXGLTXN object structure allows for outbound synchronization of GL transactions. This interface allows for the posting of site-level transactions to an external general ledger application for accounting reconciliation.

### Purpose

This interface uses a nonpersistent MBO with data from the following subrecords:

- SERVRECTRANS
- MATRECTRANS
- INVTRANS
- INVOICETRANS
- MATUSETRANS
- LABTRANS
- TOOLSTRANS

The event filter class, GLEventFilter, is used to set the events to the applicable persistent objects listed.

The SOURECEMBO field identifies the database table in which the transaction originated. Its value is derived from the GLSOURCEMBO synonym domain.

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. General ledger object predefined components for outbound integration processing

Predefined integration components	Value	Description
Object structure definition class functionality	MoutGLProcess - Service receipts	<p>Service receipts include the following entries:</p> <ul style="list-style-type: none"> <li>• Accounting entries for non-distributed service receipts created by the receiving application for services ordered on purchase orders (ISSUETYPE = RECEIPT, COSTINFO=1)</li> <li>• Accounting entries for distributed service receipts created by the receiving application for services ordered on purchase orders (ISSUETYPE = POCOST)</li> <li>• Accounting entries for purchase order services with Receipt Required = N that are directly invoiced instead of being received (ISSUETYPE = INVOICE)</li> <li>• Accounting entries for services that are not against purchase orders and are invoiced directly (ISSUETYPE = INVOICE)</li> <li>• Invoice variance transactions recorded against service receipts (ISSUETYPE = INVOICE)</li> </ul> <p>Service receipts (SERVRECTRANS) processing:</p> <ul style="list-style-type: none"> <li>• Sets SOURCEMBO to SERVRECTRANS and ISSUETYPE to the value listed.</li> <li>• INVOICE type transactions: sends out on insert.</li> <li>• POCOST and RECEIPT type transactions: if Inspection Required = N for the corresponding POLINE, sends out on insert. If inspection required = Y, sends out when status is changed to COMP.</li> </ul>

Predefined integration components	Value	Description
	MoutGLProcess - Material receipts	<p>Material receipts include the following:</p> <ul style="list-style-type: none"> <li>Accounting entries for non-distributed material receipts created by the receiving application for items/ tools ordered on purchase orders (ISSUETYPE = RECEIPT, COSTINFO = 1)</li> <li>Accounting entries for distributed material receipts created by the receiving application for items/ tools ordered on purchase orders (ISSUETYPE = POCOST)</li> <li>Accounting entries for Item transfers between storerooms (ISSUETYPE = TRANSFER and PONUM=NULL)</li> <li>Accounting entries for receipt inspection transfers of items between the receipt inspection storeroom and the purchase order line storeroom (ISSUETYPE = TRANSFER and RECEIPTREF!=NULL and PONUM!=NULL)</li> <li>Accounting entries for receipts against internal purchase orders (ISSUETYPE = TRANSFER and RECEIPTREF=NULL and PONUM!=NULL)</li> <li>Accounting entries for receipt inspection goods return of items and materials (ISSUETYPE = RETURN)</li> <li>Accounting entries for return to vendor from a storeroom or direct issue purchase order lines (ISSUETYPE = RETURN)</li> <li>Invoice variance transactions recorded against material receipts (ISSUETYPE = INVOICE)</li> <li>Accounting transaction for increasing the kit item's INVENTORY control account value when kits are made (ISSUETYPE = KITMAKE). transactions for increasing the INVENTORY control account for each constituent item of a kit when a kit is disassembled (ISSUETYPE = KITBREAK)</li> </ul> <p>Material receipts (MATRECTRANS) processing:</p> <ul style="list-style-type: none"> <li>Sets SOURCEMBO to MATRECTRANS and ISSUETYPE to value listed.</li> <li>Sends out INVOICE, RECEIPT, TRANSFER, RETURN, KITMAKE and KITBREAK type transactions on insert.</li> <li>For POCOST type transactions on insert if status is COMP (that is, on insert if Inspection Required = N, and when status changed to COMP if Inspection Required = Y).</li> </ul>
	MoutGLProcess - Inventory adjustment transactions	<p>Inventory adjustment transactions include the following:</p> <ul style="list-style-type: none"> <li>Inventory current balance adjustments (ITTYPE = CURBALADJ)</li> <li>Inventory standard/ average cost adjustments (ITTYPE = STDCOSTADJ/ AVGCOSTADJ)</li> <li>Cost difference when a kit is disassembled and there is a difference between the value of the kit and the sum of the kit component values (ITTYPE = KITCOSTVAR)</li> <li>Physical count reconciliation (ITTYPE = RECBALADJ)</li> <li>Capitalized cost adjustment (ITTYPE = CAPCSTADJ)</li> <li>Standard cost receipt adjustment (ITTYPE = STDRECADJ)</li> </ul> <p>Inventory adjustment (INVTRANS) processing:</p> <ul style="list-style-type: none"> <li>Sets SOURCEMBO to INVTRANS and ITTYPE to value listed.</li> <li>Does not send out transactions with ITTYPE = INSERTITEM, CREATEASSET and PHYSCNT, as they are considered audit records rather than accounting transactions.</li> <li>Sends out all other transactions on insert.</li> </ul>
	MoutGLProcess - Invoice transactions	<p>Invoice transactions include the following transactions created by invoice approval:</p> <ul style="list-style-type: none"> <li>Invoice TOTAL transaction (amount payable to invoice vendor, TRANSTYPE = TOTAL)</li> <li>Invoice line tax transactions (tax accounting for each TAX code for an invoice line, TRANSTYPE = TAX1:TAX5)</li> <li>Invoice currency variance transaction (TRANSTYPE = CURVAR)</li> <li>Invoice price variance transactions (TRANSTYPE = INVCEVAR)</li> </ul> <p>Invoice transaction (INVTRANS) processing:</p> <ul style="list-style-type: none"> <li>Sets SOURCEMBO to INVOICETRANS and TRANSTYPE to the value listed.</li> <li>Sends out all transactions when they are created.</li> </ul>
	MoutGLProcess - Material issue and return transactions	<p>Material issue and return transactions include the following:</p> <ul style="list-style-type: none"> <li>Accounting entries for items issued from a storeroom in the system (ISSUETYPE = ISSUE)</li> <li>Accounting entries for items returned to a storeroom (ISSUETYPE = RETURN)</li> </ul> <p>Material issue and return (MATUSETRANS) processing:</p> <ul style="list-style-type: none"> <li>Sets SOURCEMBO to MATUSETRANS and ISSUETYPE to value listed.</li> <li>Does not send out direct issue transactions that are created by PO receiving/ invoice variances in MATUSETRANS, as they are accounted for in MATRECTRANS. Identifies such transactions by their PONUM, so all MATUSETRANS transactions that have a PO reference are not sent out by this interface.</li> <li>Sends out all other transaction at time of creation.</li> </ul>

Predefined integration components	Value	Description
	MoutGLProcess - Labor transactions	Labor Transaction (LABRTRANS) processing: <ul style="list-style-type: none"> <li>Sets SOURCEMBO to LABTRANS.</li> <li>If approval not required, send out labor actuals against work orders on insert.</li> <li>If approval required, sends out transaction after it is approved (when GENAPPSERVRECEIPT is Y).</li> </ul>
	MoutGLProcess - Tool transactions	Tool Transaction (TOOLTRANS) processing: <ul style="list-style-type: none"> <li>Sets SOURCEMBO to TOOLTRANS.</li> <li>Sends out usage of tools on work orders on creation of TOOLTRANS</li> </ul>
Publish channel	MXGLTXNInterface	
Processing rules	SKIPGL	Skips the sending of the general ledger transaction based on the value in SOURCEMBO existing in the GLSOURCE control.
Integration controls	GLSOURCE	

## Inbound integration processing

The following table shows the preconfigured values used in inbound integration processing.

Table 2. General ledger object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	None
Publish channel	None
Processing rules	None
Integration controls	None

## Labor time reporting object

The MXEMPACT object structure allows for posting site-level actual time reported in the system to external applications. The approved labor actuals are sent out and all inbound labor actuals are accepted regardless of status. The status of existing records are not updated when processing inbound transactions.

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. Labor time reporting object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functionality	None
Publish channel	MXEMPACTInterface
Processing rules	SKIPEMPACT - Skips the sending of the labor pay (LABTRANS) if the transaction is not approved (GENAPPSERVRECEIPT = 0).
Integration controls	

## Inbound integration processing

The following table shows the preconfigured values used in inbound integration processing.

Table 2. Labor time reporting object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	MaxEmpactProcess - Allows add actions only. A null action is processed as an add action. LABTRANSID is not allowed to be passed with a value because the LABTRANSID is program-generated during the add action.
Publish channel	MXEMPACTInterface
Processing rules	None
Integration controls	None

## Meter reading object

The MXMETERDATA object structure allows inbound synchronization of meter reading data. This object structure supports only inbound processing. This interface does not support the processing of meter readings for work order tasks.

## Outbound integration processing

The following table shows the predefined values used in outbound integration processing.

Table 1. Meter reading object predefined components for outbound integration processing

Predefined integration components	Value and description
Object structure definition class functionality	None
Publish channel	None
Processing rules	None
Integration controls	None

## Inbound integration processing

The following table shows the preconfigured values used in inbound integration processing.

Table 2. Meter reading object predefined components for inbound integration processing

Predefined integration components	Value and description
Object structure processing class functionality	<p>MaxMeterDataProcess - The processing class verifies that the following attributes are provided:</p> <ul style="list-style-type: none"><li>• Site ID</li><li>• Asset or location</li><li>• Meter ID or condition monitoring point</li><li>• Meter reading value, reading date time, inspector</li></ul> <p>When a work order is specified, the following processing occurs:</p> <ul style="list-style-type: none"><li>• If a measurement point is specified, the processing class identifies the asset or location meter corresponding to the site and measurement point, and creates a meter reading for that asset or location meter.</li><li>• If a meter is specified, then either asset or location must be specified. If both are specified, the processing class assumes the meter belongs to the asset, and processes the meter accordingly. If only the asset or location is specified, then the meter on the corresponding entity is updated.</li></ul> <p>If no work order is specified, the following processing occurs:</p> <ul style="list-style-type: none"><li>• If a measurement point is specified, the reading is recorded for the measurement point.</li><li>• If a meter is specified, then either asset or location must be specified. If both are specified, the processing class assumes the meter belongs to the asset, and processes the meter accordingly. If only asset or location is specified, then the meter on the corresponding entity is updated.</li></ul>
Publish channel	MXMETERInterface
Processing rules	None
Integration controls	None

## System objects

System objects are MBOs that are generally used for application or metadata configuration. Updating data using system objects may require specific post-processing activities, for example, reconfiguring the database.

The following restrictions apply to the use of enterprise services, publish channels and object structures:

- You cannot enable listeners for publish channels.
- You cannot process system interfaces via interface tables or flat files.
- You must specify an action code on inbound system interfaces.
- **Object structures object**  
The MXINTOBJECT object structure allows for inbound synchronization of the definition of object structures, including column aliases. System validations that apply to users adding, deleting and modifying predefined object structures apply to the modification of object structures via the Object Structure object structure service.
- **Enterprise service object**  
The MXENTSRV object structure allows for inbound synchronization of the definition of enterprise services and their corresponding processing rules and control values.
- **Publish channel object**  
The MXIFACEOUT object structure allows for inbound synchronization of the definition of publish channels their corresponding processing rules and control values. Before publish channel creation, make sure all controls used by the publish channel exist.
- **End point object**  
The MXENDPOINT object structure allows for inbound synchronization of the definition of end points.

- [External system object](#)  
The MXEXTSYSTEM object structure allows for inbound synchronization of the definition of an external system, the enterprise services and publish channels used by the external system, and their corresponding control values.
- [Integration control object](#)  
The MXIFACECONTROL object structure allows for inbound synchronization of Integration Controls and their system level default values.
- [Invocation channel object](#)  
The MXIFACEINVOKE object structure allows for inbound synchronization of an invocation channel definition.
- [Integration queue object](#)  
The MXQUEUE object structure allows for inbound synchronization of integration queue definitions.
- [Message definition object](#)  
The MXMESSAGE object structure allows for inbound synchronization of system error and warning messages.
- [MBO configuration object](#)  
The MXOBJECTCFG object structure allows for inbound synchronization of MBO definition information.
- [Domain object](#)  
The MXDOMAIN object structure allows for inbound synchronization of domain information.
- [Communication template object](#)  
The MXCTEMPLATE object structure allows for bidirectional synchronization of communication templates that users can leverage to standardize frequently used e-mail communications and notifications.
- [Action definition object](#)  
The MXACTION object structure allows for inbound synchronization of workflow action definitions that can be used with escalation, service level agreement (SLA), and workflow processes.
- [System properties object](#)  
The MXPROP object structure allows for inbound synchronization of system properties and values.
- [Integration module object](#)  
The MXIM object structure allows for inbound synchronization of an integration module definition including properties and LMO relationships.
- [Logical management operations \(LMO\) object](#)  
The MXLMO2 object structure allows for inbound synchronization of LMOs including attributes.
- [Operational management product \(OMP\) object](#)  
The MXOMP object structure allows for inbound synchronization of OMPs, including relationships to CIs and configurations with IM and LMOs.
- [Launch entry object](#)  
The MXLAUNCH object structure allows for inbound synchronization of Launch Entries and context information.

---

## Object structures object

The MXINTOBJECT object structure allows for inbound synchronization of the definition of object structures, including column aliases. System validations that apply to users adding, deleting and modifying predefined object structures apply to the modification of object structures via the Object Structure object structure service.

---

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

---

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## Enterprise service object

The MXENTSRV object structure allows for inbound synchronization of the definition of enterprise services and their corresponding processing rules and control values.

---

## Prerequisite

Before enterprise service creation, make sure all controls used by the enterprise service exist.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## Publish channel object

The MXIFACEOUT object structure allows for inbound synchronization of the definition of publish channels their corresponding processing rules and control values. Before publish channel creation, make sure all controls used by the publish channel exist.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## End point object

The MXENDPOINT object structure allows for inbound synchronization of the definition of end points.

## Prerequisite

---

Before end point creation, make sure handlers used by end points exist.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## External system object

The MXEXTSYSTEM object structure allows for inbound synchronization of the definition of an external system, the enterprise services and publish channels used by the external system, and their corresponding control values.

## Prerequisite

---

Before external system creation, make sure all enterprise services and publish channels, end points, and controls used by the external system exist.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## Integration control object

The MXIFACECONTROL object structure allows for inbound synchronization of Integration Controls and their system level default values.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## Invocation channel object

The MXIFACEINVOKE object structure allows for inbound synchronization of an invocation channel definition.

### Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

### Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## Integration queue object

The MXQUEUE object structure allows for inbound synchronization of integration queue definitions.

### Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

### Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## Message definition object

The MXMESSAGE object structure allows for inbound synchronization of system error and warning messages.

### Prerequisite

---

In addition to the new messages added via this object structure, the messages.xml file must be updated with the corresponding message text.

### Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A

Predefined integration components	Value and description
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

## MBO configuration object

The MXOBJECTCFG object structure allows for inbound synchronization of MBO definition information.

## Prerequisite

Use this object structure with caution.

Use only add, addchange, or change action codes when synchronizing inbound data through this object structure. Do not use the replace action unless you completely replace the MXOBJECTCFG and MAXATTRIBUTECFG data.

The delete action presents the risk of deleting predefined records in the database tables associated with MXOBJECTCFG and MAXATTRIBUTECFG MBOs.

An inbound setting restriction exists on the CHANGED, EAUDITENABLED, EAUDITFILTER, EAUDITBNAME, IMPORTED, STORAGEPARTITION, MAXOBJECTID column, so the XML value is not set to the MBO.

After synchronizing inbound data with this interface, for your changes to take effect, use the Database Configuration application and select the Apply Configuration Changes action.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	psdi.iface.app.configure.MaxObjcfgProcess -  If the event that MAXOBJECTCFG is creating a view (MAXOBJECTCFG.VIEW=1), the processing class skips any MAXATTRIBUTECFG MBOs associated with the referred MAXOBJECTCFG.  This class also delays the SAVE validation on MAXOBJECTCFG until all its associated attributes are successfully added into the database.
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

## Domain object

The MXDOMAIN object structure allows for inbound synchronization of domain information.

## Purpose

Some fields in the database are associated with select value lists. These lists of defined values are known as domains (sometimes referred to as value lists).

This object structure synchronizes ALN, numeric, numeric range, table, and crossover domains definitions.

## Prerequisite

---

Update and delete operations require external systems to provide valid DOMAINID values.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

## Communication template object

---

The MXCTEMPLATE object structure allows for bidirectional synchronization of communication templates that users can leverage to standardize frequently used e-mail communications and notifications.

## Purpose

---

A communication template is a definition of a mail message with subject, message, and recipient information that is processed when certain nodes become current, or along specified workflow routing paths between nodes.

This object structure synchronizes application, change status, custom class, command line, and set value actions, but not action group.

## Prerequisite

---

Update and delete operations require external systems to provide a valid ACTIONID value.

This object structure does not support the creation of action groups.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	MXCTEMPLATEInterface
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## Action definition object

The MXACTION object structure allows for inbound synchronization of workflow action definitions that can be used with escalation, service level agreement (SLA), and workflow processes.

### Purpose

---

An action is an event that you want the system to trigger when it encounters records that meet the conditions defined by an escalation point, service level agreement, or workflow process.

This object structure synchronizes application, change status, custom class, command line, and set value actions, but not action group.

### Prerequisite

---

Update and delete operations require that external systems provide a valid ACTIONID value.

This object structure does not support the creation of action groups.

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

---

## System properties object

The MXPROP object structure allows for inbound synchronization of system properties and values.

### Purpose

---

### Prerequisite

---

## Outbound Integration Processing

---

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

---

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None

Predefined integration components	Value and description
Integration Controls	None

## Integration module object

The MXIM object structure allows for inbound synchronization of an integration module definition including properties and LMO relationships.

### Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

### Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

## Logical management operations (LMO) object

The MXLMO2 object structure allows for inbound synchronization of LMOs including attributes.

### Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

### Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

## Operational management product (OMP) object

The MXOMP object structure allows for inbound synchronization of OMPs, including relationships to CIs and configurations with IM and LMOs.

### Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A

Predefined integration components	Value and description
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

## Launch entry object

The MXLAUNCH object structure allows for inbound synchronization of Launch Entries and context information.

## Outbound Integration Processing

The following table shows the predefined values used in outbound integration processing.

Predefined integration components	Value and description
Object Structure definition class functionality	N/A
Publish Channel	N/A
Processing Rules	None
Integration Controls	None

## Inbound Integration Processing

The following table shows the preconfigured values used in inbound integration processing.

Predefined integration components	Value and description
Object Structure processing class functionality	N/A
Enterprise Service	N/A
Processing Rules	None
Integration Controls	None

## Data loading order

When you use the integration framework to load multiple sets of data into the application database, you must maintain the dependencies so that the data is loaded correctly. Use the following sequence of predefined object structures as a guide to determine the order in which you load the data.

## Object structures

- MXGLCOMP
- MXCOA
- MXVENDORMSTR
- MXVENDOR
- MXPERSON
- MXPERUSER
- MXCRAFT
- MXLABOR
- MXSTORELOC
- MXCLASSIFICATION
- MXITEM
- MXINVENTORY
- MXINVBAL
- MXINVVENDOR
- MXSERVITEM
- MXPROJ
- MXASSET
- MXWO
- MXWODETAIL
- MXWOHIER
- MXINVRES

- MXEMPACT
- MXINVISSUE
- MXGLTXN
- MXTOOLITEM
- MXPC
- MXMETERDATA
- MXPR
- MXPO
- MXRECEIPT
- MXRCVROTITM
- MXINVOICE

## System object structures

---

- MXINTOBJECT
- MXIFACECONTROL
- MXENTSRV
- MXIFACEOUT
- MXENDPOINT
- MXQUEUE
- MXEXTSYSTEM
- MXIFACEINVOKE
- MXIM
- MXLMO2
- MXOMP
- MXLAUNCH
- MXMESSAGE
- MXOBJECTCFG
- MXDOMAIN
- MXCTEMPLATE
- MXACTION
- MXPROP

## Integration data processing

---

You can configure integration components in different ways to meet your integration requirements. You can integrate with multiple external applications, and each application requires a different integration approach that is based on the integration support that is provided by that application.

- [Planning to process data for integration](#)  
Before you initiate an integration transaction, you must decide which integration components to use. You must also plan how to implement these components so that you can achieve a successful integration with the external destination for your integration.
- [Inbound data processing](#)  
The integration framework supports asynchronous and synchronous processing of inbound integration messages with object structures, enterprise services, and standard services.
- [Outbound data processing](#)  
Publish channels provide asynchronous processing of outbound messages that do not require a response from the external system. This processing can be initiated by an object event or you can publish on demand with the data export feature. Invocation channels provide synchronous processing of outbound messages that require a response or confirmation from the external system.
- [Configuring integration processing](#)  
Processing of integration messages occurs at several points during the movement of integration messages for inbound and outbound transactions. When you configure integration processing, you must ensure that source data and destination data are in compatible data structures and formats.
- [Rule-based customization](#)  
You can use processing rules to change the behavior of predefined integration processing without writing Java™ classes, automation scripts, or XSL maps. You can implement processing rules only on publish channels or on enterprise services.
- [Code-based customization](#)  
The integration framework provides placeholders in transaction flows where you can insert your own code to provide logic that customizes transaction processing. You can insert Java classes or automation scripts at selected points in the processing of object structures, publish channels, enterprise services, and invocation channels. You can also use XSL maps to transform messages.

## Planning to process data for integration

---

Before you initiate an integration transaction, you must decide which integration components to use. You must also plan how to implement these components so that you can achieve a successful integration with the external destination for your integration.

The choice of the components that you use and how you implement them is often determined by the external application that you are integrating with. These choices include the following considerations:

### Data type

Define the data, for example work orders and person data. When defined, determine whether there are predefined object structures to support each set of data or must you create more object structures.

#### Direction

For each set of data, which direction will the integration scenario implement, sending outbound transactions, receiving inbound transactions, or both? The direction of the integration can vary for each set of data.

#### Message exchange

This factor depends on the capabilities of the external application and options can include integrating data by using files (XML, JSON, or flat, such as CSV), calling web services, and posting XML or JSON over HTTP. The method of exchanging data and how often that occurs can vary for each set of data.

#### Customization

As data is exchanged, is customization within the application needed to transform message content or to apply integration business rules? If customization is required, does it use integration framework capabilities such as Java™ exit classes, automation scripts, XSL maps, or processing rules, or is customization implemented in the external application?

Depending upon the answers to these questions, you need different types of component and API configurations, which can include:

- Object structures
- Message templates, if the outbound integration messages are in the JSON or XML format
- API keys
- Publish channels and invocation channels
- Enterprise services
- Object structure services, enterprise services, and standard services
- Web services
- REST and OSLC APIs
- External systems
- Endpoints

---

## Inbound data processing

The integration framework supports asynchronous and synchronous processing of inbound integration messages with object structures, enterprise services, and standard services.

For asynchronous processing, the external system establishes and maintains a connection until the message is passed into a JMS queue. For synchronous processing, the external system establishes and maintains a connection until message processing is complete.

- **[Asynchronous processing of inbound messages](#)**  
During asynchronous processing of inbound messages, an external application calls an enterprise service and maintains a connection until the message is saved to a JMS queue and the connection ends. If an error occurs during the save of the message to the queue, the external application is responsible for reprocessing the message.
- **[Synchronous processing of inbound messages](#)**

---

## Asynchronous processing of inbound messages

During asynchronous processing of inbound messages, an external application calls an enterprise service and maintains a connection until the message is saved to a JMS queue and the connection ends. If an error occurs during the save of the message to the queue, the external application is responsible for reprocessing the message.

Asynchronous processing is managed by sequential or continuous JMS queues. Processing in a sequential queue guarantees the order of delivery of messages, based on a first in, first out order. Processing in a continuous queue delivers messages in any order.

You can use enterprise services to support the following transactions:

- Importing data from a flat file or an XML file
- Loading data from interface tables
- Receiving an XML message from an HTTP POST request

- Calling a web service that is configured to use a JMS queue
- Calling an EJB
- Using a direct JMS connection

All of these options support the use of an enterprise service, when the integration message is passed into a JMS queue. When the message is in the queue, a separate process that uses a cron task or a message-driven bean (MDB) picks up the message from the queue. The message is then processed through the enterprise service layer, the related object structure layer, and the business objects are updated. Because messages are processed through a JMS queue, no response is sent to the application that called the service and the Query operation is not supported in this processing model.

## Synchronous processing of inbound messages

You can implement synchronous inbound integration with an object structure, enterprise, or standard service. These transactions require the establishment and maintenance of a direct connection from the external application to the integration framework for the duration of the transaction.

The external application maintains the connection to the service until business objects are updated in the Maximo® database or until business objects are returned in response to a Query operation. The integration framework returns a response to the external application to confirm the success or failure of message processing.

The following options are available for sending synchronous integration messages to services:

- Posting of an XML or JSON message by using HTTP or REST API
- Starting a web service that is configured to bypass the JMS queue
- Starting an EJB

Object structure and enterprise services can use any of these options to support Create, Update, Delete, Sync, and Query operations.

## Initiation of asynchronous processing of inbound data

To initiate integration processing, the external system uses one of the supported methods to establish a connection. After the external system and enterprise service are validated, messages are placed in the JMS queue that is specified for the enterprise service.

The procedure for establishing the initial connection varies depending on the integration method that is used for the transaction. The following table describes the available methods and the connections that these methods use.

Method	Connection procedure
HTTP or HTTPS Post method	Use the following URL: <i>hostname:port/meaweb/esqueue/extsysname/entservname</i> where: <ul style="list-style-type: none"> <li>• <i>extsysname</i> is the name of the external system</li> <li>• <i>entservname</i> is the name of the enterprise service</li> </ul>
EJB	Start an EJB from a Java™ Platform, Enterprise Edition client by using the following code: <pre>public byte() processExternalDataAsync(byte[] extData, String serviceName, String sender)</pre> On the client, specify the JNDI name of the Enterprise JavaBean, ejb/maximo/remote/enterpriseservice, to look up the Enterprise JavaBean reference and to start the method. The following configurations are required on the Java Platform, Enterprise Edition client: <ul style="list-style-type: none"> <li>• Access to the <b>Home</b> and <b>Remote</b> class files</li> <li>• Access to the Java Platform, Enterprise Edition JAR files for the server</li> <li>• The URL of the server that hosts the Enterprise JavaBeans</li> <li>• The class name of the context factory</li> </ul> The client code must instantiate the default <b>InitialContext</b> object. The context derives the provider URL and the context factory from the environment.
Data import feature that uses XML or flat files	The user clicks Data Import in an application.
Data import cron task	The XMLFILECONSUMER cron task or the FLATFILECONSUMER cron task polls the source directory that is configured for data import.
Interface tables	The external system writes message data to the appropriate interface tables and updates the MXIN_INTER_TRANS queue table with information about the sequence for processing the records in the interface table.  A cron task polls the MXIN_INTER_TRANS queue table for records to be processed.
Web services	The external system starts an enterprise service that is deployed as a web service that is configured not to bypass the JMS queue.
JMS direct	The external system passes an XML message directly into the JMS queue from another queuing system, such as WebSphere® MQ.

When a connection is established, or when a cron task runs and identifies that data is ready for import, the following steps occur:

1. The integration framework checks that the external system and the enterprise service are valid and enabled.
2. If the messages are in flat file format, the integration framework checks that the object structure supports flat structures.
3. If verification fails, the integration framework notifies the sender of the error and does not process the data.
4. If the verification is successful, the integration framework identifies the inbound JMS queue that is assigned to the enterprise service and writes the message to the queue.

5. The integration framework updates the JMS message header with the names of the external system and the enterprise service.

If a transaction that contains multiple instances of a record encounters errors, error-handling varies depending on the exchange method used. The following error-handling occurs, depending on the exchange type:

- For HTTP or EJB transactions only: If a transaction contains multiple instances of a document, for example, if it contains 10 person records, a single message is written to the JMS queue, not 10 individual messages. If one of the records has a processing error, a total message processing exception occurs and none of the records is committed to the database.
- For data import transactions only: If a transaction contains multiple instances of a document, for example, if it contains 10 person records, the application writes 10 individual messages to the JMS queue. If one of the messages has a processing error, an error transaction is logged for that message and the remaining 9 messages continue to process in the application.

## Initiation of synchronous processing of inbound data

To initiate synchronous processing, the external system uses one of the supported methods to establish a connection. During the connection process, the integration framework checks that the external system and the referenced enterprise service are valid and enabled.

The procedure for establishing the initial connection varies, depending on the service that is used for the transaction. The following table describes the available methods and the connections that these methods use.

Method	Connection procedure
HTTP or HTTPS Post method	<ul style="list-style-type: none"><li>• Use the following URL for transactions that use an enterprise service: <b><i>hostname:port/meaweb/es/extsysname/entservname</i></b></li></ul> <p>Where:</p> <ul style="list-style-type: none"><li>◦ <i>extsysname</i> is the name of the external system</li><li>◦ <i>entservname</i> is the name of the enterprise service</li></ul> <ul style="list-style-type: none"><li>• Use the following URL for transactions that use an object structure service: <b><i>hostname:port/meaweb/os/osname</i></b></li></ul> <p>Where <i>osname</i> is the name of the object structure service.</p> <ul style="list-style-type: none"><li>• Use the following URL for transactions that use a standard service: <b><i>hostname:port/meaweb/ss/application service name</i></b></li></ul> <p>Where <i>application service name</i> is the name of the standard service.</p>
EJB	<ul style="list-style-type: none"><li>• For enterprise service transactions, start an EJB from a Java™ Platform, Enterprise Edition client by using the following code: <b><code>public byte[] processExternalDataSync(byte[] extData, String serviceName, String sender)</code></b></li></ul> <p>The client can use the JNDI name of the Enterprise JavaBean, <i>ejb/maximo/remote/enterpriseservice</i>, to look up the Enterprise JavaBean reference and to start the method. The following configurations are required on the Java Platform, Enterprise Edition client:</p> <ul style="list-style-type: none"><li>• For object structure service transactions, start an EJB from a Java Platform, Enterprise Edition client by using the following code: <b><code>public byte[] processMOS(byte[] reqmosData, String mosName)</code></b></li></ul> <p>The client can use the JNDI name of the Enterprise JavaBean, <i>ejb/maximo/remote/mosservice</i>, to look up the Enterprise JavaBeans reference and to start the method. The following configurations are required on the Java Platform, Enterprise Edition client:</p> <ul style="list-style-type: none"><li>• For object structure service transactions, start an EJB from a Java Platform, Enterprise Edition client by using the following code: <b><code>public byte[] action(byte[] actionData, String maxServiceName)</code></b></li></ul> <p>The client can use the JNDI name of the Enterprise JavaBean, <i>ejb/maximo/remote/actionservice</i>, to look up the Enterprise JavaBean reference and to start the method. The following configurations are required on the Java Platform, Enterprise Edition client:</p> <p>The following configurations are required on the Java Platform, Enterprise Edition client:</p> <ul style="list-style-type: none"><li>• Access to the <b>Home</b> and <b>Remote</b> class files</li><li>• Access to the Java Platform, Enterprise Edition JAR files for the server</li><li>• The URL of the server that hosts the Enterprise JavaBeans</li><li>• The class name of the context factory</li></ul> <p>The client code must instantiate the default InitialContext object. Web service	<p>Use the following URL for transactions that start a web service:</p> <p><b><i>http://hostname:port/meaweb/services/web service name</i></b></p> <p>where <i>web service name</i> is the name of a deployed web service.</p>

## Processing sequences

The same processing sequence is applied to asynchronous and synchronous messages that use an enterprise service. The processing sequences are different for synchronous messages, depending on whether they use object structures or standard services.

- [Enterprise service processing sequences](#)

An enterprise service message processes through a number of layers to query and update business object data. You can use these processing layers to customize and control processing to satisfy the integration requirements with the external application.

- [Synchronous integration with an object structure service](#)

An object structure service is accessible by using the HTTP Post, EJB, and web service invocation methods to receive synchronous object structure service messages. The operations Create, Update, Delete, Sync, and Query are supported.

- [Synchronous integration with a standard service](#)

A standard service is accessible by using the HTTP Post, EJB, and web service invocation methods to receive synchronous standard service messages.

---

## Enterprise service processing sequences

An enterprise service message processes through a number of layers to query and update business object data. You can use these processing layers to customize and control processing to satisfy the integration requirements with the external application.

For asynchronous processing, the data can originate from the following exchange methods:

- Interface tables
- HTTP Post of an XML or JSON message
- Starting a web service that is configured to use a JMS queue
- Starting an EJB
- Direct JMS connection
- Data import of a flat file, JSON or XML file

For synchronous processing, the data can originate from the following exchange methods:

- HTTP Post of an XML or JSON message
- Starting a web service that is configured to use a message queue
- Starting an EJB

The same processing sequence applies for asynchronous and synchronous processing.

Enterprise service processing occurs in the following sequence:

1. The external system calls the enterprise service.
2. Custom processing can occur at several points during the processing of enterprise services. You can run custom Java™ classes or automation scripts to manipulate the message data or you can apply an XSL map. Custom processing occurs in the following order:
  - a. If a preprocessing method is defined in a user exit class, this method is applied first.
  - b. If an external exit class is specified, this processing is applied.
  - c. If a postprocessing method is defined in a user exit class, this method is applied.
  - d. If an XSL map is specified for the enterprise service, the map is applied to convert enterprise service format to object structure format.At this point in the processing, the message must match the format of the object structure that is associated with the enterprise service.
3. Object structure processing occurs in the following order:
  - a. You can run custom Java classes or automation scripts to manipulate data during object structure processing.
  - b. If processing rules are configured for the object structure, these rules are run next.
  - c. If processing rules result in the multiplication of data for sites or organizations, the object structure message is duplicated for the additional sites or organizations.
  - d. Objects are created and object processing starts.
4. Object processing occurs in the following order:
  - a. If a preprocessing method is defined in a user exit class, this method is applied.
  - b. If an external exit class is specified, this processing is applied.
  - c. If a postprocessing method is defined in a user exit class, this method is applied.
  - d. The business objects are processed, and data is saved to the database.
5. For synchronous transactions only, for Create, Update, Delete, and Sync operations, the enterprise service provides a response to the starting application that includes the following information:
  - Indicates whether the message was processed successfully.
  - The value of the internal ID column of the main object, regardless of whether the column is part of the primary key of the main object.
  - The values of the primary key fields of the main object.
  - The values of any alternate key fields for the main object, which is configured for the object or for the object structure.
6. For synchronous transactions only, for Query operations, the entire object structure is returned. You can run custom Java classes or automation scripts to manipulate the response data, or you can apply an XSL map. You can manipulate the response data by applying an XSL map.

---

## Synchronous integration with an object structure service

An object structure service is accessible by using the HTTP Post, EJB, and web service invocation methods to receive synchronous object structure service messages. The operations Create, Update, Delete, Sync, and Query are supported.

Integration processing that is based on an object structure service occurs in the following sequence:

1. The external system uses one of the following invocation methods to initiate communication with the integration framework:
  - HTTP invocation
  - EJB invocation
  - Web service invocation
2. The integration framework receives the inbound message that identifies the object structure that is associated with the message
3. The integration framework builds the objects, based on the object structure and the content of the inbound message.

4. The integration framework applies any predefined logic to the object structure.
5. Objects are processed and data is committed to the database if the message contains an update operation, or the data is returned to the requester if the message contains a query operation.
6. If a processing error occurs, the response with an error message is returned to the caller of the service.

---

## Synchronous integration with a standard service

A standard service is accessible by using the HTTP Post, EJB, and web service invocation methods to receive synchronous standard service messages.

Integration processing that is based on a standard service occurs in the following sequence:

1. The external system uses one of the following invocation methods to initiate communication with the integration framework:
  - HTTP invocation
  - EJB invocation
  - Web service invocation
2. The objects are passed to the system, and standard system processing is applied.

---

## Enterprise service processing sequences

An enterprise service message processes through a number of layers to query and update business object data. You can use these processing layers to customize and control processing to satisfy the integration requirements with the external application.

For asynchronous processing, the data can originate from the following exchange methods:

- Interface tables
- HTTP Post of an XML or JSON message
- Starting a web service that is configured to use a JMS queue
- Starting an EJB
- Direct JMS connection
- Data import of a flat file, JSON or XML file

For synchronous processing, the data can originate from the following exchange methods:

- HTTP Post of an XML or JSON message
- Starting a web service that is configured to use a message queue
- Starting an EJB

The same processing sequence applies for asynchronous and synchronous processing.

Enterprise service processing occurs in the following sequence:

1. The external system calls the enterprise service.
2. Custom processing can occur at several points during the processing of enterprise services. You can run custom Java™ classes or automation scripts to manipulate the message data or you can apply an XSL map. Custom processing occurs in the following order:
  - a. If a preprocessing method is defined in a user exit class, this method is applied first.
  - b. If an external exit class is specified, this processing is applied.
  - c. If a postprocessing method is defined in a user exit class, this method is applied.
  - d. If an XSL map is specified for the enterprise service, the map is applied to convert enterprise service format to object structure format.At this point in the processing, the message must match the format of the object structure that is associated with the enterprise service.
3. Object structure processing occurs in the following order:
  - a. You can run custom Java classes or automation scripts to manipulate data during object structure processing.
  - b. If processing rules are configured for the object structure, these rules are run next.
  - c. If processing rules result in the multiplication of data for sites or organizations, the object structure message is duplicated for the additional sites or organizations.
  - d. Objects are created and object processing starts.
4. Object processing occurs in the following order:
  - a. If a preprocessing method is defined in a user exit class, this method is applied.
  - b. If an external exit class is specified, this processing is applied.
  - c. If a postprocessing method is defined in a user exit class, this method is applied.
  - d. The business objects are processed, and data is saved to the database.
5. For synchronous transactions only, for Create, Update, Delete, and Sync operations, the enterprise service provides a response to the starting application that includes the following information:
  - Indicates whether the message was processed successfully.
  - The value of the internal ID column of the main object, regardless of whether the column is part of the primary key of the main object.
  - The values of the primary key fields of the main object.
  - The values of any alternate key fields for the main object, which is configured for the object or for the object structure.
6. For synchronous transactions only, for Query operations, the entire object structure is returned. You can run custom Java classes or automation scripts to manipulate the response data, or you can apply an XSL map. You can manipulate the response data by applying an XSL map.

---

## Synchronous integration with an object structure service

An object structure service is accessible by using the HTTP Post, EJB, and web service invocation methods to receive synchronous object structure service messages. The operations Create, Update, Delete, Sync, and Query are supported.

Integration processing that is based on an object structure service occurs in the following sequence:

1. The external system uses one of the following invocation methods to initiate communication with the integration framework:
  - HTTP invocation
  - EJB invocation
  - Web service invocation
2. The integration framework receives the inbound message that identifies the object structure that is associated with the message
3. The integration framework builds the objects, based on the object structure and the content of the inbound message.
4. The integration framework applies any predefined logic to the object structure.
5. Objects are processed and data is committed to the database if the message contains an update operation, or the data is returned to the requester if the message contains a query operation.
6. If a processing error occurs, the response with an error message is returned to the caller of the service.

---

## Synchronous integration with a standard service

A standard service is accessible by using the HTTP Post, EJB, and web service invocation methods to receive synchronous standard service messages.

Integration processing that is based on a standard service occurs in the following sequence:

1. The external system uses one of the following invocation methods to initiate communication with the integration framework:
  - HTTP invocation
  - EJB invocation
  - Web service invocation
2. The objects are passed to the system, and standard system processing is applied.

---

## Outbound data processing

Publish channels provide asynchronous processing of outbound messages that do not require a response from the external system. This processing can be initiated by an object event or you can publish on demand with the data export feature. Invocation channels provide synchronous processing of outbound messages that require a response or confirmation from the external system,.

- [Asynchronous integration with a publish channel](#)  
The integration framework uses publish channels to process asynchronous outbound messages. The sending of a publish channel message can be initiated by an object event, or you can use the data export feature to send publish channel messages on demand.
- [Synchronous integration with an invocation channel](#)  
The integration framework uses invocation channels to process synchronous outbound messages that require a confirmation or response content from the external application. The export is started by an action class that calls the invocation channel.

---

## Asynchronous integration with a publish channel

The integration framework uses publish channels to process asynchronous outbound messages. The sending of a publish channel message can be initiated by an object event, or you can use the data export feature to send publish channel messages on demand.

Publish channels are configured for an object structure and can enable event-based integration when the main object of the object structure is updated. An update occurs, for example, when a user saves a record in an application or completes a stage in a workflow process. When the main object of an object structure is updated, an event is initiated to all publish channels that are associated with the object structure and are configured to listen for events. Users can use the data export feature in the External Systems application to initiate publish channel messages at any time.

When a publish channel message is initiated by an event or by data export, the integration framework performs a sequence of tasks:

1. Identifies the object structure and the component objects that are associated with the publish channel.
  2. Constructs the object structure for the transaction and forms an XML or JSON message that is based on the content of the objects.
  3. Applies any processing rules that are defined in the Publish Channels application.
  4. If the publish channel is associated with multiple external systems, creates copies of the object structure, one for each publish channel and external system combination.
  5. If any custom processing Java™ classes, automation scripts, or an XSL map are associated with the publish channel, processes them in the following order:
    - a. Runs the event filter class, if one is provided.
    - b. Runs the preprocessing method in the user exit processing class, if one is provided.
    - c. Runs a publish channel processing class, if one is provided.
    - d. ,
    - e. Runs the postprocessing method in the user exit class, if one is provided.
    - f. Applies an XSL map, if one is provided.
  6. Writes the XML or JSON message to the outbound queue specified for the external system.
  7. A cron task picks up the publish channel message and delivers it to the external system, which is based on the endpoint that is configured.
- [Data export feature](#)  
The publish channel supports batch processing of integration data by using the data export feature.

- [Event-based integration](#)

A publish channel can initiate an integration message in response to the processing of a system transaction, such as the update of an object.

---

## Data export feature

The publish channel supports batch processing of integration data by using the data export feature.

You initiate the data export feature by running a SQL query on the primary object of an object structure, and the number of records to send. If the query is successful, the export starts.

You initiate the data export feature by providing a SQL WHERE clause on the primary object of an object structure in the Data Export window. You can also configure the number of records to send. If the query is successful, the export starts and delivers the data based on the endpoint that is configured for the publish channel.

---

## Event-based integration

A publish channel can initiate an integration message in response to the processing of a system transaction, such as the update of an object.

You can configure publish channels to listen to events that occur on the primary object of the related object structure by selecting the Enable Listener check box in the Publish Channels application. When the main object of an object structure is updated, a publish channel message sends the updated information to the external system.

When an update to a child object initiates an update to the main object, this information is also sent to the external system. However, some updates to a child object do not initiate an update to the main object and, as a result, the updated information is not sent to the external system. For example, if an object structure is configured to support an attachment as a child object, when the user adds an attachment, the external system is not notified of this event.

To propagate an event from a child object to the primary object of the object structure, in the Object Structures application, you use the Advanced Configurations action to configure event propagation. When you configure an object structure to propagate events on child objects to the main object, the main object then sends the updated information to the external system.

If you configure event propagation for an object structure, you must monitor message activity carefully, because the configuration can initiate more messages than the external system is designed to process. For child objects that have embedded logic to update the parent object, this configuration has no impact in terms of enabling or disabling the event propagation from the child to the parent object.

---

## Synchronous integration with an invocation channel

The integration framework uses invocation channels to process synchronous outbound messages that require a confirmation or response content from the external application. The export is started by an action class that calls the invocation channel.

Sending an invocation channel message is initiated by an action Java™ class that is coded to start the channel. Invocation channels are used, for example, to call an external application to validate data, to start a process on an external application, or to retrieve data. An invocation channel can be triggered by a user interface control that is configured to call the action class that starts the channel.

When an invocation channel message is started by an action class, the integration framework performs a sequence of tasks:

1. Identifies the object structure that is associated with each invocation channel and identifies the component objects.
2. Constructs the object structure for the transaction and forms an XML message that is based on the content of the objects.
3. If any custom processing Java classes, automation scripts, or an XSL map are associated with the invocation channel request, processes them in the following order:
  - a. Runs the preprocessing method in the request user exit processing class, if one is provided.
  - b. Runs an invocation channel request processing class, if one is provided.
  - c. Runs the postprocessing method in the request user exit class, if one is provided.
  - d. Applies an XSL map, if one is provided.
4. Writes the XML message to the destination that is specified by the endpoint.
5. The endpoint handler specifies the transport mechanism to use.
6. When the response is received from the end point, if any custom Java classes, automation scripts, or XSL maps are associated with the response, processes them in the following order:
  - a. Runs the preprocessing method in the response user exit processing class, if one is provided.
  - b. Runs an invocation channel response processing class, if one is provided.
  - c. Runs the postprocessing method in the response user exit class, if one is provided.
  - d. Applies an XSL map, if one is provided.
7. Objects are built from the data in the response object structure and are passed to the system where standard processing is applied.
8. If all the objects that are created from the response object structure process successfully, they are committed to the database.

The response content can be managed by the invoker based on integration requirements, for example to update business object data or display the response to a user. A default action class is provided that you can use or extend to implement an invocation channel integration.

- [Customization of metadata properties in an invocation channel](#)

Within the external exit classes or the user exit classes of the invocation channel, you can update additional data, such as the override values for the parameters that are configured for an endpoint.

## Customization of metadata properties in an invocation channel

Within the external exit classes or the user exit classes of the invocation channel, you can update additional data, such as the override values for the parameters that are configured for an endpoint.

You can use this type of customization, for example, to derive an endpoint parameter, such as the URL, from the data in the object structure of the invocation channel. You can override the values for a number of metadata properties.

Value	Description
ENDPOINT	You can override this value to use a provided endpoint in place of the endpoint that is configured through the External System.
ENDPOINTPROPS	This value points to a hash map that can contain one or more endpoint parameters with a corresponding override value. If the endpoint configuration defines that you cannot override a property any override value in the integration context is ignored.
TARGETOBJECT	This value is the target object structure of the invocation channel.
SOURCEOBJECT	This value is the source object structure of the invocation channel.

## Configuring integration processing

Processing of integration messages occurs at several points during the movement of integration messages for inbound and outbound transactions. When you configure integration processing, you must ensure that source data and destination data are in compatible data structures and formats.

- [Configuring asynchronous processing of inbound messages by using enterprise services](#)  
Enterprise services use asynchronous processing for inbound messages that do not require a response from Maximo® Manage. To enable enterprise service processing, you configure several integration components, including an object structure, enterprise service, external system, and JMS cron task.
- [Configuring asynchronous processing of outbound messages by using publish channels](#)  
Publish channels process outbound integration messages that do not require a response from the message destination. To enable publish channel processing, you configure several integration components, including an object structure, publish channel, external system, and cron task.

## Configuring asynchronous processing of inbound messages by using enterprise services

Enterprise services use asynchronous processing for inbound messages that do not require a response from Maximo® Manage. To enable enterprise service processing, you configure several integration components, including an object structure, enterprise service, external system, and JMS cron task.

### About this task

An external system initiates a connection and sends a message that includes the names of the external system and the enterprise service. The external system maintains the connection while the integration framework checks that the enterprise service is enabled for this transaction. Valid transactions are placed into the inbound sequential JMS queue, and the connection with the external system ends. A cron task polls the JMS queue, forwards the message for enterprise service processing, and sends the message onwards for object structure processing before it is committed to the database.

### Procedure

1. In the Object Structures application, identify a predefined object structure to use or create one.
2. In the Enterprise Services application, identify a predefined enterprise service to use or create one.
3. Configure the enterprise service to use your object structure and specify a valid operation.  
The Query operation is not valid for asynchronous processing with enterprise services.
4. In the External Systems application, identify an external system to use or create one and configure it for your enterprise service:
  - a. Configure the external system to use inbound JMS queues and enable the external system.
  - b. Configure the external system to use your enterprise service and enable the service.
5. Optional: Configure the source for the integration message.

Message source	Configurations
Messages from files by using a cron task	In the Cron Task Setup application, set the data import cron task to active.
Messages from a web service call	In the Web Services Library application, create a web service that is based on your enterprise service.
Messages from interface tables	In the Cron Task Setup application, set the interface table cron task to active.

6. Configure a queue to receive the integration messages.

Queue type	Description
Continuous	On the application server, configure message-driven beans to consume queue messages.
Sequential	In the Cron Task Setup application, set the JMS cron task to active so that it can consume messages from the queue.

## Configuring asynchronous processing of outbound messages by using publish channels

Publish channels process outbound integration messages that do not require a response from the message destination. To enable publish channel processing, you configure several integration components, including an object structure, publish channel, external system, and cron task.

## About this task

---

An object structure provides the message content to the publish channel. Publish channel processing transforms the message, and the external system then forwards it to its destination queue. A cron task polls the queue on a regular schedule and delivers the message to its destination. Publish channel transactions can be initiated by an event, such as a change to the status of an object, or by starting a data export transaction in the External Systems application.

## Procedure

---

1. In the Object Structures application, identify a predefined object structure to use or create one.
2. In the Publish Channels application, identify a predefined publish channel to use or create one.
3. Optional: To enable event-based integration, configure a listener for the event:
  - a. In the Publish Channels application, select the Enable Publish Channel Listener action.  
If the listener is enabled, when the primary object of the object structure is updated, publish channel transactions are initiated.
  - b. If you want events on child objects to start publish channel transactions, in the Object Structures application, select the Advanced Configurations action and configure event propagation.
4. Optional: In the Publish Channels application, review the processing rules and add or change rules as necessary.  
Processing rules are run in the order indicated in the Sequence field. If you change the sequence values, rules run in a different order, which can have unintended results.
5. Optional: Specify any automation scripts, custom Java™ class files, or XSL maps to provide custom logic during the transformation process.
6. In the External Systems application, add the publish channel to the external system and specify the file path to the outbound sequential queue.
7. If you are using JMS queues, in the Cron Task Setup application, enable the SEQOUT instance of the JMSSEQCONSUMER cron task. For Kafka queues, configure the Kafka cron task to periodically poll the queues and deliver messages.  
The cron task delivers messages from the JMS queue to their destinations in the same order as the messages are received into the queue.

---

## Rule-based customization

You can use processing rules to change the behavior of predefined integration processing without writing Java™ classes, automation scripts, or XSL maps. You can implement processing rules only on publish channels or on enterprise services.

Processing rules can access and evaluate the values in XML and object fields, object sets, and integration and system controls. Processing rules also can change the values in XML and object fields, or stop or skip processing all or part of a message.

- [Rule definitions for objects and records](#)  
An object structure consists of one or more object records. When an object is created, the object fields are populated from the corresponding record fields before standard application processing is applied.
- [Processing rule definitions](#)  
A processing rule performs an action on a field in a record or object, or on the record or object itself. To define a processing rule, in the service or channel used for the transaction, you can specify the record or object to which the rule applies.
- [Conditions and evaluations](#)  
Processing rules are applied conditionally. Any conditions must be met before the processing or action that is specified in the rule can be performed.
- [Integration controls](#)  
Integration controls give you the ability to configure the behavior of any enterprise service or publish channel according to the requirements of individual organizations and sites. Processing rules and Java classes can access integration controls for evaluation purposes.
- [Configuring processing rules](#)  
You can configure processing rules for an object structure in the Publish Channels application or in the Enterprise Services application.

---

## Rule definitions for objects and records

An object structure consists of one or more object records. When an object is created, the object fields are populated from the corresponding record fields before standard application processing is applied.

During outbound processing, the original object is populated with the record fields from the corresponding fields. Except for certain generic integration fields, system objects are not updated in outbound messages.

For outbound processing, you can apply processing rules to object structure records only.

Use the following guidelines to apply a rule to an object structure record or to an object:

- For outbound processing, you can apply processing rules to object structure records only.
- For inbound processing, you can apply processing rules to object structure records or to objects.
  - If an inbound rule changes the key field value of an object, apply rules to the object structure record.
  - If an inbound rule does not evaluate or manipulate an object or object set, apply rules to the object structure record.
  - If an inbound rule evaluates or manipulates a user-defined field, apply rules to the object structure record.
  - If an inbound rule evaluates or manipulates an object or object field, apply rules to the object.

Apply all rules for enterprise services to either objects or to object structure records. Avoid applying rules to both objects and object structure records. If you apply processing rules to both object structures and objects, the processing time for inbound transactions increases.

---

## Processing rule definitions

A processing rule performs an action on a field in a record or object, or on the record or object itself. To define a processing rule, in the service or channel used for the transaction, you can specify the record or object to which the rule applies.

- [Processing rule initiation](#)  
For an outbound transaction, a business object event on the primary object of an object structure initiates a processing rule. For an inbound transaction, the event that initiates a processing rule is identified by the value of the Action attribute on the primary object of the inbound XML or JSON message.
- [Processing rule actions](#)  
A processing rule can act on an enterprise service or a publish channel as a whole. For example, a rule can bypass a message, or it can manipulate the value in a data field within the message.
- [Processing sequence](#)  
Processing rules are applied sequentially for each record or object within an object structure, starting with the primary object and moving down to the child objects.

---

## Processing rule initiation

For an outbound transaction, a business object event on the primary object of an object structure initiates a processing rule. For an inbound transaction, the event that initiates a processing rule is identified by the value of the Action attribute on the primary object of the inbound XML or JSON message.

When you configure publish channels and enterprise services, you specify which events to use to initiate each processing rule. You can apply a processing rule to the primary record, a child record, or an object, but the event that initiates the rule must be initiated on the primary object.

You can, for example, implement a Stop rule on the PERSON object that prevents users from changing any attribute on the person record by identifying that the rule applies on update. With this configuration, users can create or delete person records but users cannot update person records.

For outbound transactions, in the Publish Channels application you can configure one or more of the following actions on the primary object to initiate the rule:

- Insert
- Delete
- Update

When an outbound message is generated using the Data Export feature or by a programmatic call to the publish channel, all enabled processing rules are run, regardless of the event settings.

For inbound transactions, in the Enterprise Services application you can configure one or more of the following actions on the primary object to initiate the rule:

- Add
- Change or Replace (equivalent of Update)
- Delete

You can set one of these values as the Action attribute of the primary object for the inbound transaction.

---

## Processing rule actions

A processing rule can act on an enterprise service or a publish channel as a whole. For example, a rule can bypass a message, or it can manipulate the value in a data field within the message.

Three processing rule actions act on a service or channel message: stop, skip, and skip children. Four processing rule actions transform the value in a field within a service or channel message: combine, split, set, and replace.

- [Message processing actions](#)  
Message processing actions stop or skip an entire enterprise service or publish channel message, or skip entire records within the message.
- [Field transformation actions](#)  
Apply the field transformation rule to a record or object that contains the field to be transformed. A field transformation rule can be applied to a single field or multiple fields in the selected record.

---

## Message processing actions

Message processing actions stop or skip an entire enterprise service or publish channel message, or skip entire records within the message.

---

### Skip action

The skip action bypasses a message that meets specified criteria. When a skip action is applied to an inbound message, the message is not processed and is cleared from the inbound queue. When a skip action is applied to an outbound message, nothing is written to the queue and the message is not sent to an external system. Skip processing does not generate an error, but the system log file is updated with the rule that caused the skip action.

A skip action has some predefined rules. These rules look up integration control values to ensure that outbound messages have a valid status before being sent to the external system.

## Stop action

---

The stop action halts the processing of a message that meets specified criteria. An outbound message is rolled back and an error message is displayed. For inbound transactions, the message remains in the inbound queue. If the error was the result of a synchronous invocation of the enterprise service, the calling program is notified about the error.

Predefined rules are not provided with a stop action. This option is a utility for users to customize the behavior of a service or channel.

When possible, use the skip action rather than the stop action for inbound enterprise services. The stop action results in a processing error and the message remains in the inbound queue or the initiator receives an error response. These results do not occur when you use the skip action.

If a processing rule with a stop action is applied to a publish channel that is generated by the Data Export feature, the stop action is treated as a skip action. If the stop action evaluates as true, the message is skipped.

## Skip children action

---

You can apply the skip children action only to outbound messages in a publish channel. Apply the processing rule on the record or object whose child level records are skipped.

If the person structure has the person object and child objects of phone and email, you can use the skip children action on a person to strip the phone and email data from the message. Use the skip children action when a status change occurs and the external system does not need the accompanying phone and email information.

## Skip record action

---

You can apply the skip record action only to outbound messages in a publish channel. The skip record action deletes a record or object that contains your applied rule. Apply the processing rule on the record or object, and all of child records and objects, that you want to skip.

If the person object structure has a person object and a child object of phone, you can use the skip record action to strip a specific phone record from the message. Use the skip record action, for example, when you want to send the work phone number but not the home phone number for a person. The skip record rule needs a condition that identifies a home phone record to ensure that the record is skipped.

---

## Field transformation actions

Apply the field transformation rule to a record or object that contains the field to be transformed. A field transformation rule can be applied to a single field or multiple fields in the selected record.

## Set action

---

The set action writes a value to a specified data field. When you define the rule, you specify the data to be set and the source of the new value. Indicate whether the rule always writes the new value to the target field or writes the new value only when the field is null (the default action). You can use this action to initialize the value in a data field. If the rule always writes the new value to the target field, any existing value in the field is overwritten.

The source can be one of the following values:

- A value integration control
- A hard-coded value
- A system control (in the MAXVARS database table)
- Another field in the specified record or object
- A field in a related object

## Replace action

---

The replace action replaces a value in a data field with another value. When you define the rule, specify the data field that you want to update. The control that you use must be a cross-reference control. You specify the name of a cross-reference control that contains the original and replacement values for the data field.

Use this action when the database and the external system use different identifiers for the same entity. You can, for example, replace the SITEID value in a publish channel with an external PLANTID value, and replace the external PLANTID value in an enterprise service with the SITEID value.

## Combine action

---

The combine action concatenates values from multiple source fields into a single target field. When you define the rule, identify the target field and the source fields and the sequence in which the source data is to be written. The source data can be a data field or an integration control that contains a data value. You can also specify an integration control that contains the delimiter to separate the segments in the target field.

Use this action in an enterprise service processing rule when a mismatch exists between the system definition and the external system definition of an entity. An enterprise service processing rule can, for example, combine a vendor ID and a vendor location field from an external system into the COMPANY field. A publish channel processing rule can then use the split action to separate the combined field into separate values when data is sent to the external system.

The source and target fields must be in the same object. This action always overwrites the existing value in the target field. Ensure that the source and target fields are alphanumeric fields, or processing errors may occur.

## Split action

The split action is the reverse of the combine action. The split action separates the value in one field into multiple fields. When you define the rule, you identify one source field, one or more target fields, and how the rule processor identifies segments of the source field.

The fields can have the following sources:

- A field in the selected record or object
- An integration control that contains the delimiter that separates the segments in the source field

The source and target fields must exist in the same object. This action always overwrites the existing value in the target fields. Ensure that the source and target fields are alphanumeric fields, or processing errors might occur.

If you combined multiple fields in an inbound message, split the combined field into individual fields in the outbound direction. There are two ways to identify how to split the field. You can specify the length of each segment of the source field, or you can identify a delimiter that separates the segments.

If the field length of each segment of source data is constant, the rule processor breaks up the source field from left to right, based on the field length, sequence, and values that you specify. For example, target field A with a character length of 6 holds positions 1-6 of the source field. Target field B with a character length of 3 holds positions 7-9 of the source field.

If the length of the source field segments is variable, but the source field contains a distinct delimiter that identifies the segments, use the separator option. The separator option identifies an integration control that defines the separator. The same separator must delimit all the segments. The rule processor parses the source field from left to right. The processor looks for the delimiter, breaks up the string into multiple values, and moves each value into the designated target field.

## Processing sequence

Processing rules are applied sequentially for each record or object within an object structure, starting with the primary object and moving down to the child objects.

If you define multiple processing rules for a single record or object, you can modify the default processing sequence. Your modification is especially important if a rule depends on the successful result of an earlier rule. If a rule with a stop or skip action is successfully applied, no further checking occurs.

## Conditions and evaluations

Processing rules are applied conditionally. Any conditions must be met before the processing or action that is specified in the rule can be performed.

Conditions can involve evaluating or comparing XML field data, an object field, an object set, or an integration or system control.

- [Condition specifications](#)  
A condition is a grouping of one or more evaluations. Multiple conditions can be specified, and their sequence is identified by the condition number.
- [Evaluation category specifications](#)  
Before you define the specifics of an evaluation, select the type of data that must be evaluated.
- [Field to evaluate](#)  
For XML field and object field evaluations, you specify the field that you evaluate.
- [Type of evaluation](#)  
Evaluations generally involve the comparison of two values or a check for the existence of an object set or a null value.
- [When to evaluate a field](#)  
For XML field and object field evaluations, the processing rule first determines whether to evaluate the specified data.
- [Comparison field specifications](#)  
The user interface displays subsets depending on the type of evaluation (XML field, object field, object set, or control). If a processing rule uses one of the first eight evaluation types, it must specify the field (comparison field) with which it is making the comparison.

## Condition specifications

A condition is a grouping of one or more evaluations. Multiple conditions can be specified, and their sequence is identified by the condition number.

Each evaluation returns a value of true or false. If an evaluation checks whether the values of two fields are equal, for example, it returns a value of true if the fields are equal and a value of false if they are not equal. Conditions also return a value of true or false. If every evaluation within a condition is true, the condition is true. If any evaluation within the condition is false, the condition is false. If a processing rule contains multiple conditions, only one condition must be true for the action that is associated with the processing rule.

## Evaluation category specifications

Before you define the specifics of an evaluation, select the type of data that must be evaluated.

The following table describes the categories that you can use in your evaluations.

Category	Use
XML field	Evaluate a value in an integration object record field, or compare the values in two record fields.

Category	Use
Object field	Evaluate the value in an object field, or compare the values in two fields in the related objects. The object field can be part of the object structure definition. The object field can also be part of an object that is accessed in a relationship with an object in the object structure definition.
Object set	Check for the existence of records in a related object.
Control	Evaluate a value or boolean integration control or a system control.

Because enterprise service processing rules are applied before objects are built, the processing rules cannot evaluate object fields or object sets. You can use the following combinations of categories, processing direction (outbound or inbound), and record types (record or object) in your evaluations.

Direction of processing rule	XML field evaluation	Object field evaluation	Object set evaluation	Control evaluation
Outbound	Available	Available	Available	Available
Inbound (record)	Available	Not available	Not available	Available
Inbound (Object)	Available	Available	Available	Available

## Field to evaluate

For XML field and object field evaluations, you specify the field that you evaluate.

For an object evaluation, you specify the object and the relationship to access the field. If the field value is a derivative of the object, which matches the record, no relationship is required.

## Type of evaluation

Evaluations generally involve the comparison of two values or a check for the existence of an object set or a null value.

The user interface displays a subset of the types depending on the category of evaluation (XML field, object field, object set, or control). The following table lists the possible types of evaluations that you can use.

Type of evaluation	Description
EQUALS	The value in the specified field is equal to the value of a second field (the comparison field).
NOTEQUALS	The value in the specified field is not equal to the value of a second field (the comparison field).
GREATER	The value in the specified field is greater than the value of a second field (the comparison field).
GREATEROREQUAL	The value in the specified field is greater than or equal to the value of a second field (the comparison field).
LESS	The value in the specified field is less than the value of a second field (the comparison field).
LESSOREQUAL	The value in the specified field is less than or equal to the value of a second field (the comparison field).
LIKE	The value contains the expected value.
NOTLIKE	The value does not contain the expected value.
ISNULL	The specified field contains no value or a null value.
ISNOTNULL	The specified field contains a value.
NONE	This option is available only if the When to Evaluate field is configured as Changed or Not Changed. If NONE is selected, no further evaluation is necessary.
EXISTS	Records exist in the specified object set.
NOTEXISTS	No records exist in the specified object set.

## When to evaluate a field

For XML field and object field evaluations, the processing rule first determines whether to evaluate the specified data.

The system evaluates the data by checking the Evaluate When field, which can have one the following values:

Value	Action
CHANGED	The evaluation continues only if the activity that generated the message changes the specified field.
NOT CHANGED	The evaluation continues only if the activity that generated the message does not change the specified field.
ALWAYS	The evaluation continues whether or not the value of the activity that generated the message (default) changes the specified field. If you specify this option, you cannot specify a comparison type of None.

When a record is updated, a changed attribute (changed="1") appears on the corresponding field in the outbound message. This attribute determines whether the field meets the criteria in the Evaluate When field.

This attribute does not appear in messages generated by the Data Export feature. Evaluations that are applied when a value has changed, might not provide the right output in a data export scenario.

The changed attribute does not apply to inbound messages.

## Comparison field specifications

The user interface displays subsets depending on the type of evaluation (XML field, object field, object set, or control). If a processing rule uses one of the first eight evaluation types, it must specify the field (comparison field) with which it is making the comparison.

The following table lists the possible types of comparison fields that you can use in the field comparisons. Comparison of an alphanumeric source field is case sensitive.

Field	Use
Integration control	Compare the value in the specified field with the values in a list or value integration control. If a list control has multiple matching values, the evaluation is true. The true evaluation occurs only if the field value matches any one of the values in the list control. Example: Validate the STATUS of a purchase order. The current value in a STATUS field is WAPPR and the possible acceptable values that satisfy the condition are in a list control called POSEND. The values in POSEND are WAPPR, APPR, and CLOSE. If the evaluation type is EQUALS, the evaluation returns a true value.
Value	Compare the value in the specified field with a predefined value. This option is available for user-defined conditions. Regardless of the locale setting of the application server or the database, all decimal fields must use a period (.) as the decimal placeholder. Numbers to the left of the placeholder are not formatted. This format applies to inbound and outbound data. For example, \$1,738,593.64 must be in the following format: 1738593.64.  Example: A processing rule compares the value of the POLIN1 field with the value SPARE. If the evaluation type is EQUALS and the two values are the same, the evaluation returns a true value.
MAXVAR	Compare the value in the specified field with the value in a system control (a value in the MAXVARS database table). Example: Evaluate the OWNERSYSID on any enterprise service or a publish channel to determine if it is the same as MAXVARS.MXSYSID.
Boolean	Compare the value in the specified field with a Boolean value (true or false).
Comparison field	Compare the value in the specified field with another field in the same object. Example: Compare the GLDEBITACCT value and GLCREDITACCT value on a PO line or a journal entry to determine if they are equal.
Object, relationship, and field	Compare the value in the specified field with a field in a different object. Example: Check the OWNERSYSID of inventory in the system for the item-storeroom values on a receipt line or a PO Line.

## Integration controls

Integration controls give you the ability to configure the behavior of any enterprise service or publish channel according to the requirements of individual organizations and sites. Processing rules and Java™ classes can access integration controls for evaluation purposes.

Integration controls are defined at the system level. You can assign controls to one or more enterprise services or publish channels. The control values can be configured at the external system level. Two external systems that process the same enterprise service can share the same processing logic, class files, and processing rules, yet they process the data differently because they use different control settings.

- [Control levels](#)  
All master data and documents are stored at the system level, organization level, or site level. Item data is stored at the system level, accounting information at the organization level, and work orders at the site level. An implied hierarchy exists among these levels.
- [Control types](#)  
You can create four types of integration controls to meet your business needs.
- [New controls](#)  
Modifying control values at the external system level is generally sufficient to customize predefined enterprise service or publish channel processing. If new business rules are implemented or a new publish channel and enterprise service is implemented, a new control might be needed.

## Control levels

All master data and documents are stored at the system level, organization level, or site level. Item data is stored at the system level, accounting information at the organization level, and work orders at the site level. An implied hierarchy exists among these levels.

An integration control can be configured to override values at any of the following levels:

Control value	Description
System-level	A system-level value applies to all system organizations and sites. If the control is not configured for organization-level or site-level values, system processing uses the system default. If the control is configured for organization-level values, or site-level values but none exists for a particular organization or site, system processing uses the system-level value.
Organization-level	An organization-level value applies to all system sites within an organization. If a control is configured for organization-level values but none exists for a particular organization, system processing uses the system-level value.
Site-level	A site-level value applies to a specific site within a system organization. If a control is configured for site-level values but none exists for a particular site, system processing uses the organization value (if one exists) or the system-level value.

Data that is processed by enterprise services or publish channels that use a control with an organization or site override must be at the organization or site level.

## Control types

You can create four types of integration controls to meet your business needs.

## Boolean controls

---

A boolean integration control specifies a value of 0 (false) or 1 (true).

## List controls

---

A list integration control contains a list of values. You can enter multiple values for the control and optionally assign a system domain to the control. Assigning a domain ensures the validation of any value that is entered for that control, at any level. If a domain is not assigned, there is no validation of the values that are entered.

For example, work orders are sent to an external system only if the status of the work order is APPR (approved) or COMPLETE. To determine whether to send the work order, the Java™ code or the processing rule can check the status of a work order against a list control that contains these two values.

## Value controls

---

A value integration control contains a single value. You can enter a single value for the control and optionally assign a system domain to the control.

## Cross-reference controls

---

A cross-reference control replaces one value with another. In a publish channel, a system value is converted to an external system value. In an enterprise service, an external system value is converted to a system value. You can optionally assign a system domain to a cross-reference control. If a domain is specified, any system value that is specified for the control is validated against that domain. If a domain is not assigned, there is no validation of the values that are entered.

Cross-reference controls must have a one-to-one mapping between the system value and the external system value. If two system values are associated with an external system value, or two external system values with a system value, a processing error occurs.

If you create the cross-reference control to function as a multiplication control on an enterprise service, one-to-many mappings can exist. A multiplication control is a cross-reference control that copies, or multiplies, an inbound message for multiple organizations or sites. A multiplication control has one external value and multiple system values.

Multiplication controls are always specific to the external system. You identify the control as a multiplication control on the Enterprise Service tab in the Enterprise Services application.

For example, the system sites correspond to external system business units, but the two systems use different values for these entities. A cross-reference control can perform the translation between the two values. A cross-reference control in an enterprise service can translate business unit EX001 to system site MX001. In a publish channel, the same control can translate MX001 to EX001.

## Multiplication controls

---

A multiplication control can update the company in every organization in the system database. For example, use a multiplication control to update the company in every organization within the system. Value updates occur when the system receives company data using an enterprise service.

## New controls

---

Modifying control values at the external system level is generally sufficient to customize predefined enterprise service or publish channel processing. If new business rules are implemented or a new publish channel and enterprise service is implemented, a new control might be needed.

Use the following guidelines when you create new controls:

- Control names must be unique.
- To use the controls as part of a processing rule, and to set a value at the external system level, associate controls with a publish channel or enterprise service.
- When you associate a publish channel or enterprise service with an external system, all associated controls are copied to the external system level. You can assign values at the external system level.

## Configuring processing rules

---

You can configure processing rules for an object structure in the Publish Channels application or in the Enterprise Services application.

- [Defining integration control or system control evaluations](#)  
You can use a control evaluation to compare a value in a specified field with the value in an integration control. You can also use a control evaluation to compare the value in a specified field with a system control value (a MAXVARS value).
- [Defining processing rules](#)  
You can define a processing rule to perform custom enterprise service and publish channel processing. When you use a processing rule, you can perform custom inbound and outbound processing without using a Java class.
- [Adding controls](#)  
Integration controls are used to configure the behavior of any enterprise service or publish channel according to the requirements of individual organizations and sites. Control types include Boolean controls, cross-reference controls, list controls, and value controls.

- [Associating integration controls with enterprise services or publish channels](#)

You can associate integration controls with a publish channel or an enterprise service to make the control available for inbound and outbound message processing. A publish channel or an enterprise service can have an association with one or more integration controls.

- [Managing data in sub-record fields](#)

As part of an integration, you can work with the values in a single source data field to set the value, combine the value, split the value, or replace the value.

---

## Defining integration control or system control evaluations

You can use a control evaluation to compare a value in a specified field with the value in an integration control. You can also use a control evaluation to compare the value in a specified field with a system control value (a MAXVARS value).

---

### About this task

If you evaluate an integration control, it must be a Boolean or Value type control.

---

### Procedure

1. In the Enterprise Services or Publish Channels application, display the service or channel record to which the evaluation applies.
2. On the Object Structure Sub-Records table window, select the object structure to which the evaluation applies.
3. Perform one of the following actions:
  - For an enterprise service, click Add/Modify Conditions on the Object Structure Processing Rules tab or the Object Processing Rules tab.
  - For a publish channel, click Add/Modify Conditions on the Processing Rules for Sub-Record table window.
4. On the Conditions table window, click New Row.
5. In the Conditions field, enter a value.  
The condition value determines the order in which the integration framework evaluates the conditions.
6. To compare the control value with a field value, select a one of the following radio buttons and enter values in the appropriate fields.
  - Integration Control
  - MAXVAR
7. Enter values in the following fields:

Option	Description
Evaluation Type	Defines the type of evaluation that is carried out on the XML field.
Value	The value that is used in the control evaluation.

8. Click OK.

- [Defining object field evaluations](#)

You can use an object field evaluation to evaluate the value of a field in any object that is included in the definition of an object structure. You can also evaluate other business objects that can be accessed by using a WHERE clause.

- [Defining object set evaluations](#)

You use an object set evaluation to determine whether records exist in a relationship between two business objects. If the relationship returns an business object set, the evaluation returns a true result.

- [Defining XML field evaluations](#)

You can use an XML field evaluation to evaluate a value in an object structure sub-record. When you use an XML field evaluation, you can check whether a field is null, and compare values in a business object field with an integration control, a system value, or a predefined value.

---

## Defining object field evaluations

You can use an object field evaluation to evaluate the value of a field in any object that is included in the definition of an object structure. You can also evaluate other business objects that can be accessed by using a WHERE clause.

---

### About this task

Regardless of the locale setting of the application server or the database, all decimal fields must use a period (.) as the decimal placeholder. There is no formatting of numbers to the left of the placeholder. This format applies to inbound and outbound data. For example, \$1,738,593.64 must be 1738593.64.

You can use an object field evaluation to perform the following evaluations:

- Check if the field is null or not null
- Compare the value in the object field with the value of an integration control or a system control
- Compare the value in the object field with predefined value

If the data does not satisfy the comparison, the evaluation returns a false result. If the data satisfies the comparison, the evaluation returns a true result.

---

### Procedure

1. In the Publish Channels application, display the channel record to which the evaluation applies.
2. In the Object Structure Sub-Records table window, select the object structure to which the evaluation applies.
3. In the Processing Rules for Sub-Record table window, click Add/Modify Conditions.
4. On the Conditions table window, click New Row.
5. In the Conditions field, enter a value.

The condition value determines the order in which the integration framework evaluates the conditions.

6. On the Object Field tab, click New Row.

7. Enter values in the following fields:

Option	Description
<b>Object</b>	The business object that contains the field that is evaluated.
<b>Object Relationship</b>	The relationship between the defined business object and the rule business object.
<b>Field</b>	The business object field that is evaluated.
<b>Evaluation Type</b>	The type of evaluation that is carried out on the business object field.
<b>Evaluate When</b>	How often the evaluation is performed.

Enter a business object value only if it is not the in the business object on which the rule is created.

8. To compare the value of the business object field with another value, select a one of the following radio buttons and enter values in the appropriate field.

- Integration Control
- Value
- MAXVAR

9. Click OK.

10. Click Save Publish Channel.

---

## Defining object set evaluations

You use an object set evaluation to determine whether records exist in a relationship between two business objects. If the relationship returns an business object set, the evaluation returns a true result.

### Procedure

---

1. In the Publish Channels application, display the channel record to which the evaluation applies.
2. In the Object Structure Sub-Records table window, select the object structure to which the evaluation applies.
3. In the Processing Rules for Sub-Record table window, click Add/Modify Conditions.
4. On the Conditions table window, click New Row.
5. In the Conditions field, enter a value.

The condition value determines the order in which the integration framework evaluates the conditions.

6. On the Object Set tab, click New Row.

7. Enter values in the following fields:

Option	Description
<b>Object</b>	The business object that contains the field that is evaluated.
<b>Object Relationship</b>	The relationship between the defined business object and the rule business object.
<b>Evaluation Type</b>	The type of evaluation that is carried out on the business object field.

8. Click OK.

9. Click Save Publish Channel.

---

## Defining XML field evaluations

You can use an XML field evaluation to evaluate a value in an object structure sub-record. When you use an XML field evaluation, you can check whether a field is null, and compare values in a business object field with an integration control, a system value, or a predefined value.

### Procedure

---

1. In the Enterprise Services or Publish Channels application, display the service or channel record to which the evaluation applies.
2. In the Object Structure Sub-Records table window, select the object structure to which the evaluation applies.
3. Perform one of the following actions:
  - For an enterprise service, click Add/Modify Conditions on the Object Structure Processing Rules tab or the Object Processing Rules tab.
  - For a publish channel, click Add/Modify Conditions on the Processing Rules for Sub-Record table window.

4. In the Conditions table window, insert a row.

5. Optional: In the Conditions field, enter a value.

The condition value determines the order in which the integration framework evaluates the conditions.

6. In the XML Field tab, insert a row.

7. Enter values in the following fields:

Option	Description
<b>Field</b>	The XML field that is evaluated.
<b>Evaluation Type</b>	The type of evaluation that is carried out on the XML field.
<b>Evaluate When</b>	How often the evaluation is performed.

8. To compare the value of the XML field with another value, select a one of the following radio buttons and enter values in the appropriate field.

- Integration Control
- Value
- MAXVAR
- Comparison Field

9. Click OK.

---

## Defining processing rules

You can define a processing rule to perform custom enterprise service and publish channel processing. When you use a processing rule, you can perform custom inbound and outbound processing without using a Java™ class.

### Before you begin

---

Before you create a processing rule, you must consider defining:

- Whether an enterprise service or a publish channel rule evaluates an XML field or a business object field.
- The sub-record or business object on which the rule is defined.
- The actions that trigger the rule.

### Procedure

---

1. In the Enterprise Services or Publish Channels application, display the service or channel to which the rule applies.
  2. In the Object Structure Sub-Records table window, select the object structure sub-record to which the rule applies.
  3. For an enterprise service, perform one of the following actions:
    - On the Object Structure Processing Rules tab, click New Row to define an inbound processing rule on an object structure.
    - On the Object Processing Rules tab, click New Row to define an inbound processing rule on a business object.
  4. For a publish channel, click New Row to define an outbound processing rule on a business object.
  5. In the Rule field, enter a rule identifier.
  6. In the Action field, enter a value.
  7. To change the order in which the application applies the processing rules for an object, change the value in the Sequence field.  
The integration framework applies the rules sequentially starting with the primary-level object.
  8. To specify when the processing rule is applied, select one or more of the following options:
    - Select or clear the Apply on Primary Object Insert check box.
    - Select or clear the Apply on Primary Object Update check box.
    - Select or clear the Apply on Primary Object Delete check box.
  9. Save your changes.
- [Enabling processing rules](#)  
You must enable a processing rule before the rule can be applied to enterprise service or publish channel objects. An enabled processing rule indicates that it is ready to perform custom inbound and outbound processing.

---

## Enabling processing rules

You must enable a processing rule before the rule can be applied to enterprise service or publish channel objects. An enabled processing rule indicates that it is ready to perform custom inbound and outbound processing.

### About this task

---

If you disable a predefined processing rule, it can cause integration framework processing errors.

### Procedure

---

1. In the Enterprise Services or Publish Channel application, display the service or channel that contains the processing rule that you want to enable.
2. In the Object Structure Sub-Records table window, select the object to which the rule applies.
3. Specify whether you want the processing rule to be enabled or disabled.  
For the enterprise service, you can enable or disable the processing rule on the Object Structure Processing Rules or Object Processing Rules tab. For the publish channel, you can enable or disable the processing rule on the Processing Rules for Sub-Record tab.
4. Save your changes.

---

## Adding controls

Integration controls are used to configure the behavior of any enterprise service or publish channel according to the requirements of individual organizations and sites. Control types include Boolean controls, cross-reference controls, list controls, and value controls.

- [Adding Boolean controls](#)  
You can add a Boolean type control when you need an integration control that specifies a value of true or false. An enterprise service or a publish channel can use this Boolean control in its processing rule evaluations. The true or false value that you assign to the control determines whether an enterprise service or a publish channel applies a processing rule on a transaction.
- [Adding cross-reference controls](#)  
You add a cross-reference type control when you need an integration control to replace one value with another. You can replace a value in inbound or outbound messages and across multiple organizations or sites. A cross-reference control can perform the translation between a value in the asset management system and a value in the external system.

- [Adding list controls](#)

You create a list type integration control when you need a control that contains a list of values. A publish channel or an enterprise service can use this list control in its processing rule evaluations. The rule could skip the processing of the transaction when the data field value does not match any of the defined list control values.

- [Adding value controls](#)

You can create a value type integration control when you need a control that contains a single value. A publish channel or an enterprise service can use this value control in its processing rule evaluations. The rule could skip the processing of the transaction when the data field value does not match the defined control value.

---

## Adding Boolean controls

You can add a Boolean type control when you need an integration control that specifies a value of true or false. An enterprise service or a publish channel can use this Boolean control in its processing rule evaluations. The true or false value that you assign to the control determines whether an enterprise service or a publish channel applies a processing rule on a transaction.

---

### Procedure

1. In the Enterprise Services or the Publish Channels application, select the Create Integration Controls action.
2. Click Add New Control >> Add New Boolean Control.
3. Specify an identifier and description for the Boolean control.
4. Specify whether you want the Boolean control to have a default value of true or false.

Option	Default True
True value	Selected
False value	Cleared

5. Click OK to close the Boolean Control dialog box.
6. Click OK to close the Create Integration Controls dialog box.

---

### Example

You can use a Boolean control to indicate whether enterprise services or publish channels receive or send purchase order transactions. You can set a processing rule action on the enterprise services or publish channel to skip a transaction. If the default value that you assign to the Boolean control is true, and the processing rule evaluation is true, the enterprise services or publish channel receives and sends purchase order transaction updates.

---

### What to do next

You can associate an integration control with an enterprise service or a publish channel in the Enterprise Services or Publish Channels application. This association makes the integration control available for inbound and outbound message processing. You can also associate an integration control to an external system in the External Systems application. The value that you define on the control at the external level overwrites the control value that is defined at the enterprise service or publish channel level.

---

## Adding cross-reference controls

You add a cross-reference type control when you need an integration control to replace one value with another. You can replace a value in inbound or outbound messages and across multiple organizations or sites. A cross-reference control can perform the translation between a value in the asset management system and a value in the external system.

---

### About this task

A publish channel uses a cross-reference control to convert an outbound asset management system value to an external system value. An enterprise service uses a cross-reference control to convert an inbound external system value to an asset management system value. If you use synonyms, enter the external value as the control value, not the internal application value. You must use a period (.) as the decimal placeholder when you enter decimals as a control value. The numbers to the left of the placeholder are not converted. For example, \$1,738,593.64 must be 1738593.64.

---

### Procedure

1. In the Enterprise Services or Publish Channels application, select the Create Integration Controls action.
2. Click Add New Control >> Add New XRef Control.
3. Enter values in the following fields:

Option	Description
Integration Control	The identifier for the cross-reference control.
Domain	The domain that is used to check the values that are entered for the integration control.

4. In the Values table window, insert a row.
5. Enter values in the following fields:

Option	Description
Default Value	The value that is converted to or from an external system value.
Default External Value	The external system value that is converted to or from the default value.

6. Click **OK** to close the Cross-Reference Control dialog box.
7. Click **OK** to close the Create Integration Controls dialog box.

## Example

The asset management system sites correspond to external system business units, but two external systems use different values for these entities. A cross-reference control can perform the translation between the two mismatched values and the asset management system value.

A cross-reference control in an enterprise service can translate the external system site value `EX001` to an asset management system site value `MX001`.

## What to do next

You can associate an integration control with an enterprise service or a publish channel in the Enterprise Services or Publish Channels application. This association makes the integration control available for inbound and outbound message processing. You can also associate an integration control with an external system in the External Systems application. The value that you define on the control at the external level overwrites the control value that is defined at the enterprise service or publish channel level.

## Adding list controls

You create a list type integration control when you need a control that contains a list of values. A publish channel or an enterprise service can use this list control in its processing rule evaluations. The rule could skip the processing of the transaction when the data field value does not match any of the defined list control values.

## About this task

You must use a period (.) as the decimal placeholder when you enter decimals as a control value. The numbers to the left of the placeholder are not converted. For example, \$1,738,593.64 must be 1738593.64.

## Procedure

1. In the Enterprise Services or the Publish Channels application, on the Select Action menu, select Create Integration Controls.
2. Click Add New Control >> Add New List Control.
3. Enter values in the following fields:

Option	Description
Integration Control	The identifier for the list control.
Domain	The domain that is used to check the values that are entered for the integration control.

4. In the Values table window, click New Row.
5. In the Default Value field, enter a value for evaluation.
6. Click OK to close the List Control dialog box.
7. Click OK to close the Create Integration Controls dialog box.

## Example

Work orders are sent to an external system only if the status of the work order is `APPR` (approved) or `COMPLETE`. The processing rule can check the status of a work order against a list control that contains these two status values. If the status of a work order does not match the two list control values, the work order transaction is not sent to the external system.

## What to do next

You can associate an integration control with an enterprise service or a publish channel in the Enterprise Services or Publish Channels application. These associations make the integration controls available for inbound and outbound message processing. You can also associate an integration control to an external system in the External Systems application. The value that you define on the control at the external level overwrites the control value that is defined at the enterprise service or publish channel level.

## Adding value controls

You can create a value type integration control when you need a control that contains a single value. A publish channel or an enterprise service can use this value control in its processing rule evaluations. The rule could skip the processing of the transaction when the data field value does not match the defined control value.

## About this task

You can provide a default control value and assign a domain to the control to ensure the validation of any value that you enter for that control.

## Procedure

1. From the Select Action menu in the Enterprise Services or the Publish Channels application, select Create Integration Controls.
2. Click Add New Control >> Add New Value Control.

3. Enter values in the following fields:

Option	Description
Integration Control	The identifier for the value control.
Domain	The domain that is used to check the values that are entered for the integration control.
Default Value	The default value for the integration control.

4. Click OK to close the Value Control dialog box.
5. Click OK to close the Create Integration Controls dialog box.

## Example

Purchase orders are received by the asset management system only if the company type value is EX. To determine whether the purchase order is received, the processing rule can check the value of the company type against the value that is defined in the control. If the EX company value does not match the value contained in the control, the purchase order transaction is not sent to the asset management system.

## What to do next

You can associate an integration control with an enterprise service or a publish channel in the Enterprise Services or Publish Channels application. These associations make the integration controls available for inbound and outbound message processing. You can also set an integration control on an external system in the External Systems application. The value that you define on the control at the external system level overwrites the control value that is defined at the enterprise service or publish channel level.

## Associating integration controls with enterprise services or publish channels

You can associate integration controls with a publish channel or an enterprise service to make the control available for inbound and outbound message processing. A publish channel or an enterprise service can have an association with one or more integration controls.

## About this task

When you associate an integration control with a publish channel or an enterprise service, you can override the predefined values of the controls that are set at the service or channel level. You can define integration controls globally and configure the controls for each external system, according to the requirements of individual organizations and sites.

## Procedure

1. In the Enterprise Services or Publish Channels application, display the service or channel for which you want to associate an integration control.
2. Select the Associate Integration Controls action.
3. Perform one of the following actions:

Option	Description
Select integration controls individually	a. Click New Row. b. In the Integration Control field, enter a control value.
Select multiple integration controls	a. Click Select Controls. b. Select the appropriate controls. c. Click OK.

4. Click OK to close the Associate Integration Controls dialog box.

## Managing data in sub-record fields

As part of an integration, you can work with the values in a single source data field to set the value, combine the value, split the value, or replace the value.

- **Setting sub-record field values**  
You can assign a value to a specified data field to overwrite the existing value in the data field. You can indicate whether a value is always assigned or only assigned when the target data field is null.
- **Combining sub-record field values**  
You can combine the values in two or more source data fields or integration controls into a single target data field. You can combine values when mismatches occur between an asset management system value and the external system value. For example, a two-part external system key can map to a single part key in the asset management system.
- **Splitting sub-record field values**  
You can split the value in a single source data field into multiple target fields. You can split values when mismatches occur between an asset management system value and the external system value. For example, a single part asset management system key can map to a two-part key in the external system.
- **Replacing sub-record field values**  
You can replace a value in a data field with another value. You can replace a value when the external system and the asset management system have different identifiers for the same entity. For example, a plant identifier of an external system can be translated to an asset management system site identifier.

## Setting sub-record field values

You can assign a value to a specified data field to overwrite the existing value in the data field. You can indicate whether a value is always assigned or only assigned when the target data field is null.

## Before you begin

You must create a processing rule that contains a set action before you can set sub-record field values.

## Procedure

1. In the Enterprise Services or Publish Channels application, display the service or channel record to which the sub-record field set action applies.
2. On the Enterprise Services or Publish Channels tab, select the processing rule to which the sub-record field set action applies.
3. Perform one of the following actions:
  - For an enterprise service, click Sub-Record Fields on the Object Structure Processing Rules tab or the Object Processing Rules tab.
  - For a publish channel, click Sub-Record Fields on the Processing Rules for Sub-Record table window.
4. Click New Row.
5. In the Field field, enter the name of the target data field.  
This value defines the field that you want to replace.
6. Specify whether a value is always assigned or only assigned when the target data field is null.

Option	Replace When Null
Assign when data field is null	Selected
Always assign	Cleared

7. To specify the source field, select one of the following radio buttons and enter values in the appropriate fields:
  - Integration Control
  - MAXVAR
  - Field
  - Object
8. Click OK.

## Combining sub-record field values

You can combine the values in two or more source data fields or integration controls into a single target data field. You can combine values when mismatches occur between an asset management system value and the external system value. For example, a two-part external system key can map to a single part key in the asset management system.

## Before you begin

You must create a processing rule that contains a combine action before you can combine sub-record field values.

## About this task

The source and target fields must be in the same object. This action always overwrites the existing value in the target field. Ensure that the source and target fields are alphanumeric fields, or processing errors may occur.

## Procedure

1. In the Enterprise Services or Publish Channels application, display the service or channel record to which the sub-record field combine action applies.
2. On the Enterprise Services or Publish Channels tab, select the processing rule to which the sub-record field combine action applies.
3. Perform one of the following actions:
  - For an enterprise service, click Sub-Record Fields on the Object Structure Processing Rules tab or the Object Processing Rules tab.
  - For a publish channel, click Sub-Record Fields on the Processing Rules for Sub-Record table window.
4. In the Target Sub-Record Fields table window, perform one of the following actions:

Option	Description
Select target fields individually	a. Click New Row. b. In the Field field, enter a target data field. c. In the Separator Integration Control field, enter a delimiter value that separates the segments in the target field.
Select multiple target fields at one time	a. Click Select Field. b. Select the appropriate fields. c. Click OK. d. In the Separator Integration Control field, enter a delimiter value that separates the segments in the target field.

5. In the Source Sub-Record Fields for Target table window, perform one of the following actions:

Option	Description
Select source fields individually	a. Click New Row. b. Select one of the following radio buttons and enter values in the appropriate fields: <ul style="list-style-type: none"><li>• Field</li><li>• Integration Control</li></ul> c. Enter a value in the Sequence field to define the order in which the application moves segments of the source field to the target fields.

Option	Description
<b>Select multiple source fields at one time</b>	<ol style="list-style-type: none"> <li>Click Select Field.</li> <li>Select the appropriate fields.</li> <li>Click OK.</li> <li>Enter a value in the Sequence field to define the order in which the application move segments of the source field to the target fields.</li> </ol>

6. Click OK.

## Splitting sub-record field values

You can split the value in a single source data field into multiple target fields. You can split values when mismatches occur between an asset management system value and the external system value. For example, a single part asset management system key can map to a two-part key in the external system.

### Before you begin

You must create a processing rule that contains a spit action before you can split sub-record field values.

### Procedure

- In the Enterprise Services or Publish Channels application, display the service orchannel record to which the sub-record field split action applies.
- On the Enterprise Services or Publish Channels tab, select the processing rule to which the sub-record field split action applies.
- Perform one of the following actions:
  - For an enterprise service, click Sub-Record Fields on the Object Structure Processing Rules tab or the Object Processing Rules tab.
  - For a publish channel, click Sub-Record Fields on the Processing Rules for Sub-Record table window.
- In the Target Sub-Record Fields table window, perform one of the following actions:

Option	Description
<b>Select target fields individually</b>	<ol style="list-style-type: none"> <li>Click New Row.</li> <li>In the Field field, enter a target data field.</li> <li>In the Separator Integration Control field, enter a delimiter value that separates the segments in the target field.</li> </ol>
<b>Select multiple target fields at one time</b>	<ol style="list-style-type: none"> <li>Click Select Field.</li> <li>Select the appropriate fields.</li> <li>Click OK.</li> <li>In the Separator Integration Control field, enter a delimiter value that separates the segments in the target field.</li> </ol>

- In the Target Sub-Record Fields for Source table window, perform one of the following actions:

Option	Description
<b>Select source fields individually</b>	<ol style="list-style-type: none"> <li>Click New Row.</li> <li>In the Field field, enter the name of the target field that receives the first or next segment of the source data.</li> <li>If you did not specify a value in the Separator Integration Controlfield, enter a number in the Field Lengthfield.</li> <li>Enter a value in the Sequence field to define the order in which the application move segments of the source field to the target fields.</li> </ol>
<b>Select multiple source fields at one time</b>	<ol style="list-style-type: none"> <li>Click Select Field.</li> <li>Select the appropriate fields.</li> <li>Click OK.</li> <li>If you did not specify a value in the Separator Integration Controlfield, enter a number in the Field Lengthfield.</li> <li>Enter a value in the Sequence field to define the order in which the application move segments of the source field to the target fields.</li> </ol>

- Click OK.

## Replacing sub-record field values

You can replace a value in a data field with another value. You can replace a value when the external system and the asset management system have different identifiers for the same entity. For example, a plant identifier of an external system can be translated to an asset management system site identifier.

### Before you begin

You must create a processing rule that contains a replace action before you can replace sub-record field values. You must also create a cross-reference control that contains the original and new values for the data field.

### Procedure

- In the Enterprise Services or Publish Channels application, display the service or channel record to which the sub-record field replace action applies.
- On the Enterprise Services or Publish Channels tab, select the processing rule to which the sub-record field replace action applies.
- Perform one of the following actions:
  - For an enterprise service, click Sub-Record Fields on the Object Structure Processing Rules tab or the Object Processing Rules tab.
  - For a publish channel, click Sub-Record Fields on the Processing Rules for Sub-Record table window.

4. Click New Row.
5. In the Field field, enter the name of the target data field.  
This value defines the field that you want to replace. The target field must be in the sub-record object shown at the top of the dialog box.
6. In the Integration Control field, enter the name of the cross-reference type control that contains the original and new values for the target field.
7. Click OK.

---

## Code-based customization

The integration framework provides placeholders in transaction flows where you can insert your own code to provide logic that customizes transaction processing. You can insert Java™ classes or automation scripts at selected points in the processing of object structures, publish channels, enterprise services, and invocation channels. You can also use XSL maps to transform messages.

When you create or update a Java class file, you must rebuild and redeploy the application EAR file before integration components can use it. You can write a script in one of the supported scripting languages in the Automation Scripts application, or you can import a script that you created externally, and you can activate it for immediate use. When you create or update an XSL map, you can either store it in the application EAR file or in a directory on your file system.

When the customization code is configured for use, the integration framework calls the code at the appropriate point during transaction processing.

You can download sample Java classes or XSL files from the IBM® Tivoli® Open Process Automation Library (OPAL).

- [Customization Java classes and methods](#)  
You can extend the standard processing of outbound and inbound messages by using Java classes. Multiple placeholders exist in message processing flows where you can insert custom Java code to affect message content or processing or both.
- [Customization with automation scripts](#)  
You can use automation scripts in place of Java classes to extend the main Java processing classes for predefined integration components. You can use automation scripts to apply custom logic at various points during the processing of object structures, publish channels, enterprise services, and invocation channels.
- [XSL mapping](#)  
For outbound transactions, you can implement an XSL file to manipulate the data that is sent to the external system after Java exit processing is completed. For inbound transactions, you can implement an XSL file to manipulate the data to be set to the object structure after Java exit processing is completed.
- [Interface table user exit class](#)  
When you use interface tables to receive messages from an external system, you can perform customization in the polling program that retrieves the data from the interface table and sends data to the system.

---

## Customization Java classes and methods

You can extend the standard processing of outbound and inbound messages by using Java™ classes. Multiple placeholders exist in message processing flows where you can insert custom Java code to affect message content or processing or both.

- [External exit classes](#)  
External exit classes provide a base class, ExternalExit, that you can extend to customize publish channel, enterprise service, and invocation channel processing.
- [User exit classes](#)  
For inbound and outbound transactions on a publish channel, an enterprise service, or an invocation channel, a user exit class can have a preprocessor method and a postprocessor method. For inbound transactions, the user exit class can have an extra method that processes business objects just before they are committed to the database.
- [Event filter classes](#)  
For outbound asynchronous transactions that use publish channels, you can run a custom Java class or an automation script by using an event filter class. The processing for an event filter class occurs before the serialization of data in the object structure layer for an outbound message. The event filter class can insert logic that affects the creation of the integration message at this processing point.
- [Handler exit classes](#)  
Multiple predefined methods, or handlers, are provided so that you can send data to an external system, including HTTP, an enterprise Java bean call, and interface tables. Some of these methods have user exit placeholders that are available for customization.

---

## External exit classes

External exit classes provide a base class, ExternalExit, that you can extend to customize publish channel, enterprise service, and invocation channel processing.

For outbound messages, the input to the external exit class is the irData element of the XML message. The output of the class processing is the erData element of the XML message that is delivered to the target destination. For inbound messages, the input to the external exit class is the erData element of the inbound message. The output is the irData element that is delivered to the related object structure for processing into Maximo® Manage.

To use an external exit class for customization, specify your Java™ class in the Processing Class field in the Publish Channels application or in the Invocation Channels application.

An alternative approach to integration customization is to implement a user exit class. If an adapter for Oracle or SAP is installed, predefined processing classes are provided, and customizations must be done by using the user exit class. When no predefined processing classes exist, you can choose whether to implement custom code in the external exit class or the user exit class.

---

## User exit classes

For inbound and outbound transactions on a publish channel, an enterprise service, or an invocation channel, a user exit class can have a preprocessor method and a postprocessor method. For inbound transactions, the user exit class can have an extra method that processes business objects just before they are committed to the database.

- [Preprocessing method for outbound transactions](#)  
The input to the first outbound user exit point is the XML that is generated by the object structure. If you have an ERP adapter processing class, you can use either the preprocessing method or postprocessing method to implement your custom logic, depending upon your requirement.
- [Postprocessing method for outbound transactions](#)  
In the postprocessing method of the user exit, the IR element from the object structure and the ER element from the XML output of the processing class are both available for processing.
- [Preprocessing method for inbound transactions](#)  
In the preprocessing method for inbound transactions, the input is the XML message that is delivered from the external system. If necessary, you can change data in the message to affect the processing logic in the processing class.
- [Postprocessing method for inbound transactions](#)  
In the postprocessing method for inbound transactions, both the IR records and ER records are available for processing.
- [Business object processing on inbound transactions](#)  
The user exit class on an enterprise service has an additional method, setUserMboIn, that enables custom processing at the point when the business objects are created from object structure XML, but are not yet saved to the database.

---

## Preprocessing method for outbound transactions

The input to the first outbound user exit point is the XML that is generated by the object structure. If you have an ERP adapter processing class, you can use either the preprocessing method or postprocessing method to implement your custom logic, depending upon your requirement.

By using the preprocessing exit point, you can change data in the message which later alters the processing logic of a processing class when it is implemented.

Outbound message customization can be done in the preprocessor method, by using the following method:

```
public StructureData setUserValueOut(StructureData irData)
```

This method can perform the following processing:

- Validate data.
- Change system data by changing the IR record that is sent to the external system.
- Stop the message from being sent out of Maximo® Manage by throwing a system exception. The entire message is rolled back. If the message is initiated by an event, the entire message is also rolled back, including any changes that you make in an application.
- Stop the message from being sent to the external system by throwing a SKIP\_TRANSACTION exception.
- Log the transaction.

---

## Postprocessing method for outbound transactions

In the postprocessing method of the user exit, the IR element from the object structure and the ER element from the XML output of the processing class are both available for processing.

Use the following method to customize outbound messages.

```
public StructureData setUserValueOut(StructureData irData, StructureData erData)
```

The method can perform the following processes:

- Validate data.
- Change data by changing the ER record that is sent to the external system.
- Map additional data from the irData element to the erData element.
- Stop the transaction from being sent out of Maximo® Manage by throwing a system exception. The entire message is rolled back. If the message is initiated by an event, the entire message is also rolled back, including any changes that you make in an application.
- Stop the message from being sent to the external system by throwing a SKIP\_TRANSACTION exception.
- Log the transaction.

You identify the publish channel user exit class in the Publish Channels application.

---

## Preprocessing method for inbound transactions

In the preprocessing method for inbound transactions, the input is the XML message that is delivered from the external system. If necessary, you can change data in the message to affect the processing logic in the processing class.

Inbound transaction customization can be done in the first exit by using the following method:

```
public StructureData setUserValueIn(StructureData erData)
```

This method can perform the following processing:

- Validate data.
- Change external data by changing the ER record before it is mapped to the IR record and saved in the system.
- Stop further processing of the transaction by throwing an exception. For queue-based messages, the transaction remains in the queue to be reprocessed. For messages that are not queue-based, the messages are returned to the client that started the enterprise service.
- Stop the message from being processed into Maximo® Manage by throwing a SKIP\_TRANSACTION exception. In this case, the message is not saved in the system. For queue-based messages, the message is removed from the queue.
- Log the transaction.

---

## Postprocessing method for inbound transactions

In the postprocessing method for inbound transactions, both the IR records and ER records are available for processing.

Inbound transaction customization can be done in the postprocessing flow by using the following method:

```
public StructureData setUserValueIn(StructureData irData, StructureData erData)
```

The method can perform the following processes:

- Validate data.
- Change external data by changing IR record to be saved in the system.
- Map additional data from the ER record to the IR record.
- Stop further processing of the transaction by throwing an exception. For queue-based messages, the transaction remains in the queue for reprocessing. For messages that are not queue-based, the messages are returned to the client that started the enterprise service.
- Stop the message from being processed into Maximo® Manage by throwing a skip\_transaction exception. In this case, the message is not saved in the system. For queue-based messages, the message is removed from the queue.
- Log the transaction.

You identify the enterprise service user exit class in the Enterprise Services application.

---

## Business object processing on inbound transactions

The user exit class on an enterprise service has an additional method, setUserMboIn, that enables custom processing at the point when the business objects are created from object structure XML, but are not yet saved to the database.

This user exit is called after the system processing and can run on the objects that are created in the system by using the following method:

```
public void setUserMboIn(MboRemote mbo)
```

The object parameter is a reference to a primary object in the object structure.

This method is called once for the primary object. For an XML transaction with multiple nouns, the object exit is called once for each noun.

The method can perform the following processes:

- Validate data.
- Stop the transaction from being saved in the system by throwing a system exception. For queue-based messages, the transaction remains in the queue and is retried.
- Log the transaction.

You identify the user exit class in the Enterprise Services application.

---

## Event filter classes

For outbound asynchronous transactions that use publish channels, you can run a custom Java™ class or an automation script by using an event filter class. The processing for an event filter class occurs before the serialization of data in the object structure layer for an outbound message. The event filter class can insert logic that affects the creation of the integration message at this processing point.

Configure any of the following features in the Event Filter Class field of a publish channel:

- Add logic that removes unwanted fields or objects from a message to reduce the amount of data in the serialization process.
- Override default recursion logic that prevents an event from an inbound integration from sending an outbound integration message. Overriding the default behavior in this scenario can allow an outbound message to be initiated from an event that is triggered by an inbound message.
- Filter events in or out by specifying the identifier of a conditional expression. If the filter evaluates to be true, the event is filtered out. If the filter evaluates to false, the event is not filtered out.

---

## Handler exit classes

Multiple predefined methods, or handlers, are provided so that you can send data to an external system, including HTTP, an enterprise Java™ bean call, and interface tables. Some of these methods have user exit placeholders that are available for customization.

- [Enterprise bean processing user exit class](#)  
You can use an exit placeholder for class customization when transactions are sent to an external system by an enterprise bean. This exit class is optional and is called before the enterprise bean is called.
- [HTTP processing user exit class](#)  
When you send outbound transactions to an external system by using HTTP, you can use an HTTP exit placeholder for customization. This exit class is optional and is called as part of the response from the HTTP call.
- [JMS processing user exit class](#)  
When you send transactions from the system to an external system by using JMS, you can use an exit placeholder for customization. This exit class is optional and is called before the JMS is called.
- [Web service processing user exit class](#)  
You can use an exit placeholder for customization when you send transactions from the system to an external system by using a web service. This exit class is optional and is called before the web service is started.

---

## Enterprise bean processing user exit class

You can use an exit placeholder for class customization when transactions are sent to an external system by an enterprise bean. This exit class is optional and is called before the enterprise bean is called.

The implementation of this Java™ class must resolve the method signature of the enterprise bean that is started by this handler and the parameters that the method requires. If no value is specified for this property, the system applies a default exit called DefaultEJBExit. This default exit attempts to resolve the enterprise bean method signature and parameters.

This class must implement the `psdi.iface.router.EJBExit` interface and the following methods:

- The `getClassParams()` method returns the method signature in the form of an array of Java classes:  

```
public Class[] getClassParams()
```
- The `getObjectParams` method returns an array of the parameters of the enterprise beans as an array of Java objects:  

```
public Object[] getObjectParams(byte[] data, String interfaceName, String destinationName)
```
- After the successful invocation of the enterprise bean, the `responseOk()` method is called with an object as the response of the invocation:  

```
public void responseOk(Object response) throws MXException
```
- If an error is encountered during the enterprise bean invocation, the `responseError()` method is called with the originating exception as a parameter:  

```
public void responseError(Exception e) throws MXException
```

You enter the fully qualified name of the Java class in the EJBEXIT property of the endpoint that implements the enterprise bean handler.

---

## HTTP processing user exit class

When you send outbound transactions to an external system by using HTTP, you can use an HTTP exit placeholder for customization. This exit class is optional and is called as part of the response from the HTTP call.

The HTTP processing exit class runs when a response is returned to an HTTP Post from an external system. In the default implementation of the `psdi.iface.router.DefaultHTTPExit` class, the response code that is received from the external system is compared to a range of response codes. The range that is used by the default implementation is 200 - 299. If the code is outside that range, then the transaction was not delivered to the external system, and an exception is raised.

With some external systems, the response from an HTTP call is interpreted to see whether the external system accepted the message. The interpretation logic can be implemented in the HTTP exit class.

If the publish channel message is not accepted, the code must raise an exception. The message in the outbound queue is marked as an error and is not removed from the queue. If the message is accepted, the message is removed from the outbound queue. If the invocation channel message fails, the exception is returned to the invoker of the channel, and the invoker handles the exception according to the design requirements.

The HTTP processing exit class must implement the `psdi.iface.router.HTTPExit` interface and implement the following method:

```
public void processResponseData(int responseCode, String responseMsg, byte[] msgBodyData)
```

If necessary, this class can interpret the response code and throw an exception. The class can perform the following actions:

- Check the response code from the HTTP post.
- If the response code is in the error range, the exception is logged on the ERROR level, and a system exception is thrown.
- If the response code is valid, the transaction is logged on the DEBUG level.

You must specify the fully qualified name of the Java™ class in the HTTPEXIT property of the endpoint that implements the HTTP handler.

---

## JMS processing user exit class

When you send transactions from the system to an external system by using JMS, you can use an exit placeholder for customization. This exit class is optional and is called before the JMS is called.

This class must implement the `psdi.iface.router.JMSExit` class and the following method:

```
public Map getMessageProperties(Map metaData, (byte[] data,
Map origProps) throws MXException
```

This method can perform the following processes:

- Change the properties of the JMS message
- Split the data to multiple properties, to match the JMS message

You enter the fully qualified name of the Java™ class in the JMSEXIT property of the endpoint that implements the JMS handler.

---

## Web service processing user exit class

You can use an exit placeholder for customization when you send transactions from the system to an external system by using a web service. This exit class is optional and is called before the web service is started.

This class must implement the `psdi.iface.router.WSExit` interface and the following methods:

**getServiceName ()** method

The **getServiceName ()** method returns the service name of the web service to start:

```
public String getServiceName(Map metaData, String endpointURL, String serviceName, String interfaceName, String
targetNameSpace) throws MXException
```

**getEndpointURL ()** method

The **getEndpointURL ()** method returns the endpoint URL of the web service to start:

```
public String getEndpointURL(Map metaData, String endpointURL, String serviceName, String interfaceName, String
targetNameSpace) throws MXException
```

**responseOk ()** method

The **responseOk ()** method is called after a successful invocation of the external web service.

```
public void responseOk(org.w3c.dom.Document response) throws MXException
```

**responseError ()** method

If an error is encountered during the web service invocation, the **responseError ()** method is called with the originating exception as a parameter:

```
public void responseError(Exception e) throws MXException
```

**getOneWayWsInfo ()** method

The **getOneWayWsInfo ()** method returns a Boolean value that specifies whether the web service to start is one way:

```
public boolean getOneWayWsInfo(Map metaData, String endpointURL, String serviceName, String interfaceName, String
targetNameSpace, boolean oneWayWs) throws MXException
```

**getSoapAction ()** method

The **getSoapAction ()** method returns the SOAPAction HTTP header to use to start the web service:

```
public String getSoapAction(Map metaData, String endpointURL, String serviceName, String interfaceName, String
targetNameSpace, String soapAction) throws MXException
```

You must specify the fully qualified name of the Java™ class in the WSEXIT property of the endpoint that implements the web service handler.

The `psdi.iface.router.DefaultWSExit` class is a default implementation of the `WSExit` interface. This class overrides the **getEndpointURL ()** method to concatenate the service name at the end of endpoint URL to form the new endpoint URL.

---

## Customization with automation scripts

You can use automation scripts in place of Java™ classes to extend the main Java processing classes for predefined integration components. You can use automation scripts to apply custom logic at various points during the processing of object structures, publish channels, enterprise services, and invocation channels.

You define automation scripts for integration by using the Automation Scripts application. Defining a script for integration identifies which integration component the script is associated with and at what point in the processing flow that the script runs. To test scripts, you can set the log level to debug, activate the script, and use the data import or data export feature to initiate an integration transaction.

- [Creating automation scripts for integration](#)

An automation script can customize the processing of integration messages for inbound and outbound transactions. You associate an automation script with an integration component, and you configure when to insert it into integration processing.

- [Customization of object structure processing with automation scripts](#)

Object structure processing supports the simultaneous use of automation scripts and Java classes for customization. Automation scripts that are defined for an object structure can affect the processing of data that is directly processed through the object structure, such as the REST API, or through other integration components such as publish channels and enterprise services.

- [Customization of channel and service processing by using automation scripts](#)

When you create an automation script, you identify the channel or service that the script runs on. You also specify where to insert the script during the processing flow.

## Creating automation scripts for integration

An automation script can customize the processing of integration messages for inbound and outbound transactions. You associate an automation script with an integration component, and you configure when to insert it into integration processing.

### Procedure

1. In the Automation Scripts application, select the Create  $\geq$  Script for Integration action.
2. Specify an integration component to associate with the automation script and then specify the insertion point for the script.
3. Optional: Select the Activate check box if you want the script to be immediately active.
4. Optional: Specify the logging level to apply when the script executes.  
For testing purposes, if you set the logging level to debug, the logs contain useful information that helps you troubleshoot any issues.
5. Specify the scripting language of the script.
6. Either enter the script directly into the Source Code field or browse to the location where the script is stored and click Import.
7. Click Create.

## Customization of object structure processing with automation scripts

Object structure processing supports the simultaneous use of automation scripts and Java™ classes for customization. Automation scripts that are defined for an object structure can affect the processing of data that is directly processed through the object structure, such as the REST API, or through other integration components such as publish channels and enterprise services.

- [Insertion points for customization of object structure processing with automation scripts](#)

You can insert script-based processing into the Java definition classes and Java processing classes that transform object structures during integration processing.

- [Outbound processing of object structures](#)

Outbound object structure processing performs the serialization of business object (mbo) data into an XML message. During this processing, an automation script can insert custom processing logic to change the default processing behavior of the object structure. The script can be used instead of the Java definition class or can be used with it.

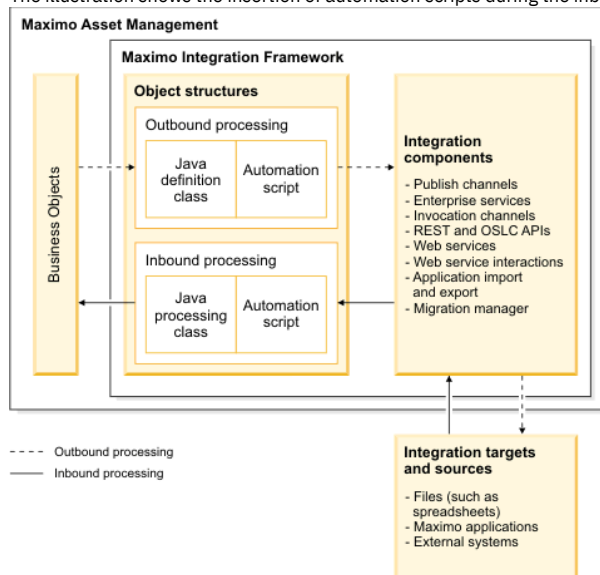

- [Inbound processing of object structures](#)

The processing of inbound messages by the integration framework supports the use of automation scripts on the object structure to support custom logic. This use of automation scripts allows customization for any inbound integration message that uses an object structure and for customization of processing Migration Manager data.

## Insertion points for customization of object structure processing with automation scripts

You can insert script-based processing into the Java™ definition classes and Java processing classes that transform object structures during integration processing.

The illustration shows the insertion of automation scripts during the inbound and outbound processing of object structures.

Outbound object structure processing implements a Java definition class that allows for the insertion of custom processing during the serialization of business object data into an XML message. You can also implement an automation script to customize the processing of the object structure. The integration framework supports the customization of an object structure to be a Java class, an automation script, or both simultaneously.

Inbound object structure processing implements a Java processing class that allows for insertion of custom processing of data from the inbound XML message before it is mapped to the business object data. In addition to the Java processing class, you can implement an automation script to customize the processing in the object structure.

---

## Outbound processing of object structures

Outbound object structure processing performs the serialization of business object (mbo) data into an XML message. During this processing, an automation script can insert custom processing logic to change the default processing behavior of the object structure. The script can be used instead of the Java™ definition class or can be used with it.

Functions, such as `skipMbo(ctx)`, are used in serialization. In the function name, `ctx` is the object in the function that is prepared by the integration framework and communicates data between the integration framework and the automation script. An automation script can affect the processing of the data and communicate those changes back to the integration framework.

Serialization includes the following functions that can be used by automation scripts to insert customized logic into the processing of the data:

`skipMbo(ctx)`

Filters object data from the XML message. APIs are available to filter data from the XML message, continue processing for data that you want in the XML message, and complete processing of the object structure after data is filtered out. For example, if the object structure is constructing an XML message for a purchase order, an automation script can insert logic that filters out purchase order line data where the line type is for service lines.

`skipCols(ctx)`

Filters a column or multiple columns from the object structure. For example, if the object structure is constructing an XML message for an asset, an automation script can insert logic that filters out a number of columns that are not needed by the system that will receive the XML message.

`overrideValues(ctx)`

Sets the value of an object structure field in the XML message. For example, if the object structure is constructing an XML message for an asset, an automation script CAN insert logic that might filter out a number of columns that are not needed by the system that will receive the XML message that is created.

- [Functions for outbound processing of object structures](#)

The `skipMBO(c)`, `skipCols(ctx)`, and `overrideValues(ctx)` functions are used in automation scripts for outbound processing of object structures. Each function has its own APIs that are available to process the data in the object structure. All example scripts are written in Jython.

- [Java definition classes and automation scripts](#)

You can use a Java definition class and an automation script at the same time on an object structure. The Java definition class is executed before the automation script for each function.

---

## Functions for outbound processing of object structures

The `skipMBO(c)`, `skipCols(ctx)`, and `overrideValues(ctx)` functions are used in automation scripts for outbound processing of object structures. Each function has its own APIs that are available to process the data in the object structure. All example scripts are written in Jython.

- [Skip processing of business objects by using the skipMbo\(ctx\) function](#)

The `skipMbo(ctx)` function filters data from the XML message that is built during the serialization process. The `skipMbo(ctx)` function can filter a Maximo® business object, continue processing the message after a business object is skipped, or terminate the processing of the message at the point of execution.

- [Skip processing of columns in business objects by using the skipCols\(ctx\) function](#)

The `skipCols(ctx)` function filters the columns of a Maximo business object from the processing of the XML message. The `ctx.skipCol(String)` API can accept one string argument to filter a single column or multiple comma-separated string arguments to filter multiple columns.

- [Set values in fields by using the overrideValues\(ctx\) function](#)

The `overrideValues(ctx)` function sets the value of a field in the XML message.

---

## Skip processing of business objects by using the skipMbo(ctx) function

The `skipMbo(ctx)` function filters data from the XML message that is built during the serialization process. The `skipMbo(ctx)` function can filter a Maximo® business object, continue processing the message after a business object is skipped, or terminate the processing of the message at the point of execution.

---

### ctx.skipMbo() API

The `ctx.skipMbo()` API filters out the processing of any Maximo business objects in the XML message.

For example, the following script executes on the `ctx.skipMbo()` API, and filters out all purchase order lines and their related purchase order cost data for the 1234 purchase order line.

```
def skipMbo (ctx) :
 if ctx.getMboName()=='POLINE' and ctx.getMbo().getString("itemnum")=="1234":
 ctx.skipMbo()
```

If you use the `ctx.skipMbo()` API on the root or primary object in the object structure, any business object that meets the criteria in the IF statement is filtered from the XML message.

## ctx.process() API

---

The ctx.process() API continues processing lines that are not filtered out by the ctx.skipMbo() API, for example:

```
def skipMbo(ctx):
 if ctx.getMboName()=='POLINE' and ctx.getMbo().getString("itemnum")=="1234":
 ctx.skipMbo()
 else
 ctx.process()
```

Executing the ctx.process() API on a row of data enables that data to be serialized. If the Java™ definition class skips that row of data, the ctx.process() API overrides the Java definition class and allows the data to be serialized.

## ctx.complete() API

---

When the ctx.complete() API is invoked, the outbound processing of the object structure is stopped for the current instance of the business object, for instances of the child business objects, and for instances of its peer-level business objects.

For example, the PO object consists of the child objects POLINE and POTERM. The POLINE object consists of a child object POCOST. When the ctx.complete() API is invoked on the PO object, the POLINE, POTERM, and POCOST objects that are related to that PO are not processed.

In the following example script, any purchase order that has a status of complete is processed without the serialization of its purchase order line data.

```
def skipMbo(ctx):
 if ctx.getMboName()=='PO' and ctx.getMbo().getString("status")=="COMPLETE":
 ctx.complete()
 else
 ctx.process()
```

---

## Skip processing of columns in business objects by using the skipCols(ctx) function

The skipCols(ctx) function filters the columns of a Maximo® business object from the processing of the XML message. The ctx.skipCol(String) API can accept one string argument to filter a single column or multiple comma-separated string arguments to filter multiple columns.

The ctx.skipCol(String) API can filter a single column of a Maximo business object. The following example script filters out the description column of the ASSET object:

```
def skipCols(ctx):
 if ctx.getMboName()=='ASSET':
 ctx.skipCol("description")
```

You can also use the ctx.skipCol(String) API to filter multiple columns. The following example script filters out the description and the asset number columns of the ASSET object:

```
def skipCols(ctx):
 if ctx.getMboName()=='ASSET':
 ctx.skipCol("description","assetnum")
```

The ctx.skipCol(String) API can filter the column of a child object in an object structure. For example, the following script filters out the METERNAME column of the ASSETMETER object:

```
def skipCols(ctx):
 if ctx.getMboName()=='ASSETMETER':
 ctx.skipCol("metername")
```

You can also use the ctx.skipCol(String) API to filter columns based on a specified value. For example, the following script filters out the description column when the assettag attribute has a value of 12593:

```
def skipCols(ctx):
 if ctx.getMboName()=='ASSET' and ctx.getMbo().getString("assettag")=="12593":
 ctx.skipCol("description")
```

---

## Set values in fields by using the overrideValues(ctx) function

The overrideValues(ctx) function sets the value of a field in the XML message.

The ctx.overrideCol() API sets the value of the field in the XML message. For example, the following script sets the value of the site ID to ABC:

```
def overrideValues(ctx):
 if ctx.getMboName()=='ASSET':
 ctx.overrideCol("SITEID","ABC")
```

In the following example script, if the description field of a purchase order is empty, the description field is set to the purchase order number:

```
def overrideValues(ctx):
 if ctx.getMboName()=='PO':
```

```
mbo = ctx.getMbo()
if mbo.isNull("description"):
 ctx.overrideCol("DESCRIPTION",mbo.getString("ponum"))
```

## Java definition classes and automation scripts

You can use a Java™ definition class and an automation script at the same time on an object structure. The Java definition class is executed before the automation script for each function.

Some of the object structures that are included in the integration framework and Migration Manager provide Java definition classes that filter data. For example, the item object structure filters items that are of the type TOOL. When an automation script is implemented with a Java definition class, the automation script can override the filtering of the Java definition class and remove the filtering of the Java class or change the filtering criteria to exclude more data from or include more data in the XML message.

For example, the Java definition class of the MXOPERLOC object structure filters out the locations of the type LABOR while allowing locations of the type OPERATING to be included in the message. You can change the filtering, add more filtering, or replace the default filtering. The following example script changes the processing to filter the locations of the type OPERATING and continues to process locations of the type LABOR:

```
def skipMbo(ctx):
 if ctx.getMboName()=='LOCATIONS':
 if ctx.getMbo().getString("type")=="LABOR":
 ctx.process()
 if ctx.getMbo().getString("type")=="OPERATING":
 ctx.skipMbo()
```

The following example script adds more filtering for the MXOPERLOC object structure by filtering out type COURIER:

```
if ctx.getMboName()=='LOCATIONS':
 if ctx.getMbo().getString("type")=="COURIER":
 ctx.skipMbo()
```

The following example script replaces the definition class filtering so that only locations of type COURIER are filtered out:

```
def skipMbo(ctx):
 if ctx.getMboName()=='LOCATIONS':
 if ctx.getMbo().getString("type")=="COURIER":
 ctx.skipMbo()
 else:
 ctx.process()
```

## Inbound processing of object structures

The processing of inbound messages by the integration framework supports the use of automation scripts on the object structure to support custom logic. This use of automation scripts allows customization for any inbound integration message that uses an object structure and for customization of processing Migration Manager data.

For integration processing, a script that is implemented on the object structure applies to messages from the following sources:

- Data import
- REST
- Application import
- Web service
- OSLC
- Integration servlet
- Integration tables

The object structure supports a Java™ processing class or an automation script. You can use a Java processing class, an automation script, or both on the same object structure. The processing supports functions that are in either the class file or the automation script.

A *context* (ctx) is passed between the processing class of the inbound object structure and the automation script, which implements the custom code. The context is supported bidirectionally. Predefined APIs are available for the context. The script framework provides a built-in Java class that prepares a context.

All of the following code examples and fragments use JavaScript. You can implement the logic at the following points in the processing:

- Before the processing of a Maximo® business object. For example, the beforeProcess(ctx) function is processed once for each noun in the inbound message before business objects that are related to the message are created.
- During the processing of a Maximo business object. For example, the beforeCreateMboSet(ctx) function is processed sequentially for each object within every noun in the inbound message. Other functions that are processed sequentially include afterCreateMboSet(ctx), mboRules(ctx), beforeMboData(ctx), and afterMboData(ctx).
- After Maximo business object processing completes. For example, the preSaveRules(ctx) and changeStatus(ctx) functions are processed once for each noun in the inbound message after the business objects are created.

In the Automation Scripts application, you can create a script for integration to include in the object structure processing.

- [Functions for inbound processing of object structures](#)  
Each function provides APIs that you can use to customize the processing of the data in the object structure.
- [Context APIs for the inbound processing of object structures](#)  
A *context* (ctx) is an object that provides convenience methods for automation scripts to pass data or trigger actions. The context is supported bidirectionally.

---

## Functions for inbound processing of object structures

Each function provides APIs that you can use to customize the processing of the data in the object structure.

- [Skip or change message processing by using the beforeProcess\(ctx\) function](#)  
The beforeProcess(ctx) function provides an injection point to run the logic in the automation script before business objects are created.
- [Create business object sets by using the beforeCreateMboSet\(ctx\) function](#)  
The beforeCreateMBOSet(ctx) function processes inbound data before the framework creates the Maximo® business objects or business object sets and can operate on all business objects in the object structure.
- [Change business objects or business object sets by using the afterCreateMboSet\(ctx\) function](#)  
The afterCreateMboSet(ctx) function processes the inbound object structure after the framework creates the Maximo business object or business object set.
- [Change processing of rules by using the mboRules\(ctx\) function](#)  
The mboRules(ctx) function can skip the processing of a business object, skip a transaction, continue processing, or create a business object. This function operates before the creation of each Maximo business object.
- [Set values in fields by using the beforeMboData\(ctx\) function](#)  
The beforeMboData(ctx) function is available when the Maximo business object is created but before the values in the business object are set by the integration framework. Processing of the object structure can change the setting of business object data. Processing can also set flags on the fields, such as the samevaluevalidation flag, which triggers field validations even when the field value is set with the current value of the field.
- [Add business objects and change values in fields by using the afterMboData\(ctx\) function](#)  
The afterMboData(ctx) function implements custom logic to create an extra related Maximo business object for inclusion in the transaction or change data in a Maximo business object. The function is available after the business object is created and the values are set in the Maximo business object by the integration framework.
- [Change the transaction before saving to the database by using the preSaveRules\(ctx\) function](#)  
The preSaveRules(ctx) function allows for extra processing that is related to the transaction as a whole. You can use the preSaveRules(ctx) function to create a related object and add it to the transaction. The function is called before the Save action and is called for each noun in the message.
- [Change status or status date by using the changeStatus\(ctx\) function](#)  
The changeStatus(ctx) function implements a status change outside the statefulMicSetIn class that is available in the integration framework. You can also use this function to set the status date with a value instead of using the system date.

---

### Skip or change message processing by using the beforeProcess(ctx) function

The beforeProcess(ctx) function provides an injection point to run the logic in the automation script before business objects are created.

For example, you can skip the processing of a message that is based on the evaluation of the data in the XML message. Another example is to change the action attribute for the message from Sync to Create.

The following JavaScript example sets the message action to Sync:

```
function beforeProcess (ctx)
{
 ctx.setMsgType ("Sync") ;
}
```

---

### Create business object sets by using the beforeCreateMboSet(ctx) function

The beforeCreateMBOSet(ctx) function processes inbound data before the framework creates the Maximo® business objects or business object sets and can operate on all business objects in the object structure.

If an automation script that is processing an object structure creates a business object set, then the createMboSet() function in the base class is skipped. Processing of a child business object supports access to the parent object by using the getParentMbo() function.

You can also use the beforeCreateMboSet(ctx) function to conditionally create the business object that is based on the data that is included in the XML message.

You cannot create a child business object that is independent of its parent business object.

The following example shows how to create a child business object from a parent business object.

```
importPackage (Packages.psdi.server) ;
function beforeCreateMboSet (ctx)
{
 var struc=ctx.getData () ;
 var ponum=struc.getCurrentData ("PO", ctx.getUserInfo ()) ;
 var siteid=struc.getCurrentData ("SITEID") ;
 var poSet = MXServer.getMXServer ().getMboSet ("PO", ctx.getUserInfo ()) ;
 poSet.setQbeExactMatch (true) ;
 poSet.setQbe ("ponum", ponum) ;
 poSet.setQbe ("siteid", siteid) ;
 var poMbo = poSet.moveFirst () ;
 var polineSet = poMbo.getMboSet ("POLINE") ;
 ctx.setMboSet (polineSet) ;
}
```

---

## Change business objects or business object sets by using the afterCreateMboSet(ctx) function

The afterCreateMboSet(ctx) function processes the inbound object structure after the framework creates the Maximo® business object or business object set.

The afterCreateMboSet(ctx) function is available to operate on all business objects in the object structure. This function can change the business object or business object set that the framework created or can inject more business objects into the business object set.

The following example sets an MboSet property to note that the created location has a type of Storeroom. This logic replaces the default logic that is in the MXSTORELOC processing class.

```
importPackage(Packages.psdi.server);
function afterCreateMboSet(ctx)
{
 var loc type = MXServer.getMXServer().getMaximoDD().getTranslator()
 .toInternalString("LOCTYPE", ctx.getData().getCurrentData("TYPE"));

 if (loc Type=="STOREROOM")
 {
 ctx.getPrimaryMboSet().setStoreroom();
 }
 else
 {
 ctx.getPrimaryMboSet().setNonStoreroom();
 }
}
```

---

## Change processing of rules by using the mboRules(ctx) function

The mboRules(ctx) function can skip the processing of a business object, skip a transaction, continue processing, or create a business object. This function operates before the creation of each Maximo® business object.

The following example shows how to skip a transaction:

```
function mboRules(ctx)
{
 ctx.skipTxn();
}
```

---

## Set values in fields by using the beforeMboData(ctx) function

The beforeMboData(ctx) function is available when the Maximo® business object is created but before the values in the business object are set by the integration framework. Processing of the object structure can change the setting of business object data. Processing can also set flags on the fields, such as the samevaluevalidation flag, which triggers field validations even when the field value is set with the current value of the field.

---

## Add business objects and change values in fields by using the afterMboData(ctx) function

The afterMboData(ctx) function implements custom logic to create an extra related Maximo® business object for inclusion in the transaction or change data in a Maximo business object. The function is available after the business object is created and the values are set in the Maximo business object by the integration framework.

When columns in the object structure are restricted, you can use the afterMboData(ctx) function to provide the logic to set those columns instead of having the integration framework set the values.

In the following example, an asset is created with the description field set to a concatenation of the EXTERNALREFID field and the description field that is passed from the object structure:

```
importPackage(Packages.psdi.server);
importPackage(Packages.psdi.mbo);
function afterMboData(ctx)
{
 var mbo = ctx.getMbo();
 var struc = ctx.getData();
 mbo.setValue("description", "FROM: "+struc.getCurrentData("EXTERNALREFID") + " DESC: "+struc.getCurrentData("DESCRIPTION"));
}
```

## Change the transaction before saving to the database by using the preSaveRules(ctx) function

The preSaveRules(ctx) function allows for extra processing that is related to the transaction as a whole. You can use the preSaveRules(ctx) function to create a related object and add it to the transaction. The function is called before the Save action and is called for each noun in the message.

## Change status or status date by using the changeStatus(ctx) function

The changeStatus(ctx) function implements a status change outside the statefulMicSetIn class that is available in the integration framework. You can also use this function to set the status date with a value instead of using the system date.

For the automation script to use the changeStatus(ctx) function, the statefulMicSetIn class or the class that extends the statefulMicSetIn class must be registered as the processing class in the object structure. You can use this function to support a status change for five parameters. The base class supports only three parameters.

The following example sets the memo field that is related to the change status action to a string value if the NP\_STATUSEMEMO field does not contain a value:

```
importPackage(Packages.psdI.server);
importPackage(Packages.psdI.mbo);

function changeStatus(ctx)
{
 var mbo = ctx.getMbo();
 var struc = ctx.getData();
 var stat = struc.getCurrentData("STATUS");
 var memo = struc.getCurrentData("NP_STATUSEMEMO");
 if(struc.isCurrentDataNull("NP_STATUSEMEMO"))
 {
 memo = "Status change via Integration";
 }
 mbo.changeStatus(stat, MXServer.getMXServer().getDate(), memo, MboConstants.NOACCESSCHECK);
}
```

## Context APIs for the inbound processing of object structures

A context (ctx) is an object that provides convenience methods for automation scripts to pass data or trigger actions. The context is supported bidirectionally. Predefined APIs are available for the context, and each function can use different contexts.

An automation script requires context methods to implement processing logic. A context is passed between the processing of the object structure and the automation script, which implements the custom code. The following table shows the context APIs and the common usage of the APIs for each of the functions:

Table 1. Context APIs as used by the functions

Context APIs	beforeProcess (ctx)	beforeCreateMboSet (ctx)	afterCreateMboSet (ctx)	mboRules (ctx)	beforeMboData (ctx)	afterMboData (ctx)	preSaveRules (ctx)	changeStatus (ctx)
ctx.setMsgType()	✓							
ctx.getProcessTable()		✓	✓	✓	✓	✓		
ctx.setProcessTable(String ProcessTable)	✓							
ctx.setMboSet(MboSet mboSet)		✓						
ctx.setMbo(Mbo mbo)		✓						
ctx.getData()	✓	✓	✓	✓	✓	✓	✓	✓
ctx.getMosDetailInfo()		✓	✓	✓	✓	✓	✓	✓
ctx.setSkipBaseAdditionalRules()							✓	
ctx.skipMbo()			✓					
ctx.skipTxn()	✓	✓	✓	✓	✓	✓	✓	✓
ctx.complete()			✓					
ctx.process()			✓					
ctx.getUserInfo()	✓	✓	✓	✓	✓	✓	✓	✓

Context APIs	beforeProcess (ctx)	beforeCreateMboSet (ctx)	afterCreateMboSet (ctx)	mboRules (ctx)	beforeMboData (ctx)	afterMboData (ctx)	preSaveRules (ctx)	changeStatus (ctx)
ctx.getParentMbo()		✓	✓	✓	✓	✓		
ctx.isPrimary()		✓	✓	✓	✓	✓	✓	✓
ctx.bypassMbo()					✓			
ctx.getMsgType()	✓	✓	✓	✓	✓	✓	✓	✓
ctx.getPrimaryMboSet()			✓	✓	✓	✓	✓	✓
ctx.getPrimaryMbo()					✓	✓	✓	✓
ctx.processAsUpdate()				✓				
ctx.processAsAdd()				✓				
ctx.processAsAddAtEnd()				✓				
ctx.log ()	✓	✓	✓	✓	✓	✓	✓	✓

The following APIs are available for inbound data processing:

ctx.getMosDetailInfo()

Provides information about the data dictionary cache for the integration framework for the object structure that is being processed.

ctx.skipMbo()

Skips the processing of a Maximo® business object.

ctx.skipTxn()

Skips the processing of an entire transaction, such as a message.

ctx.complete()

Ends the processing of the object structure at the point of execution, which means that child data is not processed.

ctx.process()

Continues the processing at the point of execution. This API is typically used as part of conditional logic.

ctx.getParentMbo()

Retrieves the parent business object. This API can be used from a child object whose business object is not yet created.

ctx.isPrimary()

Identifies whether the current business object is the root-level business object of the object structure.

ctx.getUserInfo()

Retrieves user information, which is needed if a script is creating a new business object.

ctx.bypassMbo()

Bypasses the creation of the business object and continues to the next business object that is being processed.

ctx.getMsgType()

Provides access to the message type, such as Sync or Create.

ctx.setMsgType()

Sets the message type, such as Sync or Create. This API can be used before processing begins.

ctx.getData()

Provides access to the StructureData, which is the XML message.

ctx.setMboSet(MboSet mboSet)

Sets values in a business object set.

ctx.setMbo(Mbo mbo)

Sets values in a business object.

ctx.getPrimaryMboSet()

Retrieves the root business object of an object structure during the processing of a child business object.

ctx.setProcessTable(String processTable)

Sets the table for a process. The method is used if you have a nonpersistent business object, such as MXRECEIPT, that has processing logic to determine whether the MATRECTRANS table or the SERVRECTRANS table is updated. The ctx.setProcessTable(String processTable) API is used in the beforeProcess(ctx) function.

ctx.getProcessTable()

Retrieves the table name that is set by the ctx.setProcessTable(String processTable) API.

ctx.setSkipBaseAdditionalRules()

Adds custom logic to in the preSaveRules(ctx) function to operate on a completed object structure that is now prepared in the processing.

ctx.processAsUpdate()

Sets the processing action of a business object to the Update action instead of the Add or Delete action.

ctx.processAsAdd()

Sets the processing action of a business object to the Add action instead of the Update or Delete action.

ctx.processAsAddAtEnd()

Sets the processing action of a business object to the Add action instead of the Update or Delete action and creates the business object at the end of the collection instead of at the top of the collection.

ctx.log ()

Runs a log statement from an object structure processing context.

## Customization of channel and service processing by using automation scripts

When you create an automation script, you identify the channel or service that the script runs on. You also specify where to insert the script during the processing flow.

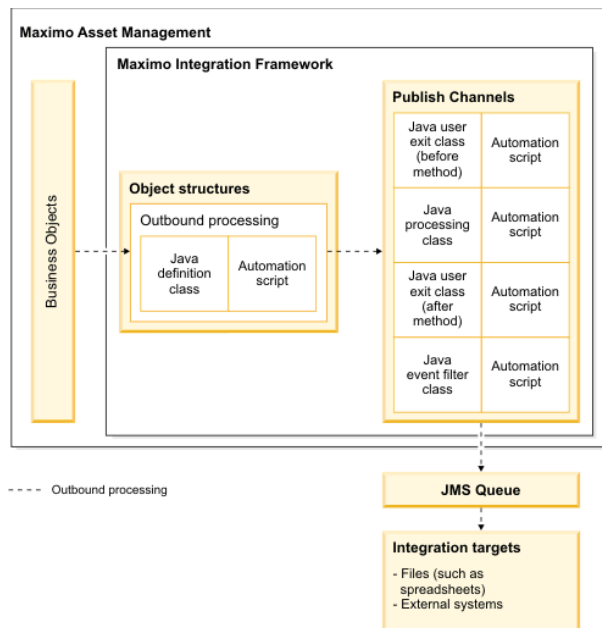

- **[Customization points during publish channel processing](#)**  
Publish channels process outbound integration messages that do not require a response. The Java processing class that is associated with a publish channel includes several hooks where you can insert code to provide custom logic.
- **[Customization points during enterprise service processing](#)**  
Enterprise services provide asynchronous and synchronous processing of inbound integration messages. You can insert code to provide custom logic to the Java request processing class for inbound processing and to the Java response processing class for outbound processing.
- **[Customization points during invocation channel processing](#)**  
Invocation channels process outbound integration messages that require a response. The invocation channel request class and the invocation channel response class include several hooks where you can insert code to provide custom logic.
- **[Examples of using automation scripts during processing by channels and services](#)**  
Channel and service processing takes a data record from the source system as an input value, manipulates the data as required, and constructs a data record for the target system. The example python scripts query input data and provide logic to manipulate the data before the output data is constructed.

---

## Customization points during publish channel processing

Publish channels process outbound integration messages that do not require a response. The Java™ processing class that is associated with a publish channel includes several hooks where you can insert code to provide custom logic.

The illustration shows the customization points during outbound processing of integration messages by using publish channels.

After object structure processing constructs the integration message, it is forwarded to the associated publish channel. You can add custom logic at the following points during publish channel processing:

- External exit class
- User exit class that runs before the external exit class
- User exit class that runs after the external exit class
- Event filter class

The message is then sent to the JMS queue for delivery to the target destination.

When you configure an external exit or user exit script for a publish channel, a predefined Java class is inserted on the channel that is used to run the script. The predefined classes are the `com.ibm.tivoli.maximo.script.ScriptExternalExit` class and the `com.ibm.tivoli.maximo.script.ScriptUserExit` class. You cannot implement a script and a Java class at the same processing point. If you attempt to create a script on a processing point where a Java class is configured, you cannot save the script.

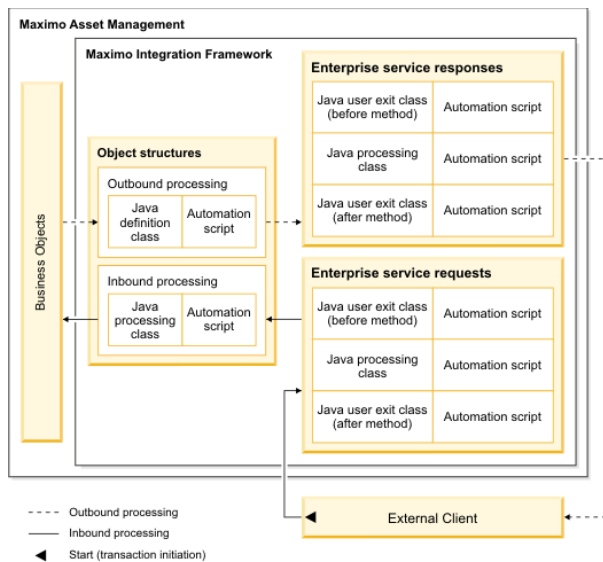

---

## Customization points during enterprise service processing

Enterprise services provide asynchronous and synchronous processing of inbound integration messages. You can insert code to provide custom logic to the Java™ request processing class for inbound processing and to the Java response processing class for outbound processing.

The illustration shows the customization points during the inbound and outbound processing of integration messages by using enterprise services.

For asynchronous messages that do not require a response, an external service opens a connection to send an enterprise service request. When the request is validated, the message is dropped into a JMS queue for enterprise services processing. For synchronous messages that require a response, the external service maintains a continuous connection during the transaction until the response is received.

In the Automation Scripts application, when you configure an automation script for an enterprise service, you specify one of the following insertion points for the script:

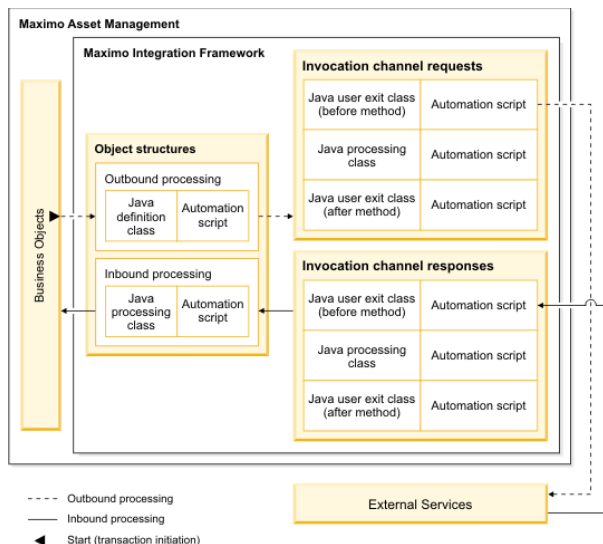

- Insertion points for inbound asynchronous processing:
  - Request, inbound: User exit class that runs before the external exit class
  - Request, inbound: External exit class
  - Request, inbound: User exit class that runs after the external class
- Insertion points for inbound synchronous processing, where a response is required:
  - Request, inbound: User exit class that runs before the external exit class
  - Request, inbound: External exit class
  - Request, inbound: User exit class that runs after the external class
  - Response, outbound: User exit class that runs before the external exit class
  - Response, outbound: External exit class
  - Response, outbound: User exit class that runs after the external class

When you configure an external exit or user exit script for the request or the response of an external service, a predefined Java class is inserted that runs the script. The predefined classes are the `com.ibm.tivoli.maximo.script.ScriptExternalExit` class and the `com.ibm.tivoli.maximo.script.ScriptUserExit` class. You cannot implement a script and a Java class at the same processing point. If you attempt to create a script on a processing point where a Java class is configured, you cannot save the script.

## Customization points during invocation channel processing

Invocation channels process outbound integration messages that require a response. The invocation channel request class and the invocation channel response class include several hooks where you can insert code to provide custom logic.

The illustration shows the customization points during inbound and outbound processing of integration messages by using invocation channels.

When a user action in Maximo® Manage starts an outbound integration transaction that requires a response, an invocation channel provides integration processing of requests and responses.

In the Automation Scripts application, when you configure an automation script for an invocation channel, you specify one of the following insertion points for the script:

- Request, outbound: User exit class that runs before the external exit class
- Request, outbound: External exit class
- Request, outbound: User exit class that runs after the external exit class
- Response, inbound: User exit class that runs before the external exit class
- Response, inbound: External exit class
- Response, inbound: User exit class that runs after the external exit class

When you configure an external exit or user exit script for the request or the response of an invocation channel, a predefined Java™ class is inserted that runs the script. The predefined classes are the `com.ibm.tivoli.maximo.script.ScriptExternalExit` class and the `com.ibm.tivoli.maximo.script.ScriptUserExit` class. You cannot implement a script and a Java class at the same processing point. If you attempt to create a script on a processing point where a Java class is configured, you cannot save the script.

---

## Examples of using automation scripts during processing by channels and services

Channel and service processing takes a data record from the source system as an input value, manipulates the data as required, and constructs a data record for the target system. The example python scripts query input data and provide logic to manipulate the data before the output data is constructed.

When Maximo® Manage starts an integration transaction, the object structure provides an internal record data (`irData`) element to a publish channel or an invocation channel. Processing manipulates the `irData` element and constructs an external record data (`erData`) element before the message is forwarded to its destination. Invocation channel transactions can require a response from the external system. Response processing passes the `erData` element to the invocation channel, which manipulates the response data and constructs the `irData` element.

When an external system starts an integration transaction, the message provides an `erData` element to an enterprise service. Processing manipulates the `erData` element and constructs an `irData` element before the message is forwarded to the associated object structure. For messages that require a response, the object structure provides the `irData` element to the enterprise service. Processing manipulates the data and constructs the `erData` element that is forwarded to its destination.

The examples consist of simple scripts that can be used for test purposes. You can use the data import and data export features in the External Systems application to start transactions to test scripts.

---

### Example: Script that changes the description of operating assets on outbound transactions

In this scenario, the `MXASSET` object structure provides `irData` to the `MYASSET` publish channel for processing. An automation script is configured to run on the external exit class of the publish channel. The script checks the status of the asset in the `irData` element. If the asset is in operating status, the script inserts a value in the description field and prints a message to the log file. The `erData` element is then constructed and is forwarded to the external system.

```
if irData.getCurrentData("STATUS") == 'OPERATING' :
 irData.setCurrentData("DESCRIPTION", "hello")
 print "MYASSET description change"
```

---

### Example: Script that changes the description of operating assets on inbound transactions

In this example, the `MYASSET` enterprise service processes an inbound message for the `MXASSET` object structure. An automation script inserts a script on the external exit class of the enterprise service. The script checks the status of the asset in the `erData` element. If the asset is in operating status, the script inserts a value in the description field and prints a message to the log file. The `irData` element is then constructed and is forwarded to the associated object structure for processing.

```
if erData.getCurrentData("STATUS") == 'OPERATING' :
 erData.setCurrentData("DESCRIPTION", "hello inbound")
 print "MYASSET inbound description has changed"
```

---

### Example: Script that changes the description of lines on a purchase order by using an automation script variable

In this example, the `MXPO` object structure provides the `irData` element to the `MYPO` publish channel for processing. An automation script is configured to run on the external exit class of the publish channel. A literal value, `world`, is defined as an input variable on the automation script. The script queries the `irData` element for purchase orders that contain purchase order lines. The script numbers each purchase order line in a sequence that starts at 1, sets `hello` as the value in the description field, and adds the input variable from the automation script. The script updates the parent purchase order before the `erData` element is constructed and forwarded to the external system.

```
lines = irData.getChildrenData("POLINE")
i = 0
if lines is not None:
 for value in lines:
 ++i
 irData.setAsCurrent(lines, i)
 irData.setCurrentData("DESCRIPTION", "hello"+world)
irData.setParentAsCurrent()
```

## Example: Script that skips transactions based on the status of records

In this example, the MXPO object structure is sent to the MYPO2 publish channel for processing. An automation script is configured to run on the user exit class before the external exit class runs. The script queries the irData element for purchase orders with a status of WAPPR and skips the processing of these purchase orders.

```
if irData.getCurrentData("STATUS") == 'WAPPR' :
 errorgroup = "iface"
 errorkey = "SKIP_TRANSACTION"
```

## Example: Script that prints transaction information to a log file to assist with troubleshooting

In this example, the MXASSET object structure provides irData to the MYASSET2 publish channel for processing. An automation script is configured to run on the external exit class. The script queries the irData element for assets with a status of operating, prints transaction information to a log file, and constructs the erData element without making any changes. To print information about the transaction, you must set logging to debug. In the Logging application, the logger is set to automation scripts and the logging level is set to DEBUG. In the Automation Scripts application, the logging level for the script is set to DEBUG.

```
if irData.getCurrentData("STATUS") == 'OPERATING' :
 print "Test script"
 variable VAR_EXIT_IFACETYPE " + ifaceTypeprint "Test script"
 variable VAR_EXIT_IFACENAME " + ifaceNameprint "Test script"
 variable VAR_EXIT_EXTSYSTEM " + extSystemprint "Test script"
 variable VAR_EXIT_MESSAGETYPE " + messageTypeprint "Test script"
 variable VAR_EXIT_EXTSYSTEM " + extSystemprint "Test script"
 variable VAR_EXIT_OSNAME " + osNameprint "Test script"
```

When an asset is exported, the following debugging information is printed to a log file:

```
18 Mar 2014 11:35:06:877 [DEBUG] [MXServer] [CID-MXSCRIPT-2022] execution completed
for cached compiled script PUBLISH.MYASSET.EXTEXT.OUT for launch point null
Test script variable VAR_EXIT_IFACETYPE MAXIMO
Test script variable VAR_EXIT_IFACENAME MYASSET2
Test script variable VAR_EXIT_EXTSYSTEM MYEXTSYS
Test script variable VAR_EXIT_MESSAGETYPE Publish
Test script variable VAR_EXIT_OSNAME MXASSET
```

## XSL mapping

For outbound transactions, you can implement an XSL file to manipulate the data that is sent to the external system after Java™ exit processing is completed. For inbound transactions, you can implement an XSL file to manipulate the data to be set to the object structure after Java exit processing is completed.

The XSL file is always called with the XML message that is output from the Java exit processing. You can register the XSL file in the application EAR file under the businessobjects/classes/ directory or you can reference it using a directory filepath that is not part of the application EAR file.

Omit the .xsl file extension to register the file in the businessobjects/classes/psdi/iface/xsl directory, for example:

```
psdi.iface.xsl.mapping
```

Include the .xsl file extension to register the file in a file directory that is accessible by the application server, for example:

```
c:/psdi/iface/xsl/mapping.xsl
```

## Interface table user exit class

When you use interface tables to receive messages from an external system, you can perform customization in the polling program that retrieves the data from the interface table and sends data to the system.

The cron task manager runs the interface table polling program. The IFACETABLECONSUMER cron task, has an optional EXITCLASS property where you can specify the fully qualified name of a Java™ exit class.

The Java data structure list represents the record from the interface tables, where the first element is always the action of the message. The remaining elements of the list are the mapped data structures and each map represents a row in the interface table for each message. The keys in the map are the column names and the values are the corresponding column values. All the column values are converted to their translated string format before they are set in the map.

The EXITCLASS class must implement the psdi.iface.intertables.IfaceTbExit interface and the following methods:

- **public void beforeQueue(long transid, String extSys, String ifaceName, List data, Connection conn)**  
This method is called after the data is received from the interface table and before the data is inserted into one of the inbound queues.
- **public void afterCommit(long transid, String extSys, String ifaceName, Connection conn)**  
This method is called after the data is inserted to an inbound queue and deleted from the interface queue table, and the database commit is done.
- **public void afterRollback(long transid, String extSys, String ifaceName, Connection conn)**  
This method is similar to the **afterCommit** method but is called if the transaction is rolled back.

This class can perform the following processes:

- Validate data.
- Change external data by changing the IR record to be saved in the system.
- Stop the transaction from being saved in the queue by throwing an exception. In this case, the transaction remains in the MXIN\_INTER\_TRANS table with the error message and is reprocessed.
- Stop the message from being sent to external system by throwing a skip\_transaction exception. In this case, message the system does not save the message; the message is removed from the queue.
- Log the transaction

The user exit that uses the **afterCommit** or **afterRollback** method can perform the following processes:

- Perform custom processing and cleanup.
- Log the transaction.

You identify this class in the Cron Task Setup application.

---

## Configuring the integration framework

Setting up the integration framework includes configuring related system properties, queues, and security. Implementing integration scenarios requires a knowledge of configuring queues and knowledge of J2EE and product security support.

- **JMS queue configuration**  
Asynchronous transactions that are exchanged using either publish channels or enterprise services, use Java™ Messaging Service (JMS) queues to exchange data with an external system.
- **Error management**  
The integration framework supports several message formats, protocols for exchanging messages, and both synchronous and asynchronous message processing. The management of errors requires multiple options to meet the varied implementation configurations that you can choose.
- **Cluster configuration**  
The integration framework can provide integration services across a cluster of application servers. If the continuous queue on a single server is inadequate for your message volume, you can add central processing units, hardware, and a cluster configuration to improve message processing performance.
- **Integration security**  
The integration framework includes support for J2EE authentication and for component-level authorization.
- **Language support**  
Your database can contain some elements, such as descriptions and long descriptions, in multiple languages. Publish channels and enterprise services can include these translated columns. The integration framework also supports the use of bidirectional language formats.

## JMS queue configuration

Asynchronous transactions that are exchanged using either publish channels or enterprise services, use Java™ Messaging Service (JMS) queues to exchange data with an external system.

For inbound processing, when an enterprise service message is received, the message is immediately written to a JMS queue and the caller of the service is released from the transaction. The message is processed from the inbound JMS queue, through the application business objects, and saved to the database. Messages remain in an inbound queue until they are successfully processed or until they are deleted from the queue. A common strategy for inbound queue implementation is to isolate the queues and the queue consumers to a separate server, or server cluster. This strategy ensures that inbound message-processing does not have a performance impact on application users.

For outbound processing, messages sent out using a publish channel are written to a JMS queue and the user who initiated the message is released from the transaction. The message is processed from the outbound JMS queue using the configured endpoint, and is delivered to the external application. Messages remain in the outbound queue until they are successfully delivered to the external application or are deleted from the queue.

There are three default message queues:

- One outbound sequential queue
- One inbound sequential queue
- One inbound continuous queue

A JMS queue implementation can operate on a single application server or across a cluster of application servers.

- **Creating and configuring a queue**  
You can choose to use a single JMS queue for multiple external systems or create a separate queue for each external system that you use. Queue creation and configuration involves multiple steps. You can use the default queues or create additional queues, depending on your integration requirements.
- **Sequential queues**  
The sequential queue is a JMS queue that uses a predefined system cron task to consume messages. Messages in sequential queues are processed on a strict first-in-first-out basis, ensuring that messages are processed in the order that they are generated and received.
- **Continuous queues**  
A continuous queue is a JMS queue with a message-driven bean (MDB) as a consumer. A continuous queue is predefined for enterprise services only and

uses multi-threaded processing to provide better system performance. A continuous queue does not guarantee the processing order of the messages as is the case with a sequential queue.

- [Queue message format](#)  
Messages that are loaded into the JMS queues by the integration framework have defined components and formats. The message body contains the XML or JSON message that is processed into the system or sent to the external system.
- [Queue selectors](#)  
Selectors act as WHERE clauses in the JMS queue consumer. Selectors can be applied to message headers and properties in either a continuous or a sequential queue.
- [Viewing and deleting messages in a JMS queue](#)  
You can view a list of the messages in a JMS queue, download these messages to view their content, and you can delete messages from configured queues. When viewing or deleting messages, you can apply a selector to limit the messages returned for processing.
- [Configuring queues with WebSphere MQ](#)  
You can use IBM® WebSphere® MQ to configure and manage queuing activities. Maximo® Manage supports any JMS 1.1 compliant JMS provider.

---

## Creating and configuring a queue

You can choose to use a single JMS queue for multiple external systems or create a separate queue for each external system that you use. Queue creation and configuration involves multiple steps. You can use the default queues or create additional queues, depending on your integration requirements.

---

### About this task

Separate queues are used to support outbound transactions and inbound transactions. Configure a queue to support either inbound or outbound transactions, not both. Configure outbound queues for use with publish channels and configure inbound queues for use with enterprise services.

---

### Procedure

1. Create and configure the message queue on the application server.
  2. In the External Systems application, add properties to the queue.  
You can create additional queues to meet system needs. If you do not use the default queues, use an application server provider for your queue configuration.
  3. In the External Systems application, configure the external system and enterprise services to use the queues.
- [Queue properties](#)  
In the External Systems application, you can configure several properties for each JMS queue.

---

## Queue properties

In the External Systems application, you can configure several properties for each JMS queue.

Property	Description
Queue JNDI Name	References the Java™ Naming and Directory Interface (JNDI) name that is configured on the application server. A default value is provided.
Queue Connection Factory Name	References the Connection Factory name that is configured on the application server. A default value is provided.
Initial Context Factory	A value that you must configure when you do not use the default queues and do not use a provided application server.
Provider URL	A value that you must configure when you do not use the default queues and do not use a provided application server.
User ID	The user ID that you configure when the queue is secured on the application server.
Password	The password that is configured when the queue is secured in the application server for the user ID.
Inbound	Identifies whether the queue is used for inbound processing. If the inbound value is null, the system uses the queue for outbound processing.
Sequential	Identifies whether the queue is a sequential queue. If the sequential value is null, the system uses the queue for continuous queue processing.
Compress	Identifies whether the messages are compressed when they are written to the queue and decompressed when they are pulled from the queue. Compression provides significantly reduced message sizes. The standard Java Inflater and Deflater APIs (java.util.zip) are used for compression.
Maximum Try Count	Identifies how many times the integration framework attempts to retry processing a message after the first time the message does not process because of errors. The system continues to retry the message until the count value is met. The value of this property must be set to one when an error queue is implemented.

---

## Sequential queues

The sequential queue is a JMS queue that uses a predefined system cron task to consume messages. Messages in sequential queues are processed on a strict first-in-first-out basis, ensuring that messages are processed in the order that they are generated and received.

When a message results in an error, the system generates an error that can be managed in the Message Reprocessing application, and does not process subsequent messages in the queue until the error is cleared.

You can configure two system sequential queues for inbound and outbound message processing. A predefined cron task, JMSSEQCONSUMER, polls the queues. There are two instances of the task, one that polls the inbound queue and one that polls the outbound queue. If you create additional sequential queues, you can configure additional instances of the cron task to point to the additional queues.

The following table lists the cron task parameters that you can configure.

Parameter	Description
MESSAGEPROCESSOR	Java™ class that processes the messages from the queue. The system provides this class.
QUEUENAME	Queue JNDI name, when the queue is created on the application server.
SELECTOR	The WHERE clause for configuring an instance of the cron task to process a subset of messages in the queue. This parameter is optional.
TARGETENABLED	Ensure that the value is at the default of 0 (false). The functionality of this flag is superseded by the donotrun functionality. Use the donotrun parameter in the cron task framework to control which servers the cron task runs on.

---

## Continuous queues

A continuous queue is a JMS queue with a message-driven bean (MDB) as a consumer. A continuous queue is predefined for enterprise services only and uses multi-threaded processing to provide better system performance. A continuous queue does not guarantee the processing order of the messages as is the case with a sequential queue.

When message processing results in an error that can be managed in the message reprocessing application, the system generates an error message and then continues processing subsequent messages in the queue. There is one default continuous queue to process inbound messages. You can choose to implement additional continuous queues, depending on your integration requirements.

- [Continuous queue performance](#)  
To improve queue performance, you can increase the number of message-driven beans for a queue and introduce additional application servers in a cluster. Because message processing is multi-threaded, errors can occur because of the random order of processing.
- [Configuring message beans](#)  
Server-specific extensions control the maximum number of beans that you can create.
- [Message caching](#)  
Continuous queue processing uses the Maximum Batch Size property, under the Activation Specification definition, to control the number of messages received from the messaging engine in a single batch.
- [Configuring an error queue for the continuous queue](#)  
You can implement an error queue on the application server that moves a message out of the main queue to a secondary queue when a message goes in error. Unless your integration scenario supports a very low volume of messages, configure an error queue to support message processing through the continuous queue.

---

## Continuous queue performance

To improve queue performance, you can increase the number of message-driven beans for a queue and introduce additional application servers in a cluster. Because message processing is multi-threaded, errors can occur because of the random order of processing.

The following examples describe errors that can occur. In both scenarios, the integration error management processing can successfully reprocess the error before the system administrator can review it.

For example, you are batch loading a large volume of item and inventory messages in the continuous queue, and multiple inventory records exist for the same item number. If an inventory message for Item A is processed before the item message that adds Item A to the system is processed, the inventory message produces an error because Item A does not exist. Processing continues with the next message.

Eventually, the item message for Item A is processed and Item A is added to the system. The failed message can then be successfully processed. In this case, the error is corrected without manual intervention.

This type of situation can occur when you load related messages in the continuous queue at the same time. Such a situation is more likely to occur when the volume of transactions is high but also can occur whenever two messages process related data concurrently.

For example, two messages try to update the same system record at the same time. One message succeeds and the other fails. However, the error management processing of the system must process the second message after the first update is completed.

---

## Configuring message beans

Server-specific extensions control the maximum number of beans that you can create.

---

## Message caching

Continuous queue processing uses the Maximum Batch Size property, under the Activation Specification definition, to control the number of messages received from the messaging engine in a single batch.

If three message-driven beans are enabled, and the batch size is 10, up to 30 messages can be cached. Test with different values to ensure that the value that you set does not impact application users or server processes.

## Configuring an error queue for the continuous queue

You can implement an error queue on the application server that moves a message out of the main queue to a secondary queue when a message goes in error. Unless your integration scenario supports a very low volume of messages, configure an error queue to support message processing through the continuous queue.

A continuous queue uses MDBs to consume messages. When a message goes in error, the MDBs continue to consume the messages in error, even after the messages reach the maximum try count that is configured for reprocessing after an initial error. The continuous selection of these messages consumes system resources and can slow down, or even prevent, other messages from being processed. Configuring an error queue for the continuous queue helps to avoid performance delays or transaction bottlenecks by passing messages in error to a secondary queue.

## Queue message format

Messages that are loaded into the JMS queues by the integration framework have defined components and formats. The message body contains the XML or JSON message that is processed into the system or sent to the external system.

### Message header

The message header can contain the JMS message ID and standard JMS header values.

Header	Description
JMSMessageID	A message ID that is generated by the system.
JMSRedelivered	Identifies whether the message was reprocessed.

### Message properties

The properties contain the following properties from the JMS provider and the integration framework. The integration framework properties are of the string data type.

Property	Description
MEAMessageID	The message ID that is generated by the integration framework.
destjndiname	The name of the queue or topic that the message is written to.
INTERFACE	The name of the publish channel (outbound queue) and the enterprise service (inbound queue).
destination	The external system name for outbound messages.
SENDER	The external system name for the inbound messages.
USER	The name of the user that is associated with the inbound integration message. This value can be used for authorization security if required.
compressed	Indicates whether the message is compressed. Values can be true or false; the default value is false. The standard Java™ Inflater and Deflater APIs (java.util.zip) are used for compression.
uncompressed_length	Stores the original message payload size before compression. This value must comply with the int [xsd:int] schema type and is present only when the compressed property is set to true.
MSG_TRK_ENABLED	Internal value.
MSG_OP_MODE	The endpoint name for the outbound messages. Fixed string MXJMS for inbound messages.
MSG_TRK_STORE_MSG	Internal value.
MSG_TRK_EXTSYS	The external system name for outbound and inbound messages.
Msgkeyval	A field name message key.
searchfieldval	A comma-separated search field value.
msgoperation	Indicates whether the publish channel or enterprise service contains a sync, create, update, or delete operation.
msgstatus	Indicates whether the message has a RECEIVED, ERROR, DELETED, or a PROCESSED status value.
msgerrmsg	Contains the exception message text.

- [Messages in text format](#)

Messages that are written to a queue by the integration framework are in byte format by default. You can use the External Systems application to ensure that messages in text format are also supported.

## Messages in text format

Messages that are written to a queue by the integration framework are in byte format by default. You can use the External Systems application to ensure that messages in text format are also supported.

To support messages in text format, select the Text check box in the Add/Modify queue window in the External Systems application. When a queue is configured to support messages in text format, all subsequent messages that are written to the queue by an integration component are in the *javax.jms.TextMessage* format instead of the default *javax.jms.BytesMessage* format.

When the queue is configured for messages in text format, the Text Message Encoding field in the External Systems application identifies the encoding of text-formatted messages in any of the inbound queues configured for the external system. When no value is provided, messages are assumed to be encoded in UTF-8. Messages that are written to the outbound queue are always encoded with UTF-8.

## Queue selectors

Selectors act as WHERE clauses in the JMS queue consumer. Selectors can be applied to message headers and properties in either a continuous or a sequential queue.

The following table lists how you can use continuous selectors in the JMS queue consumer.

Type of queue	Where to identify selector
Sequential queue	Specified as a property of the cron task.
Continuous queue	Specified in the ejb-jar.xml code of the message-driven bean.

Applying selectors splits a queue into smaller queues, each of which contains a subset of data that each cron task or message-driven bean uses. An error in one subset of the data does not stop processing in the others in a sequential queue.

While selectors provide flexibility in separating the processing of transactions, they impair the performance of poll processing. Depending on the volume of transactions, you can prefer to implement multiple queues instead of one queue with multiple selectors. Multiple queues typically provide better performance.

You can add the following statement to the SELECTOR property of the SEQJIN instance of the JMSQSEQCONSUMER to instruct the cron task to process the MXPOInterface and MXPRIInterface transactions from the corresponding external system:

```
SENDER='EXTSYS1' and INTERFACE in ('MXPOInterface', 'MXPRIInterface')
```

Add the following content to the message bean configuration in the ejb-jar.xml file to instruct the message-driven bean to process the MXPOInterface and MXPRIInterface transactions from the corresponding external system:

```
<message-selector>
 SENDER='EXTSYS1' AND INTERFACE IN ('MXPOInterface', 'MXPRIInterface')
</message-selector>
```

If two external systems send data to an inbound sequential queue, an error in any record stops the processing of all transactions in that queue to maintain a first-in-first-out processing order. Create multiple instances of a cron task, each with a selector that processes a different external system, to prevent an error in one system from stopping transactions from the second system.

Ensure that the where clauses in the selectors identify the mutually exclusive sets of transactions in a sequential queue. Include all the transactions that are inserted into the queues to ensure that all messages are processed in a first-in-first-out order.

## Viewing and deleting messages in a JMS queue

You can view a list of the messages in a JMS queues, download these messages to view their content, and you can delete messages from configured queues. When viewing or deleting messages, you can apply a selector to limit the messages returned for processing.

### About this task

Messages that are currently being processed to a continuous queue by a message-driven bean or to a sequential queue by a JMS cron task are not available to view or delete. You can deactivate the cron task to stop the processing of messages to a sequential queue. Message-driven beans continually process messages and the number of messages being processed can vary. Unless you disable message-driven beans, it is likely that not all messages can be viewed or deleted. If you view or delete messages while message-driven beans are enabled, it is possible that not all messages are available for processing.

### Procedure

1. In the External Systems application, select the Add/Modify Queues action .
2. Select a queue, and click either the View Queue Data button or the Delete Queue Data button.
3. Optional: If you select the View Queue Data option, you can specify a number in the Count field to limit the number of records to view and you can check the Count Only field if you only want to see how many messages are currently in the queue.
4. Optional: Specify one of the following selectors if you want to filter the records returned in either the View Queue Data window or in the Delete Queue Data window:

Option	Description
<b>MEAMessageID</b>	ID of the message (applies to inbound and outbound messages).
<b>INTERFACE</b>	The name of the enterprise service for inbound messages or the name of the publish channel for outbound messages.
<b>destination</b>	The name of the external system for outbound queues only.
<b>SENDER</b>	The name of the external system for inbound messages only.
<b>USER</b>	The user provided with the message. This value is optional, and applies to inbound messages only.

Selector values are case sensitive and you must enclose the value of the selector in single quotes, for example INTERFACE='MXPERSONInterface'.

---

## Configuring queues with WebSphere MQ

You can use IBM® WebSphere® MQ to configure and manage queuing activities. Maximo® Manage supports any JMS 1.1 compliant JMS provider.

- [Configuring JMS endpoints and handlers](#)  
Outbound messages in a publish channel are placed into the default queue and you must configure the JMS endpoint and handler to send the message to WebSphere MQ.
- [Configuring integration queues and WebSphere MQ provider](#)  
To replace integration framework queues with WebSphere MQ queues, configure the queues on WebSphere Application Server and add these queue definitions in the External Systems application.

---

## Configuring JMS endpoints and handlers

Outbound messages in a publish channel are placed into the default queue and you must configure the JMS endpoint and handler to send the message to WebSphere® MQ.

---

### Procedure

1. Create an WebSphere MQ provider on the WebSphere Application Server and configure an integration endpoint to point to the message queue (MQ) provider by using:
  - a. The destination JNDI name (DESTJNDINAME)
  - b. The connection factory JNDI name (CONFACTORYJNDINAME)
2. Configure the endpoint to point to the WebSphere MQ by using:
  - a. The destination JNDI name (DESTJNDINAME)
  - b. The connection factory JNDI name (CONFACTORYJNDINAME)
  - c. The provider URL (PROVIDERURL)
  - d. The initial context factory (CONTEXTFACTORY)

---

## Configuring integration queues and WebSphere MQ provider

To replace integration framework queues with WebSphere® MQ queues, configure the queues on WebSphere Application Server and add these queue definitions in the External Systems application.

---

### Procedure

1. Create the JMS queue by defining an alternate provider to replace the default provider.
2. Create a proxy queue on the WebSphere Application Server by using the WebSphere MQ provider that points to your message queue (MQ) server queue.
3. In the Add/Modify Queues dialog window in the External Systems application, add values to the Queue JNDI Name and Connection Factory fields to point to the proxy queue and connection factory.

---

### Results

Outbound messages that are destined for the default queue are delivered to the message queue (MQ), and inbound messages are retrieved from the message queue (MQ).

---

## Error management

The integration framework supports several message formats, protocols for exchanging messages, and both synchronous and asynchronous message processing. The management of errors requires multiple options to meet the varied implementation configurations that you can choose.

Queues are used by the integration framework as a staging mechanism for inbound and outbound messages. Queue error management is initiated when an error condition is identified and you can view, correct, cancel, and reprocess problematic messages.

- [Non-queue error management](#)  
When you start the synchronous processing of inbound or outbound integration messages, you are notified of any errors at the time of execution.
- [Queue-based error management](#)  
You can use the Message Reprocessing application to manage erroneous inbound and outbound asynchronous integration messages that use queues.
- [Configuring error management](#)  
To configure error management, you must configure system properties and configure the external system.
- [Error notification](#)  
When an inbound or outbound transaction results in an error in a queue, an email notification is sent to the system administrator only if no other unresolved errors are waiting in the same queue. If multiple errors exist in the queue, the system administrator must resolve all of them before notification of new errors is sent.
- [Message reprocessing](#)  
In the Message Reprocessing application, you can manage messages that are flagged with an error, including changing the message status, correcting the

message, or deleting it from the database.

- [Error management with file-based data import](#)  
The integration framework supports error management with the Message Reprocessing application which allows you to review, correct, reprocess, and delete messages that go in error when processed from an inbound queue. When data is imported from an XML file or a flat file, a second option is available that manages errors using a downloaded file instead of the Message Reprocessing application.
- [Interface table error management](#)  
Interface tables can be used for inbound and outbound data exchange. Errors can occur when writing inbound data from an interface table to a queue or outbound data from a queue to an interface table.
- [Common causes of errors](#)  
Errors when processing messages in the outbound queue occur because there is a problem delivering a message to the endpoint that is specified for the external system. Errors when processing messages in an inbound queue are typically related to a business rule validation or in the inbound processing of the enterprise service.
- [Error research](#)  
When you receive an error notification, look at the message in the Message Reprocessing application.
- [Message tracking](#)  
The Message Tracking application tracks and displays the processing history of publish channel messages and queue-based enterprise service messages.

---

## Non-queue error management

When you start the synchronous processing of inbound or outbound integration messages, you are notified of any errors at the time of execution.

Non-queue error management is necessary if an error occurs when a synchronous message is being processed. For inbound messages, instead of relying on an error queue, the integration framework responds synchronously to the caller of the process with an error message. The calling application must receive the response, correct the error, and retry the transaction.

Use the system log to troubleshoot synchronous transaction errors. The system log contains the processing exception that the integration framework issues to the caller of the process.

---

## Queue-based error management

You can use the Message Reprocessing application to manage erroneous inbound and outbound asynchronous integration messages that use queues.

Errors that occur when a message is sent from a queue to an external system are typically caused by a communication failure or a problem with database configuration when writing to interface tables or files. Errors that occur during inbound processing are typically a result of business rule validations or the inbound processing logic of the integration framework.

The sequential queue processes messages one at a time, in a first-in-first-out sequence. As a result, only a single error can exist in a sequential queue. When the integration framework encounters an error in processing a message in a sequential queue, inbound or outbound, the error management mechanism is initiated and the message is flagged as having an error. Subsequent messages in the queue are not processed until the message in error is resolved or deleted.

The continuous queue handles inbound processing only and processes messages in a multi-threaded mode. When an error occurs in the continuous queue, error management is initiated and the message is flagged as having an error. The integration framework continues to process subsequent messages in the queue. As a result, multiple errors can exist in a continuous queue.

Depending on your queue configuration, the integration framework makes several attempts to reprocess the message before determining that an error requires intervention. The system also performs the following activities when encountering an error:

- Sends a notification to one or more email accounts, informing the recipients that an error occurred. The address either is specified with the `mxe.int.admintoeemail` system property or on the message queue. An address on the message queue takes precedence over the address on the system property.
- Creates a record that can be viewed and managed in the Message Reprocessing application. This record includes the message that was placed in the queue.

---

## Configuring error management

To configure error management, you must configure system properties and configure the external system.

- [Configure notification properties](#)  
Before you use the integration framework, configure notification properties in the System Properties application. The email address properties can be superseded by email addresses that are specified for a message queue in the External Systems application.
- [Error processing with an Apache Kafka provider](#)  
When messages have errors during processing in Kafka, you can reprocess them or mark them to be deleted after they expire from Kafka.

---

## Configure notification properties

Before you use the integration framework, configure notification properties in the System Properties application. The email address properties can be superseded by email addresses that are specified for a message queue in the External Systems application.

## Procedure

---

1. Filter for the `mxe.int.adminfromemail` property and specify an email address, such as `mxintadm@example.com`.  
This address appears in error notifications that are submitted by the integration framework. Some SMTP servers require this address to be a valid email address format; some servers accept any value.
2. Filter for the `mxe.int.admintoeemail` property and specify one or more email addresses to receive notification of message processing errors. Use commas to delimit several email addresses.  
You can optionally use the email address property at the queue level to override the administrator address. Use this option if you want to specify different email addresses for each queue. If you do not configure an email address, no email notification is sent when queue processing errors occur.
3. Filter for the `mail.smtp.host` property and specify an SMTP server if none has been configured.  
This property is not unique to the integration framework, and can be configured for other applications.

---

## Error processing with an Apache Kafka provider

When messages have errors during processing in Kafka, you can reprocess them or mark them to be deleted after they expire from Kafka.

### Error processing of messages in sequential queues

---

Sequential queues do not use an error queue because only one message is in error at any time. A message in error prevents the messages behind it in the queue from processing. However, an error does not prevent new messages from being added to the queue. Kafka retains both processed and unprocessed messages in the queue, based on the retention time that is set in Kafka.

In Kafka, pay attention to the Kafka retention time. For example, if you set it to 48 hours, a message goes in error late Friday evening. Other messages stack up behind the error message. If the error message is not managed until Monday morning, the error message and other unprocessed messages might expire before messages resume processing.

Messages that are in error and expired in Kafka can be reprocessed in the Message Reprocessing application.

If messages are in a queue but are not being processed, which happens if the cron task is not active, messages can expire. Because the messages did not process with an error, they are not available in the Message Reprocessing application and are not recoverable.

If you have messages in error that you do not want to reprocess, mark the messages for deletion in the Message Reprocessing application.

### Error processing of messages in continuous inbound queues

---

A message that is in error in a continuous queue is written to the end of the queue so that it reprocesses. The number of times that an errored message can be reprocessed is determined by the value of the Maximum Retry Count field for this external system.

For continuous inbound error processing, you must set up an instance of the KAFKAERROR cron task for that continuous queue. This cron task processes the messages from the `maxinterror` table in Maximo® Application Suite.

Note: After attempting the "maximum retry count" times, the error message is set on HOLD status. This gets skipped by the KAFKAERROR cron task in favor of the next message in the error table. If you want to fix the message and retry, use the Message Reprocessing application to edit the message and change the message status to "RETRY" for the KAFKAERROR cron task to process it in the next iteration. If you do not want to process the error message anymore, mark the message for deletion in the Message Reprocessing application.

### Configuration of a redelivery delay for continuous queues

---

An administrator can configure a redelivery delay that is in effect when a retry count is specified for a continuous queue. When a redelivery delay is specified in the `mxe.int.kafkaredeldelay` property, the cron task for the queue does not rewrite a message to the end of the Kafka queue until after the delay time.

For example, if the delay is set to 30 seconds, the cron task for the continuous queue pauses for 30 seconds before it rewrites the message with errors to the end of the queue. The delay allows other messages to be processed in the queue, some of which can contain objects that are needed to successfully process the message that had errors. The drawback of using this mechanism is that the delay slows down the processor because it delays the cron task from continued processing.

To implement a redelivery delay, create the `mxe.int.kafkaredeldelay` property in the System Properties application and set a delay time in seconds.

---

## Error notification

When an inbound or outbound transaction results in an error in a queue, an email notification is sent to the system administrator only if no other unresolved errors are waiting in the same queue. If multiple errors exist in the queue, the system administrator must resolve all of them before notification of new errors is sent.

An email error message includes a Java™ error stack trace.

The same notification process is used for all errors, queues, and messages, regardless of whether the system is running in a clustered or non-clustered environment.

The following example describes error notification for a continuous inbound JMS queue that contains ten messages. The first four messages are processed successfully and an error occurs on the fifth message. Depending on the value you set for the Maximum Try Count property for the external system, the message can be retried one or more times. If the message does not process successfully, it is moved to either an error queue if one is configured, or to be manually reviewed in the Message Reprocessing application. A notification email is sent to the system administrator and subsequent messages in the queue are processed. If another

error occurs in the seventh message, email notification is not sent unless the system administrator resolved the original error. If the system administrator resolved the original error and no errors are pending, a new email notification is sent.

Multiple errors can exist only in the continuous inbound JMS queue. In a clustered environment, the system administrator can receive one email error notification per application server, depending upon the timing of the transactions in error.

The following example describes error notification for a sequential outbound or inbound queue that contains ten messages. The first four messages are processed successfully and an error occurs on the fifth message. Depending on the value you set for the Maximum Try Count property for the queue, the message can be retried one or more times. If the message continues to cause an error, an email notification is sent to the system administrator and subsequent messages in the queue are not processed until the message with the original error is resolved or, if you are using a Kafka provider, the message expires and is deleted from the Kafka queue. The administrator is notified about the first error.

An uncommon exception condition can occur with outbound JMS messages when a message is saved to the queue but the commit of the transaction to the queue fails. This exception can occur because a database connection to the JMS data store is not available. If this exception occurs, a notification is sent and the message in error is visible in the Message Reprocessing application with a status of either JMSERROR or SAVED. Because the message was not saved successfully in the queue, you cannot set the message status to RETRY, but you can process the message from the application.

---

## Message reprocessing

In the Message Reprocessing application, you can manage messages that are flagged with an error, including changing the message status, correcting the message, or deleting it from the database.

If message tracking is enabled, use the Message Tracking application to determine which tracked messages are flagged with an error. If message tracking is not enabled, you can check for transaction errors in the Message Reprocessing application.

- [Message status values](#)  
To change the status of a message, select the Change Status action in the Message Reprocessing application. The system designates a status to each message to indicate whether it is ready for processing.
- [Error messages](#)  
You can review the XML or JSON message that is generated when an error occurs and you can modify the content of the message.
- [Critical errors](#)  
Critical errors are processing exceptions that the integration framework error correction process cannot retry.
- [Correcting errors](#)  
In the Message Reprocessing application, you can either reprocess a message that is in error, or you can delete the message from the database.

---

## Message status values

To change the status of a message, select the Change Status action in the Message Reprocessing application. The system designates a status to each message to indicate whether it is ready for processing.

A message can have a status of RETRY or HOLD:

Status	Description
RETRY	The message is ready to be reprocessed by the system.
HOLD	The message is not ready to be reprocessed by the system.

The RETRY status is the default status for messages that are flagged with an error. Until you correct the processing problem, the system continues to reprocess the message according to the configured queue retry count. When the retry count condition is met, the system changes the messages status to HOLD.

You can halt message reprocessing by changing the message status to HOLD. A hold status prevents the system from reprocessing the flagged message and from updating the system database tables.

---

## Error messages

You can review the XML or JSON message that is generated when an error occurs and you can modify the content of the message.

When you manage an error in the Message Reprocessing application, you can see the following information:

- The Error Data field contains the error message.
- The message content contains the original message that was placed in the queue and is causing an error. You can edit this element.
- If available, the internal record contains the XML or JSON representation of the message at the time that the error occurred. You cannot edit the internal record but you can use it to view if integration processing changed the original message before the error occurred.

The internal record represents the object structure that was created during enterprise service and user exit processing. An internal record is available only for inbound transactions, and only when enterprise service and user exit processing complete successfully. If an internal record is available, it is provided for information only and you cannot change it.

The following example shows an error XML message:

```
<?xml version="1.0" encoding="UTF-8"?>
 <SyncMXPERSO xmlns="http://www.ibm.com/maximo"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 creationDateTime="2014-04-22T14:04:03-04:00"
```

```

 transLanguage="EN" baseLanguage="EN" messageID="11798570432187483"
 maximoVersion="7 6" event="1"
messageid="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mif.doc_gp_intfrmwk_c_error_xml_11798570432652
428">
 <MXPERSONSet>
 <PERSON action="Update">
 .
 .
 </PERSON>
 </MXPERSONSet>
</SyncMXPERSON>

```

The following example shows an internal record XML message:

```

<?xml version="1.0" encoding="UTF-8"?>
 <SyncMXPERSON xmlns="http://www.ibm.com/maximo"
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 creationDateTime="2014-04-22T14:04:03-04:00"
 transLanguage="EN" baseLanguage="EN" messageID="11798570432187483"
 maximoVersion="7 6" event="1"
messageid="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mif.doc_gp_intfrmwk_c_error_xml_11798570432652
428">
 <MXPERSONSet>
 <PERSON action="Update">
 .
 .
 </PERSON>
 </MXPERSONSet>
 </SyncMXPERSON>
</IR>
</ERROR>

```

---

## Critical errors

Critical errors are processing exceptions that the integration framework error correction process cannot retry.

Transaction processing exceptions can occur when incorrect data, such as a special character, is present in the XML or JSON file. To correct a critical error, you remove the incorrect data from the error XML or JSON message. You can see incorrect data that is associated with a critical error in the main tab of the Message Reprocessing application.

---

## Correcting errors

In the Message Reprocessing application, you can either reprocess a message that is in error, or you can delete the message from the database.

- [Reprocessing an edited message](#)  
You can view, modify, and reprocess messages in the Message Reprocessing application. After you edit the error XML or JSON message, you can save or cancel the changes without reprocessing the message.
- [Deleting messages](#)  
You can delete messages from the error message queue. After you delete a message, it cannot be reprocessed.
- [Refresh messages](#)  
You can use the Refresh icon in the Message Reprocessing application to update the message list. When you refresh the message list, you can check on the status of a specific message listings.

---

## Reprocessing an edited message

You can view, modify, and reprocess messages in the Message Reprocessing application. After you edit the error XML or JSON message, you can save or cancel the changes without reprocessing the message.

---

## About this task

You can edit only those messages that have a HOLD status. If the message has a RETRY status, the content of the message is read-only.

---

## Procedure

1. In the Message Reprocessing application, select the message that you want to modify and click the Message Details icon.
2. In the Error Data window, make any necessary changes to the message.
3. Click Process if you want to reprocess the message.  
You can click Save to save the changes without reprocessing the message or you can click Cancel to discard any changes you made.

---

## Results

If the processing is successful, the Message Reprocessing application performs the following tasks:

- Deletes the record in the error message table.
- Updates the DELETEFLAG, CHANGE BY, and CHANGE DATE attributes in the error status table

---

## What to do next

In the Message Details window, refresh the list of messages that are flagged with an error. If the message was successfully reprocessed, it is dropped from the list.

---

## Deleting messages

You can delete messages from the error message queue. After you delete a message, it cannot be reprocessed.

---

## Procedure

1. In the Message Reprocessing application, select the message records that you want to delete.
2. Select the Delete Message action.
3. Click OK.

---

## Results

When a message is deleted, the record is deleted from the MAXINTERRORMSG and MAXINTERROR tables. The application refreshes the result set and omits the deleted message listing on the main tab of the Message Reprocessing application.

---

## Refresh messages

You can use the Refresh icon in the Message Reprocessing application to update the message list. When you refresh the message list, you can check on the status of a specific message listings.

If the message reprocessing was successful, the application omits the applicable message listings. If you delete a message, the application omits the deleted message listing.

---

## Error management with file-based data import

The integration framework supports error management with the Message Reprocessing application which allows you to review, correct, reprocess, and delete messages that go in error when processed from an inbound queue. When data is imported from an XML file or a flat file, a second option is available that manages errors using a downloaded file instead of the Message Reprocessing application.

File-based error management is beneficial when you import a large number of messages that can cause a large number of errors. Managing a large number of errors in a file format can be easier and quicker than managing them individually in the Message Reprocessing application.

- [File-based error management](#)  
You can use file-based error management with the data import feature. File-based error management provides the ability to identify all integration messages flagged with an error and download a complete file that contains all errors. The downloaded file is in a format that is consistent with the file that was used for the import.
  - [Configuring error management in data import cron tasks](#)  
You can set the ISFILEEXTRACT parameter in the XMLFILECONSUMER and FLATFILECONSUMER cron tasks to identify the error management mechanism that you want to use.
  - [Information extracted by file-based error management](#)  
File-based error management provides the ability to download a reprocessable file that contains all of the error messages that originated from a single input file.
- 

## File-based error management

You can use file-based error management with the data import feature. File-based error management provides the ability to identify all integration messages flagged with an error and download a complete file that contains all errors. The downloaded file is in a format that is consistent with the file that was used for the import.

To configure file-based error management, in the Data Import window, select the File-based Error Management check box.

When you select the File-based Error Management check box and leave the Import Preview check box cleared, you receive a system message after the inbound messages are processed successfully to the queue.

Inbound processing logic identifies processing errors on any of the messages in the source file and makes these failed messages available for download in a reprocessable file. The Message Reprocessing application provides a facility to download the reprocessable file.

Selecting the File-based Error Management check box means that any integration messages flagged with an error are available only in the reprocessable file and are not displayed in the messages section of the Message Reprocessing application.

## Configuring error management in data import cron tasks

You can set the ISFILEEXTRACT parameter in the XMLFILECONSUMER and FLATFILECONSUMER cron tasks to identify the error management mechanism that you want to use.

The following table contains the possible values for the ISFILEEXTRACT parameter:

Value	Error management mechanism
0	Error management is handled in the Message Reprocessing application.
1	File-based error management is handled in the Data Import window and in the reprocessable file.

File-based error management means that any integration messages flagged with an error are available only in the reprocessable file and are not displayed in the messages section of the Message Reprocessing application.

## Information extracted by file-based error management

File-based error management provides the ability to download a reprocessable file that contains all of the error messages that originated from a single input file.

The following table contains the information available in the Error Extract section of the Message Reprocessing application.

Field	Description
Import file	Name of the source file that generated the reprocessable file.
Enterprise service	Name of the enterprise service that was used to import the source file.
External system	Name of the external system that was used to import the source file.
Import date	Date and time when the data import process initiated processing of the source file.
Imported count	Total number of messages imported from the original source file.
Processed count	Number of messages processed successfully.
Error count	Number of messages that have errors.
File format	Format of the source file.
Available to extract	Identifies whether the inbound processing of the source file has completed.
Extract icon	Action button that initiates the file download process. To assure that the source file has been completely processed by the import mechanism, files are only available for download when the sum of error count and processed count is equal to the imported count.
Delete icon	Action button that deletes the selected record from the Error Extract table. You can only delete table records if the sum of the error count and processed count is equal to the imported count.

- [Downloading reprocessable files](#)

You can download a reprocessable file and fix the processing errors identified in the file. You can then attempt to reload the reprocessable files without removing any of the error message description information that is contained in the file.

- [Reprocessable file format](#)

When you download the reprocessable file, it is provided in the same format as the original input file. If you use the flat file format, the file uses the same delimiter and text qualifier. The default file name for the reprocessable file is `<UniqueFileIdentifier>_<OriginalFileName>.<OriginalFileExtension>`

- [Deleting reprocessable files](#)

You can permanently delete data that is available to reprocess as a file.

## Downloading reprocessable files

You can download a reprocessable file and fix the processing errors identified in the file. You can then attempt to reload the reprocessable files without removing any of the error message description information that is contained in the file.

### Procedure

1. In the Message Reprocessing application, identify the source file from which you will be downloading its corresponding errors.
2. Verify that the source file has been fully processed by the data import process.  
The sum of the error count field and the processed count field must equal the imported count field.
3. Click the Download icon.
4. Save the reprocessable file to your client or to an accessible file server location.

## Reprocessable file format

When you download the reprocessable file, it is provided in the same format as the original input file. If you use the flat file format, the file uses the same delimiter and text qualifier. The default file name for the reprocessable file is `<UniqueFileIdentifier>_<OriginalFileName>.<OriginalFileExtension>`

## Example of an XML reprocessable file

A reprocessable file based on an XML file, includes an additional element in the main MBO of the original object structure. For example, a reprocessable file generated based on MXASSET information includes the MAXINTERROMSG element as part of the asset elements.

```
<?xml version="1.0" encoding="UTF-8"?>
<SyncMXASSET xmlns="http://www.ibm.com/maximo" transLanguage="EN">
 <MXASSETSet>
 <ASSET>
 <ANCESTOR />
 <ASSETID>94</ASSETID>
 <ASSETNUM>THREE_T2002</ASSETNUM>
 <ASSETTAG />
 <ASSETTYPE />
 ...
 ...
 <WARRANTYEXPDATE>2020-12-24T00:00:00-05:00</WARRANTYEXPDATE>
 <YTDCOST>0.0</YTDCOST>
 <MAXINTERROMSG>
 The following error occurred while processing ASSET.BMXAA4147E -
 Item set error1 does not exist.
 </MAXINTERROMSG>
 </ASSET>
 ...
 ...
 </MXASSETSet>
</SyncMXASSET>
```

## Example of flat format reprocessable file

Reprocessable files that follow a flat file structure include an additional column. For example, a reprocessable file generated based on MXASSET information includes the MAXINTERROMSG column at the end of the original record structure:

```
EXTSYS1,MXASSETInterface,,EN
ASSETNUM,AS_DESCRIPTION,AS_DESCRIPTION_LD,HIERARCHYPATH,AS_SITEID,MAXINTERROMSG
T-SP500_error,autospray,,,TEXAS,
The following error occurred while processing ASSET.BMXAA4049E -
The value specified T-SP500_error exceeds the maximum field length.
```

## Deleting reprocessable files

You can permanently delete data that is available to reprocess as a file.

### Procedure

1. In the Message Reprocessing application, identify the row of reprocessable data that you want to delete.
2. Click the Delete icon.

## Interface table error management

Interface tables can be used for inbound and outbound data exchange. Errors can occur when writing inbound data from an interface table to a queue or outbound data from a queue to an interface table.

If an error is encountered by the cron task that pulls an outbound message from a queue, the message remains in the queue until the error condition is addressed. Errors may occur for the following reasons:

- The interface table does not exist.
- There is database error due to lack of space.
- The message content, as defined by the object structure, was altered but the interface table was not recreated to reflect the new message format.

When an outbound message reaches an interface table, it is the responsibility of the external application to retrieve that data and manage errors based on their integration implementation.

The cron task that writes inbound messages to a queue can encounter errors for the following reasons:

- The JMS queue is deactivated or free space is not available.
- The enterprise service or external system name is not valid.
- The enterprise service is not enabled for the external system.
- The external system is not enabled.

When an error occurs during inbound interface table processing, the polling program writes the exception trace in the IMPORTMESSAGE column of the MXIN\_INTER\_TRANS queue table. For the first error in the MXIN\_INTER\_TRANS queue table, the system sends an email notification to the administrator. You can resolve the error condition by updating the row of data in MXIN\_INTER\_TRANS, for example, correcting the value of the external system name, or by updating the configuration data in the application, for example, marking the enterprise service as enabled.

After the cron task processes subsequent records in the MXIN\_INTER\_TRANS queue table, it switches to an idle state that is based on the defined cron task processing intervals. When processing resumes, the cron task tries to process the records in error, as well as new records added to the MAX\_INTER\_TRANS queue table.

After sending an error notification, the cron task does not send notification of additional errors if the queue table contains one transaction that is marked in error. It is assumed that the person who was notified of the initial error sees and corrects additional errors when the queue table is examined. After all current errors are corrected, the cron task sends a notification when it encounters a new error.

Any errors that occur after the cron task successfully writes an interface table message to an inbound queue are managed by the error handling process for the queues.

---

## Common causes of errors

Errors when processing messages in the outbound queue occur because there is a problem delivering a message to the endpoint that is specified for the external system. Errors when processing messages in an inbound queue are typically related to a business rule validation or in the inbound processing of the enterprise service.

For outbound processing, typical problems are disruptions of the communication link to the external application, issues with the database table space, or file space issues in the external application. To resolve an outbound error, you typically do not need to modify the XML or JSON message.

The following table describes the most common message errors that you can encounter and provides suggestions for correcting them. Correcting an error in the message can create a mismatch in data between the sending and receiving systems.

Error type	Description	Actions
Sequence error	Caused by sequencing problems between messages. The system stops message processing when a record references another record that is in a pending state.	This error is applied to ensure that records process in the correct order. Depending on the direction of the message transaction and the processing logic that applies, the processing can self-correct the error when the record that was in the pending state has processed.
Data error	Occurs because the data or record does not exist in the system database, and is not part of the inbound messages in the queue.	Add the missing data to the system database.
Communication error	Caused by communication problems with the external system from system failures or network issues.	Restore communication with the external system.
Message error	Caused by erroneous message data values.	<ul style="list-style-type: none"><li>• Change the transaction status to HOLD.</li><li>• Correct the error message.</li><li>• Change the transaction status to RETRY to reprocess the transaction.</li></ul>

---

## Error research

When you receive an error notification, look at the message in the Message Reprocessing application.

---

### No messages in error exist

If no message in error exists in the Message Reprocessing application, the message was retried and the error was not encountered again. The error message was deleted when the message was successfully processed.

For example, an error occurs in an inbound receipt message due to an incorrect general ledger (GL) account. After the error occurs, an online user enters that GL account in the system. The message is reprocessed successfully and the data is saved.

In another example, an outbound transaction encounters a communication error. When the communication problem is resolved, the message is sent to the external system and the message in error is deleted.

---

### One or more messages in error exist

When an error occurs in a sequential JMSQueue (inbound or outbound), processing of the queue stops until the error is resolved.

Messages are available to review and resolve in the Message Reprocessing application.

When an error occurs in a continuous queue, processing of the queue continues and additional errors can occur before the initial error is resolved. Multiple messages in error can exist in the Message Reprocessing application.

---

## Message tracking

The Message Tracking application tracks and displays the processing history of publish channel messages and queue-based enterprise service messages.

The Message Tracking application works with the Message Reprocessing application. When you use the Message Tracking application, you can determine which messages are flagged with an error. You then can select a failed message and go to the Message Reprocessing application to take appropriate action to correct erroneous data.

- **Message details**  
When you enable message tracking, the integration framework writes all processed messages to the MAXINTMSGTRK table. A status is assigned to each message which represents its current position in the queue-based processing cycle. Individual message events are displayed in the Message Details window.
- **Message status values**  
Every inbound and outbound queue-based message that is registered in the Message Tracking application has a status value that indicates its position in the transaction processing cycle.
- **Message events**  
The Message Tracking application tracks and displays inbound and outbound queue-based transaction processing events. Transaction processing events trigger the system to update the MAXINTMSGTRK table.
- **Message tracking configuration**  
You can track messages that are sent through publish channels or that are received from enterprise services.
- **Enabling message tracking**  
Enable message tracking for outbound transactions in the Publish Channels application and for inbound transactions in the Enterprise Services application.

---

## Message details

When you enable message tracking, the integration framework writes all processed messages to the MAXINTMSGTRK table. A status is assigned to each message which represents its current position in the queue-based processing cycle. Individual message events are displayed in the Message Details window.

When you enable message tracking, queue messages that existed before the function was enabled are not identified by the message tracking logic. When you disable message tracking, pre-existing queue messages that existed before the function was disabled are identified but new messages are not identified.

Messages have the following attributes, and values are assigned based on the originating enterprise service or publish channel data:

- Integration mode: The name of the integration mode used in processing the message. For inbound messages, the system assigns an MXJMS default value. For outbound messages, the system assigns the name of the endpoint that is used in message processing.
- Operation: The processing operation the system applies to the tracked message, which can be any of SYNC, UPDATE, QUERY, DELETE, CREATE, and PUBLISH.
- System: The name of the external system that is associated with either the enterprise service or publish channel.
- Integration component: The name of the enterprise service or publish channel.
- Adapter: The name of the adapter that is associated with either the enterprise service or publish channel.
- Queue name: The name of the queue used by the integration framework to process the message.

The following attributes are assigned values at the time the transaction record is created.

Attribute	Value
Received Datetime	The date and time the message was received in the queue.
Message ID	Unique message identifier that is assigned by the integration framework.
Search ID	Message identifier that is assigned by an external application and that is used in the message searches.
External Message ID	Unique message identifier that is assigned by an external application.

The following attributes have dynamic values that change based on the transaction events.

Attribute	Value
Current® Status	The most current processing status for the tracked message.
Status	The status that is associated with the individual message event in the transaction history.
Status Date	The status date for the individual message event in the transaction history.
Error	The error message for the individual error message event in the transaction history.

---

## Message status values

Every inbound and outbound queue-based message that is registered in the Message Tracking application has a status value that indicates its position in the transaction processing cycle.

The message tracking status indicates whether the message was successfully received or processed. The message tracking status also indicates whether the message was deleted, or flagged with errors.

---

## Inbound message status

Inbound messages can have the following status values:

Status	Description
ERROR	Message processing failed due to validation problems.
DELETED	Message was deleted from the queue.
PROCESSED	Message was successfully processed.

Status	Description
RECEIVED	Message was successfully written to the inbound queue.

## Outbound message status

Outbound messages can have the following status values:

Status	Description
ERROR	Message processing failed due to validation problems.
DELETED	Message was deleted from the queue.
PROCESSED	Message was successfully processed.
RECEIVED	Message was successfully written to the outbound queue.

## Message events

The Message Tracking application tracks and displays inbound and outbound queue-based transaction processing events. Transaction processing events trigger the system to update the MAXINTMSGTRK table.

The following message table attributes are updated according to event type:

- STATUS
- STATUSDATETIME
- ERRORMSG

The following inbound and outbound events update the MAXINTMSGTRK table:

Table 1. Tracked inbound and outbound events

Event	Details
Message is written to queue	<p>A record is created in the message tracking table when the integration framework first writes the message to the queue. When the message is successfully written to the queue, the message record status is set to RECEIVED.</p> <p>If the integration framework encounters an error when it is writing an inbound message to the queue, it sends a message to the process caller detailing the cause of failure.</p>
Error in message processing	The existing record in the message tracking table. When the asset management system encounters a processing error, it updates the message record status to ERROR. If you resend your message and a processing error occurs again, the asset management system maintains the ERROR message status.
End-of-queue processing	<p>The following transaction processing events update the existing record:</p> <ul style="list-style-type: none"> <li>• The asset management system successfully completes the message processing and updates the message record status to PROCESSED. Because the processing cycle is complete, no further updates are made to the message tracking table.</li> <li>• If you delete the message from the queue, the asset management system sets the message record status to DELETED. The message tracking table is no longer updated.</li> </ul>

## Message tracking configuration

You can track messages that are sent through publish channels or that are received from enterprise services.

In the Publish Channels and Enterprise Services applications, you can configure the following message tracking functions:

- Enable or disable message tracking.
- Store transaction messages in the database along with the tracking details.
- Specify the message data that the Message Tracking application search function uses by using an XPATH expression.
- Uniquely identify messages with a single ID value by using an XPATH expression.
- Identify messages with a search ID value by using an XPATH expression.

The XPATH expressions that are associated with the external message ID values and the search ID values can identify multiple nodes in an XML file. In this case, the message ID and search ID values are registered as a comma-separated list of values. Database field lengths are applicable to external ID and search ID fields. If necessary, you can adjust the length of these fields in the Database Configuration application.

## Stored messages

When you configure message tracking, messages and message tracking details are saved in the database and can be viewed in the Message Reprocessing application.

## External message tracking ID

Each inbound message has an external message identifier that is stored in the MAXINTMSGTRK table. With the Message Tracking application, you can use this external message ID to locate specific messages. The syntax that you use to identify a message node must be a fully qualified XPATH expression.

To find all messages for the MXPERSONInterface enterprise service, specify the following fully qualified XPATH expression in the External Message ID field:

```
{http://www.ibm.com/maximo}SyncMXPERSO@messageID
```

When a multi-noun inbound message is received, the integration framework uses the XPATH expression for the external message ID to identify the message. If the XPATH expression points to an element included in each one of the nouns in the inbound message, the integration framework creates a multi-noun, comma-separated list of external identifiers.

## Search ID

---

By specifying an XPATH expression to identify nodes, the integration framework can perform efficient multi-noun searches. The system stores the search identifier in the MAXINTMSGTRK table.

To find all messages for the MXPERSOInterface enterprise service, create the following fully qualified XPATH expression as the search ID:

```
{http://www.ibm.com/maximo}SyncMXPERSO/{http://www.ibm.com/maximo}MXPERSOSet/{http://www.ibm.com/maximo}PERSON/{http://www.ibm.com/maximo}PERSONID
```

When a multi-noun inbound message is received, the integration framework uses the XPATH expression for the search ID to identify the message. If the XPATH expression points to an element included in each one of the nouns in the inbound message, the integration framework creates a multi-noun, comma-separated list of search identifiers.

---

## Enabling message tracking

Enable message tracking for outbound transactions in the Publish Channels application and for inbound transactions in the Enterprise Services application.

## Procedure

---

1. In the Publish Channels application or the Enterprise Services application, select the channel or service that processes integration messages.
2. Select the Message Tracking action.
3. In the Message Tracking Setting window, select the Enable Message Tracking check box.
4. Optional: Select the Store Message check box to store transaction messages.
5. Optional: In the External Message ID field, specify one or more XPATH expressions to locate specific messages.
6. Optional: In the Search ID field, specify one or more XPATH expressions to search for messages.

---

## Cluster configuration

The integration framework can provide integration services across a cluster of application servers. If the continuous queue on a single server is inadequate for your message volume, you can add central processing units, hardware, and a cluster configuration to improve message processing performance.

When you implement a server cluster, you can use multiple servers simultaneously to process inbound messages. These messages are processed in the continuous queues by using message-driven beans (MDBs). Cluster configurations facilitate the processing of messages in large volumes.

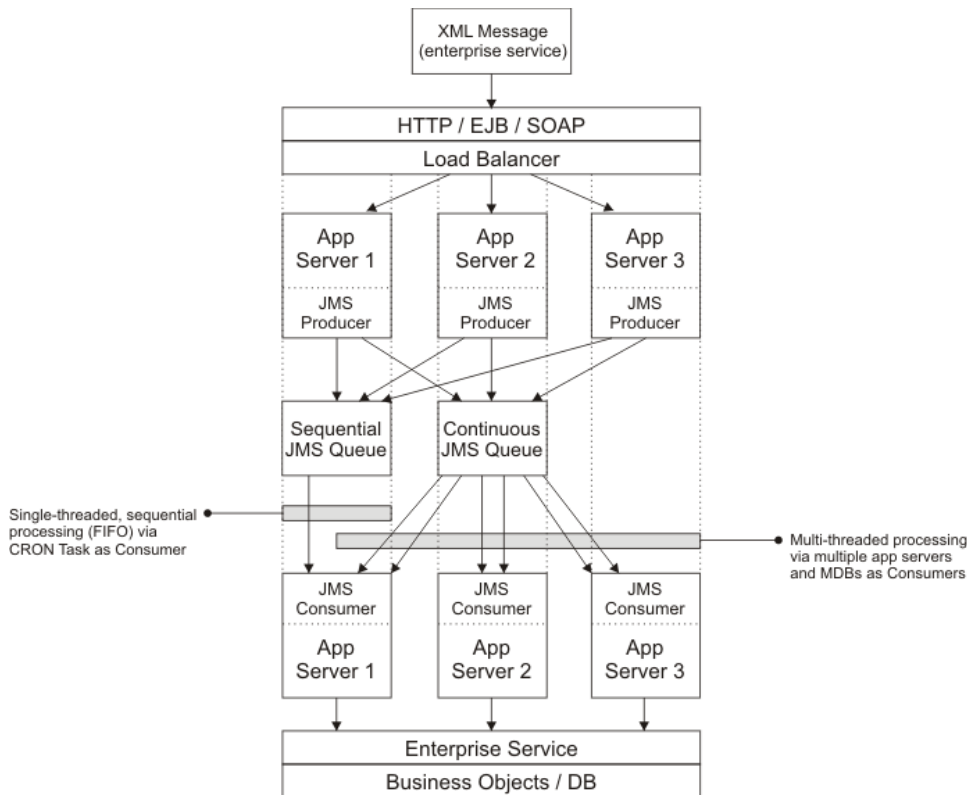

- [JMS queues in a server cluster](#)  
In a cluster configuration, JMS queues are associated with one member of the server cluster and access to the queues is provided by the Java™ Naming and Directory Interface (JNDI) service.
- [Configuring the cron task](#)  
The interface table cron task, the data import cron task, and the JMS queue cron task are cluster-aware functions. By default, the cron task framework runs a task on a randomly chosen server. You can configure a cron task to run on a specific application server within a server cluster. Use the donotrun parameter in the cron task framework to control which servers the cron task runs on.
- [Configuring a message processing server](#)  
For high volumes of inbound messages, you can improve server efficiency by moving inbound message processing to a separate application server or server cluster.
- [Global directory configuration](#)  
In a cluster environment, if you configure a global directory for management of integration files, the directory must be accessible to all members of the cluster.
- [Access to services by inbound messages](#)  
Enterprise services, object structure services, and standard services can all function in a server cluster.

---

## JMS queues in a server cluster

In a cluster configuration, JMS queues are associated with one member of the server cluster and access to the queues is provided by the Java™ Naming and Directory Interface (JNDI) service.

The JDNI service is available across all the members on the cluster.

All cluster members can produce messages into the sequential queue. A single-threaded cron task reads the messages in the sequential queue to support first-in-first-out processing.

The continuous queue is multi-threaded on the consumer side to support message processing in high volumes. In this queue, the message processing order is not considered.

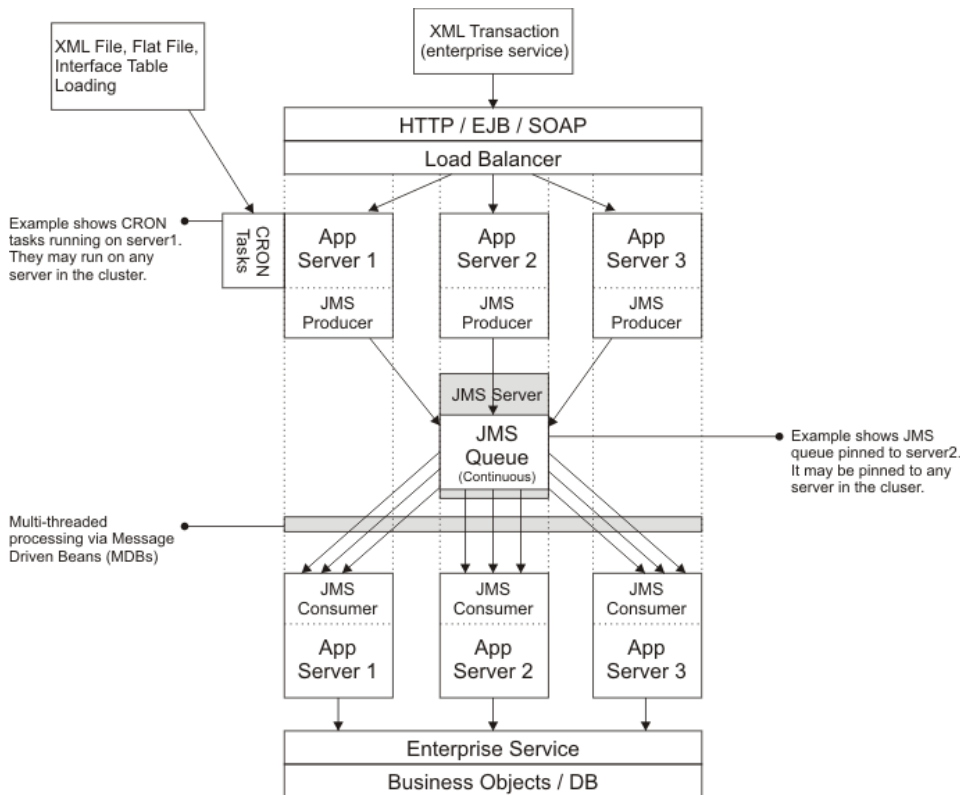

Enterprise service messages that use the sequential queue are processed in a strict sequential order. Message processing is single-threaded. Clustering does not significantly impact the processing performance of messages through the sequential queue.

- [Continuous queue on an application server cluster](#)  
In a clustered environment, you can pin the continuous JMS queue to one member of the cluster.
- [Sequential queue on an application server cluster](#)  
The sequential queue receives JMS producer messages and processes the JMS consumer messages.

## Continuous queue on an application server cluster

In a clustered environment, you can pin the continuous JMS queue to one member of the cluster.

The following diagram shows an example of a cluster configuration on an application server. The continuous queue receives JMS producer messages and processes the JMS consumer messages.

In the example, three application servers exist in the clustered environment. The continuous JMS queue is pinned to one member of the cluster.

The processing occurs when the integration framework receives enterprise service messages by using HTTP, enterprise beans, and SOAP actions. The load balancer directs the application server to drop enterprise service messages into the continuous queue. Each member of the cluster places messages into the queue, which exists on one member of the cluster.

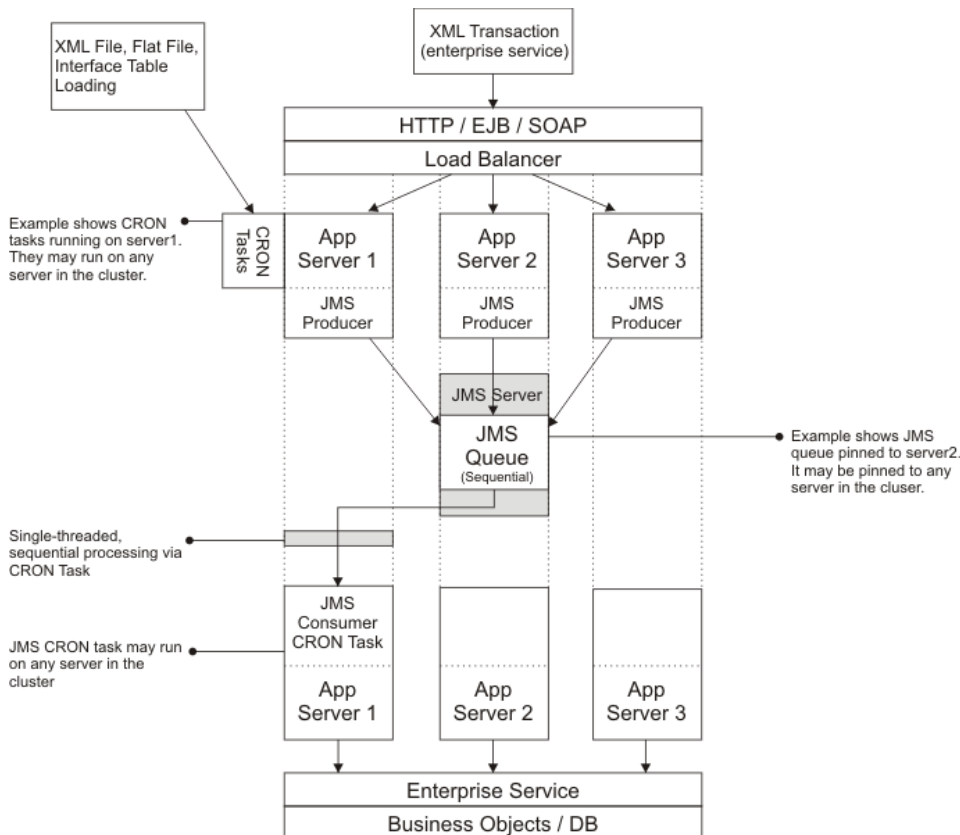

An integration cron task delivers enterprise service messages from flat or XML files and interface tables. The cron tasks that place messages into the queue can run on any server in the cluster.

After messages are in the queue, all application servers can simultaneously pull messages from the queue and process them into the system. Message-driven beans must be enabled on each application server in the cluster.

## Sequential queue on an application server cluster

The sequential queue receives JMS producer messages and processes the JMS consumer messages.

The following diagram shows one example of a cluster configuration on application servers.

In the example, three application servers exist in the clustered environment. The sequential JMS queue is pinned to one member of the cluster.

The processing occurs when the integration framework receives enterprise service messages by using HTTP, enterprise beans, and SOAP actions. The load balancer directs the application server to drop enterprise service messages into the sequential queue. Each member of the cluster places messages into the queue, which exists on one member of the cluster.

An integration cron task delivers enterprise service messages from flat or XML files and interface tables. The cron tasks that place messages into the queue can run on any server in the cluster. Once messages are in the queue, the application server that is running the JMS consumer cron task processes messages in a sequential order.

Unlike the continuous queue, there is no multi-threading of messages by design. A cluster implementation does not significantly impact the processing performance of messages that process through the sequential queue.

## Configuring the cron task

The interface table cron task, the data import cron task, and the JMS queue cron task are cluster-aware functions. By default, the cron task framework runs a task on a randomly chosen server. You can configure a cron task to run on a specific application server within a server cluster. Use the `donotrun` parameter in the cron task framework to control which servers the cron task runs on.

## Configuring a message processing server

For high volumes of inbound messages, you can improve server efficiency by moving inbound message processing to a separate application server or server cluster.

### Procedure

1. Deploy a separate application EAR file on the message processing server or server cluster.
2. On the message processing application server or server cluster, use the `donotrun` parameter in the cron task framework to control which servers the cron task runs on.
3. Optional: Configure message-driven beans to pull data from the inbound continuous queue.  
Do not enable message-driven beans for inbound processing within the server or server cluster that is dedicated for online users. You can run other background processing cron tasks on this server or server cluster.
4. Optional: Grant user interface access to users who use of the data import feature.

## Global directory configuration

In a cluster environment, if you configure a global directory for management of integration files, the directory must be accessible to all members of the cluster.

Depending upon your use of the integration framework components, files may or may not be written to the global directory. In a multitenancy environment, a global directory is required. One of the main reasons for configuring a global directory is to support the use of file-based endpoints. If you intend to use file-based endpoints for invocation channels and messages are initiated by application users that are configured in a UI cluster, all members of the cluster must have visibility to the global directory.

To define the global directory, update the `mxe.int.globaldir` system property in the System Properties application.

---

## Access to services by inbound messages

Enterprise services, object structure services, and standard services can all function in a server cluster.

An inbound transaction can access the relevant service with any of the following communication methods:

- REST API, Internet Inter-ORB Protocol (IIOP), and enterprise beans
- HTTP and HTTPS servlet
- SOAP, HTTP, and HTTPS servlet

---

## Enterprise beans

With a single server, the provider URL for accessing the JNDI tree is the single server URL. With a server cluster, the provider URL can be the URL of any of the servers that has the enterprise beans deployed. All members of the cluster share the JNDI tree and any member of the cluster can look for and retrieve a cluster.

Following a cluster look up, the client retrieves a cluster-aware proxy of the enterprise beans which load balances all the subsequent calls that use that proxy. Load balancing happens transparently to the client code. There is no difference between the code for a single server and for a cluster setup. A separate enterprise bean is deployed for each type of service: object structure service, enterprise service, and standard service.

---

## HTTP servlet

The integration servlet is deployed across all members of the cluster. With a single server configuration, the URL is the HTTP and HTTPS URL of that server. With a cluster server configuration, the URL is the HTTP and HTTPS URL of the load balancer for the cluster. A separate servlet is deployed for each type of service: object structure, enterprise, and standard service.

The URL formats for each service are shown in the following table. The `meaweb` variable in the URL represents the value you specify for the `mxe.int.webappurl` in the System Properties application.

Service	URL
Object structure service	<code>http://hostname:port/meaweb/os/object structure name</code>
Enterprise service (bypassing queue)	<code>http://hostname:port/meaweb/es/extsysname/enterprise service name</code>
Enterprise service (through the queue)	<code>http://hostname:port/meaweb/esqueue/extsysname/enterprise service name</code>
Standard service	<code>http://hostname:port/meaweb/ss/standard service name</code>

---

## Web services

Integration web services are homogeneously deployed across all the server members in the cluster. Web service access for a cluster is the same as for a single server, except that the web service URL and Web Service Definition Language (WSDL) URL point to the cluster instead of to a specific server in the cluster.

The following properties must point to the cluster URL:

- Web application URL `mxe.int.webappurl`
- UDDI registry inquiry URL `mxe.int.uddiinurl`
- UDDI registry publish URL `mxe.int.uddipuburl`

The URL to access a web service is `http://hostname:port/meaweb/services/web service name`. The `meaweb` variable in the URL represents the value you specify for the `mxe.int.webappurl` in the System Properties application.

---

## Integration security

The integration framework includes support for J2EE authentication and for component-level authorization.

- [Authentication security](#)  
You can configure J2EE authentication security for JMS queues, EJB, HTTP, and web services. You can also configure authentication security for remote integration APIs and for the Java™ handler classes for outbound routing.
- [Authorization security](#)  
You can configure authorization security at application level, object level, object structure level, or at the level of a method defined in a standard service. After user authentication completes, the integration framework checks that the user has been granted the authority to send messages to the target application, object, object structure, or method.

---

## Authentication security

You can configure J2EE authentication security for JMS queues, EJB, HTTP, and web services. You can also configure authentication security for remote integration APIs and for the Java™ handler classes for outbound routing.

- [Configuring J2EE security](#)  
The integration framework supports basic J2EE security to restrict access based on authentication and authorization.
- [Interface table security](#)  
Interface tables use the default database authentication and authorization. If authentication and authorization are in effect, external programs that read or write to the interface tables must provide proper authorization. To read from and write to the interface tables, the USERNAME and PASSWORD values are configured for the endpoint that implements the interface table handler.
- [Securing remote integration APIs](#)  
Some MicService remote APIs secure access by forcing the user of those methods to provide the UserInfo object. If a valid UserInfo object is not provided, an error occurs and the call is not completed.
- [Outbound router handler security](#)  
The outbound router handlers have support for authorization and confidentiality. The enterprise bean, HTTP, JMS, web service, and interface table handlers have support for security.

---

## Configuring J2EE security

The integration framework supports basic J2EE security to restrict access based on authentication and authorization.

- [Configuring J2EE restrictions for JMS queues](#)  
The JMS queues that are used by integration processing support J2EE security, based on user ID and password-based authentication and authorization. You can prevent unauthorized access to the queue by assigning a user ID and password to the Java Naming and Directory Interface (JNDI) name, even if the JNDI name of the queue is known.
- [Securing enterprise bean access](#)  
If J2EE Authentication on the system is enabled, you must enable the security for each enterprise bean in the deployment descriptors.
- [Securing the HTTP servlet](#)  
The HTTP servlet is a J2EE component that handles inbound HTTP posts. To secure the HTTP servlet, you must first secure the enterprise bean. You can use HTTP basic authentication to secure the HTTP servlet. Authorized users, with a valid user name and password can post an XML transaction to the system.
- [Securing web services](#)  
You can secure integration web services by using HTTP basic authentication in standard J2EE security. These security settings provide access to web services to authorized users with a valid user name and password.

---

## Configuring J2EE restrictions for JMS queues

The JMS queues that are used by integration processing support J2EE security, based on user ID and password-based authentication and authorization. You can prevent unauthorized access to the queue by assigning a user ID and password to the Java™ Naming and Directory Interface (JNDI) name, even if the JNDI name of the queue is known.

---

## About this task

Multiple queues can use the same or different user identifications.

---

## Procedure

1. On the administrator console for the server, specify user ID and password values for the following properties, to enable J2EE restrictions:
  - java.naming.security.principal (user ID)
  - java.naming.security.credentials (password)
2. In the External Systems application, select the Add/Modify Queues action and specify the same user ID and password that you provided in Step 1.  
This step provides access to the queue to the integration producer and consumer programs.
3. To provide access to the continuous queue, under the <enterprise-beans> section in the ejb-jar.xml file, add the <security identify> elements shown in bold text:

```
<enterprise-beans>
 <message-driven
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mif.doc_gp_intfrmwk_t_security_j2ee_restriction
s_MessageDriven_JMSContQueueProcessor_1">
 <ejb-name>JMSContQueueProcessor-1</ejb-name>
 <ejb-class>psdi.iface.jms.JMSContQueueProcessor</ejb-class>
 <transaction-type>Container</transaction-type>
 <message-driven-destination>
 <destination-type>javax.jms.Queue</destination-type>
 </message-driven-destination>
 <env-entry>
 <env-entry-name>MESSAGEPROCESSOR</env-entry-name>
 <env-entry-type>java.lang.String </env-entry-type>
 <env-entry-value>
 psdi.iface.jms.QueueToMaximoProcessor
 </env-entry-value>
 </env-entry>
 </message-driven>
</enterprise-beans>
```

```

</env-entry>
 <security-identity>
 <run-as>
 <role-name>maximouser</role-name>
 </run-as>
 </security-identity>
</message-driven>

```

- Under the <assembly-descriptor> section in the ejb-jar.xml file, add the <security-role> elements shown in bold text:

```

<assembly-descriptor>
 <security-role>
 <role-name>maximouser</role-name>
 </security-role>
 <container-transaction>
 <method>
 <ejb-name>JMSSContQueueProcessor-1</ejb-name>
 <method-name>*</method-name>
 </method>
 <trans-attribute>Required</trans-attribute>
 </container-transaction>
</assembly-descriptor>

```

## Securing enterprise bean access

If J2EE Authentication on the system is enabled, you must enable the security for each enterprise bean in the deployment descriptors.

### About this task

Under the <enterprise-beans> section of the ejb-jar.xml file, three integration EJBs are deployed with a default value of 1, which indicates that no authentication is required.

The <ejb-name> to service mapping is:

<ejb-name>	Service
enterpriseservice	Enterprise Service
mosservice	Object Structure Service
actionservice	Standard Service

### Procedure

- To force authentication, change the ALLOWDFLTLOGIN value to 0 (false), for each of three services, indicated in bold in the following code example:

```

<enterprise-beans>
<session
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mif.doc_gp_intfrmwk_t_security_enterprise_bean_S
ession_enterpriseservice">

 <role-link>maximouser</role-link>
 </security-role-ref>
</session>

```

Client programs call the secure version of the enterprise bean methods for each service type:

- Enterprise service: `secureProcessExtneralDataAsync(..)` , `secureProcessExtneralDataSync(..)`
  - Object structure service: `secureProcessMOS(..)`
  - Standard service: `secureAction(..)`
2. To create a secure context for calling the enterprise bean, perform either one of the following tasks:
- Add the following code to to the client code:

```

Properties env = new Properties();
.
.
.
if(userid != null && password != null)
{
 env.put(Context.SECURITY_CREDENTIALS, password);
 env.put(Context.SECURITY_PRINCIPAL, userid);
}

Context ctx = new IntialContext(env);
//instead of using the default IntialContext() constructor

```

- Use the default `IntialContext` constructor to pass the security information through `-D` parameters in the `.bat/.sh` script that launches the client:

```

-Djava.naming.security.principal=<username>
-Djava.naming.security.credentials=<password>

```

The SSL version of the Internet Inter-ORB protocol performs data encryption in the provider URL, while the system communicates with the enterprise bean.

## Securing the HTTP servlet

The HTTP servlet is a J2EE component that handles inbound HTTP posts. To secure the HTTP servlet, you must first secure the enterprise bean. You can use HTTP basic authentication to secure the HTTP servlet. Authorized users, with a valid user name and password can post an XML transaction to the system.

### About this task

To enable HTTP basic authentication, modify the `web.xml` file of the Web application:

- Remove the comments from the `<security-constraint>` section of the integration servlets. There are three `<security-constraint>` sections, one for each type of service: enterprise service, object structure service, and standard service.

The `<web-resource-name>` to service mapping is:

<code>&lt;web-resource-name&gt;</code>	Service
Enterprise Service Servlet	Enterprise Service
App Service Servlet	Standard Service
Object Structure Service Servlet	Object Structure Service

## Procedure

1. In the web.xml file, uncomment the security constraint sections for each service type, as in the following code example:

```
<!--
<security-constraint>
 <web-resource-collection>
 <web-resource-name>Enterprise Service Servlet</web-resource-name>
 <description>
 Enterprise Service Servlet (HTTP POST) accessible by authorized users
 </description>
 <url-pattern>/es/*</url-pattern>
 <url-pattern>/esqueue/*</url-pattern>
 <http-method>GET</http-method>
 <http-method>POST</http-method>
 </web-resource-collection>
 <auth-constraint>
 <description>
 Roles that have access to Enterprise Service Servlet (HTTP POST)
 </description>
 <role-name>maximouser</role-name>
 </auth-constraint>
 <user-data-constraint>
 <description>data transmission gaurantee</description>
 <transport-guarantee>NONE</transport-guarantee>
 </user-data-constraint>
</security-constraint>

<security-constraint>
 <web-resource-collection>
 <web-resource-name>App Service Servlet</web-resource-name>
 <description>
 App Service Servlet (HTTP POST) accessible by authorized users
 </description>
 <url-pattern>/ss/*</url-pattern>
 <http-method>GET</http-method>
 <http-method>POST</http-method>
 </web-resource-collection>
 <auth-constraint>
 <description>
 Roles that have access to App Service Servlet (HTTP POST)
 </description>
 <role-name>maximouser</role-name>
 </auth-constraint>
 <user-data-constraint>
 <description>data transmission gaurantee</description>
 <transport-guarantee>NONE</transport-guarantee>
 </user-data-constraint>
</security-constraint>

<security-constraint>
 <web-resource-collection>
 <web-resource-name>Object Structure Service Servlet</web-resource-name>
 <description>
 Object Structure Service Servlet (HTTP POST) accessible by authorized users
 </description>
 <url-pattern>/os/*</url-pattern>
 <http-method>GET</http-method>
 <http-method>POST</http-method>
 </web-resource-collection>
 <auth-constraint>
 <description>
 Roles that have access to Object Structure Service Servlet (HTTP POST)
 </description>
 <role-name>maximouser</role-name>
 </auth-constraint>
 <user-data-constraint>
 <description>data transmission gaurantee</description>
 <transport-guarantee>NONE</transport-guarantee>
 </user-data-constraint>
</security-constraint>

-->
```

2. Verify that the <security-role> section in the web.xml file is not commented out, as in the following example code:

```
<security-role>
 <description>An Integration User</description>
 <role-name>maximouser</role-name>
</security-role>
```

3. Change the value from 0 to 1 in the useAppServerSecurity <env-entry-name> section, as in the following example:

```
<description>
 Indicates whether to use Application Server security or not
</description>
<env-entry-name>useAppServerSecurity</env-entry-name>
<env-entry-type>java.lang.String</env-entry-type>
<env-entry-value>1</env-entry-value>
</env-entry>
```

## What to do next

---

You can securely deploy a web service by using a Secure Socket Layer (SSL) for HTTPS posts. Configure the SSL on the application server with the appropriate digital certificates.

## Securing web services

---

You can secure integration web services by using HTTP basic authentication in standard J2EE security. These security settings provide access to web services to authorized users with a valid user name and password.

### Procedure

---

1. Similar to the procedure for securing the HTTP servlet, in the web.xml file, uncomment the <security-constraint> section for the web service invocation, as in the following example

```
<security-constraint>
 <web-resource-collection>
 <web-resource-name>Integration Web Services</web-resource-name>
 <description>
 Integration Web Services accessible by authorized users
 </description>
 <url-pattern>/services/*</url-pattern>
 <http-method>GET</http-method>
 <http-method>POST</http-method>
 </web-resource-collection>
 <auth-constraint>
 <description>
 Roles that have access to Integration Web Services
 </description>
 <role-name>maximouser</role-name>
 </auth-constraint>
 <user-data-constraint>
 <description>data transmission gaurantee</description>
 <transport-guarantee>NONE</transport-guarantee>
 </user-data-constraint>
</security-constraint>
```

2. Verify that the <security-role> section in the web.xml file is not commented out, as in the following example code:

```
<security-role>
 <description>An Integration User</description>
 <role-name>maximouser</role-name>
</security-role>
```

3. Change the value from 0 to 1 in the useAppServerSecurity <env-entry-name> section, as in the following example:

```
<description>
 Indicates whether to use Application Server security or not
</description>
<env-entry-name>useAppServerSecurity</env-entry-name>
<env-entry-type>java.lang.String</env-entry-type>
<env-entry-value>1</env-entry-value>
</env-entry>
```

4. For web service invocation, ensure that the client program uses the following user name and password calls in the JAX-RPC Call object:

```
call.setProperty(Call.USERNAME_PROPERTY, username);
call.setProperty(Call.PASSWORD_PROPERTY, password);
```

## What to do next

---

You can securely deploy a web service by using a Secure Socket Layer (SSL) for HTTPS posts. Configure the SSL on the application server with the appropriate digital certificates.

## Interface table security

---

Interface tables use the default database authentication and authorization. If authentication and authorization are in effect, external programs that read or write to the interface tables must provide proper authorization. To read from and write to the interface tables, the USERNAME and PASSWORD values are configured for the endpoint that implements the interface table handler.

## Securing remote integration APIs

---

Some MicService remote APIs secure access by forcing the user of those methods to provide the UserInfo object. If a valid UserInfo object is not provided, an error occurs and the call is not completed.

The following remote methods are protected because they either provide sensitive information or perform sensitive data transaction processing:

- `exportData(..)`
- `deleteQueueData(..)`
- `processExternalData(..)` (both versions)
- `query(..)`
- `viewQueueData(..)`
- `loadData(..)`
- `loadSystemData(..)`
- `processObjectStructure(..)`
- `routeData(..)`

To run these methods, the caller must retrieve a valid `UserInfo` object and pass it to the method to gain access to the secure layer.

A `UserInfo` object is a serialized object that contains user details including user, password, locale, language, and time zone information, that is used for security purposes.

The system uses REST API and Java™ Remote Method Protocol (JRMP). You can communicate to the system services by using a secure version of JRMP protocol using SSL.

---

## Outbound router handler security

The outbound router handlers have support for authorization and confidentiality. The enterprise bean, HTTP, JMS, web service, and interface table handlers have support for security.

---

## Authorization security

You can configure authorization security at application level, object level, object structure level, or at the level of a method defined in a standard service. After user authentication completes, the integration framework checks that the user has been granted the authority to send messages to the target application, object, object structure, or method.

Manage provides configurable user-based and group-based authorization for its applications by using security signature options (sigoptions). A Manage application is the resource unit that is protected by the access control list (ACL) and sigoptions are the unit permissions for that resource. To secure an integration resource, such as an object structure, you can associate that resource with a Manage application and the object structure then inherits its permissions from the application.

However, this tightly coupled configuration may not be ideal for some users. For example, users who are authorized to use the Asset application may not want authorization to use the MXAPIASSET object structure for integration purposes. In this case, you can configure the object structure to have its own authorization.

A security administrator can configure the sigoptions for an object structure independent of the configuration for an application. These sigoptions are the unit permissions for the object structure.

To provide the most flexible security configuration, it is recommended that all object structures have their own authorization independent of applications.

---

## Object-level authorization

Object-level authorization is based on the security configuration that is set in the Data Restrictions tab of the Security Groups application. This security configuration applies to data that is accessed by both Manage applications and integration processing. For integration processing, if an object or attribute is marked as read-only or hidden, inbound message data processing is limited to queries. You cannot insert, update, or delete data in an object or attribute that is marked as read-only or hidden.

---

## Object structure-level authorization

If the `mxe.int.enableosauth` system property is set to 1, you must configure the authorization of the object structure before external users or applications can access and update data by using that object structure. When the system property is set to 0, authorization configuration is not required.

You configure object structure-level authorization by using the Configure Object Structure Security action in the Object Structures application. You can configure authorization for the object structure in the following two ways:

1. You configure the object structure to inherit its authorization from a related application.
  - To configure the authorization in this way, in the Authorization Name field, specify the application name. The signature options of the application are used by default for the object structure. You can add additional signature options to apply to both the object structure and the application.
2. You configure the object structure to have its own authorization by using signature options.
  - To configure the authorization in this way, check the Use Object Structure for Authorization Name check box. The authorization name is set to the object structure name, and the default insert, delete, save, and read options are assigned. For some object structures, you can then create signature options for any supported services that are available by using the object structures. Click Select Service Option to view and create signature options for these services.

After authorization for the object structures is defined, a security administrator can configure the authorization for a security group by using the Security Groups application.

---

## Application-level authorization

You configure application-level authorization in the Object Structures application. In the Authorized Application field, specify the application to authorize. The specified application and the user group of the integration message user together provide authorization for inbound integration messages for object structures and enterprise services. The combination of application and user group also provide authorization for the export of data related to this object structure.

If you use the REST API, you might need to configure application-level authorization to access business object resources.

## Standard service authorization

Standard service authorization does not support the use of a condition that you associate with the signature option. Any condition that you assign is ignored.

You can configure a standard service transaction to take on the same security profile for the integration user as if that user entered the transaction through an application. This level of authorization requires manual configuration. The application service must have a properly annotated method and the service must be registered in the Database Configuration application. Assign a signature option to a standard service to limit access to the users or groups that are authorized for the selected option.

Run a SQL script that updates the MAXSERVSECURITY table with the details of the standard service to authorize. The insert statement for the MAXSERVSECURITY must include the fields listed in the following table.

Field	Description
MAXSERVSECURITY ID	A unique ID that is numeric. You can, for example, query the max(MAXSERVSECURITYID) from MAXSERVSECURITY and use the next sequential value.
ROWSTAMP	A unique ID that is numeric. You can, for example, query the max(ROWSTAMP) from MAXSERVSECURITY and use the next sequential value.
SERVICENAME	The service name registered in the Database Configuration application (MAXSERVICE.SERVICENAME).
APP	The application name where the signature option is configured to (MAXAPPS.APP).
METHODNAME	The name of the annotated method in the application service.
OPTIONNAME	This value is a combination of the signature option table for the application and the signature option (SIGOPTION.OPTIONNAME).

## Language support

Your database can contain some elements, such as descriptions and long descriptions, in multiple languages. Publish channels and enterprise services can include these translated columns. The integration framework also supports the use of bidirectional language formats.

A single database can contain data in multiple languages. You specify the base language when you install the application. If your system uses a language that differs from the base language, you can enable the integration framework to send and receive data that is not in the base language data.

- [Default processing of multiple languages](#)  
When you log in, you can choose a language code other than the base language for the system. In any application, you can then enter language-specific values for columns that are designated as translatable.
- [Multilanguage attributes](#)  
The root element of the XML structure for services and channels includes language attributes that specify the language attributes for the record.
- [Bidirectional language support](#)  
The integration framework supports bidirectional languages such as Arabic and Hebrew and enables data exchange with external systems that use different bidirectional language formats. Bidirectional languages combine characters that you read from right to left with some characters, such as numbers or dates, that read from left to right.
- [Bidirectional language formats](#)  
The default bidirectional formats used by the integration framework are based on Unicode standards. These formats can differ from the formats used by external systems.
- [Configuring bidirectional language support for external systems](#)  
Specify the bidirectional language format used by an external system to enable the correct transformation of data to (and from) the default format.

## Default processing of multiple languages

When you log in, you can choose a language code other than the base language for the system. In any application, you can then enter language-specific values for columns that are designated as translatable.

By default, outbound transactions contain the applicable column values in the language that is associated with the login session. The language values display whether the transaction is initiated by an application or the data export feature. For example, if the base language of your system is English, you can log in as a French user and update an item record with a French description. The outbound message contains the item description in French, even when the description also exists in English, or a third language.

If a database table contains translatable columns, the database contains a corresponding table called L\_tablename, for example, ITEM and L\_ITEM. The L\_tablename table stores the non-base language values for every translated column except the long description. Long descriptions in all languages are in the LONGDESCRIPTION table.

To include translated values in the outbound message, include the L\_tablename and LONGDESCRIPTION objects in the applicable object structures. Provide the base language values as a service input to object structures that have the L\_tablename as part of their object definition. Your service input must be in the core object, and all other languages must be in the additional language enabled object.

For example, when English is the base language, the ITEM table contains the English description of an item and the L\_ITEM table contains the French and German descriptions of that item. The LONGDESCRIPTION table contains the English, French, and German long descriptions.

When you add the `L_tablename` object to an object structure, assign the same value to the `transLanguage` and `baseLanguage` attributes. Otherwise, the base language values are not available and are processed for the multilanguage-enabled fields.

## Multilanguage attributes

The root element of the XML structure for services and channels includes language attributes that specify the language attributes for the record.

The following language attributes are used:

- The **baseLanguage** attribute identifies the base language of the system or application that generates outbound message. For inbound transactions, this attribute is not validated.
- Output XML or JSON includes the **langenabled** attribute on every translatable column, as shown in the following example:  

```
<DESCRIPTION langenabled="1">Item 1 description</DESCRIPTION>
```
- The **transLanguage** attribute identifies the language in which the values for applicable multilanguage fields are specified. If this attribute is missing or does not contain a value, all data is assumed to be in the base language. If the **transLanguage** value cannot be interpreted, or if the value does not identify a valid language, an error is returned to the service requester.

## Bidirectional language support

The integration framework supports bidirectional languages such as Arabic and Hebrew and enables data exchange with external systems that use different bidirectional language formats. Bidirectional languages combine characters that you read from right to left with some characters, such as numbers or dates, that read from left to right.

The integration framework can transform the bidirectional formats of all inbound and outbound data to and from the bidirectional format specified for the external system. The transformations apply to synchronous and asynchronous communications for enterprise services, object structure services, and standard services. You can also transform the bidirectional formats of files you import with a cron task or when you use the data import feature.

## Bidirectional language formats

The default bidirectional formats used by the integration framework are based on Unicode standards. These formats can differ from the formats used by external systems.

Bidirectional formats have five parameters.

Parameter	Value	Flags	Default	Details
Text Type	<ul style="list-style-type: none"><li>• Implicit</li><li>• Visual</li></ul>	<ul style="list-style-type: none"><li>• I</li><li>• V</li></ul>	I: Implicit (logical)	
Text Orientation	<ul style="list-style-type: none"><li>• LeftToRight</li><li>• RightToRight</li><li>• ContextualLeftToRight</li><li>• ContextualRightToLeft</li></ul>	<ul style="list-style-type: none"><li>• L</li><li>• R</li><li>• C</li><li>• D</li></ul>	L: LeftToRight	
Text Symmetric Swapping	<ul style="list-style-type: none"><li>• On</li><li>• Off</li></ul>	<ul style="list-style-type: none"><li>• Y</li><li>• N</li></ul>	Y: On	
Text Shaping	<ul style="list-style-type: none"><li>• Not Shaped</li><li>• Shaped</li><li>• Isolated</li></ul>	<ul style="list-style-type: none"><li>• N</li><li>• S</li><li>• B</li></ul>	N: Not Shaped	Arabic only
Numerals Shaping	<ul style="list-style-type: none"><li>• National</li><li>• Nominal</li><li>• ContextualNational</li><li>• ContextualNominal</li></ul>	<ul style="list-style-type: none"><li>• H</li><li>• N</li><li>• C</li><li>• T</li></ul>	N: Nominal	Arabic only

## Configuring bidirectional language support for external systems

Specify the bidirectional language format used by an external system to enable the correct transformation of data to (and from) the default format.

### Procedure

1. Optional: Select the Bidirectional Format action in the External Systems application for enterprise services or in the Invocation Channels application for object structure services.
2. Select the bidirectional language format used by the external system from the list of options and click OK.

## Results

---

After setting the bidirectional language format used by an external system, transformation to the appropriate format occurs automatically during integration processing.

---

## Exporting and importing file-based data

The integration administrator can initiate export and import data from within the External Systems application to support, for example, integrating data using files. The import process includes the ability to preview a data load from a file to validate the data prior to saving it to the database. The import process also includes an option to manage errors that result from file loading in the same file format as the imported file

You can use file-based error management as an alternative to managing errors through the Message Reprocessing application. Importing data from files, in flat file, JSON, or XML format, can be done on a scheduled basis using a predefined cron task. Additionally, administrators can enable an application for export and import, and users can then export and import data directly from within the enabled application.

- [Exporting and importing data in the External Systems application](#)  
You can initiate a data export in the Publish Channels tab of the External Systems application. You can initiate a data import in the Enterprise Services tab of the External Systems application.
- [Importing S3 data by using cron tasks](#)  
To import data from Cloud Object Storage, you can use a cron task to import data that is read by the Simple Storage Service (S3) handler.
- [Cron tasks for processing inbound data](#)  
If you want to schedule file loads rather than using the data import window, you must create, configure, and enable the XMLFILECONSUMER cron task and the FLATFILECONSUMER cron task before cron task message processing can occur.
- [Configuring applications for data export and import](#)  
To enable application-based data import and export you must define the content of an object structure and enable this object structure for import and export.

---

## Exporting and importing data in the External Systems application

You can initiate a data export in the Publish Channels tab of the External Systems application. You can initiate a data import in the Enterprise Services tab of the External Systems application.

- [Exporting data](#)  
To export a batch of message data to an external system, you can use the data export feature in the External Systems application. You can initiate the export process for each publish channel that is associated with an external system.
- [Exporting data in sequential batches](#)  
To export multiple batches of message data to an external system, you can use the Bulk Data Exports action in the External Systems application. When you use this feature, exports are processed in order based on the sequence that you specify for the publish channels.
- [Importing file-based data](#)  
You can use the data import feature to load data from either XML, JSON, or flat, delimited files to update the database. You can preview and validate the data prior to loading it and committing it to the database. You can choose to manage errors with the Message Reprocessing application or by extracting errors to a file format that is the same as the imported file format.
- [Importing data by using a REST API call](#)  
You can use the Get External Data option on the Enterprise Services tab in the External Systems application to import data from external sources using a REST API call.

---

## Exporting data

To export a batch of message data to an external system, you can use the data export feature in the External Systems application. You can initiate the export process for each publish channel that is associated with an external system.

## Before you begin

---

You must configure an endpoint to the data destination.

In addition to configuring an endpoint, you must enable both the external system and the publish channel before you can export data. The data for export must either be in an XML, JSON, or delimited flat file format that conforms to the object structure schema. A delimited flat file, such as comma separated, is a flattened version of the object structure schema format.

---

## Procedure

1. In the External Systems application, click the Publish Channels tab and select the publish channel that you want to export.
2. In the End Point field, specify the destination for the outbound data.
3. Click Data Export to specify more criteria for the data export. Enter selections in one or more of the following fields.
  - a. In the Export Condition field, specify a SQL query to select records for export.  
For example, specify `assetnum like '11%' and siteid='BEDFORD'` to export all asset records that start with 11 and are in the Bedford site.  
The query must be specified on the primary or top-level object in the publish channel object structure.

The query can affect the size of the exported message. The export process performs the standard outbound processing on the result set of the query for the selected publish channel.

- b. In the Export Order By field, specify one or more fields by which records are sorted on export.

You can specify ASC or DESC order.

For example, specify `assetnum DESC` to order the exported data by descending asset ID.

The ORDER BY statement must apply to the primary, or top-level, object in the integration object.

- c. In the Export Count field, specify a value to limit the number of records in the export file.

If the result of the query contains more records than the number you specify, those records are not included in the exported data.

4. To break up the data and store it in the queue as separate files, specify a value in the Batch Size field.

If the number of records is larger than the batch size that you specify, the export data is split into a transaction with multiple files and stored separately.

5. Click OK to begin exporting the data.

## Results

When the data is exported, it is formed into a message and dropped into the outbound queue that is configured for the publish channel and its corresponding external system. Then, the message is processed from the outbound queue to the configured endpoint. If an error occurs when delivering a message to the endpoint, you can manage and view the data export messages that are flagged with an error in the Message Reprocessing application.

## Exporting data in sequential batches

To export multiple batches of message data to an external system, you can use the Bulk Data Exports action in the External Systems application. When you use this feature, exports are processed in order based on the sequence that you specify for the publish channels.

## Before you begin

Before you set up bulk data exports, complete the following tasks:

- Configure an endpoint to the data destination.
- Configure and enable the external system.
- Configure the publish channels for the export.

## About this task

Data is exported sequentially based on the order of the publish channels that you specify in the Bulk Data Exports window.

Data is processed using a cron task instance in the BULKEXPORT cron task. If no cron task instance exists for the external system, a cron task instance that matches the name of the external system for exporting the data is automatically generated. If the cron task instance already exists for the external system, it is activated when you click Process.

When a cron task is active, the In Process check box is selected. No other process for this external system can be started when the cron task is active. Only one export can occur at a time.

When all data in a publish channel is processed, the data is committed. If you have multiple batches in a publish channel, data is committed only after all batches are processed.

If an error occurs for any publish channel, processing is stopped, and an error message is displayed. No data for that channel is committed until the error is corrected. You can correct the error and click Process to restart the process. When you click Process, the publish channel that has the error is reprocessed, and processing continues with the next channel in the sequence. Data is not reprocessed for the publish channels that were successfully committed before the error occurred.

When the cron task is completed, it is automatically deactivated.

Table 1. Buttons in the Bulk Data Export window

Button	Function
Save	Saves any changes that you made in the Bulk Data Exports window.
Cancel	Closes the Bulk Data Exports window but does not save your changes. To save changes, click Save before you click Cancel.
Refresh	Reloads the Bulk Data Exports window and updates the fields to display the status of the data export process.
Reset	Restarts the bulk data export process for all the publish channels that are included in this external system.
Process	Starts the bulk data export process.

## Procedure

1. In the External Systems application, locate and open the external system that you want to use.
2. On the System tab, in the Outbound Sequential Queue field, specify a destination for the outbound data.
3. From the More Actions menu, select Bulk Data Exports.
4. For the publish channels that you want to export, add rows sequentially in the order that you want to process the data and enter details for the export in the following fields:

Option	Description
--------	-------------

Option	Description
<b>Sequence</b>	Enter a number to specify the order in which to process the publish channel data. If you add sequence numbers in increments of ten, it is easy to insert additional publish channels if the need arises at a later date. For example, if you have sequence numbers 10 and 20, and later you want to export a publish channel between those two rows, you can add a sequence number of 15.
<b>Publish Channel</b>	Specify the publish channel to use for the export.
<b>Batch Size</b>	Optional. Specify the number of records to include in each JMS message for the selected publish channel. For example, if you have 100 messages and specify a batch size of 50, the result is 2 JMS messages. If the number of records is larger than the batch size that you specify, the export data is split into a transaction that has multiple files that are stored separately. Even though the records are processed in multiple batches, only one commit occurs for the entire publish channel.
<b>Export Condition</b>	Optional. Specify an SQL query to select records for export. For example, specify <code>assetnum like '11%'</code> and <code>siteid='BEDFORD'</code> to export all asset records that start with 11 and are in the Bedford site. The query must be specified on the primary or top-level object in the publish channel object structure.
<b>Export Order By</b>	Optional. Specify one or more fields by which to sort records that you export. You can specify <code>ASC</code> for ascending order or <code>DESC</code> for descending order. For example, specify <code>assetnum DESC</code> to order the exported data by descending asset ID. The <code>ORDER BY</code> statement must apply to the primary or top-level object in the integration object.
<b>Error Message</b>	If an error occurs during the export process, this field displays an error message.
<b>Enabled</b>	Select this field in the table row to enable the publish channel.
<b>Processed</b>	If this publish channel was processed, this field displays a check mark.
<b>User Defined</b>	Indicates whether you created the publish channel or it was predefined in the application.

5. Click Save.
6. Click Cancel to close the window.
7. From the More Actions menu, select Bulk Data Export.
8. To export the data, click Process.

## Importing file-based data

You can use the data import feature to load data from either XML, JSON, or flat, delimited files to update the database. You can preview and validate the data prior to loading it and committing it to the database. You can choose to manage errors with the Message Reprocessing application or by extracting errors to a file format that is the same as the imported file format.

### Before you begin

Before data can be imported, if you plan to import data from a flat file, such as a .csv file, the enterprise service object structure must support flat file structures. Ensure that the Support Flat File Structure check box is selected on the associated object structure record in the Object Structures application. You also must enable both the external system and the enterprise service before you can import data.

### About this task

The data import process can use a predefined or user-defined enterprise service.

## Procedure

1. In the External Systems application, display the external system that contains the enterprise service from which you want to import data.
2. On the Enterprise Services tab, select the enterprise service from which you want to import data.
3. Click Data Import.
4. Optional: Select the Import Preview check box to examine the data before importing and committing the data to the database. Use the preview option to sample data records. This feature is not intended to support a large file containing hundreds of records. Processing synchronously processes the file to the business objects and returns any error messages encountered, without committing any updates to the database.
5. Specify the type of file that you want to use for the file import.

Option	Description
<b>XML file</b>	Imported data is in XML format.
<b>Flat file</b>	Imported data is in a delimited flat file. If necessary, modify the Delimiter and Text Qualifier values.
<b>JSON file</b>	Imported data is in JSON format.

6. In the Specify Import File field, enter the file name path the imported file uses for identification and storage.
7. Select the File-based Error Management check box if you want to manage any errors you encounter through a file in the same format as the file being imported. This option is an alternative to managing errors with the Message Reprocessing application.
8. Click OK to begin the import data process.

### What to do next

When the data import is executed, the file that is selected for import is formed into multiple messages and dropped into the inbound queue that is configured for the enterprise service and its corresponding external system. The messages are then processed from the inbound queue to the application objects for updating. The processing of messages from an inbound queue requires the enablement of the related cron task when the sequential queue is used or the enablement of Message Driven Beans for the continuous queue. If errors occur when processing a file, you can manage and view the data import messages that are flagged with an error in the Message Reprocessing application.

---

## Importing data by using a REST API call

You can use the Get External Data option on the Enterprise Services tab in the External Systems application to import data from external sources using a REST API call.

### Before you begin

---

Before you import external data, you must complete the following tasks:

- Configure and enable the external system.
- Configure an inbound queue for the external system.
- Configure an endpoint for the import.
- Configure the enterprise services for the import.

### About this task

---

When you complete the following procedure, the REST API that you specify is called, and data is imported into Maximo® Manage. The process runs in the background as a cron task that uses the endpoint that you specify. When the response is received, data is split into individual transactions and stored in the queue. Data is processed based on either the JMS or Kafka queue that you specify for the external system.

### Procedure

---

1. In the External Systems application, select the external system to use for importing data.
2. On the Enterprise Services tab, select the enterprise service to use for importing data.
3. Click Get External Data.
4. In the Get External Data window, enter the following information for importing your data:

Option	Description
Select Data Type	Select either JSON or XML.
End Point	Select the endpoint for your REST API call.
Queue based	If your import is queue-based, select the checkbox.

5. Click OK.

---

## Importing S3 data by using cron tasks

To import data from Cloud Object Storage, you can use a cron task to import data that is read by the Simple Storage Service (S3) handler.

### About this task

---

To import data, configure an endpoint that uses the S3 handler to read the data. Then, import the data by using one of the following cron tasks:

LOADXMLJSONOBJECT

Loads XML and JSON files from cloud storage.

LOADFLATOBJECT

Loads flat files, such as CSV files, from cloud storage.

### Procedure

---

1. Provision Cloud Object Storage and create the following three buckets in any S3 volume for the data that you want to load:

<load bucket name>

Stores the files that you import.

<load bucket name>recovery

Used to recover files that you import.

<load bucket name>backup

Contains the backup for files that you import.

2. In the End Points application, create an endpoint that specifies the S3 handler.  
For more information, see [Configuring an endpoint](#).
3. In the Cron Task Setup application, create and activate the cron task instance to import the files:
  - a. Create a cron task instance for the cron task that you want to use to import files. You can select one of the following cron tasks:

Table 1. Cron tasks for loading S3 files

Cron task	Description
LOADXMLJSONOBJECT	Loads XML and JSON files from cloud storage.
LOADFLATOBJECT	Loads flat files, such as CSV files, from cloud storage.

When you configure the ENDPOINTNAME parameter for the cron task instance, ensure that you specify the end point that you created in step 2. The endpoint name must be in uppercase.

- b. Provide any other instance details and enter a schedule for running the cron task instance.
- c. Activate the cron task.

## Cron tasks for processing inbound data

If you want to schedule file loads rather than using the data import window, you must create, configure, and enable the XMLFILECONSUMER cron task and the FLATFILECONSUMER cron task before cron task message processing can occur.

- [XMLFILECONSUMER cron task](#)  
The XMLFILECONSUMER cron task is the mechanism that you use to load XML files without any application user intervention.
- [FLATFILECONSUMER cron task](#)  
The FLATFILECONSUMER cron task is the mechanism that you use to load flat files without any application user intervention.
- [LOADFLATOBJECT cron tasks](#)  
To import flat files, such as CSV files, from Simple Storage Service (S3) cloud object storage, add a cron task instance to the LOADFLATOBJECT cron task and specify the appropriate parameters for importing flat files.
- [LOADXMLJSONOBJECT cron task](#)  
To import data in XML and JSON formats from Simple Storage Service (S3) cloud object storage, add a cron task instance to the LOADXMLJSONOBJECT cron task and specify the appropriate parameters for importing the files.

## XMLFILECONSUMER cron task

The XMLFILECONSUMER cron task is the mechanism that you use to load XML files without any application user intervention.

The XMLFILECONSUMER cron task has the following predefined parameters:

Parameter	Description
EXTERNALSYSTEM	A required parameter value that identifies the external system value that the cron task data load process uses.
SOURCEDIRECTORY	A required parameter value that defines the directory where source files are loaded. This directory must exist on the application server.
ENTERPRISESERVICE	A required parameter value that identifies the enterprise service name that the cron task uses to process all files that are located in the source directory.
FILENAME	An optional parameter value that determines whether the cron task data load process selects source files based on its file name.
USEREXITCLASSES	An optional custom processing class value that defines additional cron task capability (for example, file load order).
TARGETENABLED	Ensure that the value is at the default of 0 (false). The functionality of this flag is superseded by the donotrun functionality. Use the donotrun parameter in the cron task framework to control which servers the cron task runs on.
ISFILEEXTRACT	When set to 1 (true), this parameter indicates that file-based error management is used for inbound message processing.

All XML files that are available in the source directory are associated with a specific external system – enterprise service when you add a value to the EXTERNALSYSTEM, SOURCEDIRECTORY, and the ENTERPRISESERVICE parameters. These XML files also are loaded into the integration framework.

The files that match the cron task file name property are associated with a specific external system – enterprise service and are loaded into the system when you add a value to the EXTERNALSYSTEM, SOURCEDIRECTORY, ENTERPRISESERVICE, and FILENAME parameters

## FLATFILECONSUMER cron task

The FLATFILECONSUMER cron task is the mechanism that you use to load flat files without any application user intervention.

## Cron task parameters

The FLATFILECONSUMER cron task has the following predefined parameters:

Table 1. FLATFILECONSUMER cron task parameters

Parameter	Description
SOURCEDIRECTORY	A required parameter value that defines the directory where source files are loaded. This directory must exist on the application server.
DELIMITER	A required parameter that indicates the character that is used as field delimiter in the flat file. The default value is , (comma).
USEREXITCLASSES	A custom processing class value to enable additional cron task capability (for example file load order).
TEXTQUALIFIER	A required parameter value that defines the character that is used as text qualifier in the flat file. The default value is “ (double quotation marks).
TARGETENABLED	Ensure that the value is at the default of 0 (false). The functionality of this flag is superseded by the donotrun functionality. Use the donotrun parameter in the cron task framework to control which servers the cron task runs on.
ISFILEEXTRACT	When set to 1 (true), this parameter indicates that file-based error management is used for inbound message processing.

All files available at the source directory are processed by the FLATFILECONSUMER cron task when you add a value to the SOURCEDIRECTORY parameter. The external system and the enterprise service are identified from the first record in the flat file that is imported, which is part of flat file definition.

## Cron task processing properties

The FLATFILECONSUMER cron task uses the following processing properties for inbound messages:

- File processing order - The order in which files are loaded on to the server that is determined by the XML file time stamp. The cron task user exit class can be used to overwrite the inbound message processing logic.
- File split - Multi-noun files that are processed by the FLATFILECONSUMER cron task are split before they are written to the queue. The cron task identifies if the file that is loaded is a multi-noun XML file. If the XML file is a multi-noun file, the integration framework uses the enterprise service key columns to identify where the file split occurs. For example, PONUM and SITE in the MXPOInterface enterprise service.
- Queue processing - The FLATFILECONSUMER cron task identifies the queue in which the flat file is loaded. The location is based on the queue (continuous or sequential) specified at the external system and enterprise service level.

The cron task creates an index file (recovery\_filename.txt) that contains a reference to the last successfully processed noun when you process a multi-noun file. The entry in the index file is updated when the noun is successfully committed to the queue. Index files are available in the RECOVERY folder which is created in the cron task source directory.

The FLATFILECONSUMER cron task uses the index file name to identify the file that was processed before the server or queue problem was encountered. The cron task continues to process the XML file starting at the last successfully committed noun in the index file. Errors that are identified after a message is successfully written to an inbound queue must be resolved in the Message Reprocessing application.

## LOADFLATOBJECT cron tasks

To import flat files, such as CSV files, from Simple Storage Service (S3) cloud object storage, add a cron task instance to the LOADFLATOBJECT cron task and specify the appropriate parameters for importing flat files.

Table 1. LOADFLATOBJECT cron task parameters

Parameter	Description
DELIMITER	Parameter that specifies the character that is used to separate text strings in the flat file that you import.
ENDPOINTNAME	Parameter that specifies the name of the endpoint to use for loading files. The endpoint name must be in upper case.
ISFILEEXTRACT	When set to 1 (true), this parameter indicates that file-based error management is used for inbound message processing.
TEXTQUALIFIER	Parameter that is used to enclose a value that you want to handle as a single text string. All text that follows the text qualifier character and precedes the next occurrence of the character is added as a single value. For example, if you use a comma as your delimiter but you want a city and state to remain as one entry, you can use the % sign as a text qualifier, as shown in the following example:  %Dallas, Texas%  Then, "Dallas, Texas" will be handled as a single text string and the comma is not treated as a delimiter for your text.
USEREXITCLASS	An optional custom processing class value that defines additional cron task capability (for example, file load order).

## LOADXMLJSONOBJECT cron task

To import data in XML and JSON formats from Simple Storage Service (S3) cloud object storage, add a cron task instance to the LOADXMLJSONOBJECT cron task and specify the appropriate parameters for importing the files.

Table 1. LOADXMLJSONOBJECT cron task parameters

Parameter	Description
FILETYPE	Parameter that specifies whether the files to process are in XML or JSON format.
ENDPOINTNAME	Parameter that specifies the name of the endpoint to use for loading files. The endpoint name must be in upper case.
ENTERPRISESERVICE	A required parameter value that identifies the enterprise service name that the cron task uses to process all files that are located in the source bucket.
ISFILEEXTRACT	When set to 1 (true), this parameter indicates that file-based error management is used for inbound message processing.
USEREXITCLASS	An optional custom processing class value that defines additional cron task capability (for example, file load order).
EXTERNALSYSTEM	A required parameter value that identifies the external system value that the cron task data load process uses.

## Configuring applications for data export and import

To enable application-based data import and export you must define the content of an object structure and enable this object structure for import and export.

- [Defining the object structure content](#)  
Application users can be granted access to export or import data directly from an application. An administrator can identify an appropriate object structure for an application and grant export and import capabilities to manage application data in a file, such as a CSV file that can be maintained in spreadsheet.
- [Enabling data import and export in an application](#)  
After you define the content of the object structure, you must enable an application for data import and export. Data import and data export are separate features. You can set up security access to limit access to each of these features.
- [Initiating data export and import in an application](#)  
After enabling data export and import in an application, icons are added to the toolbar of the application for starting the transactions.

---

## Defining the object structure content

Application users can be granted access to export or import data directly from an application. An administrator can identify an appropriate object structure for an application and grant export and import capabilities to manage application data in a file, such as a CSV file that can be maintained in spreadsheet.

---

### About this task

Determine the object structure to use for the integration transactions and then modify the content of the object structure to limit data exchange to the content that is required.

---

### Procedure

1. In Application Designer, open the workspace for the application that you want to enable and note the value in the Main Object field in the header area. This value must be the main object in the object structure that you modify for application data import and export.
2. In the Object Structures application, specify the name of the main object in the Object Structure field to filter for object structures based on this object. If the search does not return any object structures based on the main object, you must create an object structure and the following steps do not apply.
3. If the search returns multiple object structures, select an object structure where the value in the Consumed By field is set to Integration.
4. Review the content of the object structure to answer the following questions:
  - a. Is the main object of the object structure the same as the main object of the application that you want to enable for data export and import?
  - b. Does the object structure include child objects that contain data that users do not need to import or export?  
For example, the MXPERSO object includes the PHONE, EMAIL, and SMS child objects. Your users may want to import and export data for the PERSON and PHONE objects only.
5. After you review the content of the object structure, you can choose to use the predefined object structure with all of its existing content or to duplicate this object structure and modify its content.  
If you make changes to a predefined object structure, it can affect any other integration scenarios that use this object structure. Duplicating the object structure and using this as a template does not cause unexpected behavior for other integration users.
6. Assuming that you duplicate the object structure to provide a new object structure for this scenario, delete any child objects that are not necessary for your integration users.
7. For each object that remains in the object structure, select the Include/Exclude Fields option in the Select Action menu, and deselect all fields that users do not require to import or export.  
This step limits the data fields to only those needed by the application users.
8. If delimited flat files are required (for use in a spreadsheet), select the Support Flat Structure check box.  
This step activates a validation to ensure that every column for every object in the object structure has a unique name. If the validation fails, an Alias Conflict indicator is set.
9. If the object structure contains an alias conflict, select the Add/Modify Alias option in the Select Action menu to assign a unique alias for any field name where a duplicate exists.  
Alias conflicts do not exist in any of the predefined object structures.
10. Save the object structure.

---

### What to do next

The content of the object structure is now configured and you can grant application access to it in the Object Structures application.

---

## Enabling data import and export in an application

After you define the content of the object structure, you must enable an application for data import and export. Data import and data export are separate features. You can set up security access to limit access to each of these features.

---

### Procedure

1. In the Object Structures application, select the object structure that you want to enable for data import and export.  
The object structure must specify Integration in the Consumed By field.
2. Select the Add/Modify Application Export Support action.
3. In the Add/Modify Application Export Support window, insert a row.  
In the Details section, the value in the Application field defaults to the application that has the same main object as the main object of the object structure.
4. Specify either XML File or Flat File as the format for data export files.
5. In the Maximum Count field, specify the maximum number of rows that can be exported during a single execution. Leave the field empty or specify 0 to allow export of an unlimited number of rows.
6. If you enable multiple object structures for the application export and you want this object structure to be the default, select the Is Default checkbox.
7. Save the export configuration.
8. Select the Add/Modify Application Import Support action and repeat the same procedures to configure data import for the application. Save your changes.

---

### Results

After you enable data export and import, actions are added to the Actions menu of the application.

---

### What to do next

Enable security group access to one or both of these actions.

---

## Initiating data export and import in an application

After enabling data export and import in an application, icons are added to the toolbar of the application for starting the transactions.

- **Exporting application data**  
You can export data from an application if the application and security are configured for this action.
- **Importing application data**  
After you enable data import for an application and security access, users can import new and updated application data. For example, you can import a bulk load of asset records.

---

## Exporting application data

You can export data from an application if the application and security are configured for this action.

---

### Procedure

1. In the List tab of the application, select one or more records, and then select the Application Export action.
2. In the Application Export window, review the export settings and make any necessary adjustments:
  - a. Optional: Specify a different value in the Object Structure field if you do not want to use the default object structure for the export.  
You can specify an alternate object structure only if another object structure has been enabled for this application.  
If you specify an alternate object structure, the window refreshes to include the Export Configuration section where you can configure additional settings.
  - b. Optional: If the value in the Selected to Export field exceeds the value in the Export limit field, you can cancel the export and use a different filter to reduce the number of records to export.  
The value in the Export limit field is set by the administrator, and cannot be exceeded, regardless of the number of records selected.
3. Optional: In the Export Configuration section, specify the data format.
  - a. If you select XML format, specify the operation for the export, for example Sync.
  - b. If you select Flat File format, specify values in the Delimiter and Text Qualifier fields.
4. Click OK to start the export. Save the export file locally.  
If the Save dialog box does not open, change the security settings of your browser to enable automatic prompting for downloads.

---

## Importing application data

After you enable data import for an application and security access, users can import new and updated application data. For example, you can import a bulk load of asset records.

---

### Procedure

1. In the application, select the Data Import action.
2. Review the information in the Data Import window.  
if you do not want to use the default object structure for the import, you can specify a different value in the Object Structure field.
3. Optional: If you specified an alternate object structure, in the expanded Import Configuration section, specify the following values:
  - a. If you specify the Flat File format, you can specify values in the Delimiter, Text Qualifier, Action, and Language Code fields, or accept the default values.
  - b. If you specify the XML or JSON format, no additional settings are required because the incoming XML file specifies the operation, language code and action code.
4. Review the value in the Import limit field.  
You cannot change this value. If the limit is set, for example, to 100 records, and the import file contains 200 records, only the first 100 records are imported.
5. Select the import file.
6. Optional: Select Import Preview to process the file but not save data to the database.  
Use this option to test the data load and validate that there are no errors prior to loading. Any errors are displayed and you can apply corrections to the input file and attempt the import again.
7. Click OK to start the import.  
Because data import is a synchronous process, you must wait in the application until the import is complete and a confirmation message appears. If the import encounters errors, no data is loaded, as the file is processed as a single transaction with a single commit.

---

## Federated MBO integration

Maximo® Manage supports the sharing of data between Maximo Manage and external systems in several ways.

The most common way to share information using the Maximo Manage is to replicate data between the systems. A federated resource can share system data without replicating external system data in Maximo Manage.

MBOs are a set of Java™ classes that implement the data persistence layer and business rules in Maximo Manage. With [Federated MBO Integration](#), you can associate Maximo Manage objects with data from an external system, and persist the data outside of the Maximo Manage database. The external data must be exposed through a JSON REST API in order for the data to be available as an MBO.

External data can be registered using the Maximo Manage JSON Resources application. External systems can share data with Maximo Manage when needed rather than replicating the information into the Maximo Manage environment. The federated MBO retrieves the most up to date version of the data from an external application.

---

## Integration APIs

The integration framework supports the use of REST (Representational State Transfer) application programming interface (API), and the sharing of lifecycle data between applications based on Open Services for Lifecycle Collaboration (OSLC) integration.

You can see complete content about REST APIs in the [Maximo® REST API community](#).

- [REST JSON API enhancements](#)  
The REST APIs provide enhanced support for querying Maximo Manage data. The REST APIs are also referred to as the JSON APIs.
- [Data import and export with REST API](#)  
You can use REST APIs to export data from your C system into an external system or application and to import data from an external system or application into your Manage system. You can export and import JSON, XML, or CSV files.
- [REST API as an RMI batch file replacement](#)  
You use REST APIs instead of using Remote Method Invocation (RMI) batch files to work with the product. RMI is not supported in Maximo Manage.
- [Communication with external applications through REST API](#)  
You use REST API with your client-based tools to interact with the product from any custom extensions or external applications.

---

## REST JSON API enhancements

The REST APIs provide enhanced support for querying Maximo® Manage data. The REST APIs are also referred to as the JSON APIs.

The new REST API resources evolved from the legacy REST API and provide similar capabilities but remove the requirement to use OSLC namespaces. The new REST API is sometimes referred to as the REST/JSON API because of the end-to-end support of the JSON data format. Legacy APIs were used before version 7.1 of Maximo Manage.

You use API keys to enable an inbound machine-to-machine integration for an external client. API keys can be used by the REST and OSLC APIs and also can be used as part of the Manage integration framework.

The following enhanced support and capabilities are available with the new REST APIs:

- Related object queries, multi-attribute text search, and custom queries
- Bookmarking, notifications, and image association
- Metadata support that uses the JSON schema
- Dynamic query views
- GROUP BY queries
- Custom JSON elements that are appended to the object structure JSON
- Access to Swagger documentation for APIs
- Integration with the Manage cache framework
- API keys for native authentication in inbound machine-to-machine integrations
- Support for importing and exporting data as XML, JSON and CSV files.

The new REST APIs can be used when a Manage package that is not customized is installed and set up with users and groups.

You can see complete content about REST APIs in the [Maximo REST API community](#).

---

## Data import and export with REST API

You can use REST APIs to export data from your C system into an external system or application and to import data from an external system or application into your Manage system. You can export and import JSON, XML, or CSV files.

---

## Importing data

To import data, you must choose a Manage object structure that references the Manage business objects that consume the data. If you use a CSV file, you must select an object structure that is enabled for flat files. All object structures that are for a primary API are flat-file enabled.

The syntax is validated for the data before the data is stored in an internal Manage repository.

The following table contains examples of importing data by using REST APIs:

Table 1. Examples of importing data

Use case	REST API calls and responses
Data is synchronously imported from a CSV file that contains 10 records	<p>The following call is used:</p> <pre>POST /maximo/api/os/object structure?action=importfile</pre> <p><i>CSV file content</i></p> <p>The following response is returned:</p> <pre>{   "validdocs":10 }</pre>
Asset and site data is synchronously imported from a JSON file array	<p>The following call is used:</p> <pre>POST /maximo/api/os/object structure?action=importfile Filetype: JSON [   {     "assetnum":"asset number",     "siteid":"site ID"   },   {     "assetnum":"asset number",     "siteid":"site ID"   } ]</pre>
Data is asynchronously imported from a CSV file	<p>The following call is used:</p> <pre>POST /maximo/api/os/object structure?action=importfile&amp;name=filename.csv&amp;async=1</pre> <p><i>CSV file content</i></p>

Note: When doing a CSV export that is using a .notation attribute or its alias, the output was in lower-case. This issue is now fixed in Maximo® Manage 8.5 and the output is now in upper-case.

The APIFILEIMPORT cron task retrieves the imported data and processes the content. The cron task runs every 30 minutes, and you can configure how frequently the cron task runs.

After you import data, a location URL that contains the status of the APIFILEIMPORT cron task is provided. If an error occurs while the cron task processes the data, the response to the location URL is embedded with a URL that connects to an error file, which you can download. When the error is resolved, import the file again. Ensure that you specify a new name for the name query parameter.

If you are using a JSON file, to enable this error response, the Filetype request header must be JSON.

The following response is an example of the response to the location URL when an error occurs. The file type is JSON.

```
{
 "iscomplete": true,
 "totalcount": 3,
 "errcount": 1,
 "requirer": "Username",
 "fileimportreqqueueid": 3,
 "format": "JSON",
 "errorfile": "http://host:port/maximo/api/fileimporterrfile/3",
 "_rowstamp": "1521573",
 "iscancelled": false,
 "reqdatetime": "2019-02-20T14:08:22-05:00",
 "name": "testloc3.json",
 "href": "http://host:port/maximo/api/os/mxapifileimportqueue/_dGVzdGxvYzMuYWVnbg--",
 "pindex": 3,
 "osname": "MXAPIOPERLOC"
}
```

## Exporting data

If you export data by using REST APIs for a machine-to-machine integration, you must create an API key for the external client.

The default file format to export data is JSON.

For example, the following REST API call exports asset, site, and location data from the MXAPIASSET object structure as a CSV file:

```
GET /api/os/mxapiasset?oslc.select=assetnum,siteid,status,location&oslc.pageSize=100&
oslc.where=status="OPERATING"&_format=csv&apikey=API key
```

For more information about the new REST APIs, see the [Maximo REST API](#).

## REST API as an RMI batch file replacement

You use REST APIs instead of using Remote Method Invocation (RMI) batch files to work with the product. RMI is not supported in Maximo® Manage.

RMI is a Java™ protocol that allows external applications to communicate with the product. You use REST APIs and configured API keys to communicate with the product through its REST client. The REST APIs offer similar features to those features that are available with RMI.

The following code sample shows a GET call to the viewQueueDataApi WebMethod in the MIC AppService service. The URI for the AppService is http://host:port/maximo/api/sevice/MIC.

```
Map<String,String> qp = new HashMap<String,String>();
qp.put("action", "wsmethod:viewQueueDataApi");
qp.put("count", ""+count);
if(selector != null)
{
 qp.put("selector", ""+selector);
}
qp.put("queueName", ""+queueName);
byte[] data = new RestClient(serviceurl)
 .withApiKey(System.getProperty("apikey"))
 .withQueryParams(qp)
 .invoke();
```

Similarly, you can make a POST call, as shown in the following code sample:

```
new RestClient(serviceurl)
 .withApiKey(System.getProperty("apikey"))
 .withQueryParams(qp)
 .withMethod(RestClient.HTTPMETHOD_POST)
 .invoke(data); //data is a byte[] - request payload
```

This type of call can be made with methods that are marked as WebMethods and are thus enabled for REST API. You also can use similar code to call an object structure or combination of object structures to get the correct placement for your job.

---

## Communication with external applications through REST API

You use REST API with your client-based tools to interact with the product from any custom extensions or external applications.

In Maximo® Asset Management, Remote Method Invocation (RMI) can be used to interact with the product from custom extensions or external applications. However, RMI is not supported outside of the Maximo server process in the fully containerized environment of Maximo Manage. You use REST API instead of RMI for interactions with the product from custom extensions or external applications.

To help with using REST API, the product provides a sample HTTP client, which is the com.ibm.tivoli.maximo.oslc.provider.RestClient class. This sample HTTP client is a library of many useful methods and other libraries.

---

## REST API benefits for integrating with the product

REST API in the product offers the following key benefits to integration administrators:

- A REST API client can be written in the language of your choice, while with RMI, you can write only in the Java™ language.
- REST API promotes ease of customization and integration with your client applications by using object structures.
- REST API can use API keys for authentication and authorization. All communication with the product can be done with any basic HTTP client, such as the sample RestClient HTTP client that is included with the product.
- Well-designed REST API calls provide high scalability with less network traffic. Several ways to design and code the REST API calls are explained in the following sections.

---

## REST API coding options

REST API coding is generally at a fairly high level, but the product offers options to make the code granular if you require granularity. You can code your API calls as multiple REST calls, bulk REST calls, or REST calls that use automation scripts.

The amount of generated network traffic can vary, depending on the way that you code the REST API interaction for your client. If REST API interactions are not coded correctly, client and product performance might be negatively impacted.

---

## Multiple individual REST calls

If you are moving from using RMI in earlier product versions, you can convert your RMI calls to REST calls on a one-to-one basis. However, RMI allows granular API use in the Java SDK that is provided with Maximo Manage, while the REST APIs are higher level. Additionally, it is possible that not every RMI call has an equivalent REST API call because REST APIs are not available for all of the Java SDK of the product.

Network traffic can be high if you code with multiple REST calls because of the number of network calls.

---

## Bulk REST calls

With bulk REST calls, you write code for one call that acts on a set of records that meet your criteria. Bulk REST calls offer better network performance than multiple individual REST calls. However, you might have issues with lack of equivalency of REST APIs with granular RMI calls.

---

## REST calls that use automation scripts

REST calls that use automation scripts offer the best granularity and network performance. With this approach, you can access the full Java SDK, which is not possible with the other approaches.

You write an automation script in the Automation Scripts application and call that script using the REST client. The scripting framework carries forward the API query parameters to the script. The automation script can be written in many languages.

Coding REST API using automation scripts also gives you a way to organically create REST APIs that suit your environment and that can be used elsewhere.

---

## Integration queries

The integration framework supports queries from external systems. You can execute a query for object structures and enterprise services by using HTTP, REST APIs, or a Simple Object Access Protocol (SOAP) request in a web service. Queries can be in the form of XML messages or REST API JSON.

Support for XML queries is based on the system Query By Example (QBE) capability that is available from the List tab of most applications. XML-based queries provide the same query support that is provided in the applications except for attribute searches that are available in some system applications. Integration query time outs are controlled by the `mxs.db.Query.Timeout` system property.

- [Query services](#)  
Object structure services and enterprise services support query operations. An external source can use a service to run a query and to retrieve data from a system. In both cases, the object structure schema defines the XML content for the query request and the query response.
- [Creating an enterprise service query](#)  
An external source can use an enterprise service to run a query and to retrieve data from a system.
- [Web service queries](#)  
Query services that are created in the Enterprise Services application and the Object Structures applications can be deployed as web services. To support querying, you must configure enterprise web services to bypass the JMS queues.
- [Query XML structure](#)  
The name of the root element of a query is the concatenation of the operation (Query) and the name of the associated object structure. For example, `QueryMXPERS`ON, where `MXPERS`ON is the object structure.
- [Query selection criteria](#)

---

## Query services

Object structure services and enterprise services support query operations. An external source can use a service to run a query and to retrieve data from a system. In both cases, the object structure schema defines the XML content for the query request and the query response.

For an object structure that has more than two levels of business objects, the query framework supports the use of business object attributes in the top two levels of the request XML. The query response XML contains all the objects in the object structure.

All system-provided object structures with a Consumed By value of `INTEGRATION`, support the query operation by default. You can configure an object structure to support the query operation only and no other operations that support updating objects. You can use the Object Structures application to create additional object structures which provide support for the query operation.

---

## Creating an enterprise service query

An external source can use an enterprise service to run a query and to retrieve data from a system.

---

### About this task

A sample enterprise service query, `MXINVBALQInterface`, is provided. You can use this sample as a reference when you create query enterprise services.

---

### Procedure

1. If one does not exist, create an object structure containing the objects that the query needs to access.
2. Define an enterprise service that implements the object structure you intend to use for the query.
3. Specify Query as the operation on the enterprise service.
4. Associate the enterprise service with an external system, and enable the external system and its enterprise service.

---

## Web service queries

Query services that are created in the Enterprise Services application and the Object Structures applications can be deployed as web services. To support querying, you must configure enterprise web services to bypass the JMS queues.

A successful response to a query that is run in a web service returns the query result set. If the result set is empty (it contains no records), the XML that is returned in the SOAP body contains the following empty `MXPERS`ONSet tag:

```
<max:QueryMXPERSResponse xmlns:max="http://www.ibm.com/maximo"
 creationDateTime="2011-04-28T21:49:45"
 baseLanguage="EN" transLanguage="EN" messageID="12345"
 maximoVersion="7.5" rsStart="1" rsCount="10" rsTotal="10">
```

```
</max:MXPERSONSet>
</max:QueryMXPERSONResponse>
```

If an error occurs, an HTTP response code of 500 is returned, along with a SOAP fault detailing the error message.

Use the following URL for the query web service:

**http://hostname:port/meaweb/services/web\_service\_name**

- The host:port/meaweb is the value of the integration web application URL property.
- The web service name is the name of the web service.

You deploy query enterprise and object structure services as web services using the Web Services Library application.

## Query XML structure

The name of the root element of a query is the concatenation of the operation (Query) and the name of the associated object structure. For example, QueryMXPERSON, where MXPERSON is the object structure.

### Root element

The name of the root element of a query is the concatenation of the operation and the name of the object structure, for example, QueryMXPERSON, where MXPERSON is the object structure. The following table lists the attributes that can apply specifically to the root element of a query, a response to a query, or both. All attributes in this table are optional.

Attribute	Description	Type	Applicable to
uniqueResult	Specifies whether the query expects one record or multiple records in a response. Value 0 (default): The query can return multiple records.  Value 1: The query can return a single record; otherwise, an error occurs.	Boolean	Query
maxItems	If the query can return multiple records, this attribute limits the number of records to be returned at one time. If this attribute is not specified, the response contains the entire result set.	PositiveInteger	Query
rsStart	In the query request: Use with maxItems to specify the first record to be returned in a response.  If maxItems equals 10 and rsStart is not specified, the response returns results 0 through 9. To receive results 10 through 19, resend the query with rsStart equals 10.  If rsStart is not specified, the response starts with the first record in the result set. If the number of records in the query result set is lower than the value of rsStart, the response returns no records.	Integer	Query
rsStart	In the query response: This value matches the rsStart value in the corresponding request.  If the corresponding request contains a maxItems value, the rsStart value in requests for additional records is rsStart + rsCount + 1.  If this attribute is not specified, the response starts with the first record in the result set and includes the number of records specified by the rsCount attribute.	Integer	Response
rsCount	The number of records that are returned in the message. rsCount does not reflect any rows that may be skipped as part of the response processing layer.	Integer	Response
rsTotal	The total number of records in the result set. If the query does not specify a maxItems value, the rsTotal value is the same as the rsCount value.	Integer	Responses (output)

For example, the response to this query request returns records 11 through 20 of the query result set by virtue of setting the rsStart value to 11 and the maxItems value to 10.

```
<max:QueryMXINVBAL xmlns:max="http://www.ibm.com/maximo"
 creationDateTime="2011-04-28T21:49:45"
 baseLanguage="EN" transLanguage="EN" messageID="12345"
 maximoVersion="7.5" uniqueResult="0" maxItems="10" rsStart="11">
 <max:MXINVBALQuery orderBy="string" operandMode="OR">
```

The following query result set contains a total of 35 rows, as noted by rsTotal, but only rows 11 through 20 are returned.

```
<max:QueryMXINVBALResponse xmlns:max="http://www.ibm.com/maximo"
 creationDateTime="2011-04-28T21:49:45"
 baseLanguage="EN" transLanguage="EN" messageID="12345"
 maximoVersion="7.5" rsStart="11" rsCount="10" rsTotal="35">
 <max:MXINVBALSet>
 .
 .
 .
 </max:MXINVBALSet>
```

## Query operator

The QueryOperatorType data type supports the use of different operators. Your query request XML can use the different operators to filter the data that is returned to the querying external source.

## QueryMXPERSOn element

---

The QueryMXPERSOn element has the following types:

- The QueryMXPERSOn element is type QueryMXPERSOnType.
- QueryMXPERSOnType has element MXPERSOnQuery, which is type MXPERSOnQueryType.
- MXPERSOnQueryType has elements for all the configured attributes of the PERSON object and all of its child objects (EMAIL, PHONE, and SMS).

The QueryMXPERSOn operation element uses the following attributes:

- uniqueResults – Is a Boolean value that when set to 1 (True), directs the query to return a single and unique record when the value is set to 1 (True). If more than one record is found, an error is returned. When the attribute is not provided, the default value is 0 (false).
- maxItems – When this value is set to 10 on the query, it limits the number of records that are returned in the query to 10, even when the result set of the query may be greater than 10. When the attribute is not defined, all rows in the result set of the query are returned.
- rsStart – When this value is set to 11 on the query, all the records in the result set are returned starting with record 11. The query result skips records 1 - 10. When the attribute is not defined, the records are returned starting with record 1 in the result set.

The MXPERSOnQuery content element uses the following additional attributes:

- orderby – Using this value is equivalent to using an Order By in a SQL statement. The attribute can contain a list of comma-separated field names that also include ASC and DESC options. When the attribute is not defined, the query returns records in the order that it was retrieved by the database.
- operandMode – This value has two valid values, AND and OR. The system uses this value when one or more fields is used for evaluation in a query execution. When you use the AND value, all field evaluations must be true. When you use the OR value, only one of the field evaluations must be true. When the attribute is not defined, the default value is AND.

## QueryMXPERSOnResponse element

---

The QueryMXPERSOnResponse element has the following types:

- Element QueryMXPERSOnResponse is type QueryMXPERSOnResponseType.
- The QueryMXPERSOnResponseType has element MXPERSOnSet, which is type MXPERSOnSetType.
- MXPERSOnSetType has elements for all the configured attributes of the PERSON object and elements for child objects defined in the object structure (PHONE, EMAIL, XYZ, and SMS).

The QueryMXPERSOnResponse element has the following attributes:

- rsStart – This value contains the value set on the query request. If the value is not defined on the request, the default response value is 1.
- rsCount – This value contains the number of records that are returned in the query response.
- total – This value contains the number of records in the final query result set. The total value can be more than the number of records that are returned when the maxItems attribute is used in the query request.

---

## Query selection criteria

The object structure element of a query request contains the selection criteria for the query. A query can select records based on a single value, a range of values, or a provided 'where' clause. The integration framework supports the use of query operators such as = or >.

Selection criteria apply only to attributes of objects in the top two levels of the object structure; that is, the primary object and its immediate child objects. However, the response includes data from all the objects in the object structure.

- [Field selection](#)  
A field-based query compares the value in a database field with the value in the XML field of the query request.
- [Field evaluation](#)  
The operator attribute compares the value of a database field with one or more values and has the format **operator = value**.
- [Range selection](#)  
A query can search for records with a value that falls within a range of values. The format depends on whether the selection criterion is open-ended or it contains an upper and lower range.
- [Where clause selection](#)  
A query can search for records based on a SQL 'Where' clause that can be provided as part of the integration query XML. The Where clause offers support for more complex queries and the querying of classification-related data.

---

## Field selection

A field-based query compares the value in a database field with the value in the XML field of the query request.

The following sample query searches for employees:

```
<QueryMXPERSOn>
 <MXPERSOnQuery>
 <PERSON>
 </PERSON>
 </MXPERSOnQuery>
</QueryMXPERSOn>
```

The following sample query searches for employees where the PERSONID is equal to ATI and STATUS is equal to ACTIVE.

```

<QueryMXPERSOn>
 <MXPERSOnQuery>
 <PERSON>
 <PERSONID operator ="=">ATI</PERSONID>
 <STATUS operator ="=">ACTIVE</STATUS>
 </PERSON>
 </MXPERSOnQuery>
</QueryMXPERSOn>

```

The **operandMode** attribute of the MXPERSOnQuery element defines the statement that is run with an AND or an OR condition between the field evaluations. The default condition that is used by the system is the AND condition. Additionally, the **operandMode** attribute can be provided at a field level. In this case, a field element can have multiple occurrences and can be evaluated for different conditions, such as a quantity field being evaluated as less than 2 or greater than 10.

The following sample query searches for employees where PERSONID is like %ATI%. The operand represents the default behavior and requires no operator value.

```

<QueryMXPERSOn>
 <MXPERSOnQuery>
 <PERSON>
 <PERSONID>ATI</PERSONID>
 </PERSON>
 </MXPERSOnQuery>
</QueryMXPERSOn>

```

The following sample query searches for inventory balances where the bin number is not null.

```

<QueryMXINVBAL>
 <MXINVBALQuery>
 <INVBALANCES>
 <BINNUM operator ="!="></BINNUM>
 </INVBALANCES >
 </MXINVBALQuery>
</QueryMXINVBAL>

```

The following sample query searches for the inventory balances where the bin number is null.

```

<MXINVBAL>
<INVBALANCES>
<BINNUM>NULL</BINNUM>
</INVBALANCES >
</MXINVBAL>

```

The following sample query uses the equivalent of a SQL IN clause to search for the employees whose status is ACTIVE or INACTIVE.

```

<QueryMXPERSOn>
 <MXPERSOnQuery>
 <PERSON>
 <STATUS>ACTIVE, INACTIVE</STATUS>
 </PERSON>
 </MXPERSOnQuery>
</QueryMXPERSOn>

```

The following sample query searches for employees where the PERSONID starts with the letter A.

```

<QueryMXPERSOn>
 <MXPERSOnQuery>
 <PERSON>
 <PERSONID operator ="SW">A</PERSONID>
 </PERSON>
 </MXPERSOnQuery>
</QueryMXPERSOn>

```

The following sample query searches for employees where the PERSONID ends with the letter Z.

```

<QueryMXPERSOn>
 <MXPERSOnQuery>
 <PERSON>
 <PERSONID operator ="EW">Z</PERSONID>
 </PERSON>
 </MXPERSOnQuery>
</QueryMXPERSOn>

```

## Field evaluation

The operator attribute compares the value of a database field with one or more values and has the format **operator = value**.

The value attribute can have the following values.

Value	Description
=	equal
!=	not equal
&lt;	less than
&lt;=	less than or equal
&gt;	greater than

Value	Description
&gt;=	greater than or equal
EW	Ends With
SW	Starts With

Use the less than and greater than attributes with numeric values and date fields only.

For example, to find all employees that have an ACTIVE status, format the query as follows:

```
<QueryMXPERSO
<MXPERSOQuery>
<PERSON>
<STATUS operator ="=">ACTIVE</STATUS>
</PERSON>
</MXPERSOQuery>
</QueryMXPERSO>
```

## Range selection

A query can search for records with a value that falls within a range of values. The format depends on whether the selection criterion is open-ended or it contains an upper and lower range.

The following sample query searches for purchase orders where the DEPARTMENT is greater than 1000.

```
<QueryMXPERSO
<MXPERSOQuery>
<PERSON>
< DEPARTMENT operator=">=">1000</DEPARTMENT>
</PERSON>
</MXPERSOQuery>
</QueryMXPERSO>
```

The following sample query searches for person records where the PERSONID is greater than 1000 and less than 20000. The query uses two instances of a single field element, the first with the From selection criteria, and the second with the To selection criteria:

```
<QueryMXPERSO
<MXPERSOQuery>
<PERSON>
< PERSONID operator=">=">1000</PERSONID >
< PERSONID operator="<=">20000</PERSONID >
</PERSON>
</MXPERSOQuery>
</QueryMXPERSO>
```

## Where clause selection

A query can search for records based on a SQL 'Where' clause that can be provided as part of the integration query XML. The Where clause offers support for more complex queries and the querying of classification-related data.

The use of the 'Where' clause is mutually exclusive from the use of individual elements. If a query request provides data for the Where element and other elements in the XML, only the WHERE element is used in the query execution.

The WHERE element is located on the same level as the top-level object in an object structure (purchase order), as in the following example:

```
<QueryMXPO xmlns="http://www.ibm.com/maximo">
 <MXPOQuery>
 <PO> </PO>
 <WHERE> </WHERE>
 </MXPOQUERY>
</QueryMXPO>
```

The WHERE element is available in the schema only when the operation is Query and can exist only once. To join multiple tables in the query, use 'exists' within the Where clause, in the same manner as the WHERE clause from the List tab of an application. The following sample query, using the MXPO object structure, retrieves purchase orders that have a PO Line for Item number 1002:

```
<QueryMXPO xmlns="http://www.ibm.com/maximo">
 <MXPOQuery>
 <WHERE>(siteid = 'BEDFORD') and (exists (select 1 from maximo.poline where
 (i temnum='1002') and (ponum=po.ponum and revisionnum=po.revisionnum and
 siteid=po.siteid)))</WHERE>
 </MXPOQUERY>
</QueryMXPO>
```

The result of this query retrieved two purchase orders (not all elements are included in the example):

```
<?xml version="1.0" encoding="UTF-8"?>
<QueryMXPOResponse xmlns="http://www.ibm.com/maximo" xmlns:xsi="http://www.w3.org/
2001/XMLSchema-instance" creationDateTime="2012-03-21T11:20:13-04:00"
transLanguage="EN" baseLanguage="EN" messageID="1332343214013260273" maximoVersion=
"7 5 20110413-2230 V7500-721" rsStart="0" rsTotal="2" rsCount="2">
 <MXPOSet>
```

```

## Interface tables

Interface tables are an option for integration with systems that use database tables to exchange data. This integration option applies only to enterprise services and publish channels and is always processed asynchronously, by using JMS queues.

Within an external system, there can be one or more publish channels and enterprise services that are being used for integration with interface tables. Any channel or service that is using an interface table must be associated with an object structure that is configured to support flat files and all alias conflicts must be resolved.

### Location of interface tables

---

The endpoint definition for an external system or a publish channel points to the database where its interface tables are stored. The database can be the local application database or a remote database. The predefined content includes the **MXIFACETABLE** interface table endpoint which points to the application database. You can add additional endpoints for remote databases.

### Names of interface tables

---

The integration framework registers interface table names to an enterprise service or a publish channel. Default names for interface tables are not provided. Apply the following guidelines when naming interface tables:

- Publish channels and enterprise services that use the same object structure can use the same interface table name or different interface table names.
- Publish channels and enterprise services that use a different object structure must use different interface table names.

### Interface queue tables

---

The interface queue tables identify the sequence in which a receiving system processes the records in the respective interface tables. Two queue tables exist, one for inbound transactions and the other for outbound transactions. Some transactions depend on the successful processing of a previous transaction, for example you must create a user before you can add that user to a security group. The receiving system must process the records in the same sequence in which the sending system created the records.

Table 1. Interface queue table

Interface queue table	Direction
<b>MXOUT_INTER_TRANS</b>	Outbound
<b>MXIN_INTER_TRANS</b>	Inbound

External applications that pull data for outbound messages can use the outbound interface queue table (mxout\_inter\_trans). However, the external applications can also choose to use other methods of consuming outbound messages that meet their integration requirements.

All inbound and outbound transactions must have a record that is inserted into the corresponding inbound or outbound queue table. This record contains a TRANSID value, a unique identifier that identifies the interface table to which the transaction data is written. The corresponding interface table uses the TRANSID value to identify the record or records that are associated with the transaction. You can identify the contents of a transaction by looking up all the records with a given TRANSID value in the corresponding interface table.

The sequence of TRANSID identifies the sequence in which records are processed by the integration framework. For example, when users and security groups are entered into the system, the TRANSID values for the user record must be lower than the TRANSID values for the security group records that reference that user.

The difference between the MXIN\_INTER\_TRANS and MXOUT\_INTER\_TRANS queue tables is the direction of the interface table records that they track. The external system must write to the MXIN\_INTER\_TRANS queue table, and the integration framework must read from it. The integration framework writes to the MXOUT\_INTER\_TRANS queue table, and the external system reads from it.

The external system can use the MXOUT\_INTER\_TRANS table or retrieve outbound records from interface tables. The interface queue tables are generated the first time that you create interface tables for an endpoint. Each endpoint has its own interface queue tables and a counter for maintaining the outbound TRANSID value.

- [Creation of interface tables](#)  
When an enterprise service and a publish channel use the same interface table, the Create Interface Tables window displays a list of interface tables based on the uniqueness of the interface table name and its corresponding endpoint.
- [Regeneration of interface tables](#)  
When columns are added or deleted from the system database tables, you must regenerate all local and remote interface tables that are associated with those object structures.
- [Deletion of interface tables and records](#)  
When related inbound transaction records are successfully processed in an interface table, the corresponding record is deleted from the MXIN\_INTER\_TRANS queue table. The deletion indicates that the transaction was delivered successfully to the inbound JMS queue.
- [Format of interface tables](#)  
An interface table has the same format as its corresponding object structure, including persistent and nonpersistent columns and excluding any columns that are excluded from the object structure.
- [Interface table polling](#)  
A predefined cron task polls the interface queue table and uses the IFACENAME, EXTSYSNAME, and TRANSID values to place the corresponding records into the appropriate inbound JMS queue for processing. The interface polling process checks that the names of the external system and enterprise service are valid and enabled.
- [Processing interface tables on an external system](#)  
To enable an external system to use interface tables, you must create interface tables, define backup procedures for restoring interface tables, and configure the archiving of interface tables.

---

## Creation of interface tables

When an enterprise service and a publish channel use the same interface table, the Create Interface Tables window displays a list of interface tables based on the uniqueness of the interface table name and its corresponding endpoint.

You can create interface tables for enterprise services and publish channels when the associated object structures are marked as flat supported. The Support Flat Structure check box must be selected on the object structure. All alias conflicts must also be resolved for the object structure before you can create an interface table.

You can create interface tables for data synchronization on enterprise services and on publish channels. Interface tables do not support Query and Invoke operations. You can create interface tables for a specific endpoint. You must identify where the tables are created.

The database location that is referenced by the endpoint can be a local database or a remote database. When you create interface tables on a local database, the columns are registered in the system data dictionary. Local interface tables that use a database table and a database column show all updates (except insertions and deletions) to a base column attribute (such as data type) when you run the database configuration operation. When columns are added to or deleted from the base table, you must regenerate the corresponding enterprise service and the publish channel interface tables to apply the column changes. No changes are applied in the remote databases. You must regenerate remote interface tables to apply the column changes.

---

## Regeneration of interface tables

When columns are added or deleted from the system database tables, you must regenerate all local and remote interface tables that are associated with those object structures.

You regenerate interface tables by using the Create Interface Tables action in the External Systems application. If you select the Rename Existing check box, the application backs up existing data in the corresponding interface table to the INTERFACETABLENAME\_BAK table.

If necessary, you can restore the data to the new table. Depending on the configuration of a multitenancy environment, you may need to request the assistance of the system provider to access the data that you want to restore. If you do not back up the table, the table is dropped and the data is lost when you regenerate the table. You cannot regenerate an interface table when the MXIN\_INTER\_TRANS queue table contains a record that points to that interface table. When a row exists in that queue table, the corresponding inbound transaction is ready to process, or the inbound transaction is in error.

The interface table creation process does not check for records in the MXOUT\_INTER\_TRANS queue table.

You can set the `mxe.int.usedbinfoforifacetsb` property so that the processing of interface tables does not require an exact match between the object structure and the interface table. When the property is set to 1 (true), the interface process refers to the existing table to determine what to insert into the table rather than the object structure definition. This process avoids invalid column name errors when the endpoint is writing to the interface table.

If you add a new attribute to an interface table, the table must be regenerated to align with the object structure definition.

A utility is available on the Maximo® Manage Content Library that can check an interface table and its related object structure to identify when they are not synchronized. This utility can also update the object structure to exclude columns when those columns do not exist in the interface. See this link for more information: <https://www.ibm.com/developerworks/community/wikis/home?lang=en#!/wiki/IBM%20Maximo%20Asset%20Management/page/Maximo%207.5%20Interface%20Table%20Utility>.

---

## Deletion of interface tables and records

When related inbound transaction records are successfully processed in an interface table, the corresponding record is deleted from the MXIN\_INTER\_TRANS queue table. The deletion indicates that the transaction was delivered successfully to the inbound JMS queue.

Records are deleted from the MXIN\_INTER\_TRANS queue table and not from the individual interface tables. The system administrator determines when and how to delete records from the interface tables.

For outbound transactions, the external system must manage the deletion and archiving of data in the queue table and interface tables. You cannot delete interface tables in the user interface or by deleting the corresponding object structure. An administrator must manage the archiving of data in the interface tables and can drop the table, if necessary.

---

## Format of interface tables

An interface table has the same format as its corresponding object structure, including persistent and nonpersistent columns and excluding any columns that are excluded from the object structure.

The interface table includes additional columns that identify the sequence in which the sending system writes, and the receiving system processes the records in the various interface tables.

---

## Key columns

If the interface table represents a hierarchical object structure with parent-child object relationships, the table does not include any part of the child object key columns that are included in the parent object key columns. For example, PERSONID is a key column in the PERSON, PHONE, EMAIL, and SMS records. The PERSONID column appears only at the parent (PERSON) level in the MXPERSON\_IFACE interface table.

---

## Duplicate columns and aliases

The XML representation of a hierarchical object structure contains duplicate column names, but interface table and flat file representation do not. If an object structure has duplicate non-key column names in both a parent object and a child object, a duplicate column name error occurs when the interface table or a flat file record is generated.

To resolve this issue, change the alias name for one of the duplicate column names. Every system database column can have an alias alternate name. When an alias exists, the system uses the alias when interface tables and flat files are generated. Change the alias to eliminate the duplicate column name error.

Most columns do not have an alias, but some columns have aliases that support the predefined enterprise services or publish channels.

A column within an object structure can have a single alias. If the object structure is used by multiple publish channels and enterprise services, a change to an alias affects every interface table that is associated with the object structure.

The columns in the predefined object structures have system-assigned aliases. Check for duplicates when you create a hierarchical object structure or when you add an object to a predefined object structure. The Add/Modify Alias window shows the fields and aliases for the objects in a selected object structure, and identifies any duplicate alias names with a check in the duplicate column. If a duplicate alias exists, overwrite its value in the ALIASNAME column.

## Restricted columns

The HASLD field is an internal system column that is excluded from all object structures. Do not include this column in any object structure that is associated with an interface table. The LANGCODE field is also excluded from the predefined object structures.

## Integration processing columns

The following table shows the columns that are used in the interface table sequencing, retrieval, and processing. Some columns are in either the interface queue tables or the interface tables; some are in both places.

Table 1. Integration processing columns

Column name	Interface queue table	Interface table	Description
IFACENAME	Yes	No	The IFACENAME column contains the name of the enterprise service or the publish channel that is used in a transaction. The column is populated in outbound transactions. For inbound transactions, the external system must populate the column with the name of the enterprise service or the publish channel that corresponds to the row that is inserted into an interface table.
TRANSID	Yes	Yes	<p>The TRANSID column in an interface queue table is a sequential number that uniquely identifies an integration transaction. The TRANSID and the interface table name, identifies a unique transaction. The interface queue table can contain one record with a TRANSID value. The corresponding interface table can have one or more records with the TRANSID, depending on the number of records that are written to that interface table as part of that enterprise service or the publish channel.</p> <p>If a transaction writes to multiple interface tables, the interface queue table contains a separate record with a unique TRANSID value for each interface table.</p> <p>Each interface queue table maintains its own TRANSID counter. The outbound TRANSID value is initialized when the interface queue table records are generated. You must create and maintain the TRANSID counters that populate the inbound queue tables and the interface table records.</p> <p>If the external systems do not correctly manage the inbound TRANSID counters, sequential processing is not guaranteed. Ensure that the TRANSID values that the external system generates does not duplicate the TRANSID value that is generated. Errors occur if duplicate TRANSID values exist and when you process the same object structure in both an inbound and an outbound direction by using a single interface table.</p> <p>Each endpoint has its own set of interface queue tables and its own outbound TRANSID counter.</p>
TRANSSEQ	No	Yes	When multiple records in an interface table share the same TRANSID value, the TRANSSEQ column provides a secondary sequence number that indicates the sequence in which those records should be processed.
EXTSYSNAME	Yes	No	The EXTSYSNAME column in the interface queue tables can contain inbound or outbound data. For inbound transactions, the column contains the name of a valid and enabled external system that is defined in the integration framework. For outbound transactions, the column contains the name of the external system that is the destination of the transaction.
ACTION	Yes	No	<p>The ACTION column contains the action to perform on the external system (outbound) or on the integration framework (inbound). The following actions can be used:</p> <ul style="list-style-type: none"> <li>• Add: Inserts the data that is provided in the message.</li> <li>• Delete: Deletes the parent data, and any related child data, from the database.</li> <li>• Change: Updates parent and child data contents of the message, but does not delete existing child data that is not explicitly specified in the message.</li> <li>• Replace: Replaces the existing records with the contents of the message and deletes existing child data that is not referenced in the message.</li> <li>• AddChange: If the primary record does not exist, processes as an add action and, otherwise, processes as a change action.</li> <li>• Null: If the primary record does not exist, processes as an add action and, otherwise, process as a replace action.</li> </ul>
IMPORTMESSAGE	Yes (used inbound only)	No	The IMPORTMESSAGE column holds any error message that was produced when the interface table row was moved to the inbound queue.

Column name	Interface queue table	Interface table	Description
TRANSLANGUAGE	Yes	No	The TRANSLANGUAGE column identifies the language of the transaction. For an outbound transaction, this value indicates the language of the user who initiated the transaction. For an inbound transaction, this value indicates the language of the transaction. Any attributes that support a multilanguage environment are expected to be in the language that the TRANSLANGUAGE value defines.
MESSAGEID	Yes (used outbound only)	No	The MESSAGEID column is a unique identifier that the system assigns to every outbound transaction.
IFACETBNAME	Yes (used outbound only)	No	The IFACETBNAME column is the name of the interface table that corresponds to the IFACENAME column. This column applies to outbound transactions only.

## Long description columns in an Oracle Database

Long description columns are stored in a CLOB (character large object) column in an Oracle Database. Interface tables contain two versions of each CLOB column, one with data type CLOB, and one with data type ALN with a character length of 4000. In the following example, the name of the CLOB column is the column alias. The name of the alphanumeric column is the column alias with the suffix 2.

Table 2. Long description columns in an Oracle Database

Data type	Name of description column
CLOB	PERSON_DESCRIPTION_LD
ALN	PERSON_DESCRIPTION_LD2

The system populates both columns in outbound transactions. For inbound transactions, the integration framework uses the value in the ALN column if it is not null; otherwise, the value in the CLOB column is used.

## Interface table polling

A predefined cron task polls the interface queue table and uses the IFACENAME, EXTSYSNAME, and TRANSID values to place the corresponding records into the appropriate inbound JMS queue for processing. The interface polling process checks that the names of the external system and enterprise service are valid and enabled.

You must configure the cron task to initiate interface table polling. You can also perform additional tasks to enhance performance during interface polling.

- [Interface table polling cron task](#)  
The IFACETABLECONSUMER cron task is a predefined cron task that polls the inbound interface queue table for new records to process.
- [Advanced interface table polling](#)  
You can perform advanced configuration of the interface table polling process to improve its performance when reading data from interface tables.

## Interface table polling cron task

The IFACETABLECONSUMER cron task is a predefined cron task that polls the inbound interface queue table for new records to process.

The interface table polling process checks that the external system and enterprise service names are valid and currently enabled. If they are not, the record is marked in error and remains in the interface table.

If you disable interface table polling, new records remain in the interface tables. The messages that were sent to the inbound JMS queue are processed.

You must set up a mechanism to retrieve outbound transactions from the interface tables. You can use a polling program, as the system does for inbound transactions, triggers, or any other mechanism.

The cron task has the following parameters that you can configure. All parameters are optional.

Table 1. Interface table polling cron task parameters

Parameter	Description
EXITCLASS	Java™ exit class that enables the manipulation of data before it is written to an inbound queue.
ENDPOINT	Endpoint that is associated with the interface table. The default value is the predefined endpoint value that points to the local database.
ENTERPRISESERVICE	Enterprise service to be polled. The default (null value) is all enterprise services. If you specify a value for this parameter, you also must specify a value for the EXTSYSNAME parameter. The values limit the polling thread to a specific enterprise service instead of the default behavior, which polls for all enterprise services.
TARGETENABLED	Ensure that the value is at the default of 0 (false). The functionality of this flag is superseded by the donotrun functionality. Use the donotrun parameter in the cron task framework to control which servers the cron task runs on.
EXTSYSNAME	External system to be polled.
QUEUETABLE	Enterprise service queue table. The default value is MXIN_INTER_TRANS.

## Advanced interface table polling

You can perform advanced configuration of the interface table polling process to improve its performance when reading data from interface tables.

If you send inbound messages through the continuous JMS queue and do not require messages to be maintained in first-in-first-out sequence, you can improve the performance of interface table polling.

## Multiple cron tasks

---

The interface table polling process uses instances of the IFACETABLECONSUMER cron task to read all messages from all interface tables for all external systems that write to the tables. To improve performance, you can introduce multithreaded polling by configuring multiple instances of the IFACETABLECONSUMER cron task in the Cron Task Setup application.

For each instance, you define selectors by assigning values to the EXTSYSNAME and ENTERPRISESERVICE parameters, for example, EXTSYSNAME=EXTSYSNAME1 and ENTERPRISESERVER=MXPERSONInterface. All selectors must be mutually exclusive among the multiple instances to avoid processing a message more than once.

The performance benefit of multithreaded polling can be further realized in a clustered configuration. The IFACETABLECONSUMER instances can run on different servers to balance the load. To designate an instance of the IFACETABLECONSUMER cron task to run on a specific application server, set the TARGETENABLED parameter to 1 and, on the application server, set `-DIFACETBCONSUMER.<instance name>=1`.

If you configure multiple instances of a cron task the selectors must be mutually exclusive, so that messages are not processed multiple times. Selectors must retrieve all the enterprise service transactions that you use, so that no messages are left unprocessed.

## Multiple queues

---

You can improve performance by setting up multiple interface queue tables. For example, you can write each interface to a separate queue table and define separate cron tasks to process the queue tables independently of one another. You also can set up separate queue tables for each external system and, within each queue table, define selectors for each interface. Depending upon the complexity of your integration, you can use multiple queue tables instead of multiple selectors. To set up multiple queue tables, create the queue tables in the same database as the interface tables, and include all the columns that are in the MXIN\_INTER\_TRANS queue table. You must design the external system to write to the appropriate queue tables. Ensure that the external system does not insert an interface table message into more than one queue table so that the message is not processed multiple times.

## Processing interface tables on an external system

---

To enable an external system to use interface tables, you must create interface tables, define backup procedures for restoring interface tables, and configure the archiving of interface tables.

- [Enabling inbound processing](#)  
To configure inbound processing of interface table data from an external system, you must create a TRANSID counter and create records for the interface table and queue.
- [Enabling outbound processing](#)  
To configure outbound processing, you must set up and configure a process, such as a polling program or a trigger, to retrieve transactions from the MXOUT\_INTER\_TRANS queue table.

## Enabling inbound processing

---

To configure inbound processing of interface table data from an external system, you must create a TRANSID counter and create records for the interface table and queue.

### Before you begin

---

To use interface tables, you must create the tables and configure the IFACETABLECONSUMER cron task.

## Procedure

---

1. Create and initialize the outbound TRANSID counter.
2. Create records for each interface table that an inbound transaction writes to, populating each record with the following information:
  - a. The transaction data
  - b. The incremented TRANSID value
  - c. If multiple records exist for the same interface table, the incremented TRANSSEQ value
3. Create an MXIN\_INTER\_TRANS queue record with the following information:
  - a. The same TRANSID value that is contained the interface table record
  - b. The name of the enterprise service that corresponds to the interface table, in the IFACENAME column
  - c. Optional: The ACTION value
  - d. The identifier of the external system, in the EXTSYSNAME column
4. Perform a single commit, to commit all records for a transaction at one time.

## Enabling outbound processing

---

To configure outbound processing, you must set up and configure a process, such as a polling program or a trigger, to retrieve transactions from the MXOUT\_INTER\_TRANS queue table.

## Before you begin

---

To use interface tables, you must create the tables.

## Procedure

---

1. Set up a process to retrieve interface table transactions by using the MXOUT\_INTER\_TRANS queue table. You can use a polling program, a trigger, or any other mechanism.
2. For the polling program to process transactions sequentially configure it to read the records in the MXOUT\_INTER\_TRANS queue table in the TRANSID sequence.
3. Enable each record in the MXOUT\_INTER\_TRANS queue table:
  - a. Access the interface table that you just identified, and retrieve the first record in which the TRANSID value matches the TRANSID value in the current MXOUT\_INTER\_TRANS queue record. If the interface table contains multiple records with the same TRANSID value, retrieve and process them in TRANSSEQ sequence.
  - b. Process data according to the value in the ACTION column of the interface queue table.
4. Commit all records for a single database transaction.
5. Delete the current record from the MXOUT\_INTER\_TRANS queue table.

## What to do next

---

Implement error management, based on your external system requirements.

## Integration modules

---

An integration module provides a mechanism for a process management product to invoke an external operational management product. You can configure an integration module to automate logical management operations, such as software deployment, by using an operational management product.

A process management product can invoke an integration module from an application, a workflow process, or an escalation process. The integration module then invokes an operational management product. The operational management product automates a service management process, such as a software deployment. The implementation returns the results to the process management product.

If predefined modules are provided with your operational management product, use the process solution installer to load them into the integration framework. If you are familiar with the programming interface for the operational management product, you can create integration modules when one does not exist.

- [Integration module components](#)  
An integration module is composed of defined integration framework components. You can configure the integration module to be implemented as a Java™ class or as an invocation channel.
- [Implementation prerequisites](#)  
Before any integration module implementations occur, you must ensure the logical management operation is associated to one or more integration modules. The integration module then must have an association with an operational management product. Finally, the logical management operations on each operational management product must be enabled.
- [Implementation properties](#)  
The integration framework can automatically process integration data when you implement an integration module. You can customize the implementation if you want to bypass parts of the automatic process.
- [Invocation channel or Java class implementation](#)  
You can implement an integration module either as a Java class or as an invocation channel. Before developing an integration module, review the advantages and disadvantages to invocation channel or Java class usage.
- [Integration module processing](#)  
Process management products use a system action to initiate an integration module. The action can be associated with an escalation or a workflow, or can be initiated from a menu or a button. The process management product provides an action class that invokes the integration module and processes the response that the integration module returns.
- [Configuring integration modules](#)  
Integration modules receive data requests from process management products and return the response data from operational management products.
- [Configuring logical management operations](#)  
You can create a logical management operation to define an action that a process management product executes from the integration framework. You also can define what specific object field attributes that they logical management operation uses.

## Integration module components

---

An integration module is composed of defined integration framework components. You can configure the integration module to be implemented as a Java™ class or as an invocation channel.

When you install a predefined integration module, integration module artifacts with the Java class and XSL files are provided. An integration module also provides logical management operation definitions.

- [Integration module definitions](#)  
When you install an integration module, the options that you select are used to form the module definitions.

- [Operational management products](#)

An operational management product automates system processes, such as software deployment. Operational management product services are run on assets, such as servers. The assets are referred to as configuration items.

- [Logical management operations](#)

Logical management operations identify the actions that integration modules support, such as Get Status and Deploy Software. A logical management operation consists of a data source, target, and specific object field attributes that the source and target use during a process invocation.

---

## Integration module definitions

When you install an integration module, the options that you select are used to form the module definitions.

The integration module definition includes the following information:

- The name, version, and description of the integration.
- Operational management product and version.
- Handler that identifies the protocol that the integration module uses to invoke an operational management product.
- Integration module implementation choice, either a Java™ class or invocation channel.

The following components are contained in the integration module definition:

- The logical management operations that the integration module supports.
- The integration module properties that are unique to the integration module. Use the properties to configure the behavior of the integration module.

---

## Operational management products

An operational management product automates system processes, such as software deployment. Operational management product services are run on assets, such as servers. The assets are referred to as configuration items.

Multiple instances of operational management products can exist in a production environment. More than one operational management product can manage a single configuration item. Each operational management product has its own unique identifier, a source token, for each configuration item.

The database includes a repository of operational management product and configuration item information. This information includes relationships between the operational management products and configuration items, and the source tokens that drive the integration between process management products and operational management products.

---

## Logical management operations

Logical management operations identify the actions that integration modules support, such as Get Status and Deploy Software. A logical management operation consists of a data source, target, and specific object field attributes that the source and target use during a process invocation.

Logical management operations act as interfaces between the process management product and the integration module. You can design and develop integration modules and process management products independently. You can install logical management operation definitions with a product and you can also create logical management operations in the Logical Management Operations application.

The definition of a logical management operation contains the following properties:

Property	Description
Name	The name of the action, such as Get Status or Deploy Software.
Namespace	A unique qualifier, such as com.ibm.tivoli.deployment.
Invocation pattern	<ul style="list-style-type: none"><li>• Synchronous: The process management product issues a request and the integration module returns the results of the operation immediately.</li><li>• Asynchronous one-way: The process management product issues a request, and no response is returned.</li><li>• Asynchronous deferred response: The process management product issues a request, and a token identifies the instance of the request. The process management product passes the token as input to another logical management operation, which then obtains the status of the original request.</li><li>• Asynchronous callback: The process management product issues a request, and a token identifies the instance of the request. The operational management product uses a token to perform a call-back to identify and to report the status of the original request. The call-back, which is provided by the integration module, inserts or updates a business object.</li></ul>
Source business object	The input object for the logical management operation.
Response business object	The output of the object for the logical management operation.
Business object attributes	The specific attributes of the objects that are needed either for input or output and their data types.

Input objects and input object attributes identify the data that the process management product passes to the integration module. If the logical management operation is configured with input attributes and does not contain an input object, the process management product can pass any business object that has the required input attributes. If an input object is specified, the process management product must pass the business object to the integration module. The response object and attributes identify the data that the integration module returns.

---

## Implementation prerequisites

Before any integration module implementations occur, you must ensure the logical management operation is associated to one or more integration modules. The integration module then must have an association with an operational management product. Finally, the logical management operations on each operational management product must be enabled.

---

## Logical management operation associations

Typically, there is a one-to-one communication between a logical management operation and an operational management product function. However, a single logical management operation invocation can cause the integration module to invoke an operational management product multiple times.

An integration module that uses an invocation channel can run logical management operations only in the following circumstances:

- The source object that is defined on the logical management operation must match the main object of the request object structure that you define on the invocation channel.
- If the invocation channel is not configured to process a response, you cannot associate a response object with the logical management operation.
- The response object that you define on the logical management operation must match the main object of the response object structure that you define on the invocation channel. The match must occur when you configure the invocation channel to process a response.

---

## Operational management product associations

The integration module can support multiple logical management operations for an operational management product. When you run the integration module, the name and namespace values of the logical management operation specify the action to perform.

Operational management product and integration module associations are created when the `OMPPRODUCTNAME` and `OMPVERSION` values are added to the integration module. If multiple versions of the operational management product are used with the integration module, use a null value for the `OMPVERSION`.

---

## Logical operation management enablement

More than one integration module can implement the same logical management operation on an operational management product. Use the `ISPRIMARY` attribute to identify the preferred integration module for the logical management operation on the operational management product. Only one integration module can have the `ISPRIMARY` value set to a true for any given logical management operation - operational management product combination.

---

## Implementation properties

The integration framework can automatically process integration data when you implement an integration module. You can customize the implementation if you want to bypass parts of the automatic process.

- [Integration module parameters](#)  
The integration framework provides integration module input parameters, including source and response objects and object sets, and endpoint names. These parameters are passed when you run an integration module as a Java™ class or as an invocation channel.
- [Integration module process flow](#)  
Java-based integration modules populate the logical management operation response object or response object set with the results of the operation. For invocation channels, you can specify a mapping from the operational management product response to the response object or set. The integration framework copies the data into the response object or set.
- [Endpoints](#)  
An integration module that contains an invocation channel must use an endpoint. A Java class integration module can use an endpoint or use a custom approach to external service invocations.

---

## Integration module parameters

The integration framework provides integration module input parameters, including source and response objects and object sets, and endpoint names. These parameters are passed when you run an integration module as a Java™ class or as an invocation channel.

The following table lists the `psdi.iface.omp.IMConstants` interface parameters and their names.

Name	Description
IM	The instantiated ServiceInvoker object which can be a Java integration module or an invocation channel.
IMNAME	The name of the integration module.
IMVERSION	The version of the integration module.
LMONAME	The name of the logical management operation that is invoked.
LMONAMESPACE	The name space of the logical management operation that is invoked.
OMPGUID	The globally unique identifier (GUID) of the operational management product that the integration module uses.
ENDPOINTNAME	The name of the endpoint that the integration module uses to communicate with the operational management product.
ENDPOINTPROP	A map of <i>String.psdifmic.MaxEndPointPropInfo</i> properties that override the endpoint properties.
USERNAME	The user name that the integration framework uses to communicate with the endpoint.
PASSWORD	The password for USERNAME.

---

## Integration module process flow

Java™-based integration modules populate the logical management operation response object or response object set with the results of the operation. For invocation channels, you can specify a mapping from the operational management product response to the response object or set. The integration framework copies the data into the response object or set.

Integration modules must quickly return to their callers. If the external service is a long-running service, the integration module must create another thread. The new thread makes the call to the operational management product, while the original thread returns to the caller.

Integration modules perform the following processing tasks:

1. Retrieve input from the source object or source object set.
2. If applicable, retrieve the integration module-specific properties.
3. Perform all processing logic that the logical management operation requires before it calls the operational management product.
4. Call the operational management product.
5. If applicable, handle the operational management product response.
6. If applicable, populate the response object or response object set with the return data.
7. Return processing information back to the caller.

---

## Endpoints

An integration module that contains an invocation channel must use an endpoint. A Java™ class integration module can use an endpoint or use a custom approach to external service invocations.

Endpoints contain URL properties and handler properties that specify the transport mechanism to use. An endpoint with a web service handler has different properties than an endpoint with a command-line handler. Integration module endpoints and endpoint properties can be overwritten at run time when the process management product passes endpoint properties as input to the integration module. The USERNAME and PASSWORD properties that are returned from the credential mapper can also override the endpoint properties.

Java integration modules can communicate directly with an operational management product or external integration module, without the use of an endpoint. If you do not use an endpoint, you eliminate the need for the Java integration module to convert source objects into the required XML format. When you exclude endpoint use, you can use any communication protocol that is supported by the operational management product. Integration modules are not required to use endpoints. You can configure the integration module to communicate with an operational management product by using integration module properties.

The integration framework provides predefined handlers that support communication protocols such as HTTP and web services. If a predefined handler is not available to support the operational management product service protocol, implement an external integration module. The external integration module acts as an interface to the operational management product service that can use one of the available handler protocols. An alternative solution is to write a custom handler that supports the operational management product service protocol.

Configure a different endpoint for each operational management product to establish individual protocols for each product. The handler that you define for the endpoint must match the handler that you configure for the integration module.

Integration modules based on invocation channels require an endpoint. The endpoint name is one of the parameters the integration framework passes as input to the invocation channel. The caller of the integration module can override the endpoint name.

Regardless of whether you use an endpoint handler to communicate with the operational management product, the integration module must handle scenarios that require multiple invocations of the operational management product for a single logical management operation execution.

---

## Invocation channel or Java class implementation

You can implement an integration module either as a Java™ class or as an invocation channel. Before developing an integration module, review the advantages and disadvantages to invocation channel or Java class usage.

- [Invocation channel and Java class comparison](#)  
Before you develop an integration module, consider the advantages and disadvantages of using a Java class or an invocation channel.
- [Invocation channel implementation](#)  
Invocation channels use object structures in its implementations to expand the message data content. The object structure uses the object that the process management product passes as the source object to build an entire record that can consist of multiple related objects.
- [Java class implementation](#)  
Integration modules can be implemented to use Java class files. Using a Java class file eliminates the need for integration component registration and configuration. Additionally, all the underlying integration module implementations are transparent to the process management product.

---

## Invocation channel and Java class comparison

Before you develop an integration module, consider the advantages and disadvantages of using a Java™ class or an invocation channel.

---

## Advantages and disadvantages of using an invocation channel

Implementing an integration module by using an invocation channel has the following advantages:

- An invocation channel is useful when you pass complex data to the endpoint. It is also useful when you can define a clear mapping between the fields in the source object and the input the endpoint requires.
- Can support hierarchical object structures on input and output transactions.
- The integration framework handles the conversion of objects to XML, and XML to objects.
- Can be configured to use processing classes, user exits, and XSL mapping for inbound and outbound transactions.
- The integration framework performs endpoint invocation.
- Can be invoked directly without an association to an integration module or a logical management operation.
- A simple integration can be implemented using system configuration that does not require you to restart the application server.

Implementing an integration module by using an invocation channel has the following disadvantages:

- Requires more registration and configuration of system artifacts, even when the invocation is simple.
- Multiple applications cannot use the integration module with different business objects.
- Requires additional knowledge of the integration framework.
- Supports only a single invocation of the configured endpoint. It requires additional coding to support multiple invocations.
- Requires additional coding to support a long-running service. By default, the invocation channel waits for a response from the endpoint.

## Advantages and disadvantages of using a Java class

---

Implementing an integration module by using a Java class has the following advantages:

- Requires less registration and configuration of system artifacts.
- Can be used by different applications while using different business objects.
- Can be designed to make multiple external invocations.
- Can use different communication protocols for different logical management operations and operational management products.
- Supports the use of another thread to accommodate a long-running service.
- Can implement multiple logical management operations, even when the input configuration and the output configuration is different.
- Is less likely to require the use of an external integration module.

Implementing an integration module by using a Java class has the following disadvantages:

- Requires you to perform more Java coding.
- Does not support an object structure with a parent and child relationship as input or output. Only the parent object can be used as input, and the Java code must find the child relationship.
- Conversions of objects to XML and XML to objects must be coded when you use an endpoint handler.
- Customization must be built into the design of the integration module. Customization cannot be added later without redeploying the code.
- Use of any integration framework components, such as an endpoint handler, must be coded in the Java class.

---

## Invocation channel implementation

Invocation channels use object structures in its implementations to expand the message data content. The object structure uses the object that the process management product passes as the source object to build an entire record that can consist of multiple related objects.

The objects that are identified in the object structures are used in the XML message creation. When you use an invocation channel, the data must conform to the XML schemas specified for the associated object structures, and you must define an endpoint for the invocation channel.

Invocation channels support optional inbound and outbound processing exit classes. The integration framework uses processing exit classes to implement additional logic. The inbound and outbound processing exit classes must be instances of the Java™ class `psdi.iface.migexits.ExternalExit`.

For outbound transactions, the integration framework calls the following method:

```
public StructureData setDataOut(StructureData irData)
```

For inbound transactions, the integration framework calls the following method:

```
public StructureData setDataIn(StructureData erData)
```

When you override these methods, you can perform additional integration module processing. The properties that are passed to the invocation channel are available to the processing classes.

The following outbound processing class code shows you how to retrieve the operational management product globally unique identifier when you run an invocation channel:

```
import psdi.server.MXServer;
import psdi.iface.omp.IMConstants;
import psdi.iface.omp.OmpServiceRemote;
import psdi.iface.mic.*;
import psdi.iface.migexits.*;
.
.
.
public class OutboundCIEExit extends ExternalExit implements IMConstants
{
 public StructureData setDataOut(StructureData irData)
 throws MXException, RemoteException
 {
 IntegrationContext cntx = IntegrationContext.getCurrentContext();
 String ompGUID = cntx.getStringProperty(OMPGUID);
```

```
.
. .
}
}
```

Additional features of the invocation channel include user exit Java classes and an XSL mapping layer. You can configure the XSL mapping layer to do XML mapping or data transformation.

If the object structure that you need for your integration module invocation does not exist, you can create an object structure in the Object Structures application. You also can use XML with the MXINTOBJECT object structure to create object structures as part of the installation process.

---

## Java class implementation

Integration modules can be implemented to use Java™ class files. Using a Java class file eliminates the need for integration component registration and configuration. Additionally, all the underlying integration module implementations are transparent to the process management product.

Java class integration modules must implement the `psdi.iface.mic.ServiceInvoker` Java interface. The service invoker Java interface is included in the `businessobjects.jar` file. Include the integration module Java class in the system class path at run time.

The service invoker Java interface has variations of the following method signature:

```
public byte[] invoke(Map String, Object metaData,
MboRemote sourceMbo, MboRemote targetMbo, String endPointName)
throws MXException, RemoteException;
```

- **metaData** is a map of the name and value properties that includes:
  - The integration module name and version.
  - The logical management operation name and name space.
  - The operational management product globally unique identifier.
  - The endpoint name and any endpoint properties that are being overwritten.
- **sourceMbo** is the source object that you defined on the logical management operation.
- **targetMbo** is the response object that you defined on the logical management operation
- **endPointName** is the name of the endpoint that you use for communication with the operational management product.

If you configure the integration module to implement multiple logical management operations, the integration module must determine which logical management operation is being called. At run time, the integration module retrieves the `LMONAME` and `LMONAMESPACE` properties from the **metaData** input map:

```
import psdi.iface.omp.IMConstants;
. .
.
String lmoName = metaData.get(IMConstants.LMONAME);
String lmoNamespace = metaData.get(IMConstants.LMONAMESPACE);
```

The integration module can retrieve logical management operation data from the source object. The following example code retrieves logical management operation values from the source object:

```
String guid = sourceMbo.getString("GUID");
int packID = sourceMbo.getInt("PACKID");
boolean hasSubs = sourceMbo.getBoolean("HASSUBS");
```

In the example, the logical management operation has an alphanumeric input attribute called globally unique identifier, an integer attribute called `PACKID`, and a Boolean attribute called `HASSUBS`.

Service invoker methods can take a **MboSetRemote** set of values as a source input, instead of a single **MboRemote** value. In some cases, the integration module passes all of the objects in the object set to the operational management product. In other cases, the integration module passes only the first object in the set. There are no set rules that apply to the integration module behavior, but you must clearly define the expected behavior in the logical management operation description.

---

## Integration module processing

Process management products use a system action to initiate an integration module. The action can be associated with an escalation or a workflow, or can be initiated from a menu or a button. The process management product provides an action class that invokes the integration module and processes the response that the integration module returns.

- [Identification of integration components](#)  
The initiation action class identifies the components required for the integration, including the logical management operation, the operational management product, and the integration module.
- [Integration module invocation](#)  
Integration modules can be implemented either as Java™ classes or as invocation channels. Integration module instances are called service invokers because they implement the Java interface `psdi.iface.mic.ServiceInvoker`.
- [Integration module response processing](#)  
If a logical management operation has a response object, the integration module updates the response object with the results from its invocation. The action class determines whether to save the results to the database. If the action class does not save the results, you can save the data when you view the response results in the user interface.

## Identification of integration components

The initiation action class identifies the components required for the integration, including the logical management operation, the operational management product, and the integration module.

The logical management operation runs a process, such as software deployment, on a configuration item by using an operational management product. The process management product provides the necessary input to the integration module, based on the input business objects and attributes that are defined on the logical management operation.

The Java™ action class identifies an operational management product that runs the logical management operation on the selected configuration item. When you install configuration items and operational management products, the component relationships are also installed.

An integration module record identifies which logical management operations are supported on an operational management product. When the integration modules, configuration items, and operational management products are registered, the process management product Java class performs a lookup. The Java class determines which integration modules that it invokes based on the configuration items that it uses.

The integration framework includes a service that provides the following utility methods to assist the class with integration module lookups.

Utility method	Function
<code>psdi.iface.app.omp.OmpSetRemote getOMListForIM (String imName, String imVersion)</code>	Retrieves a list of the operational management products that are associated with the integration module.
<code>psdi.iface.app.im.MaxIMSetRemote getIMListForLMO (String lmoName, String lmoNamespace)</code>	Retrieves a list of the integration modules that implement the specified logical management operation.
<code>psdi.iface.app.im.MaxIMSetRemote getIMListForLMOWithOMP (String lmoName, String lmoNamespace)</code>	Retrieves a list of the integration modules that implement the specified logical management operation on any operational management products.
<code>psdi.iface.app.im.MaxIMSetRemote getIMListForOMP (String ompGuid)</code>	Retrieves the list of the integration modules that implement at least one logical management operation on the operational management product.
<code>Collection getIMListForOMPAndLMO (String ompGUID, String lmoName, String lmoNamespace)</code>	Retrieves the list of integration modules that implement the logical management operation on the specified operational management product. Returns a collection of <code>psdi.iface.omp.OmpImLmoRelInfo</code> objects.
<code>Collection getIMListForOMPAndLMO (String ompHostname, String ompProductname, String ompManufacturer, String lmoName, String lmoNamespace)</code>	Retrieves the list of integration modules that implement the logical management operation on the specified operational management products. Returns a collection of <code>psdi.iface.omp.OmpImLmoRelInfo</code> objects.
<code>psdi.iface.omp.OmpImLmoRelInfo getPreferredIM (String ompGUID, String lmoName, String lmoNamespace)</code>	Retrieves the preferred integration module that implements the logical management operation on the specified operational management product.
<code>psdi.iface.omp.OmpImLmoRelInfo getPreferredIM (String ompHostname, String ompProductname, String ompManufacturer, String lmoName, String lmoNamespace)</code>	Retrieves the preferred integration module that implements the logical management operation on the specified operational management product.

## Integration module invocation

Integration modules can be implemented either as Java™ classes or as invocation channels. Integration module instances are called service invokers because they implement the Java interface `psdi.iface.mic.ServiceInvoker`.

The service invoker interface hides the underlying implementation from the caller. The invocation of the integration module by the caller is the same, regardless of the underlying implementation.

- [Service invoker property map](#)  
The `getServiceInvoker` utility methods return a map of name and value pairs.
- [Invoke methods](#)  
The integration framework provides some invoke methods that the caller uses to invoke an integration module. Invoke methods use properties to determine what object data is returned to the caller. The properties also determine what action is taken on the returned data and how the integration framework communicates with the caller.
- [Operational management product service method](#)  
Use the operational management product service method when the action class has a relationship to a configuration item, or when it has a configuration item globally unique identifier (CIGUID) attribute.
- [Service invoker utility methods](#)  
The `getServiceInvoker` utility includes methods that retrieve an instance of an integration module for a logical management operation and an operational management product.

## Service invoker property map

The `getServiceInvoker` utility methods return a map of name and value pairs.

The `psdi.iface.omp.IMConstants` Java™ interface defines the names of the properties that are returned in the map. The property `IMConstants.IM` contains the instance of the integration module that the process management product invokes.

The property `IMConstants.ENDPOINTNAME` contains the name of the endpoint that is associated with in the operational management product, integration module, and logical management operation relationship. In most cases, the endpoint property is the value that the process management product passes to the integration module. However, in unusual cases, the action class overwrites the configured endpoint.

If a credential mapper is configured, the `getServiceInvoker` utility methods call the credential mapper to retrieve the `USERNAME` and `PASSWORD` that is used for endpoint communication. These properties are returned by the utility methods in a map that is identified by the property `IMConstants.ENDPOINTPROPS`. The caller can overwrite any endpoint properties by adding them to this map.

Before the action class calls the integration module, it must populate the source object with the logical management operation input fields. The action class then passes the source object data to the integration module with the mapping that is returned by the `getServiceInvoker` utility method. The action class provides the logical management operation response object to the integration module when necessary.

The logical management operation response object requires attributes. The action class must ensure that the response object has the logical management operation attributes. The attributes can be persistent or nonpersistent. The response object typically contains the source object data.

## Invoke methods

The integration framework provides some invoke methods that the caller uses to invoke an integration module. Invoke methods use properties to determine what object data is returned to the caller. The properties also determine what action is taken on the returned data and how the integration framework communicates with the caller.

The service invoker interface has four invoke method signatures:

- `public byte[] invoke(Map <String, Object> metaData, MboRemote sourceMbo, MboRemote targetMbo, String endPointName)`
- `public byte[] invoke(Map <String, Object> metaData, MboRemote sourceMbo, MboSetRemote targetMboSet, int action, String endPointName)`
- `public byte[] invoke(Map <String, Object> metaData, MboSetRemote sourceMboSet, MboRemote targetMbo, String endPointName)`
- `public byte[] invoke(Map <String, Object> metaData, MboSetRemote sourceMboSet, MboSetRemote targetMboSet, int action, String endPointName)`

The action class passes the following properties when it calls one of the invoke methods on the instantiated service invoker.

Property	Description
metaData	The property map that the <code>getServiceInvoker</code> utility method returns.
Source object and object set	The object with the input attributes that are defined on the logical management operation. This property can contain a null value.
Target object and object set	The object and object set that contains the return data. This property can contain a null value.
Action	This parameter indicates whether existing objects in the <code>targetMboSet</code> are updated, or new objects are added. The possible values for action are: <ul style="list-style-type: none"><li>• <code>psdi.mbo.MboSetRemote.INSERTONLY</code></li><li>• <code>psdi.mbo.MboSetRemote.UPDATEONLY</code></li></ul>
Endpoint name	The name of the endpoint that the integration module uses for communication.

## Operational management product service method

Use the operational management product service method when the action class has a relationship to a configuration item, or when it has a configuration item globally unique identifier (CIGUID) attribute.

When the action class has an authorized configuration item, instead of an actual configuration item, you can use the configuration item globally unique identifier attribute of the authorized configuration item.

The following service method retrieves a list of the preferred integration modules (service invokers). The integration modules implement the specified logical management operation on the operational management products that manage the specified actual configuration item.

```
public Collection Map getServiceInvokerListForCIAndLMO(String
actCIGUID, String lmoName, String lmoNamespace, UserInfo userInfo)
```

Each operational management product that has a relationship with the specified actual configuration item, returns the preferred integration module for the logical management operation.

## Service invoker utility methods

The `getServiceInvoker` utility includes methods that retrieve an instance of an integration module for a logical management operation and an operational management product.

The following table lists the utility methods provided with the `getServiceInvoker` utility.

Utility method	Function
----------------	----------

Utility method	Function
<code>Map&lt;String, Object&gt; getServiceInvoker (psdi.iface.omp.OmpImLmoRelInfo ompImLmoRelInfo, psdi.security.UserInfo userInfo)</code>	Retrieves the service invoker for the specified integration module, logical management operation, and operational management product.
<code>Map&lt;String, Object&gt; getServiceInvoker (psdi.iface.app.im.OmpImLmoRelRemote ompImLmoRelRemote, psdi.security.UserInfo userInfo)</code>	Retrieves the service invoker for the specified integration module, logical management operation, and operational management product.
<code>Map&lt;String, Object&gt; getServiceInvoker (String ompGUID, String imName, String imVersion, String lmoName, String lmoNamespace, psdi.security.UserInfo userInfo)</code>	Retrieves the service invoker for the specified integration module, logical management operation, and operational management product.
<code>Map&lt;String, Object&gt; getServiceInvoker (String ompGUID, String lmoName, String lmoNamespace, psdi.security.UserInfo userInfo)</code>	Retrieves the service invoker for the preferred integration module for the specified operational management product and logical management operation.
<code>Collection&lt;Map&gt; getServiceInvokerListForCIAndLMO (String actCIGUID, String lmoName, String lmoNamespace, psdi.security.UserInfo userInfo)</code>	Retrieves a list of the service invokers for the preferred integration modules that implement the specified logical management operation on the operational management products. The operational management products have a relationship with the configuration item.

## Integration module response processing

If a logical management operation has a response object, the integration module updates the response object with the results from its invocation. The action class determines whether to save the results to the database. If the action class does not save the results, you can save the data when you view the response results in the user interface.

If the response object is the primary object from the application, or if the updated object is based on a relationship with the primary object of the application, the action class does not save the object. Instead, the user interface prompts you to save the object. However, if the updated object is unrelated to the primary application object, the action class saves and commits the changes.

## Configuring integration modules

Integration modules receive data requests from process management products and return the response data from operational management products.

- [Creating integration modules](#)  
You can create an integration module to pass data between local and external applications. Depending on your needs, you can implement an integration module as an invocation channel or Java™ class. Both the invocation channel and Java class have access to the database and all the objects in memory at the time a process management product invokes an integration module.
- [Selecting logical management operations for integration modules](#)  
You can use the Select Operations dialog box to associate one or more logical management operations with an integration module record. Logical management operations define an action that a process manager product runs from an application.
- [Associating a logical management operation with an integration module](#)  
You can associate a logical management operation with an integration module to define the actions that are taken on an operational management product. Process management products, such as Change or Deploy, call upon an integration module to run an operational management product. The operational management product then runs the logical management product, such as deploy software, and notifies the process management product of the action status.

## Creating integration modules

You can create an integration module to pass data between local and external applications. Depending on your needs, you can implement an integration module as an invocation channel or Java™ class. Both the invocation channel and Java class have access to the database and all the objects in memory at the time a process management product invokes an integration module.

### Procedure

1. In the Integration Modules application, click New Integration Module.
2. In the Name and Version fields, enter a unique integration module name and version number combination.  
The version field must start with a v and be followed by an integer between 0 to 9, inclusive. The integer can then be followed by a decimal point (.) and up to 17 additional integers. For example, v2.99. or v9.123456.
3. Optional: Enter values in the following fields:

Option	Description
<b>Operational Management Product Name</b>	The operational management product that the integration module invokes. If an integration module works with multiple products, you do not specify a product name.
<b>Operational Management Product Version</b>	The version value of the product that the integration module invokes. If an integration module works with multiple versions of an operational management product, you do not specify a version value.

Option	Description
<b>Handler Name</b>	The protocol that the integration module uses to invoke an operational management product. If the invocation channel has an associated end point, you cannot configure a handler for the integration module.
<b>Invocation Channel Name</b>	The name of the invocation channel that the integration module runs. The integration module uses either an invocation channel or a Java class. Specify only one of them.
<b>Class Name</b>	The name of the Java class that the integration module runs. The integration module uses either an invocation channel or a Java class. Specify only one of them.

4. Click Save Integration Module.

## What to do next

You can associate a logical management operation to an integration module to define the actions that process managers run. You also can associate an operational management product to an integration module to define the external applications that you can invoke from a process management product.

## Selecting logical management operations for integration modules

You can use the Select Operations dialog box to associate one or more logical management operations with an integration module record. Logical management operations define an action that a process manager product runs from an application.

### Before you begin

You first must associate the logical management operation with an operational management product before a process management product can run a logical management operation. The logical management operation records that you associate with an integration module that uses an invocation channel must have a source object name value. This value must be the same as the top source object that is registered to the invocation channel. Additionally, the logical management operation records must have a response object name value when the invocation channel that processes responses. This value must be the same as the top object registered to the invocation channel. You can define the logical management operation source and response object values in the Logical Management Operations application.

### Procedure

1. In the Integration Modules application, select the integration module that you want to associate to the logical management operations.
2. On the Logical Management Operations tab, click Select Operations.
3. Select the logical management operations that you want to associate to the integration module record.
4. Click OK.
5. Click Save Integration Module.

## What to do next

You can associate an operational management product to an integration module to define the external applications that you can invoke from a process management product.

- [Selecting logical management operations for operational management products](#)  
You can use the Select Operations dialog box to associate one or more logical management operations to an operational management product. The association that you make to the operational management product enables the logical management operation. The enablement indicates that the logical management operation is ready for use.

## Selecting logical management operations for operational management products

You can use the Select Operations dialog box to associate one or more logical management operations to an operational management product. The association that you make to the operational management product enables the logical management operation. The enablement indicates that the logical management operation is ready for use.

### Before you begin

A logical management operation must be associated with an integration module before it can be enabled on an operational management product.

### Procedure

1. In the Integration Modules application, select the integration module that you want to associate to the logical management operations.
2. On the Operational Management Products subtab, select the operational management product that you want to associate to the logical management operations.
3. In the Logical Management Operations for Operational Management Product table window, click Select Operations.
4. Select the logical management products that you want to enable for the operational management product.
5. Click OK.
6. Click Save Integration Module.

---

## Associating a logical management operation with an integration module

You can associate a logical management operation with an integration module to define the actions that are taken on an operational management product. Process management products, such as Change or Deploy, call upon an integration module to run an operational management product. The operational management product then runs the logical management product, such as deploy software, and notifies the process management product of the action status.

### Before you begin

---

You first must associate the logical management operation with an operational management product before a process management product can run a logical management operation. The logical management operation records that you associate with an integration module that uses an invocation channel must have a source object name value. This value must be the same as the top source object that is registered to the invocation channel. Additionally, the logical management operation records must have a response object name value when the invocation channel that processes responses. This value must be the same as the top object registered to the invocation channel. You can define the logical management operation source and response object values in the Logical Management Operations application.

### About this task

---

The invocation pattern value determines whether the logical management operation is long-running. It also determines how the process management product expects a response from the operational management product.

### Procedure

---

1. In the Integration Modules application, select the integration module that you want to associate with a logical management operation.
2. On the Logical Management Operations subtab, click New Row.
3. Enter values in the following fields:

Option	Description
<b>Logical Management Operation Name</b>	Identifies the actions that integration modules support, and the actions that the process management products request.
<b>Namespace</b>	Identifies the domain for the logical management operation name. An example is <code>com.ibm.mss</code> .

4. Click Save Integration Module.

### What to do next

---

You can associate an operational management product to an integration module to define the external applications that you can invoke from a process management product.

- [Associating an operational management product with an integration module](#)

You can associate an operational management product to an integration module to define the external applications that you can invoke from a process management product. Process management products, such as Change or Deploy, call upon an integration module to run an operational management product. The operational management product then runs the logical management product, such as deploy software, and notifies the process management product of the action status.

---

## Associating an operational management product with an integration module

You can associate an operational management product to an integration module to define the external applications that you can invoke from a process management product. Process management products, such as Change or Deploy, call upon an integration module to run an operational management product. The operational management product then runs the logical management product, such as deploy software, and notifies the process management product of the action status.

### Before you begin

---

Before a process management product can call an integration module to run a logical management operation on an operational management product, configure the following components:

- Define and configure a logical management operation
- Associate the integration module with the logical management operation and operational management product
- Enable the logical management operation for the integration module on the operational management product

### About this task

---

You can build and configure relationships between integration modules, operational management products, and logical management operations. You can also perform the following actions:

- Associate multiple operational management products with an integration module
- Enable logical management operations on the operational management product for the integration module
- Specify a default integration module to use for a particular logical management operation on an operational management product
- Configure the end point for an integration module and operational management product combination when the invocation channel has no associated end point

## Procedure

1. In the Integration Modules application, select the integration module that you want to associate with an operational management product.
2. On the Operational Management Products subtab, click New Row.
3. Enter a values in the following fields:
  - Operational Management Product
  - End Point
4. In the Logical Management Operations table window, click New Row.
5. Enter a value in the Logical Operation Management Name field.  
Default values display in the Namespace and Description fields.
6. Optional: Select the Is Primary check box to make the integration module the default integration module for the selected logical management operation.  
Select the Is Primary check box when you enable the selected logical management operation on more than one integration module record.
7. Click Save Integration Module.

## What to do next

You can associate a logical management operation with an integration module to define the actions that are taken on an operational management product.

## Configuring logical management operations

You can create a logical management operation to define an action that a process management product executes from the integration framework. You also can define what specific object field attributes that they logical management operation uses.

- [Creating logical management operations](#)  
You can define the invocation pattern on a logical management operation. The pattern value determines whether the logical management operation is long-running and how the process management product expects a response from the operational management product.
- [Adding attributes to logical management operations](#)  
You can add attributes to a logical management operation to identify the specific object field attributes the logical management operation data source and target use. You can define the individual attribute entries for both input and output logical management operation invocations.

## Creating logical management operations

You can define the invocation pattern on a logical management operation. The pattern value determines whether the logical management operation is long-running and how the process management product expects a response from the operational management product.

## Before you begin

You must define a logical management operation relationship to an operational management product and integration module before you can invoke any processes.

## Procedure

1. In the Logical Management Applications application, click New Logical Management Operation.
2. In the Name field, specify a logical management operation identifier.
3. Enter values in the following fields:

Option	Description
Source Object Name	The input object for the logical management operation.
Invocation Pattern	The pattern of a logical management operation invocation.
Name Space	The secondary identifier for the logical management operation record.
Response Object Name	The output of the object for the logical management operation.

4. Click Save Logical Management Operation.

## Adding attributes to logical management operations

You can add attributes to a logical management operation to identify the specific object field attributes the logical management operation data source and target use. You can define the individual attribute entries for both input and output logical management operation invocations.

## About this task

Input object attributes identify the data that the process management product passes to the integration module. Output object attributes identify the data that the integration module returns. Only the respective attributes of the selected source and response objects are available for field selections. If you have not defined either a source or response object, all object attributes are available for selection.

## Procedure

1. In the Logical Management Applications application, select the logical management operation for which you want to add an attribute.
2. In the Attributes for LMO window, click New Row.
3. Enter a value in the Name field.
4. Optional: Clear the Input check box to indicate that the attribute is for the output of a logical management operation invocation.
5. Optional: Clear the Required check box to indicate the field attribute is not required in the logical management operation invocation.

---

## Launch in Context feature

You use the Launch in Context application to create and modify launch entry records which open an external application in the same or a different browser session. You can open applications independently or as part of an application integration scenario.

The launch entry record can utilize the following options in the Application Designer to open an external application:

- Action menu items
- Hyperlinks
- Buttons

You use the Launch in Context application to create and update launch entries. A launch entry defines a URL that opens a console for an external application. The launch entry can pass data, referred to as context, from the application to the external console. You can configure a console URL for any application with a web-based console. Additionally, you can configure console URLs for consoles that use Java™ Web Start. You cannot use a launch entry to open applications that are not enabled for the web. You can configure a launch point from any application.

- [Preparation of the external application](#)

Most external applications have a web-based console that you can open from a URL in a web browser. The launch-in-context feature supports the web application (servlet or JSP), portal, and Java Web Start console types.

- [Launch entry URL into an external application](#)

A launch entry URL value can contain substitution variables that use data from the related business objects that you are viewing in the application.

- [Launch entry URL into a product application](#)

A launch entry URL value can contain attribute variables and a SQL Where clause variable.

- [Enabling launch-in-context](#)

To open a browser window in an external application that can contain contextual data, a user must be able to activate the launch in the source application. The user must also have security rights to view the menu item or toolbar button. The target application must be configured to accept the window request from a remote application, and arrangements must be in place to secure the transaction.

---

## Preparation of the external application

Most external applications have a web-based console that you can open from a URL in a web browser. The launch-in-context feature supports the web application (servlet or JSP), portal, and Java™ Web Start console types.

To perform a navigation, the external application console must support the land-in-context capability that accepts data that is passed to it in a URL. The external console uses the URL to open a window with the data that was passed in the URL.

If the external application does not have a land-in-context capability, the launch-in-context feature can open a standard start page within the console, without the contextual data. If the application supports single sign-on authentication, application users are authenticated and directed to the external console. If single-sign on authentication is not implemented, the external console opens a login panel to authenticate the application user.

---

## Launch entry URL into an external application

A launch entry URL value can contain substitution variables that use data from the related business objects that you are viewing in the application.

For example, for a launch entry that is implemented in the Person application, you can substitute the name value into the URL string by using the attribute name, **{attributename}**. The following URL is a URL for the Person application that uses the PERSONNAME attribute:

`https://extsyshost:9045/tcWebUI/interactionhandler?actionId=viewPerson&Person={PERSONNAME}`

You can also provide an attribute from an object that is related to the main business object by specifying the relationship name and the attribute name **{relationshipname.attributename}**. The following URL includes a city attribute from an address. Use this URL in the People application when the ADDRESS object is related to a PERSON object with a relationship named ADDRESS:

`https://extsyshost:9045/WebUI/interactionhandler?actionId=viewCity&cityname={ADDRESS.CITY}`

Use the **{sourcetoken}** and the **{reportinghostname}** values in a URL when you want to launch to an operational management product console.

---

## Launch entry URL into a product application

A launch entry URL value can contain attribute variables and a SQL Where clause variable.

An external application can launch into the product, open a specific product application, and search for specific business objects to display.

When launching into the product, the product sign on screen is presented. After the user signs on, the specified application opens. Optionally, you can include the username and password in the URL to bypass the sign on screen but only if a Secure Socket Layer (SSL) is configured to secure HTTP access.

The URL to launch into the product has the following format:

```
http://<server>:<port>/<maximo>/ui/<product.jsp>?event=loadapp&value=<appID>
```

The following example URL opens the Work Order Tracking application and displays the work order with an ID of 1000

```
http://<server>:<port>/<maximo>/ui/<maximo.jsp>?event=loadapp&value=wotrack&attrname1=WONUM&attrvalue1=1000:
```

The search for a record has similar behavior to the List tab in an application, where the filter row has multiple values filled in across the columns. The names of the attributes are the database names of the primary MBO for the application being launched.

If advanced searching is required, you can add a SQL WHERE clause to the URL, in the format used in the following example:

```
http://<server>:<port>/maximo/ui/maximo.jsp?event=loadapp&value=wotrack&sqlwhere=WONUM%3D1000
```

The sender must provide valid URLs. In the previous example, an invalid "=" value was converted to "%3D".

If a URL includes both attribute-type parameters and a SQL Where clause parameter, the SQL Where clause parameter is used and the attribute-type parameters are ignored.

---

## Enabling launch-in-context

To open a browser window in an external application that can contain contextual data, a user must be able to activate the launch in the source application. The user must also have security rights to view the menu item or toolbar button. The target application must be configured to accept the window request from a remote application, and arrangements must be in place to secure the transaction.

- [Creating a launch entry](#)  
You can create a launch entry to open an external application in the same or in a new browser session. Launch entry records create website-based links between applications and external operational management products or websites.
- [Configuring a signature option for a launch point](#)  
When you create a signature option for a launch point, it becomes available to use within the user interface controls.
- [Adding a launch point to an application menu](#)  
After you configure a signature option for a launch point, you can add the option to an application menu. The procedure is similar for adding the launch point to an action or to a toolbar menu.
- [Adding a button as a launch point](#)  
To add a button to an application that acts as a launch point, configure a button to use the signature option for the launch point.
- [Adding a condition to a launch point](#)  
You can create a condition and then associate the condition with the signature option for the launch point. When you associate a condition with a signature option, the user interface behavior is changed based on the condition and the data that is being viewed.

---

## Creating a launch entry

You can create a launch entry to open an external application in the same or in a new browser session. Launch entry records create website-based links between applications and external operational management products or websites.

---

### Procedure

1. In the Launch in Context application, click New Launch Entry.
2. In the Launch Entry Name field, specify a launch entry identifier.
3. In the console URL field, specify the URL for a website or the console for an operational management product that you want to open in a browser session.
4. In the Target Browser Window field, specify one of the following values:
  - The `_usecurrent` value (default) opens an application or website in the current browser session.
  - The `_blank` value open an application or website in a new browser session.
5. Optional: If the target of the launch entry is a console for an operational management product, specify its name and version in the OMP Product Name and the OMP Version fields.
6. In the Launch Contexts table, click New Row.
7. In the Resource Object Name field, you can specify a business object that restricts use of the launch entry record to applications that support this object.  
A launch entry can support single or multiple business objects. No restrictions apply to the use of the launch entry if you do not select any business objects. Launch entry classification value attributes. The classification value can restrict the displayed launch entries. Multiple business objects support the classification attribute. The classification restriction is implemented at run time when you use system conditions. Out of box conditions are available to control your launch entry behavior. You also can create your own conditions.  
For example, if you specify `PERSON` in this field, you can use the launch entry only in the People application. You can use the launch entry record in any application when the field value is null.
8. In the Resource Classification field, if classification attributes are defined for the specified resource object, you can select attributes that restrict the display of launch entries.  
Many business objects support classification attributes. The classification restriction is implemented at run-time when you use system conditions. Predefined conditions are available to control launch entry behavior. You also can create your own conditions.
9. Select the Include Child Classifications check box to include resource classifications for child objects in the launch entry record.
10. Click Save Launch Entry.

## What to do next

---

You can associate launch entry records with signature options in the Application Designer application. These associations define and control the menu actions for launch entry use.

- **Properties specific to operational management products**

When you create a launch entry record, some properties are specifically for use with operational management products.

---

## Properties specific to operational management products

When you create a launch entry record, some properties are specifically for use with operational management products.

When you associate an operational management product to a launch entry, the framework searches for the product name on the operational management product servers in the database that manages the configuration item. If you provide the operational management product version, the framework searches for the specified version. The server data populates the `{sourcetoken}` and `{reportinghostname}` variables in the launch URL.

To determine what configuration item you are working with, the integration framework looks for a configuration item globally unique identifier (CIGUID) attribute in the business object that you are viewing. If you are viewing the configuration item business object, the globally unique identifier (GUID) attribute is used instead.

The source token is an attribute of the configuration item and operational management product server relationship. The operational management product console accepts the source token as the configuration item identifier. When you include a `{sourcetoken}` in the launch URL, the framework replaces it with the corresponding source token for the selected operational management product server.

The reporting host name is the host name of the selected operational management product server. When the `{reportinghostname}` value is in the URL for the launch entry, the framework replaces it with the host name of the selected operational management product. The source token and host name information is loaded from the discovery engine. If the host name information is not loaded from the discovery engine, you must add the operational management product server information to your database.

---

## Configuring a signature option for a launch point

When you create a signature option for a launch point, it becomes available to use within the user interface controls.

### Procedure

---

1. In the Application Designer, select the application where you want to configure a launch point.
2. Select the Add/Modify Signature Options action.
3. In the Add/Modify Signature Options window, click New Row.
4. Specify values in the Option and Description fields.
5. In the Advanced Signature Options table, select the Associate to Launch Entry To Enable The Launch in Context option.  
To access the Advanced Signature Options table, scroll to the end of the Add/Modify Signature Options window, and click Maximize to show the available options.
6. In the Launch Entry Name field, specify the name for the launch entry.
7. Click OK to return to the Application Designer.
8. Click Save Application Definition to commit the modifications to the application to the database.

---

## Adding a launch point to an application menu

After you configure a signature option for a launch point, you can add the option to an application menu. The procedure is similar for adding the launch point to an action or to a toolbar menu.

### Procedure

---

1. In the Application Designer, choose one of the following actions:
  - Add/Modify Select Action Menu
  - Add/Modify Toolbar Menu
2. Click New Row.
3. In the Element Type field, specify the OPTION value.
4. In the Key Value field, specify the name of the signature option that you configured for the launch point.
5. In the Position field, specify a number to indicate the relative position of the item in the menu.
6. In the Tabs field, select one of the following values:
  - Select the MAIN value if the launch URL contains substitution variables.
  - Select the ALL value if the launch URL does not contain substitution variables.
7. Specify values in other, optional fields as appropriate.
8. Click OK to return to the Application Designer.
9. Click Save Application Definition to commit the modifications to the application to the database.

---

## What to do next

Before users can see the new menu item or toolbar button, you must grant user and group access privileges to it. Grant the privileges in the Options section of the Applications tab in the Security Groups application.

---

## Adding a button as a launch point

To add a button to an application that acts as a launch point, configure a button to use the signature option for the launch point.

---

### Procedure

1. In the Application Designer, click Control Palette.
2. Drag a push button control to the application workspace.
3. Open the Properties window for the push button control.
4. In the Label field, specify the name that you want to appear on the button.
5. In the Event field, specify the name of the signature option.
6. Click OK to return to the Application Designer.
7. Click Save Application Definition to commit the modifications to the application to the database.

---

## Adding a condition to a launch point

You can create a condition and then associate the condition with the signature option for the launch point. When you associate a condition with a signature option, the user interface behavior is changed based on the condition and the data that is being viewed.

---

### Procedure

1. In the Security Groups application, select the group for which you want to apply a condition.
  2. In the Application tab, select the application for which you want to apply the condition.
  3. In the Options table, select the condition value that you created.
  4. Click Save Group.
- [Signature option conditions](#)  
You can apply conditions to control the user interface behavior based on the data that is being viewed.

---

## Signature option conditions

You can apply conditions to control the user interface behavior based on the data that is being viewed.

The integration framework provides a predefined condition class, `psdi.iface.app.launch.LaunchCICCondition`, to hide launch entry menu items when the current object classification does not match the launch entry classification value. This condition applies to any object that has a classification attribute.

Launch entry menu items can also be hidden when the operational management product that is configured on the launch entry does not manage the configuration item. This condition applies to launch entries that you associate with a configuration item object or actual configuration item object.

You can configure a condition to use the predefined condition class. You also can configure a condition to implement a custom condition using the Conditional Expression Manager application.

The launch point is available from the application, regardless of the data that is being viewed, when you do not use a condition. The data you view is restricted to the signature option security settings for a user group. You also can configure your security settings to hide a launch point, based on set group access privileges.

If you use a Java™ condition class, you must change the condition EXPRESSION attribute to the name of the launch entry. The Java class can identify which launch entry is executed. The expression attribute value must be an exact match to the name of the launch entry and values are case-sensitive.

---

## Integrating with Workday Connector

You can integrate IBM® Maximo® Manage and Workday Human Capital Management (HCM) to synchronize your HCM data and integrate IBM Maximo Manage and Workday Financial to synchronize your financial data. By completing an integration with Workday Connector, you can synchronize data between systems and access more accurate cost and time reporting information.

Workday Connector facilitates the sharing of financial and HCM data between Maximo and Workday Financial and Workday HCM. The connector eliminates the need for double data entry in both systems and results in accurate costing and time reporting information that is collected in Workday.

---

## System requirements

The integration uses existing integration components of each application to complete the integration.

- IBM Maximo Application Suite.
- IBM App Connect Enterprise version 12.0 or later.

- Workday Web Service version 35.1.
- [Workday Human Capital Management \(HCM\) overview](#)  
You can configure an integration between IBM Maximo Manage and Workday Human Capital Management (HCM).
- [Workday Financials overview](#)  
You can integrate IBM Maximo Manage and Workday Financials.

## Workday Human Capital Management (HCM) overview

You can configure an integration between IBM® Maximo® Manage and Workday Human Capital Management (HCM).

The HCM integration facilitates the HR master data from Workday to be populated in Maximo automatically. Once in Maximo, this data can be leveraged to perform accurate time reporting for maintenance-related activities which are then sent back to Time Reporting in Workday, eliminating the need for technicians to enter their maintenance time in both systems.

## Integration overview

Integration between Maximo Manage and Workday HCM supports the following HCM use cases:

- The integration creates Maximo Person, Labor, Craft, and Skill data from Workday HCM Worker data.
- The integration creates Workday Time reporting data from Maximo Labor reporting data.

For more information, see [Workday HCM](#).

## Data flow

The first integration imports the following Workday HCM Worker data into Maximo Manage data:

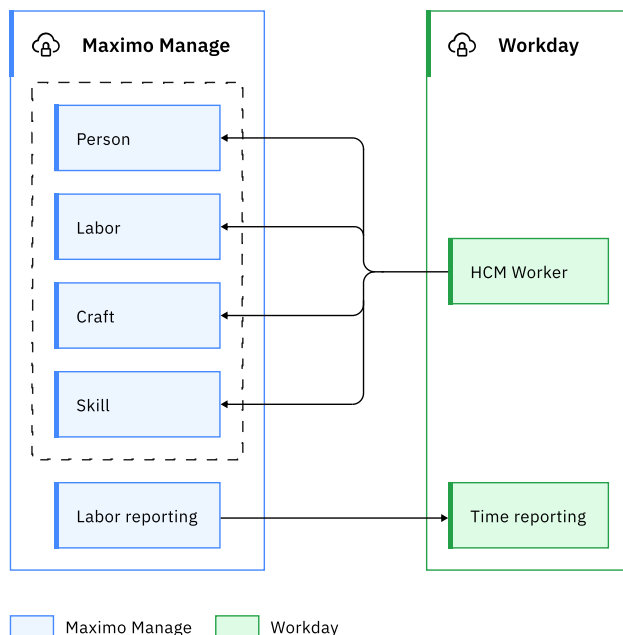

- Person records
- Skill records
- Craft records
- Labor records

When the integration is created, the Labor records can be assigned to Maximo work orders to complete maintenance activities.

When a person who is associated with a labor record reports their time in Maximo Manage, a second integration sends the work order labor reporting data to Workday time reporting data.

The following diagram shows how Workday HCM worker data is integrated by using Maximo Manage. This approach is done by a Maximo cron task.

Figure 1. Integration overview of Maximo Manage and Workday HCM

- [Workday worker integration](#)  
Workday Worker data is used to create Maximo Person, Labor, Crafts, and Skills data.

- [Workday Time Tracking integration](#)

The Time Tracking integration creates Workday Time Reporting data from Maximo Labor Reporting data. This integration can optionally be implemented based on the business requirements.

## Related information

---

- [Working with cron tasks](#)

---

## Workday worker integration

Workday Worker data is used to create Maximo Person, Labor, Crafts, and Skills data.

### Data flow

---

A new Maximo cron task is provided to get HCM Worker data from Workday. A cron task is an existing Maximo® Manage component that facilitates processes that run in the background, supports flexible scheduling features, and uses parameters that administrators can configure based on their business requirements. Customers can set a preferred frequency for the cron task. For example, it might be hourly, daily, or weekly.

The Maximo cron task initiates an App Connect Flow service that uses the parameters that are provided by the administrator and then calls the Workday APIs for HCM Worker by using the Workday Connector. When the Workday HCM data is retrieved from Workday, the Connector Flow calls three Maximo enterprise services to load the Maximo skill, craft code, person, and labor records.

Workday HCM data can be filtered based on the configurable parameters, organization, and job family. The configurable parameters are set in the cron task by the administrator.

## Related information

---

- [Working with cron tasks](#)

---

## Workday Time Tracking integration

The Time Tracking integration creates Workday Time Reporting data from Maximo® Labor Reporting data. This integration can optionally be implemented based on the business requirements.

### Data flow

---

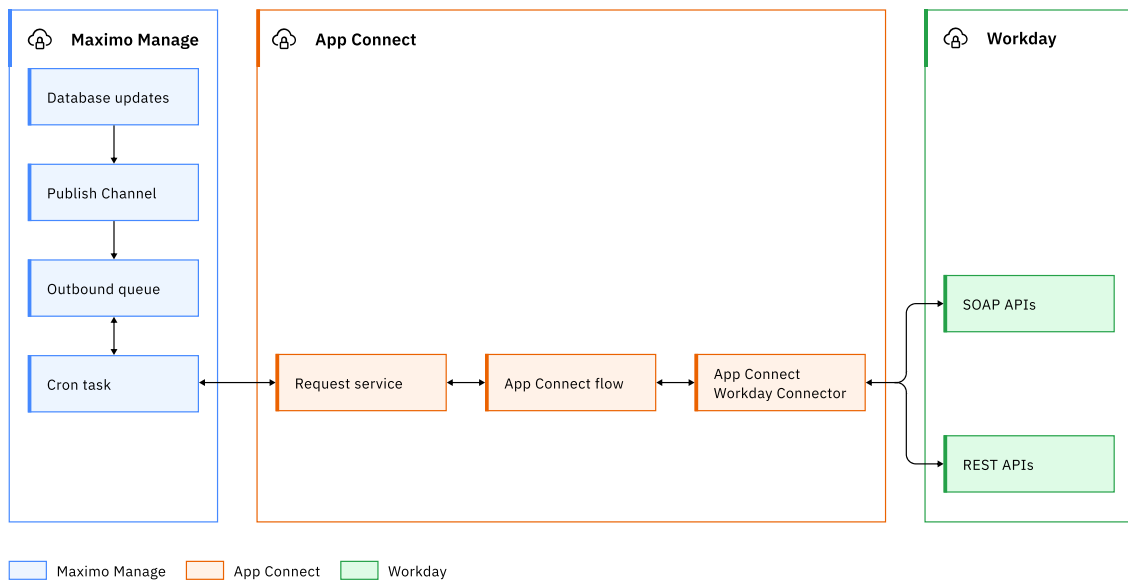

Maximo Manage provides Employee Actuals Publish Channel to send labor transaction data to external applications. This solution provides a duplicate of this publish channel to send labor transactions to Workday.

Transactions are triggered by events that capture the saving of a new approved labor transaction in Maximo. The publish channel listens for object events. When the publish channel is triggered, these transactions are saved in an outbound queue and delivered to an App Connect service. The App Connect service maps the transaction to the Workday Time Reporting API to create time reporting transactions in Workday.

The following diagram shows how Maximo labor transactions are sent to Workday:

Figure 1. Sending Maximo Manage data to Workday

## Workday Financials overview

You can integrate IBM® Maximo® Manage and Workday Financials.

### Integration overview

Integration between Maximo Manage and Workday Financials is to support the following use cases:

- The integration creates Maximo General Ledger components and Charts of Accounts from Workday Financials account data.
- The integration creates Workday General Ledger data from Maximo journal transactions.

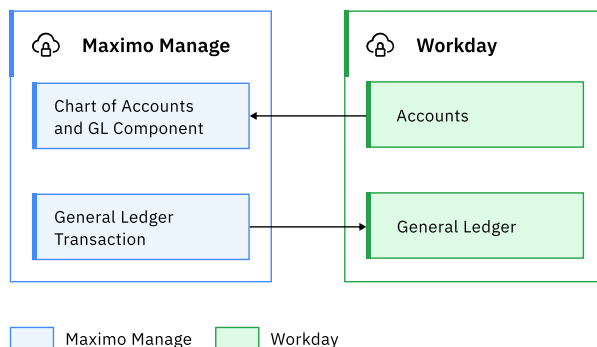

For more information, see [Workday Financials](#).

### Data flow

The first integration imports Workday Financials account data into Maximo General Ledger components and charts of accounts. When the integration is created, the Maximo General Ledger components and Charts of Accounts data can be used in Maximo journal transactions.

When a journal transaction is created in Maximo Manage, a second integration sends the data to the Workday General Ledger.

Figure 1. Maximo Manage and Workday Financials overview

- [Workday Account integration](#)  
The Workday Account integration creates Maximo General Ledger components and charts of accounts from Workday Account data.
- [Workday Journal transaction integration](#)  
Maximo General Ledger integration creates a Workday Journal transaction data from Maximo Manage.

## Workday Account integration

The Workday Account integration creates Maximo® General Ledger components and charts of accounts from Workday Account data.

### Data flow

A new Maximo cron task is provided to support pulling Workday Account data. A cron task is an existing Maximo Manage component that facilitates processes that run in the background, supports flexible scheduling features, and uses parameters that administrators can configure based on their business requirements. Customers can set a preferred frequency for the cron task. For example, it might be hourly, daily, or weekly.

The Maximo Manage cron task initiates an App Connect flow service that uses the parameters that are provided by the administrator and then calls the Workday APIs for Financial Accounts by using the Workday Connector. When the Workday Financials data is retrieved from Workday, the Connector Flow calls two Maximo enterprise services to load the Maximo General Ledger components and Maximo chart of accounts.

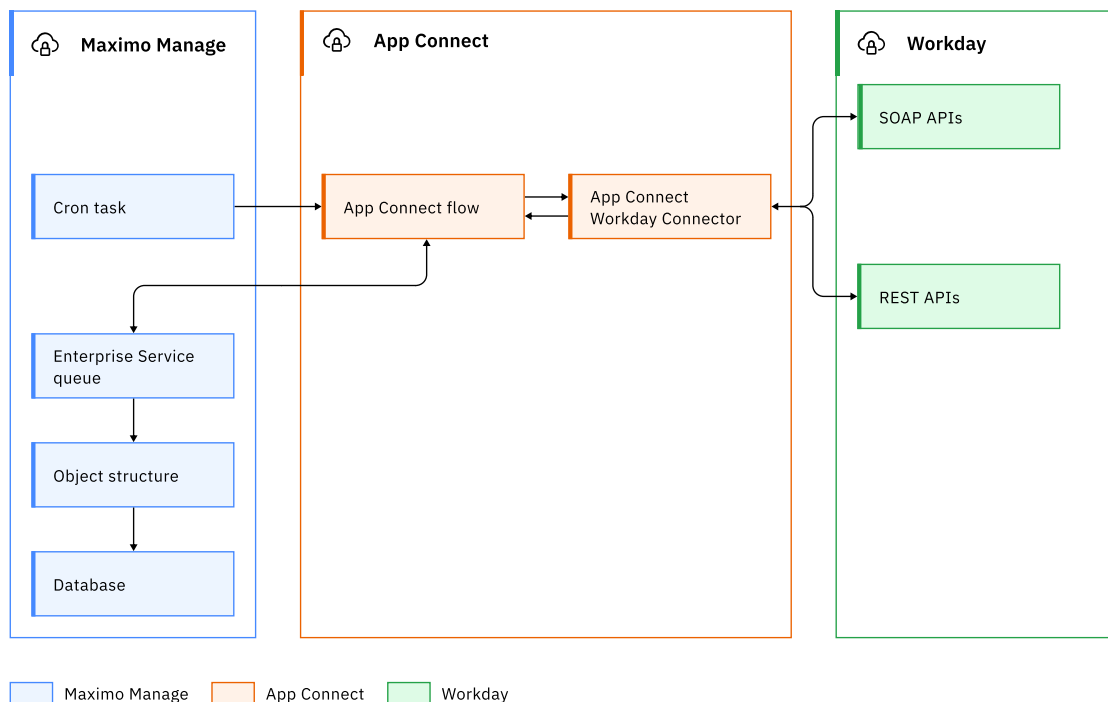

Processing the Workday Account data populates the entire set of accounts for a specific account set.

### Process flow

The following diagram shows how Workday Financials data is integrated with Maximo Manage. This approach is driven by a Maximo cron task.

1. The Maximo cron task initiates a pull of data.
2. The App Connect flow uses Workday Connector to pull data.
3. The App Connect flow uses Maximo enterprise services to update the Maximo data. Enterprise services provide error management.

Figure 1. Workday Account data into General Ledger components and charts of accounts in Maximo Manage

## Workday Journal transaction integration

Maximo® General Ledger integration creates a Workday Journal transaction data from Maximo Manage.

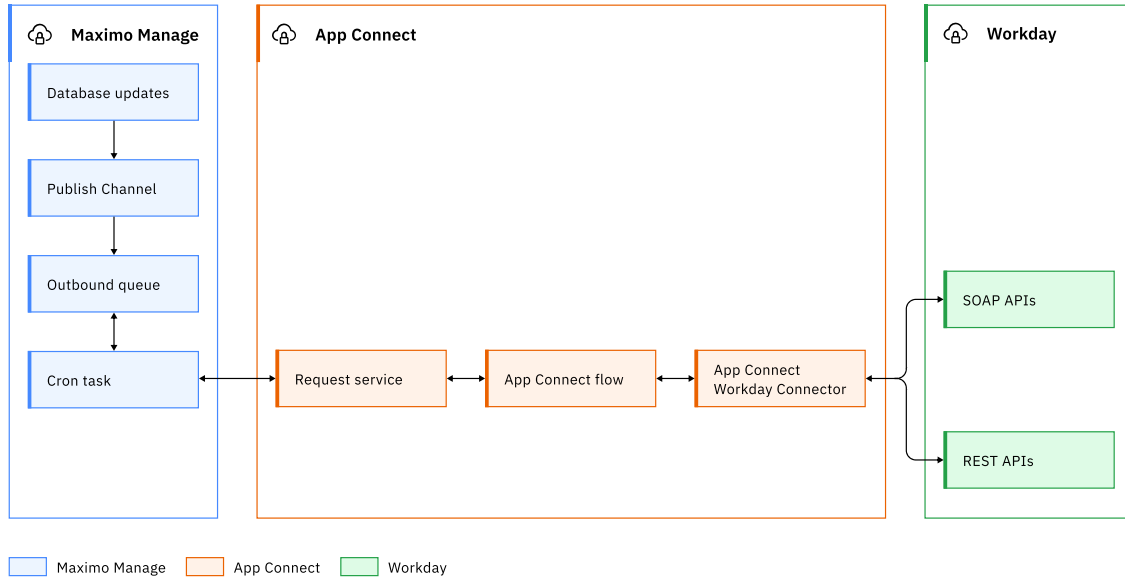

Maximo Manage provides a Journal Transaction Publish Channel to send Maximo journals to external applications. This solution provides a duplicate of this channel to send journals to Workday. Transactions are triggered by events that capture the saving of a new journal transaction in Maximo. The publish channel listens for object events, such as inserts, updates, and deletes. When the publish channel is triggered, these transactions are then saved in an outbound queue and delivered by an App Connect service. The App Connect service maps the transaction to the Workday Journal API to create journal transactions in Workday.

### Data flow

The following diagram shows how Maximo journal transactions are sent to Workday.

1. A Maximo publish channel is registered for events.
2. Events trigger message through the publish channel to an outbound queue.
3. An external system endpoint delivers message to App Connect flow.
4. App Connect flow uses Workday Connector to update Workday.

Figure 1. General Ledger Journal data from Maximo Manage into Workday data

## Envizi ESG Suite and TRIRIGA Application Suite Connectors

IBM® TRIRIGA® Application Suite and IBM Maximo® Application Suite customers have access to a collection of predefined integrations between each other and IBM Envizi ESG Suite.

These integrations can be used in various combinations to enable many use-cases and they can each be configured for more flexibility.

- Maximo Connector for TRIRIGA supports the following use cases:
  - Bidirectional loading, and continuous synchronization of portfolio data such as people, locations, and assets.
  - Bidirectional routing of service requests between TRIRIGA Application Suite and Maximo Application Suite.
  - Automatic shadowing of work tasks in TRIRIGA Application Suite with work orders in Maximo Application Suite to enable facility teams to plan, budget, and project manage in TRIRIGA Application Suite while work tasks are reflected in Maximo Application Suite as work orders.
- Maximo Connector for Envizi automatically synchronizing asset location and meter readings from Maximo Application Suite to Envizi ESG Suite to automate tracking of energy usage and calculating related scope 1 and 2 emissions of electricity, natural gas, and water.
- [Integrating with Maximo Connector for Envizi](#)  
The connector to integrate Maximo Application Suite and Envizi ESG Suite is released with the name IBM Maximo Connector for Envizi. This connector supports the following capability through App Connect flows.
- [Integrating with Maximo Connector for TRIRIGA](#)  
Maximo Connector for TRIRIGA integrates Maximo Application Suite and TRIRIGA Application Suite.

## Integrating with Maximo Connector for Envizi

The connector to integrate Maximo® Application Suite and Envizi ESG Suite is released with the name IBM® Maximo Connector for Envizi. This connector supports the following capability through App Connect flows.

- Automatically synchronize asset location and meter readings from Maximo Application Suite to Envizi ESG Suite to automate tracking of energy usage and calculating its related scope 1 and 2 emissions of Electricity, Natural Gas, and Water.
- [Overview](#)  
You can use Maximo Connector for Envizi to share data between Maximo Application Suite and Envizi ESG Suite.
- [App Connect](#)  
IBM App Connect is middleware that provides a flexible environment for integration solutions to transform, enrich, route, and process business messages and data. It is a prerequisite for all the portfolio connectors, and it is made available as a supporting program through TRIRIGA Application Suite 11.3 and Maximo Application Suite 8.9.

- [Installing Maximo Connector for Envizi](#)  
The Maximo Connector for Envizi must be installed by using Maximo Application Suite to create an integration with Envizi ESG Suite.
- [Configuring Maximo Connector for Envizi](#)  
Configuring the Maximo Connector for Envizi is a three-step process that begins with configuring the App Connect followed by configuring the Envizi ESG Suite and then Maximo Application Suite.
- [Troubleshooting connection errors](#)  
You can troubleshoot the common errors that occur, their causes, and their resolutions.

## Overview

You can use Maximo® Connector for Envizi to share data between Maximo Application Suite and Envizi ESG Suite.

## Use case example

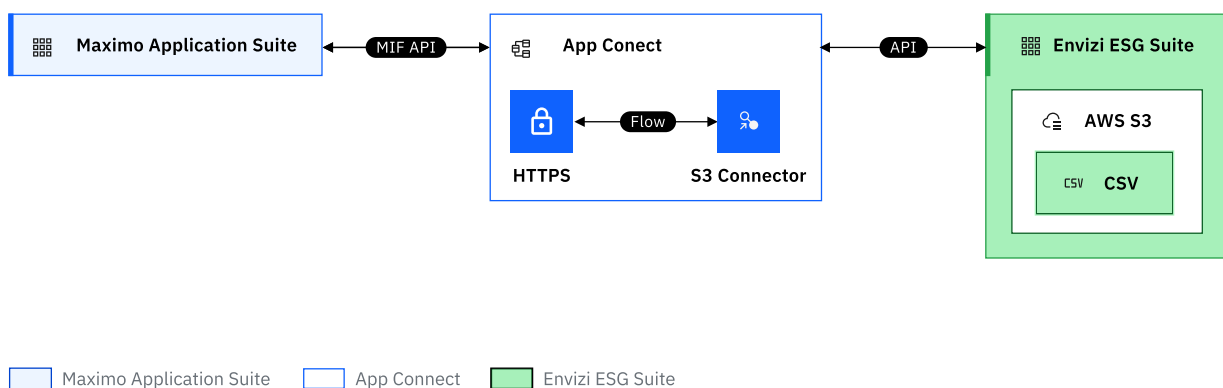

Corporate sustainability managers can gather and maintain accurate sustainability data for their portfolio of assets directly from Maximo Application Suite where those assets are managed. Location data from Maximo Application Suite serves as a baseline for all other sustainability reports in Envizi ESG Suite. Continuously updated meter readings data captured in Maximo Application Suite Electricity, Gas, Water enables accurate greenhouse gas accounting and performance reporting in Envizi ESG Suite.

## Connector architecture

IBM App Connect provides a flexible environment for integration solutions to transform, enrich, route, and process business messages and data.

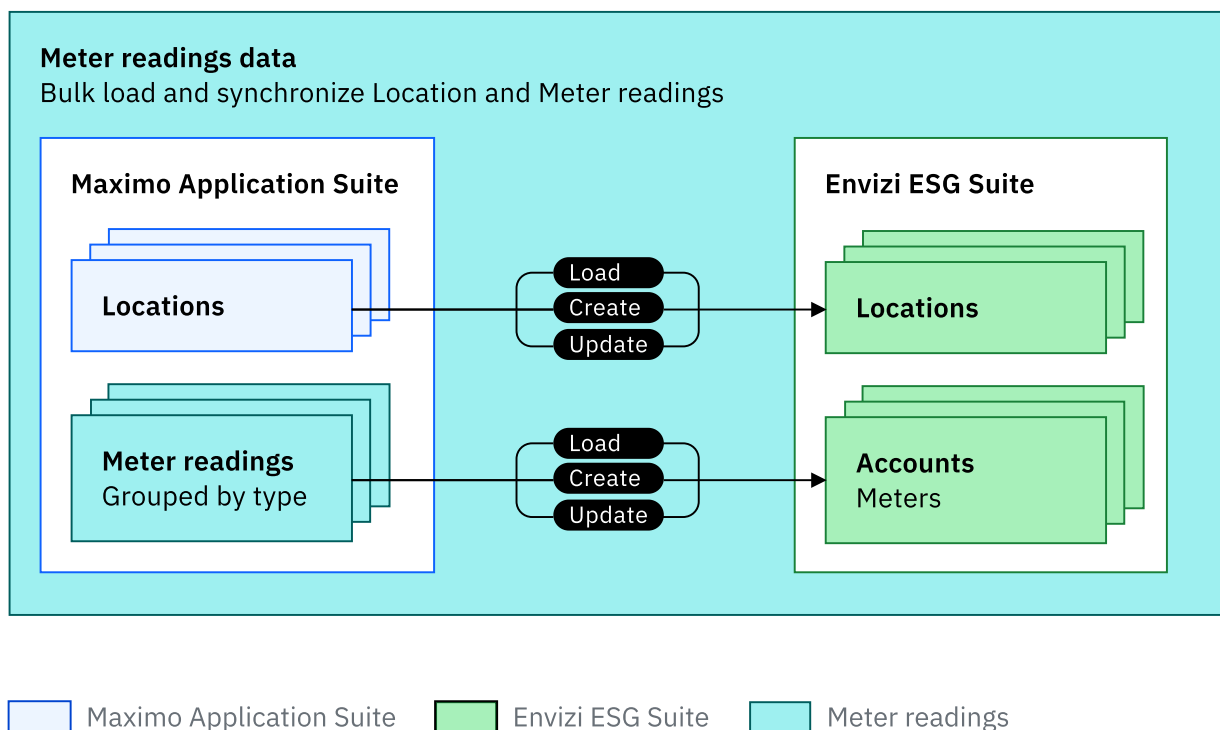

App Connect flows enable specific integration use cases by connecting to predefined APIs to route and map data. Mappings are predefined and can be customized.

The Maximo Integration Framework for Maximo Application Suite and Envizi API framework for Envizi ESG Suite is used and enabled through provided packages that can be imported.

## Data mapping diagram

The data mapping diagram illustrates the record types that are available by the APIs and App Connect flows.

## App Connect

IBM® App Connect is middleware that provides a flexible environment for integration solutions to transform, enrich, route, and process business messages and data. It is a prerequisite for all the portfolio connectors, and it is made available as a supporting program through TRIRIGA® Application Suite 11.3 and Maximo® Application Suite 8.9.

App Connect flows enable specific integration use cases by connecting to predefined APIs to route and transform data. Flows can be applied in different combinations to support various use cases. Flows handle the data mapping and data validation, and they can be modified for individual requirements. These flows are run based on events or on a schedule.

- [Installing App Connect](#)  
Installing App Connect provides you its flows by using which you can integrate two systems to share data.
- [App Connect flows](#)  
A flow is included with the connector to map records between Envizi ESG Suite and Maximo Application Suite that exports locations and meter readings along with all the necessary mapping fields.

## Installing App Connect

Installing App Connect provides you its flows by using which you can integrate two systems to share data.

### Procedure

- App Connect Pro SaaS is available in the IBM Cloud® catalog.
- App Connect Enterprise on-premises can also be provisioned within your Red Hat® OpenShift® cluster directly from the Red Hat OpenShift operator. For more information about installing the operator, see [Deploying IBM® App Connect](#).

## App Connect flows

A flow is included with the connector to map records between Envizi ESG Suite and Maximo® Application Suite that exports locations and meter readings along with all the necessary mapping fields.

Table 1. Files naming convention for flow.

File	Flow	Destination	Operation
------	------	-------------	-----------

File	Flow	Destination	Operation
PLUSZMXTOS3_v1_1_0.yaml	Locations and Meter Reading	Maximo Application Suite to Envizi ESG Suite	Bulk Load or Load Changes

## Installing Maximo Connector for Envizi

The Maximo® Connector for Envizi must be installed by using Maximo Application Suite to create an integration with Envizi ESG Suite.

The installation procedure depends on the version of Maximo Application Suite that is installed.

- [Installing Maximo Connector for Envizi in Maximo Application Suite 8.10](#)  
The Maximo Connector for Envizi can be installed by using the Catalog page in Maximo Application Suite 8.10.
- [Installing Maximo Connector for Envizi in Maximo Application Suite 8.9](#)  
The Maximo Connector for Envizi can be installed by using the customized .zip file that is provided from Passport Advantage. This .zip file contains all of the configurations that are necessary to complete the installation process.

## Installing Maximo Connector for Envizi in Maximo Application Suite 8.10

The Maximo® Connector for Envizi can be installed by using the Catalog page in Maximo Application Suite 8.10.

### Procedure

1. In Maximo Application Suite, click the Administration icon, and from the side navigation menu, click Catalog.
2. Click the Add-ons tab, search for the Envizi Connector, and click its tile.
3. On the Envizi Connector page, review the information and then click Configure.
4. On the Update Manage workspace configuration page, in the Components section, in the New version column, select latest.
5. Click Apply Changes and then click Confirm to begin the installation. The process can take between 20 minutes to a couple of hours based on the cluster resources.
6. Optional: In the Red Hat® OpenShift® cluster, monitor the logs that are created in the build pods of the Manage namespace.

## Installing Maximo Connector for Envizi in Maximo Application Suite 8.9

The Maximo® Connector for Envizi can be installed by using the customized .zip file that is provided from Passport Advantage. This .zip file contains all of the configurations that are necessary to complete the installation process.

### Procedure

1. In Maximo Application Suite, click Administration icon.
2. On the Suite administration page, click the Applications tile.
3. On the Applications page, click Manage.
4. On the Manage page, click Actions, then click Update configuration.
5. In the Configurations list, click the edit icon for Customization.
6. In the Customization section, set System managed to off and then click Add customization archive.
7. In the File address field, enter the path of the .zip file that contains the configurations.
8. Scroll up the page, click Apply changes, and then click Confirm to update the instance. The process can take between 20 minutes to 1-2 hours depending on the cluster resources.
9. Optional: In the Red Hat® OpenShift® cluster, monitor the logs that are created in the build pods of the Manage namespace.

## Configuring Maximo Connector for Envizi

Configuring the Maximo® Connector for Envizi is a three-step process that begins with configuring the App Connect followed by configuring the Envizi ESG Suite and then Maximo Application Suite.

### Before you begin

- Ensure that you have an instance of App Connect Enterprise or App Connect Pro with the Designer component.
- Ensure that you have administrative access to your Maximo Application Suite instance with an API key that is generated for this integration.
- Ensure that you have an Amazon Simple Storage Service (Amazon S3) bucket for your Envizi ESG Suite instance.
- Import the App Connect certificate to Maximo Application Suite to enable encrypted communication.
- Ensuring that location meter data supports the units of measurement.
- [Configuring App Connect](#)  
You configure App Connect by creating accounts and importing flows in App Connect. After configuration, the connection need to be authenticated by creating an API key.

- [Check data and add App Connect certificate](#)  
Before you can use Maximo Connector for Envizi, you must add necessary certificates and ensure the correct configuration of data, such as the unit of measure and service address in Maximo Application Suite.
- [Configuring Maximo Application Suite for integration](#)  
To configure Maximo Application Suite for integration, you deploy the build and configure artifacts, such as endpoints and cron tasks.
- [Using the connector](#)  
You can use the Maximo Connector for Envizi by controlling cron tasks and flows. You can start or stop the cron tasks or flows based on the activity you want to complete.
- [Testing the configuration](#)  
To test that the configuration is complete and sending a test payload to test connectivity.

---

## Configuring App Connect

You configure App Connect by creating accounts and importing flows in App Connect. After configuration, the connection need to be authenticated by creating an API key.

- [Adding account for S3 server and HTTP connectors](#)  
Before you can import App Connect, you must create accounts for the S3 server and HTTP connectors.
- [Importing and configuring App Connect flows](#)  
The flows can be imported by using App Connect and then need to be configured for the HTTP account that was created for the connector.
- [Authenticating on-premises and cloud basedApp Connect](#)  
Authenticate the App Connect connection by creating an API key.

---

## Adding account for S3 server and HTTP connectors

Before you can import App Connect, you must create accounts for the S3 server and HTTP connectors.

---

### Procedure

1. In App Connect, open the Catalog page.
2. In the Search application field, type the name of the connector for the account.
3. If the App Connect instance does not have an account for the connector, click Connect to create a new account. Else, open the account selection drop down, and click Add a new account.
4. Enter the necessary details for the connector.
  - For S3, specify the S3 server and user account.
  - For HTTP, specify an authentication key or username and password that is needed for Maximo® Application Suite.
5. Click Connect and in the Account, select newly created account.  
Note: App Connect creates an account with a generic name in sequential order. For example, if Account 1 and Account 2 are present, the new account is named as Account 3.
6. Click options icon (three dots) and then click Rename Account.
7. Enter an account name and click Rename Account. This name can now be used by the connector in the flow.

---

## Importing and configuring App Connect flows

The flows can be imported by using App Connect and then need to be configured for the HTTP account that was created for the connector.

---

### Procedure

1. In App Connect, open the Dashboard.
2. Click New and select Import Flow.
3. Browse the flow's .yaml file and click Import. The flow is now be imported and opened.

---

## Configuring the flow to use the right accounts

It is important to check whether the imported flow is using the right accounts for the connectors.

### Procedure

1. On the recently imported flow, click Edit Flow and check if the connectors are using the right accounts.
2. To change the account for any connector, select the connector and open the account's name list.
3. Select the account name that you want to use from the list.

---

## Authenticating on-premises and cloud basedApp Connect

Authenticate the App Connect connection by creating an API key.

## About this task

---

For on-premises App Connect, basic authentication is used.

## Procedure

---

1. In App Connect, open your flow and on the Manage tab, click Test.
2. From the side menu, click POST and then open the Try It tab.
3. Use the authentication in the End Point section when you configure Maximo® Application Suite.

## Authenticating cloud-based App Connect

---

### Procedure

1. In App Connect, open your flow and on the Manage tab, click Create API key and documentation link.
2. Enter name for the API key and click Create.  
Note: Make a note of this key. The Maximo Application Suite end point is configured to send this API key as the value for the X-IBM-Client-Id header when the App Connect flow API is called.
3. Open the API Documentation Link in another tab.
4. Click Route to see the URL.
5. In the Details tab, copy POST link that starts with HTTP.  
Note: Test this API by using a tool such as Postman before you use the API in Maximo Application Suite.

---

## Check data and add App Connect certificate

Before you can use Maximo® Connector for Envizi, you must add necessary certificates and ensure the correct configuration of data, such as the unit of measure and service address in Maximo Application Suite.

- [Check the data correctness](#)  
Certain data, such as unit of measurements or service address, needs to be correctly maintained in the Maximo Application Suite to make integration with Envizi ESG Suite work as expected.
- [Adding the App Connect certificate in Maximo Application Suite 8.9 and later](#)  
You must import the App Connect certificate in Maximo Application Suite to enable encrypted communication for Maximo Connector for Envizi.
- [Adding the App Connect certificate in Maximo Asset Management 7.6.1.2 and later](#)  
You must import the App Connect in Maximo Asset Management to enable encrypted communication for Maximo Connector for Envizi. Configuring the WebSphere® certificate tests the connection to a Secure Sockets Layer (SSL) port and retrieves the signer from the server during the connection establishment.

---

## Check the data correctness

Certain data, such as unit of measurements or service address, needs to be correctly maintained in the Maximo® Application Suite to make integration with Envizi ESG Suite work as expected.

- Data for location meters can be exported to Envizi ESG Suite only if the units of measurement are configured. To add or modify units of measurement, see [Adding unit of measurement](#).
- A service address must be configured in the location for proper functioning of Envizi ESG Suite's features. To add a service address, see [Adding service address](#).
- [Adding unit of measurement](#)  
In the Maximo Application Suite, you must add the units of measurement that are used to export the data for location meters to Envizi ESG Suite.
- [Adding service address](#)  
A service address must be configured for the location in Maximo Manage to ensure proper functioning of features in Envizi ESG Suite.

---

## Adding unit of measurement

In the Maximo® Application Suite, you must add the units of measurement that are used to export the data for location meters to Envizi ESG Suite.

## About this task

---

Data for location meter can be exported to Envizi ESG Suite only if the unit of measurement is configured in Maximo Application Suite.

The current integration with Envizi ESG Suite supports only the following units of measurement for the location meter data.

Table 1. Units of measurement that are supported for Maximo Connector for Envizi.

Meter Type	Supported Unit of Measure
Electric	GJ, kWh, MWh
Natural Gas	GJ, MJ, kWh, m3, mmbtu, therm
Water	litre, klitre, m3, gallon

## Procedure

1. In Maximo Manage, from the side navigation menu, click Inventory > Item Master.
2. On the left pane, click Unit of Measure and Conversion > Add/Modify Units of Measure.
3. Add the missing units and then click OK.

## Adding service address

A service address must be configured for the location in Maximo® Manage to ensure proper functioning of features in Envizi ESG Suite.

## About this task

A service address must be configured with the following fields.

- Street Address
- City
- State
- Post Code
- Country
- Latitude
- Longitude

## Procedure

1. In Maximo Manage, from the side navigation menu, click Administration > Service Address.
2. Form the Common Actions menu, click New Service Address and add field details.
3. From the side navigation menu, click Assets > Location and search for the location to associate the service address.
4. In the Service Address field, click the Detail Menu icon and then click Select Value.
5. Search and select the service address that you created.

## Adding the App Connect certificate in Maximo Application Suite 8.9 and later

You must import the App Connect certificate in Maximo® Application Suite to enable encrypted communication for Maximo Connector for Envizi.

## Procedure

1. Extract the App Connect certificate from an imported flow URL.
2. In App Connect, go to the flow's page, click Test and then click Try It to get the URL.
3. In Maximo Application Suite, click the AppSwitcher icon, click the Workspaces card, and then open the workspace where Maximo Manage is deployed.
4. Click Actions, click Update configuration, and then click the pencil icon for Imported Certificates.
5. Disable System managed, click Add, enter the extracted certificate in the fields, and then click Confirm.
6. Click Apply Changes to update the truststore with the new certificate.

## Adding the App Connect certificate in Maximo Asset Management 7.6.1.2 and later

You must import the App Connect in Maximo® Asset Management to enable encrypted communication for Maximo Connector for Envizi. Configuring the WebSphere® certificate tests the connection to a Secure Sockets Layer (SSL) port and retrieves the signer from the server during the connection establishment.

## Procedure

1. Log in to the WebSphere console that is hosting the Maximo Application Suite server.
2. Go to Security > SSL certificate & key management. Under Related Items, click Key stores and certificates.
3. Click CellDefaultTrustStore and go to the next page.
4. In the Additional Properties section, click Signer certificates.
5. From this page, click Retrieve from Port and enter the fields details using the following table.

Table 1. Adding details for retrieving fields from the port .

Field	Value
Host	The host from the imported flow URL
Port	443
Alias	appconnect

6. After all three are entered, click Retrieve signer information, and the information from the URL gets populated.
7. Click Save and then repeat the process for NodeDefaultTrustStore.

## Configuring Maximo Application Suite for integration

To configure Maximo® Application Suite for integration, you deploy the build and configure artifacts, such as endpoints and cron tasks.

- **Deploying the Maximo Application Suite build**  
Within Maximo Application Suite, the integration provides integration components in .dbc script files and Java™ classes as part of the solution. These components must be installed in the Maximo Application Suite environment. Components and other content that is created for this integration solution is identified by names that begin with PLUSZ.
- **Configuring artifacts**  
You must configure meter groups, endpoints, and cron tasks in Maximo Application Suite so that data is shared as expected.

## Deploying the Maximo Application Suite build

Within Maximo® Application Suite, the integration provides integration components in .dbc script files and Java™ classes as part of the solution. These components must be installed in the Maximo Application Suite environment. Components and other content that is created for this integration solution is identified by names that begin with PLUSZ.

## Deploying Maximo Application Suite 8.8 and later

### Procedure

1. In Maximo Manage, go to Admin dashboard.
2. Select the workspace in which the instance is deployed and update the configuration.
3. Go to Customization section and link to the location of the .zip file in the field. For more information, see [setting customizations](#).
4. Click Apply Changes to update the instance with the customization.

## Deploying IBM® Maximo Asset Management 7.6.1.2 and later

### Procedure

1. On the Maximo Asset Management administrative workstation, overwrite the SMP directory, which is /opt/IBM/SMP/maximo, with the contents from the .zip file that is provided. The .zip file contains the Java classes and .dbc files.
2. Shutdown the Maximo server.
3. To install the components, open the /opt/IBM/SMP/maximo/tools/maximo directory, run the **UpdateDB** command.
4. To build the Maximo EAR file, open the /opt/IBM/SMP/maximo/deployment directory and run the **./buildmaximoea.sh** command.
5. Deploy the new Maximo EAR file on all Maximo servers.
  - a. In the WebSphere® console, go to Applications, > Application types, > Websphere enterprise applications.
  - b. Select MAXIMO and then click Update button.
  - c. Select Browse and select the EAR file from Step 4.
  - d. Click Next and accept defaults from all pages.
  - e. After deployment, click Save.
6. Start the applications and MXServer.

## Configuring artifacts

You must configure meter groups, endpoints, and cron tasks in Maximo® Application Suite so that data is shared as expected.

- **Meter groups configuration**  
All the meters that need to sync with Envizi ESG Suite must be in the right meter groups.
- **Configuring endpoints**  
Configuring endpoint is needed so that API key can be sent for calling the App Connect flow API.
- **Cron tasks**  
The integration can export locations and location meter readings from Maximo Application Suite. Two cron tasks for locations and two for meter readings are configured to fetch data from the integrated system.
- **Configuring Cron Task**  
Cron tasks must be configured with proper parameters to fetch the locations and meter readings based on the type of cron task. Running the cron task pulls the data based on configured parameters.

---

## Meter groups configuration

All the meters that need to sync with Envizi ESG Suite must be in the right meter groups.

Following table depicts the expected meter groups for each type of meter.

Table 1. Meter and Meter groups

Meter Group	Meters
PLUSZ_ELEC	Electric Meters
PLUSZ_GAS	Natural Gas Meters
PLUSZ_WTR	Water Meters

To assign or change meter group for a meter, see [Assigning meter groups to assets](#).

---

## Configuring endpoints

Configuring endpoint is needed so that API key can be sent for calling the App Connect flow API.

---

### Procedure

1. In the Maximo® Manage, go to Integration in side pane and then click End Points.
2. Under the End Point column, search PLUSZ.
3. Click on the PLUSZEXPORT endpoint and configure the parameters needed to execute the App Connect flow.

Table 1. Adding endpoint parameter details.

Field	Value
URL	The full URL to the flow's API, which is shown in the API Documentation Link in App Connect.
HEADERS	Replace the YourAPIKeyHere with the API key for the App Connect flow. Note: Do not remove ,Content-Type:application/json.
HTTPMETHOD	Do not change the default value POST.

---

## Cron tasks

The integration can export locations and location meter readings from Maximo® Application Suite. Two cron tasks for locations and two for meter readings are configured to fetch data from the integrated system.

- Always-on Cron Task - For pulling the live or recent data from locations and meter readings, and is supposed to be run frequently. It pulls the data that comes into the system after the last time it ran. Based on its running frequency, the system automatically decides the window of dates or timestamps to pull the data from. These Cron Task Instances uses the suffix as always\_on.
- On-demand Cron Task - Even though it is a cron task, it is supposed to run one time on-demand, when the user wants to pull data between fixed dates or timestamps. After the first cron event runs, it must be stopped to avoid pulling the same data again. It might be needed during initial setup of the system, as starting the Always-on Cron pulls data as and when it arrives. It can also be used anytime in the future to pull any historical data on-demand. The start date OVERRIDESTARTDATE and end date OVERRIDEENDDATE must be configured before starting the cron task. These Cron Task Instances uses the suffix on\_demand.
- [Basic cron task parameters](#)  
Basic parameters are used to fetch the data such as base URL for Maximo Application Suite, name, and timestamp.
- [Advance cron task parameters](#)  
Advance parameters are used to fetch more detailed data in an organized format. You can fetch data from specific object structure, apply conditions, and sort the data.

---

## Basic cron task parameters

Basic parameters are used to fetch the data such as base URL for Maximo® Application Suite, name, and timestamp.

### MXURL

The base URL of the Maximo Application Suite instance. It includes the protocol, domain name, and the port number, for example, `http://example.maximo.com:9080`. Do not enter a `/` at the end. In the absence of port number, the default port for the protocol is used, which is 80 for http and 443 for https.

For Maximo Application Suite deployments, you must use the route to the Maximo Manage instance domain. You can find this route in Red Hat® OpenShift® under Networking. Routes within the Maximo Manage namespace. The route must be of the format `workspace.manage.instanceid`.

### CUSTOMER

The name of the customer. It is used to name the CSV files that are supplied by Envizi ESG Suite.

### OVERRIDESTARTDATE

Used only for on-demand cron tasks. The start timestamp for getting data. The date must be specified in ISO 8601 format, for example, 2022-06-26T23:09:30-07:00, where -07:00 represents time zone offset of UTC-07:00 hours.

#### OVERRIDEENDDATE

Used only for on-demand cron tasks. The end timestamp for getting data. Similar to the OVERRIDESTARTDATE, the date must be specified in ISO 8601 format.

---

## Advance cron task parameters

Advance parameters are used to fetch more detailed data in an organized format. You can fetch data from specific object structure, apply conditions, and sort the data.

#### SELECT

Names of the fields from the object structure.

#### FROM

The name of the object structure.

#### WHERE

The OSLC condition for data selection.

#### ORDERBY

The sequence in which the data is obtained.

#### TARGETDATECOLUMN

Name of the DateTime column in the object structure that is used to filter records between a date-time window.

#### ENDPOINTNAME

The name of the Maximo® Application Suite endpoint that is configured to connect to the App Connect flow.

#### PAGESIZE

The maximum number of records that are obtained from Maximo Application Suite in one API call. It is also the maximum number of records in the CSV file.

---

## Configuring Cron Task

Cron tasks must be configured with proper parameters to fetch the locations and meter readings based on the type of cron task. Running the cron task pulls the data based on configured parameters.

---

### Procedure

1. In Maximo® Manage, from the side navigation menu, click System Configuration > Platform Configuration > Cron Task Setup.
2. In the Cron Task column, search for **PLUSZ**.
3. Click the PLUSZEXPORT cron task.
4. In the Cron Task Instances, click Calendar icon to set the schedule.
5. After it is configured, click OK.
6. Select the Cron Task Instance to configure Parameters.
7. Go to the Cron Task Parameters section and configure the Value column as needed. Ideally, only the CUSTOMER and MXURL parameters need to be edited for all instances. For the on-demand cron tasks, the OVERRIDESTARTDATE and OVERRIDEENDDATE parameters need to be edited.
8. Click Save.

---

## Using the connector

You can use the Maximo® Connector for Envizi by controlling cron tasks and flows. You can start or stop the cron tasks or flows based on the activity you want to complete.

- [Starting or stopping cron task instance](#)  
You can start or stop the cron tasks in Maximo Manage.
- [Starting or stopping App Connect flows](#)  
You can start or stop the App Connect flows.

---

## Starting or stopping cron task instance

You can start or stop the cron tasks in Maximo® Manage.

---

### Procedure

1. In Maximo Manage, from the side navigation menu, click System Configuration > Platform Configuration > Cron Task Setup.
2. Search the cron task to be stopped or started in the Cron Task column.
3. In the Active? column, set the switch to on or off to start or stop the cron task respectively.
4. Click Save.

## Starting or stopping App Connect flows

You can start or stop the App Connect flows.

### Procedure

1. Whether you are on the Dashboard or inside the flow, click the menu icon on the flow's tile.
2. Click Start API to start or click Stop API to stop the flow.

## Testing the configuration

To test that the configuration is complete and sending a test payload to test connectivity.

### Procedure

1. In Maximo® Manage, from the side navigation menu, click Integration, > End Points.
2. In the End Point column, search for PLUSZExport.
3. Click Test to start the test.
4. Send a test payload that is a valid object. For example, {"Hello": "World"}.
5. If the response is anything other than Bad Request, troubleshoot the issue. For more information, see [troubleshooting](#).

## Troubleshooting connection errors

You can troubleshoot the common errors that occur, their causes, and their resolutions.

Table 1. Troubleshooting common errors for Maximo Connector for Envizi.

Error	Cause	Resolution
Response code received from the HTTP request from the endpoint is not successful	Invalid URL in the integration object.	Ensure that the URL for all of the components are entered correctly. Make sure that no accidental spaces are at the beginning or the end.
404: Not Found	Flow is not running.	Make sure that the flow is running before you start the cron tasks.
PKSync error	Certificate error.	Confirm that the certificate is configured correctly.

## Integrating with Maximo Connector for TRIRIGA

Maximo® Connector for TRIRIGA® integrates Maximo Application Suite and TRIRIGA Application Suite.

This connector supports the following capabilities through a collection of App Connect flows:

- Bidirectional loading and continuous synchronization of portfolio data, such as people, locations, and assets.
- Bidirectional routing of service requests between TRIRIGA Application Suite and Maximo Application Suite.
- Automatic shadowing of work tasks in TRIRIGA Application Suite with work orders in Maximo Application Suite, which enables facility teams in planing, budgeting, and project management in TRIRIGA Application Suite while work tasks are reflected in Maximo Application Suite.
- [Overview](#)  
You can use Maximo Connector for TRIRIGA to share data between Maximo Application Suite and TRIRIGA Application Suite.
- [App Connect](#)  
IBM App Connect is middleware that provides a flexible environment for integration solutions to transform, enrich, route, and process business messages and data. It is a prerequisite for all the portfolio connectors, and it is made available as a supporting program through TRIRIGA Application Suite 11.3 and Maximo Application Suite 8.9.
- [Installing Maximo Connector for TRIRIGA](#)  
The Maximo Connector for TRIRIGA must be installed by using Maximo Application Suite to create an integration with TRIRIGA Application Suite.
- [Configuring Maximo Connector for TRIRIGA](#)  
Configuring Maximo Connector for TRIRIGA is a three-step process that begins with configuring App Connect followed by configuring TRIRIGA Application Suite and then configuring Maximo Application Suite.
- [Troubleshooting connection errors](#)  
Depending on the direction of the flow, cross-referencing errors from two systems can help identify the root cause of an issue with the integration.

## Overview

You can use Maximo® Connector for TRIRIGA® to share data between Maximo Application Suite and TRIRIGA Application Suite.

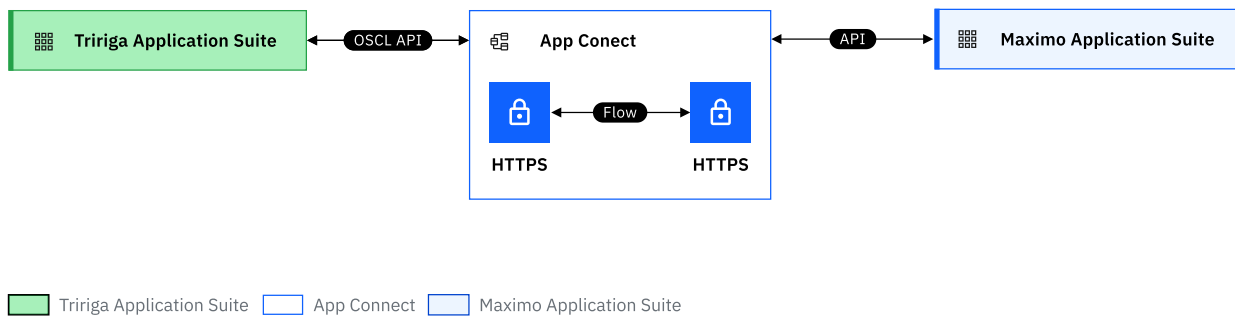

## Use case examples

- TRIRIGA Application Suite is the system of record for people and space data while Maximo Application Suite is the system of record for assets. The maintenance team wants consistent reports across the entire organization and more streamlined operations. The Spaces flows that are provided in the App Connect can be used to bulk load all Spaces data from TRIRIGA Application Suite into locations in Maximo Application Suite. Then, the data is continuously synchronized when it is updated in TRIRIGA Application Suite by the facility management team. It applies to assets, or people data in both directions.
- Employees use in TRIRIGA Application Suite to submit a service request for a broken elevator. Because elevators are maintained in Maximo Application Suite, the flow creates a corresponding service request in Maximo Application Suite that is assigned to technicians and then resolved. When this service request is updated, the changes are automatically reflected in the TRIRIGA Application Suite service request so that the originator of the request remains informed of its status. This flow can also operate in reverse if a service request originates from Maximo Application Suite for a maintenance operation that must be tracked in TRIRIGA Application Suite.
- The facility management team has a capital project in TRIRIGA Application Suite to upgrade all the lights to LEDs. A budget, scope, and tasks are already defined in the project. The flow can then create corresponding work orders in Maximo Application Suite for each task to get started by technicians by using Maximo Manage and Maximo Mobile. When the tasks are updated in Maximo Application Suite, those updates flow back into TRIRIGA Application Suite and are reflected in the project plan.

## Connector architecture

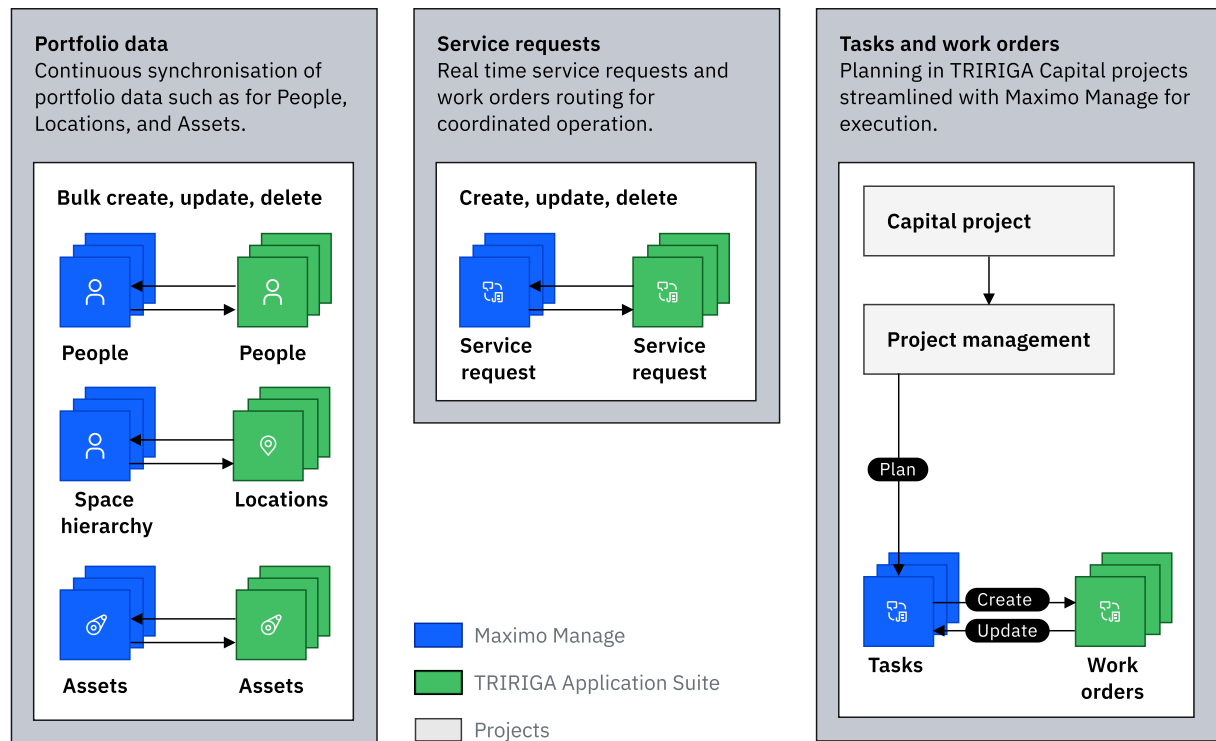

IBM® App Connect provides a flexible environment for integration solutions to transform, enrich, route, and process business messages and data. App Connect flows enable specific integration use cases by connecting to predefined APIs to route and map data. Mappings are predefined and can be customized.

The Maximo Integration Framework for Maximo Application Suite and OSLC API framework for TRIRIGA Application Suite is used and enabled through provided packages that can be imported.

## Data mapping diagram

The data mapping diagram illustrates the record types that are available by the APIs and App Connect flows.

## App Connect

IBM® App Connect is middleware that provides a flexible environment for integration solutions to transform, enrich, route, and process business messages and data. It is a prerequisite for all the portfolio connectors, and it is made available as a supporting program through TRIRIGA® Application Suite 11.3 and Maximo® Application Suite 8.9.

App Connect flows enable specific integration use cases by connecting to predefined APIs to route and transform data. Flows can be applied in different combinations to support various use cases. Flows handle the data mapping and data validation, and they can be modified for individual requirements. These flows are run based on events or on a schedule.

- [Installing App Connect](#)  
Installing App Connect provides you its flows by using which you can integrate two systems to share data.
- [App Connect flows](#)  
There are more than 20 flows that are included with the connector to map records between TRIRIGA Application Suite and Maximo Application Suite. These flows include all the necessary mapping fields. You can use these flows in various combinations to implement your integration use cases.

## Installing App Connect

Installing App Connect provides you its flows by using which you can integrate two systems to share data.

### Procedure

- App Connect Pro SaaS is available in the IBM Cloud® catalog.
- App Connect Enterprise on-premises can also be provisioned within your Red Hat® OpenShift® cluster directly from the Red Hat OpenShift operator. For more information about installing the operator, see [Deploying IBM® App Connect](#).

## App Connect flows

There are more than 20 flows that are included with the connector to map records between TRIRIGA® Application Suite and Maximo® Application Suite. These flows include all the necessary mapping fields. You can use these flows in various combinations to implement your integration use cases.

Table 1. Files names for flows from Maximo Application Suite to TRIRIGA

#### Application Suite.

File	Flow	Operation
PLUSIMXPerson2TRI_v1_0_0.yaml	People	Batch and individual records
PLUSIMXAsset2TRI_v1_0_0.yaml	Assets	Batch and individual records
PLUSIMXServiceReq2TRI_v1_0_0.yaml	Service Requests	Single record at a time
PLUSIMXWorkOrder2TRI_v1_0_0.yaml	Work Orders or Tasks	Single record at a time

Table 2. Files names for flows from TRIRIGA Application Suite to Maximo Application Suite.

File	Flow	Operation
PLUSITRIPerson2MX_v1_0_0.yaml	People	Single record at a time
PLUSITRIOrg2MX_v1_0_0.yaml	People	Single record at a time
PLUSITRISpace2MX_v1_0_0.yaml	Locations or Spaces	Single record at a time
PLUSITRISpaceClass2MX_v1_0_0.yaml	Locations or Spaces	Single record at a time
PLUSITRILocPath2MX_v1_0_0.yaml	Locations or Spaces	Single record at a time
PLUSIMXLocation2TRI_v1_0_0.yaml	Locations or Spaces	Batch and individual records

PLUSITRIFLOORBATCH_v1_0_0.yaml	Batch Floors	Batch
PLUSITRIASSETBATCH_v1_0_0.yaml	Batch Assets	Batch

For more detailed mapping of all the fields, see the [data mapping spreadsheet](#).

## Installing Maximo Connector for TRIRIGA

The Maximo® Connector for TRIRIGA® must be installed by using Maximo Application Suite to create an integration with TRIRIGA Application Suite.

The installation procedure depends on the version of Maximo Application Suite that is installed.

- [Installing Maximo Connector for TRIRIGA in Maximo Application Suite 8.10 and later](#)  
The Maximo Connector for TRIRIGA can be installed by using the Catalog page in Maximo Application Suite 8.10 and later.
- [Installing Maximo Connector for TRIRIGA in Maximo Application Suite 8.8 and 8.9](#)  
The Maximo Connector for TRIRIGA can be installed by using the customized .zip file that is provided from Passport Advantage. This .zip file contains all of the configurations that are necessary to complete the installation process.
- [Installing Maximo Connector for TRIRIGA in Maximo Asset Management 7.6.1.2 and later](#)  
The Maximo Connector for TRIRIGA can be installed by deploying the new EAR file on all the Maximo servers.

## Installing Maximo Connector for TRIRIGA in Maximo Application Suite 8.10 and later

The Maximo® Connector for TRIRIGA® can be installed by using the Catalog page in Maximo Application Suite 8.10 and later.

### Procedure

1. In Maximo Application Suite, click the Administration icon, and from the side navigation menu, click Catalog.
2. Click the Add-ons tab, search for the TRIRIGA Connector, and click its tile.
3. On the TRIRIGA Connector page, review the information and then click Configure.
4. On the Update Manage workspace configuration page, in the Components section, in the New version column, select latest.
5. Click Apply Changes and then click Confirm to begin the installation. The process can take anywhere between 20 minutes to couple of hours based on the cluster resources.
6. Optional: In the Red Hat® OpenShift® cluster, monitor the logs that are created in the build pods of the Manage namespace.

## Installing Maximo Connector for TRIRIGA in Maximo Application Suite 8.8 and 8.9

The Maximo® Connector for TRIRIGA® can be installed by using the customized .zip file that is provided from Passport Advantage. This .zip file contains all of the configurations that are necessary to complete the installation process.

## Procedure

---

1. In Maximo Application Suite, click Administration icon.
2. On the Suite administration page, click the Applications tile.
3. On the Applications page, click Manage.
4. On the Manage page, click Actions, then click Update configuration.
5. In the Configurations list, click the edit icon for Customization.
6. In the Customization section, set System managed to off and then click Add customization archive.
7. In the File address field, enter the path of the .zip file that contains the configurations.
8. Scroll up the page, click Apply changes, and then click Confirm to update the instance. The process can take between 20 minutes to 1-2 hours depending on the cluster resources.
9. Optional: In the Red Hat® OpenShift® cluster, monitor the logs that are created in the build pods of the Manage namespace.

---

## Installing Maximo Connector for TRIRIGA in Maximo Asset Management 7.6.1.2 and later

The Maximo® Connector for TRIRIGA® can be installed by deploying the new EAR file on all the Maximo servers.

## Procedure

---

1. To update the Java™ classes and .dbc files, on the Maximo Admin workstation, replace the Maximo SMP directory /opt/IBM/SMP/maximo with the contents from the solution .zip file that is provided.
2. Shutdown the Maximo server.
3. Run the **UpdateDB** command to install the solution components.
  - a. Open the /opt/IBM/SMP/maximo/tools/maximo directory.
  - b. Run the **./updatedb.sh** command.
4. Build the Maximo EAR file.
  - a. Open the /opt/IBM/SMP/maximo/deployment directory.
  - b. Run the **./buildmaximoear.sh** command.
5. Deploy the new Maximo EAR file on all Maximo servers.
  - a. In the WebSphere console, click Applications > Application types > WebSphere enterprise applications.
  - b. Click MAXIMO and then click Update.
  - c. Click Browse and select the EAR file that you built.
  - d. Click Next and accept all default values.
  - e. After deployment, click Save.
6. Start the applications and the Maximo server.

---

## Configuring Maximo Connector for TRIRIGA

Configuring Maximo® Connector for TRIRIGA® is a three-step process that begins with configuring App Connect followed by configuring TRIRIGA Application Suite and then configuring Maximo Application Suite.

## Before you begin

---

- Ensure that you have an instance of App Connect Enterprise or App Connect Pro with the Designer component.
- Ensure that you have administrative access to your Maximo Application Suite instance with an API key that is generated for this integration.
- Ensure that you have TRIRIGA Application Suite with dedicated user and password for this integration.
- Ensure a secure connection between TRIRIGA Application Suite, App Connect, and Maximo Application Suite. You can use Secure Gateway. For more information, see [Getting started with Secure Gateway](#).
- Import the App Connect certificate to Maximo Application Suite to enable encrypted communication.
  - For version 8.9 and later, see [Adding App Connect certificate in Maximo Application Suite 8.9 and later](#).
  - For version 7.6.1.2 and later, see [Adding App Connect certificate in Maximo Asset Management 7.6.1.2 and later](#).
- Import the App Connect certificate to TRIRIGA Application Suite to enable encrypted communication. For more information, see [Adding certificate in TRIRIGA Application Suite](#).
- [Configure App Connect](#)  
The App Connect needs to be configured by creating account for the systems that are integrated through the connector. The configuration process also includes importing flows in App Connect, which define which data can be shared between integrated systems.
- [Add App Connect certificate](#)  
Before you can use Maximo Connector for TRIRIGA, you must add necessary certificates in Maximo Application Suite and TRIRIGA Application Suite.
- [Configuring TRIRIGA Application Suite for integration](#)  
To use Maximo Connector for TRIRIGA, the TRIRIGA Application Suite must be configured by importing object migration package and configuring the integration object.
- [Configuring Maximo Application Suite for a new organization](#)  
Configure your instance of Maximo Application Suite to receive records from TRIRIGA Application Suite.

- [Testing the configuration](#)  
You can test that the configuration is complete by sending a test payload.

---

## Configure App Connect

The App Connect needs to be configured by creating account for the systems that are integrated through the connector. The configuration process also includes importing flows in App Connect, which define which data can be shared between integrated systems.

- [Authenticating App Connect](#)  
Establish the connection between two systems by using App Connect. Access to an instance of App Connect with a deployed instance of a Designer is required.
- [Importing App Connect flows](#)  
The flows can be imported by using either App Connect Enterprise or App Connect SaaS.

---

## Authenticating App Connect

Establish the connection between two systems by using App Connect. Access to an instance of App Connect with a deployed instance of a Designer is required.

---

### Before you begin

Note: IBM® App Connect Professional or App Connect Enterprise is needed to run these flows. The flows have been tested on IBM Cloud® App Connect, AWS App Connect, as well as the containerized version of App Connect.

To establish the connection between two systems, two HTTP accounts must be created on the Catalog page.

---

### Procedure

1. After all of the connectors are loaded, in the HTTP field, enter `http`.
2. For the first account, select Connect to begin setting up the initial HTTP account.  
Note: App Connect creates an account with a generic name in sequential order. For example, if Account 1 and Account 2 are present, the new account is named as Account 3.
3. Use the following table to associate the proper credentials for the accounts.

Table 1. Account names and their details.

Flow	Account Name	Username	Password	API key	API location	API key name
Maximo® Application Suite to TRIRIGA® Application Suite	mxtririga	Your TRIRIGA username	Your TRIRIGA password			
TRIRIGA Application Suite to Maximo Application Suite	trimaximo			Your Maximo API key	header	apikey

4. After the account is connected, open the Catalog page and in the HTTP section, rename the new account to match the names that you created, such as mxtririga.

---

## Importing App Connect flows

The flows can be imported by using either App Connect Enterprise or App Connect SaaS.

- Locate the .yaml files in the provided .zip file.
- Import the Selected Flows into App Connect Enterprise or App Connect SaaS on IBM Cloud®.
- [Importing flows by using App Connect Enterprise \(CP4I\) and App Connect SaaS \(AWS\)](#)  
Flows need to be imported by using App Connect Enterprise for Maximo® Connector for TRIRIGA® so they can be used to start or stop sharing data between an integrated systems..
- [Importing flows by using App Connect SaaS \(IBM Cloud\)](#)  
Flows need to be imported by using App Connect SaaS for Maximo Connector for TRIRIGA so they can be used to start or stop sharing data between an integrated systems.

---

## Importing flows by using App Connect Enterprise (CP4I) and App Connect SaaS (AWS)

Flows need to be imported by using App Connect Enterprise for Maximo® Connector for TRIRIGA® so they can be used to start or stop sharing data between an integrated systems..

---

### Procedure

1. On the App Connect Dashboard, click New and then click Import Flow.

2. Provide the file to import for the flow.  
The flow is uploaded onto the App Connect instance.
3. Click the Edit flow to see the individual nodes of this flow. Be sure to select the HTTP account that was configured for Maximo Application Suite to TRIRIGA Application Suite for the connector.
4. Click Done.
5. Click the options icon and then click Start API.
6. After the flow is running, on the Test tab, select POST. Click Try It. Take note of the URL and security credentials.

---

## Importing flows by using App Connect SaaS (IBM Cloud)

Flows need to be imported by using App Connect SaaS for Maximo® Connector for TRIRIGA® so they can be used to start or stop sharing data between an integrated systems.

---

### Procedure

1. In App Connect, in the API Info section of the Manage tab, ensure the path that points to the flow is correct in Route field. The path is used to create the necessary flow URL.
2. In the Sharing outside of Cloud Foundry organization section, click Create API key and documentation link.
3. Provide a name to generate an API key to use with this flow along and a documentation link. The end of the URL in the documentation has the path that completes the route URL.
4. Copy the end of the URL that begins with tri and add it to the flow URL.  
Note: The six-character string that precedes the path on the documentation must match the last six characters of the route that is specified in the Route field.

---

## Add App Connect certificate

Before you can use Maximo® Connector for TRIRIGA®, you must add necessary certificates in Maximo Application Suite and TRIRIGA Application Suite.

- [Adding the App Connect certificate in Maximo Application Suite 8.9 and later](#)  
You must import the App Connect certificate in the Maximo Application Suite to enable an encrypted communication for Maximo Connector for TRIRIGA .
- [Adding the App Connect certificate in Maximo Asset Management 7.6.1.2 and later](#)  
You must import the App Connect in Maximo Asset Management to enable an encrypted communication for Maximo Connector for TRIRIGA . Configuring the WebSphere® certificate tests the connection to a Secure Sockets Layer (SSL) port and retrieves the signer from the server during the connection establishment.
- [Adding the App Connect certificate in TRIRIGA Application Suite](#)  
You must import the App Connect certificate in TRIRIGA Application Suite to enable encrypted communication for Maximo Connector for TRIRIGA .

---

## Adding the App Connect certificate in Maximo Application Suite 8.9 and later

You must import the App Connect certificate in the Maximo® Application Suite to enable an encrypted communication for Maximo Connector for TRIRIGA® .

---

### Procedure

1. Extract the App Connect certificate from an imported flow URL.
2. In the App Connect, go to the flow's page, click Test, and then Try It to get the proper URL.
3. In Maximo Application Suite, click the AppSwitcher icon, click the Workspaces card, and then open the workspace where Maximo Manage is deployed.
4. Click Actions, click Update configuration, and then click the pencil icon for Imported Certificates.
5. Disable System managed, click Add, enter the extracted certificate in the fields, and then click Confirm.
6. Click Apply Changes to update the truststore with the new certificate.

---

## Adding the App Connect certificate in Maximo Asset Management 7.6.1.2 and later

You must import the App Connect in Maximo® Asset Management to enable an encrypted communication for Maximo Connector for TRIRIGA® . Configuring the WebSphere® certificate tests the connection to a Secure Sockets Layer (SSL) port and retrieves the signer from the server during the connection establishment.

---

### Procedure

1. Log in to the WebSphere console that is hosting the Maximo server.
2. Go to Security > SSL certificate & key management. Under Related Items, click Key stores and certificates.
3. Click CellDefaultTrustStore and go to the next page.
4. In the Additional Properties section, click Signer certificates.
5. On this page, click Retrieve from Port and enter the fields details using the following table.

Table 1. Adding details for retrieving fields from the port .

Field	Value
Host	The host from the imported flow URL
Port	443
Alias	appconnect

6. Click Retrieve signer information.  
The information from the URL is populated.
7. Click Save and then repeat the process for NodeDefaultTrustStore.

## Adding the App Connect certificate in TRIRIGA Application Suite

You must import the App Connect certificate in TRIRIGA® Application Suite to enable encrypted communication for Maximo® Connector for TRIRIGA .

Use the following command to import the App Connect certificate:

```
cat <<EOF | oc create -f -
apiVersion: truststore-mgr.ibm.com/v1
kind: Truststore
metadata:
 name: my-tas-truststore
spec:
 license:
 accept: true
 includeDefaultCAs: true
 servers:
 - "example.com:443"
 certificates:
 - alias: alias_1
 crt: |
 -----BEGIN CERTIFICATE-----
 ...
 Certificate 1
 ...
 -----END CERTIFICATE-----
 ...
 - alias: alias_n
 crt: |
 -----BEGIN CERTIFICATE-----
 ...
 Certificate n
 ...
 -----END CERTIFICATE-----
EOF
```

For more information, see [Additional CA certificates](#) from TRIRIGA Application Suite documentation.

## Configuring TRIRIGA Application Suite for integration

To use Maximo® Connector for TRIRIGA®, the TRIRIGA Application Suite must be configured by importing object migration package and configuring the integration object.

- [Importing object migration packages](#)  
You import the object migration package to configure TRIRIGA Application Suite.
- [Configuring an integration object](#)  
Procedure to configure an integration object for the record that is sent.
- [Running in production](#)  
Once the configuration of the applications is complete and the connectivity between systems is working as expected, you need to deploy the flow as an integration server via the App Connect dashboard.

## Importing object migration packages

You import the object migration package to configure TRIRIGA® Application Suite.

### About this task

Import the OM Package that is labeled APICconnector into the TRIRIGA Application Suite instance.

## Procedure

1. In TRIRIGA Application Suite, from the menu, select Tools > Administration > Object Migration and select New Import Package to begin the import process. For more information, see [Object Migration overview](#) in the IBM® TRIRIGA documentation.
2. From the menu, select Portfolio > People > My Profile and select the user profile that triggers the action. The Date Time Format field must contain a value in Coordinated Universal Time.

---

## Configuring an integration object

Procedure to configure an integration object for the record that is sent.

---

### Procedure

1. In TRIRIGA® Application Suite, click Tools > System Setup > Integration > Integration Object.
2. In the Name column, type in `apic` and select the record of an integration object that is sent.
3. In the dialog, on the General tab, specify the App Connect flow http URL and the credentials.

---

## Running in production

Once the configuration of the applications is complete and the connectivity between systems is working as expected, you need to deploy the flow as an integration server via the App Connect dashboard.

---

### Procedure

1. On the dashboard view of the Designer application, click the overflow menu of the flow's tile.
2. Select Export, and then Runtime flow asset (BAR).
3. In the App Connect dashboard instance, select Create Server and then the type of integration you want to run.  
Note: The flows work with all types of integration sizes. Hence, pick the one that is right for your deployment.
4. Import the bar file you downloaded into the section on the Integrations tab.
5. Go to the Configuration screen and secure the server. For more information, see [Securing a REST-based integration in IBM App Connect](#).
6. Provide the server details such as name, version, and correct license to use.
7. Click Create when you are ready to deploy.

---

## Configuring Maximo Application Suite for a new organization

Configure your instance of Maximo® Application Suite to receive records from TRIRIGA® Application Suite.

Encrypted communication must be enabled by importing the App Connect certificate to Maximo Application Suite. For more information, see [Adding certificate for 8.9+](#) or [7.6.1.2+](#).

- [Creating the TRIRIGA organization](#)  
You must create a new organization in Maximo Application Suite for TRIRIGA Application Suite.
- [Creating a clearing account in the chart of accounts](#)  
You must create a clearing account in chart of accounts for the TRIRIGA organization.
- [Creating the TRIMAIN site](#)  
You must create a main site for TRIRIGA Application Suite.
- [Generating API keys](#)  
You must generate an API key for the MXINTADM user and securely store it for later use in the integrated system. By using this API key, the integrated system can access data from Maximo Application Suite.
- [Creating integration controls](#)  
Integration controls map fields between Maximo Application Suite and TRIRIGA Application Suite. These integration controls help translate specific external values into values Maximo understands.
- [Enabling object structure security](#)  
Procedure to enable object structure security so that user can transact against the specific object structure.
- [Setting definitions in Application Designer](#)  
Setting the definitions for objects to be used in the integration. Based on the set definition, each object shares the data between integrated systems.

---

## Creating the TRIRIGA organization

You must create a new organization in Maximo® Application Suite for TRIRIGA® Application Suite.

---

### Procedure

1. In Maximo Manage, from the side navigation menu, click Administration > Organizations and then from the Common Actions menu, click New Organization.
2. In the Organization field, enter `TRIRIGA` and provide a description, such as `TRIRIGA Organization`.
3. Enter the following values in the fields.

Table 1. Adding values for an organization

Field Name	Value
Base Currency 1	USD
Item Set	SET1
Company Set	COMPSET1
Default Item Status	PENDING
Default Stock Category	STK

4. In the Common Actions menu, click Save Organization.  
Note: Set the organization to Active after creating a clearing account in next topic.
5. To activate the organization, set Active to on.

---

## Creating a clearing account in the chart of accounts

You must create a clearing account in chart of accounts for the TRIRIGA® organization.

### Procedure

---

1. In Maximo® Manage, from the side navigation menu, click Financial > Chart of Accounts and in the Organizations table, click the TRIRIGA organization.
2. From the More Actions, click GL Component Maintenance.
3. Add a row with the following values.

Table 1. GL component details

Field Name	Value
GL Component Value	1001
Description	Testing
Active	Yes

Note: Activate the organization created in the previous topic.

---

## Creating the TRIMAIN site

You must create a main site for TRIRIGA® Application Suite.

### Procedure

---

1. In Maximo® Manage, from the side navigation menu, click Administration > Organizations and open the TRIRIGA organization.
2. On the Sites tab, click the New Row icon.
3. In the Site field, enter TRIMAIN and in the Description field, enter MAIN Site.
4. Set the site to Active.
5. Save the organization.

---

## Generating API keys

You must generate an API key for the MXINTADM user and securely store it for later use in the integrated system. By using this API key, the integrated system can access data from Maximo® Application Suite.

### About this task

---

By using an API key, the external system can access and interact with data in the Maximo Manage system. For more information, see [API keys application](#). Opening the page for creating an API key in Maximo Asset Management and Maximo Application Suite differs slightly.

### Procedure

---

1.

For Maximo Application Suite	For Maximo Asset Management 7.6.1.2 and later
From the side panel, go to Integration > API Keys and then click Add API key.	Go to Administration > Administration > Integration > API Keys and then click Add API key.

2. In the User field, click the search icon and then search MXINTADM user.
3. In the User column, select the MXINTADM user and then click OK.
4. Click Create to generate an API key.
5. On the MXINTADM tile, click Copy key and securely store the API key for later use.

## Creating integration controls

Integration controls map fields between Maximo® Application Suite and TRIRIGA® Application Suite. These integration controls help translate specific external values into values Maximo understands.

### Procedure

1. In Maximo Manage, from the side navigation menu, click Integration > Enterprise Services and then click Create Integration Controls.
2. Click Add New Control > Add New XRef Control. Refer to the following table to create five cross-reference integration controls.

Table 1. Adding integration controls and their values

Integration Control	Maximo value	External value	Description	Domain
PLUSILOCSTATUS	ACTIVE	ACTIVE	TRIRIGA Location Status mapping for inbound flows.	LOCASSETSTATUS
	INACTIVE	REVIEW IN PROGRESS		
	OPERATING	OPERATING		
PLUSIORG	TRIMAIN	IBM®	Organization mapping for Tririga	
	TRIRIGA	TRIRIGA		
PLUSIORGEN	TRIRIGA	EAGLENA	Tririga Organization mapping for Inbound flow	
	TRIRIGA	IBM		
	TRIRIGA	MAXIMO ORG		
	TRIRIGA	TRIRIGA		
PLUSIPRIORITY	1	High	Priority mapping for Tririga	
	2	Medium		
	3	Low		
PLUSISITEEN	TRIMAIN	BEDFORD	Tririga Location mapping for inbound flows	
	TRIMAIN	SPACE 01		
	TRIMAIN	TRIMAIN		

3. Go to the Integration > Enterprise Services and then click New Enterprise Service. Create enterprise services as given in the following table.

Table 2. Associate enterprise service with integration controls.

Enterprise Service	Control
PLUSIASSET	PLUSIORGEN
	PLUSIPRIORITY
	PLUSISITEEN
PLUSILOCATION	PLUSILOCSTATUS
	PLUSISITEEN
	PLUSISTATUS
PLUSIPERSON	PLUSIORGEN
	PLUSISITEEN
PLUSIWO	PLUSIWOPRIORITY

4. Go to the Integration > Publish Channels and then click New Publish Channel. Create publish channels as given in the following table.

Table 3. Associate publishing channels with integration controls.

Publish Channel	Control
PLUSIASSET	PLUSIPRIORITY
PLUSILOCATION	
PLUSIPERSON	PLUSIORG
PLUSISR	
PLUSIWO	PLUSIWOPRIORITY
	PLUSIWOSTART

5. To verify the integration controls, go to the PLUSITRIRIGA External System.
  - a. From the side navigation menu, click Integration > External Systems.
  - b. In the System field, enter PLUSITRIRIGA and then click the PLUSITRIRIGA external system.
  - c. From the More Actions menu, click Setup Integration Controls.
  - d. Ensure that all five integration controls are listed.

## Enabling object structure security

Procedure to enable object structure security so that user can transact against the specific object structure.

### Procedure

1. In Maximo® Manage, from the side navigation menu, click Integration > Object Structures and search for **MXPERSON** and then select the **MXPERSON** object structure.
2. From the More Actions menu, click Configure Object Structure Storage and enable Use Object Structure for Authorization Name.  
Repeat these steps for the following objects.
  - MXASSET
  - MXOPERLOC
  - MXSR
  - MXWO
  - MXDOMAIN
3. From the side navigation menu, select Security > Security Groups and select your security group.
4. On the Object Structures tab, filter for **MXPERSON**.
5. Click Grant Listed Options for This Object Structure and then save the group.  
Note: Repeat this procedure for all other changed structures.

## Setting definitions in Application Designer

Setting the definitions for objects to be used in the integration. Based on the set definition, each object shares the data between integrated systems.

### About this task

To add fields in the user interface to support the connector, you set definitions for the following objects in the Application Designer.

- Person
- Asset
- Location
- Service Request
- Work Order

### Procedure

1. In the Maximo® Manage, from the side navigation menu, click System Configuration > Platform Configuration > Application Designer.
2. Add attributes for the person object.
  - a. In the Application field, search for **PERSON** and then click the **PERSON** to open it.
  - b. On the Workspace page, on the Person tab, select the section where you want to add the three text fields.
  - c. From the Common Actions menu, click Control Palette and add a multipart textbox.
  - d. Right-click on the multipart text box, select Properties, and add the values from the following table and then click Save Definition.  
Note: Ensure that the Attributes are taken from the **PERSON** object.

Table 1. Adding attributes for the PERSON object

Type of Control	Label	Attribute	Attribute for Part 2 for multipart textbox	Lookup	Input Mode for Part 2 for multipart textbox
Multipart Textbox	TRIRIGA Location Path	PLUSIPRIMARYLOCPATH	PLUSILOCATIONPATH.DESCRPTION	VALUelist	Read only
Multipart Textbox	TRIRIGA Primary Organization	PLUSIORGPATH	PLUSIORGANIZATIONPATH.DESCRPTION	VALUelist	Read only
Textbox	TRIRIGA Record ID	EXTERNALREFID (From the Person Object)			

3. Add attributes for the asset object.
  - a. In the Application field, search for **ASSET** and then click the **ASSET** to open it.
  - b. Follow the same procedure as followed for the **PERSON** object.  
Note: Ensure that the Attributes are taken from the **ASSET** object.

Table 2. Adding attributes for the ASSET object.

Type of Control	Label	Attribute	Attribute for Part 2 for multipart textbox	Lookup	Input Mode for Part 2 (For Multipart Textbox)
Multipart Textbox	TRIRIGA Building Equipment Spec	PLUSIASSETSPECNAME	PLUSIASSETSPECCLASS.DESCRPTION	VALUelist	Read only
Multipart Textbox	TRIRIGA Primary Organization	PLUSIORGPATH	PLUSIORGANIZATIONPATH.DESCRPTION	VALUelist	Read only
Multipart Textbox	TRIRIGA Location Path	PLUSILOCPATH	PLUSILOCATIONPATH.DESCRPTION	VALUelist	Read only
Textbox	TRIRIGA Record ID	EXTERNALREFID (From the Asset Object)			

4. Add attributes for the location object.
  - a. In the Application field, search for **LOCATION** and then click the **LOCATION** to open it.
  - b. Follow the same procedure as followed for the **PERSON** object.  
Note: Ensure that the Attributes are taken from the **LOCATION** object.

Table 3. Adding attributes for the LOCATION object.

Type of Control	Label	Attribute	Attribute for Part 2 for multipart textbox	Lookup	Input Mode for Part 2 for multipart textbox
Multipart Textbox	TRIRIGA Space Classification	PLUSISPACECLASSIFICATION	PLUSISPCCLASSIFICATION.DESCRPTION	VALUelist	Read only

Type of Control	Label	Attribute	Attribute for Part 2 for multipart textbox	Lookup	Input Mode for Part 2 for multipart textbox
Multipart Textbox	TRIRIGA Parent Location	PLUSIPARENTLOCATION	PLUSIPARENTPATH.DESCRPTION	VALUELIST	Read only
Textbox	TRIRIGA Record ID	EXTERNALREFID (From the Location Object)			

5. Add attributes for the location object.

- In the Application field, search for SR and then click to open it.
- Follow the same procedure as followed for the PERSON object.

Note: Ensure that the PLUSIREQCLASSID attribute is taken from the TICKET object.

Table 4. Adding attributes for the Service Request object.

Field Name	Value
Attribute	PLUSIREQCLASSID
Attribute for Part 2	PLUSIREQCLASS.DESCRPTION
Lookup	VALUELIST
Input Mode for Part 2	Readonly

6. Add attributes for the location object.

- In the Application field, search for WOTRACK and then click to open it.
- Follow the same procedure as followed for the PERSON object.

Note: Ensure that the PLUSIREQCLASSID attribute is taken from the WORKORDER object.

Table 5. Adding attributes for the Work Order object.

Type of Control	Label	Attribute	Attribute for Part 2 for multipart textbox	Lookup	Input Mode for Part 2 for multipart textbox
Multipart Textbox	Tririga Location Path	PLUSILOCPATH	PLUSILOCPATH.DESCRPTION	VALUELIST	Read only
Multipart Textbox	Tririga Primary Organization	PLUSIORGPATH	PLUSIORGPATH.DESCRPTION	VALUELIST	Read only
Textbox	External Ref ID	EXTERNALREFID (From the WorkOrder Object)			

## Testing the configuration

You can test that the configuration is complete by sending a test payload.

### Procedure

- In Maximo® Application Suite, go to the Integration > End Points.
- In the End Point, search the endpoint to test and then click Test begin the test.
- In the Test data section, send a test payload that is a valid object, such as {"Hello": "World"}.
- Click Test, if the response is anything other than Bad Request, troubleshoot the issue. For more information, see [Troubleshooting connection errors](#).
- In TRIRIGA® Application Suite, use a tool such as Postman to test the connectivity of the App Connect flow. You can use a sample JSON payload from the [TRIRIGA APIs repository](#).

## Troubleshooting connection errors

Depending on the direction of the flow, cross-referencing errors from two systems can help identify the root cause of an issue with the integration.

For example, if you face a Not Found error in Maximo® Application Suite in Message Reprocessing while you run the flow, double-check the logs in App Connect to see whether there is a corresponding error. If a corresponding error exists, the root cause might be related to what is sent out of Maximo Application Suite. If no, then the message never left Maximo Application Suite, and you must check the flow to ensure that it is running as expected.

### Find logs in App Connect

- In App Connect SaaS and AWS, click the clipboard icon on the side panel to view the logs.
- In App Connect Enterprise, the logs are found in the Integration Server pod. If running from App Connect Designer, this integration server is found in the App Connect namespace in Red Hat® OpenShift®. Typically the Designer integration server has four pods and the logs can be found in the pod with a similar naming convention to des-01-quickstart-ma-designer-designer-flows.

## Common errors from Maximo Application Suite

Note: At the time of testing the endpoints, ensure that they are entered correctly in End Points.

Table 1. Troubleshooting common errors from Maximo Application Suite

Error	Cause	Resolution
Response code received from the HTTP request from the endpoint is not successful	Invalid URL in the integration object.	Double check that all of the components are entered correctly in the URL. Make sure that no accidental spaces are added at the beginning or the end.

Error	Cause	Resolution
404: Not Found	The flow is not running.	Make sure that the flow is running before the cron tasks are started.
PKSync error	Certificate error.	Confirm that the certificate is configured correctly.

## Message Reprocessing

Errors in Maximo Application Suite can be found in Message Reprocessing in Maximo Manage.

Table 2. Troubleshooting common errors from message reprocessing

Error	Cause	Resolution
Bad Request error	Either an incorrect payload is being sent out or the account configurations are wrong.	Double check to make sure the accounts from the App Connect prerequisite section are correct and that the item in Maximo Application Suite has all of the mapped fields.

## Common errors from TRIRIGA Application Suite

Table 3. Troubleshooting common errors from TRIRIGA Application Suite

Error	Cause	Resolution
404 - Not Found: Cannot POST	Invalid URL in the integration object.	Double-check that all of the components are entered correctly in the URL for the specific integration object.
404 - API doesn't exist	The flow is not running.	Double-check that the flow is Active in App Connect.
404 - The HTTP request returned with an error 404 "Not Found"	Incorrect App Connect connector configuration.	Double-check that the credentials that are used in the HTTP post node in App Connect are correct.

Note: If the integrations do not work as intended, in the Admin Console in TRIRIGA Application Suite, clear the OSLC cache.

## Integration reference information

Reference information includes a guide to the XML structures and schemas used by the integration framework, the system properties you can set, and predefined collaboration switches provided with applications.

- [System properties for integration](#)  
System properties define the behavior and characteristics of the integration framework. To review or change integration framework properties, filter for the properties in the System Properties application.
- [Integration XML](#)  
Most integration XML messages are based on an object structure and an operation that a channel or service performs. Standard services, however, do not support object structures and predefined XML schemas are used to construct these XML messages.
- [Collaboration switches](#)  
Collaboration switches use a concept of ownership to help users manage the synchronization of inbound data between the integration framework and an external system. The switches provide the ability to control specific subprocesses within an application, based on the ownership of different data objects within a transaction.

## System properties for integration

System properties define the behavior and characteristics of the integration framework. To review or change integration framework properties, filter for the properties in the System Properties application.

## General integration properties

To see a list of general integration properties, specify `mxe.int` as a filter term in the System Properties application. For Boolean properties (true/false), a value of 0 means false, and a value of 1 means true.

Table 1. General integration properties

Property	Description	Default value
mxe.int.allowdefaultlogin	Controls default login for MIF. When set to 0 (false), default login is prevented. This property overrides the ALLOWDFLTLOGIN setting for the default integration user in the ejb-jar.xml file.	0
mxe.int.containerdeploy	Deploy web services to the application server container. When set to 0 (false), web services are deployed to the product container.	0
mxe.int.credentialmapperclassname	Credential mapper classname is a class file that can be used for mapping credential information when an integration module is implemented.	No default value
mxe.int.generateboolean	Generate Boolean as schema Boolean.	1
mxe.int.globaldir	Specifies the location of a global directory which stores files that are related to integration	No default value
mxe.int.queueusercachesize	Number of users that are cached for inbound queue messages.	10

Property	Description	Default value
mxe.int.resolveschema	Resolves all schema includes to contain inline schema definition.	1
mxe.int.servicedeployer	Web services deployer class is a custom Java™ class for web service deployment when the default deployer class is not used.	No default value
mxe.int.uddiinqurl	Represents the integration UDDI registry inquiry URL.	No default value
mxe.int.uddiname	Represents the integration UDDI registry user ID.	No default value
mxe.int.uddipassword	Integration UDDI registry password.	No default value
mxe.int.uddipuburl	Integration UDDI registry publish URL.	No default value
mxe.int.validateupdates	Validates the database updates completed by integration. When set to 1 (true), the deletion of business objects, attributes, indexes, and relationships by a user through the Database configuration application are validated against integration content. The validation ensures that the data that is deleted is not referenced by an integration component. If a reference exists, the user is not able to complete the delete action.	1
mxe.int.validatepackage	Validates the Migration Manager database updates by integration.	0
mxe.int.verifywebappurl	Verifies web application URL when schema files are generating.	1
mxe.int.webappurl	Represents the integration web application URL. Configure this property to contain the correct host name and port number.	http://localhost/meaweb
mxe.int.wsdlcurrentschema	Shows the current schema definition in WSDL.	1
mxe.int.wsdlinclude schema	Includes the schema directly in the WSDL.	1
mxe.int.wsdlnamespace	Represents the integration WSDL namespace.	http://www.ibm.com/maximo/wsd
mxe.int.xmlnamespace	Represents the integration XML namespace.	http://www.ibm.com/maximo
mxe.int.binarytext	Converts a text value to base 64 encoded value.	0
mxe.int.defaultaction	The default action for flat file import.	AddChange
mxe.int.defaultoperation	The default operation for the application export.	Sync
mxe.int.defaultuser	Represents the Integration default login user.	mxintadm
mxe.int.doclink.maxfilesize	Represents the maximum file size (MB) for attachments that are included as part of an integration message.	10
mxe.int.enabledatemillis	Enables the dates with milliseconds part.	0
mxe.int.expupdatetender	Updates the SENDERSYSID field on the primary object during data export.	0
mxe.int.extractretrycount	The File Extract Retry Count is the number of times an error message is retried during data import when using file-based error management.	0
mxe.int.flatfiledelimiter	Integration flat file text delimiter is the default delimiter value that is used for application import enablement and for data import.	,
mxe.int.flatfilenewline	Retains new line character in flat files. For fields, such as descriptions, that can contain new line characters, the characters are retained in the integration messages when the property value is 1 (true).	0
mxe.int.interactiveimport	Performs the application import as interactive.	0
mxe.int.keyresponse	Provides response content for inbound integration messages for all operations. When set to 1 (true), response content, that includes the primary object key values, is provided for all service operations. When set to 0 (false), response content is provided for Query and Create operations only.	1
mxe.int.maxextractdocs	Represents the number of error documents that are written to each temporary file when an extract file is building .	1000
mxe.int.mdbdelay	Represents the wait time in milliseconds before a message from the error queue is processed.	-1
mxe.int.propagatouser	Propagate authenticated user through the inbound queue. When set to 1 (true), the user of the integration message is saved with the queue message and used during the processing of the message because it is processed from the queue to the business objects.	0
mxe.int.savemessage	Indicates the save JMS message.	0
mxe.int.setglobalnsaln	Controls the truncation of characters that are sent to interface tables.	0
mxe.int.textqualifier	The flat file text qualifier is the default text qualifier value in application import enablement and in data import.	"
mxe.int.updatec oafromglcomp	Updates the Chart of Accounts that contain an identified component. When set to 1 (true), processing of inbound GL component data initiates related updates to any chart of account data that references the GL component.	1

Property	Description	Default value
mxe.int.usescientific	Uses scientific notation for double values.	1
mxe.int.validatexmltext	Validates XML element value for invalid XML characters. When set to 1 (true), an outbound message is validated to ensure that all data in the message uses valid XML characters. If messages contains invalid characters, the operation stops and no outbound message is delivered.	0
mxe.int.whereclausepolicy	Sets the where-clause policy for an integration query.	parse
mxe.int.adminfromemail	The email address FROM integration administration, which is used as the From email address when integration initiates an email. Must be a valid email address format, such as from@example.com.	No default value
mxe.int.admintoemail	The email address TO integration administration, which is used as the To email address when integration initiates an email. Must be a valid email address format, such as to@example.com. You can provide more than one email address in a comma-separated list.	No default value
mxe.int.usedbinforifaceth	Sets the processing for interface tables. When set to 1, the interface process refers to the existing table to determine what to insert into the table rather than the object structure definition.	0
mxe.int.enableosauth	Enables the authorization configuration of object structures.	1

## REST integration properties

To see a list of REST API integration properties, specify **mxe.rest** as a filter term in the System Properties application. For Boolean properties (true/false), a value of 0 means false, and a value of 1 means true.

Table 2. REST API integration properties

Property	Description	Default value
mxe.rest.format.json.mimetypes	The REST supported mime types for JSON.	application/json
mxe.rest.format.xml.mimetypes	The REST supported mime types for XML.	application/xml,text/xml
mxe.int.allowrestnpsort	Allow sorting with nonpersistent attributes in REST API.	0
mxe.int.disableglvalidation	Disable GL account validation when creating an organization.	0
mxe.int.groupname	The default integration group name.	INTADMIN
mxe.rest.handler.mbo	The REST MBO resource handler.	com.ibm.tivoli.maximo.rest.MboResourceRequestHandler
mxe.rest.handler.os	The REST object structure resource handler.	com.ibm.tivoli.maximo.rest.OSResourceRequestHandler
mxe.rest.handler.ss	The REST standard service resource handler.	com.ibm.tivoli.maximo.rest.MaxServiceResourceRequestHandler
mxe.rest.serializer.mbo.imglib.image	The REST serializer for the imglib MBO for image format.	com.ibm.tivoli.maximo.rest.ImageLibSerializer
mxe.rest.serializer.mbo.json	The REST serializer for MBO for JSON format.	com.ibm.tivoli.maximo.rest.MboJSONSerializer
mxe.rest.serializer.mbo.xml	The REST serializer for MBO for XML format.	com.ibm.tivoli.maximo.rest.MboXMLSerializer
mxe.rest.serializer.os.json	The REST serializer for object structures for JSON format.	com.ibm.tivoli.maximo.rest.OSJSONSerializer
mxe.rest.serializer.os.xml	The REST serializer for object structures for XML formats.	com.ibm.tivoli.maximo.rest.OSXMLSerializer
mxe.rest.serializer.ss.json	The REST serializer for standard services for JSON format.	com.ibm.tivoli.maximo.rest.ServiceMethodResponseJSONSerializer
mxe.rest.serializer.ss.xml	The REST serializer for standard services for XML format.	com.ibm.tivoli.maximo.rest.ServiceMethodResponseXMLSerializer
mxe.rest.webappurl	Token Authentication on Web Application URL.	No default value
mxe.rest.mbo.blockaccess	Blocks access to the comma-separated list of MBOs.	No default value
mxe.rest.mbo.defaultformat	The REST default format for all MBOs.	xml
mxe.rest.mbo.imglib.defaultformat	The REST default format for the MBO imglib.	image
mxe.rest.os.blockaccess	Blocks access to the separated list of object structures.	10
mxe.rest.os.defaultformat	The REST default format for all object structures.	xml
mxe.rest.ss.defaultformat	The REST default format for all standard service response	xml
mxe.rest.supportedformats	The REST supported formats for a response.	xmljsonimage
mxe.rest.whereclausepolicy	Sets the where clause policy for REST query.	parse

## OSLC integration properties

To see a list of OSLC integration properties, specify **mxe.oslc** as a filter term in the System Properties application. For Boolean properties (true/false), a value of 0 means false, and a value of 1 means true.

Table 3. OSLC integration properties

Property	Description	Default value
mxe.oslc.dftconsumer version	The default OSLC version that the consumer uses.	2
mxe.oslc.dftversion	The default OSLC version for an OSLC provider.	2

Property	Description	Default value
mxr.oslc.enableprovider	Enables the OSLC provider.	1
mxr.oslc.idleexpiry	Indicates the idle expiry time.	300
mxr.oslc.webappurl	The provider's public URL.	http://localhost/maximo/oslc/
mxr.oslc.collectioncount	Adds the total count in the OSLC collection.	0
mxr.oslc.defaulttep	The default OSLC Endpoint.	OSLCDEFAULT
mxr.oslc.defaultformat	The default format for OSLC.	oslcjson
mxr.oslc.errorresponse	The OSLC Error Response Format.	1
mxr.oslc.addpodnameheader	Allow podname to be added to the response header	0
mxr.oslc.preferproviderdesc	Prefers OSLC provider description for resource registry reconciled URLs	false
mxr.oslc.prefersmallpreview	Prefers small preview for OSLC consumer.	false
mxr.oslc.prettyjson	Pretty printed JSON.	0
mxr.oslc.prettyrdf	Pretty printed RDF.	0
mxr.oslc.prqueryep	The Provider Registry Query Endpoint.	PROVIDERREGISTRY
mxr.oslc.prcREATEep	Represents the Provider Registry Create Endpoint.	No default value

## Integration XML

Most integration XML messages are based on an object structure and an operation that a channel or service performs. Standard services, however, do not support object structures and predefined XML schemas are used to construct these XML messages.

- [XML message overview](#)  
When you configure object structures, the integration framework specifies an appropriate XML schema that defines the content and structure of integration messages.
- [XML structure](#)  
A typical integration XML message has a root element, an object structure element, and elements for the objects that are defined for the object structure. Object elements contain elements for object fields and elements can contain one or more attributes. Attribute names and values are case-sensitive.
- [Integration XML schemas](#)  
XML schemas for channels and services, excluding standard services, are based on the configuration of the objects that are included in the object structure. You can generate schemas in the integration applications.

## XML message overview

When you configure object structures, the integration framework specifies an appropriate XML schema that defines the content and structure of integration messages.

## Message content

The following channels and services can be used for XML messages based on an object structure:

- Invocation channel
- Publish channel
- Enterprise service
- Object structure service

The following operations are supported:

- Create
- Delete
- Invoke
- Publish
- Query
- Sync
- Update

Operation values are case-sensitive.

## Message structure overview

The standard format for an integration XML message begins with a root element that contains an object structure element. The object structure element contains elements for the primary object and its fields and for any child objects that are defined for the object structure. The following example is based on the PERSON object structure, where the primary object and its fields precede child objects and their fields.

```
<?xml version="1.0" encoding="UTF-8"?>
<max:SyncMXPERSOn xmlns:max="http://www.ibm.com/maximo"> (Root element)
 <max:MXPERSOnSet> (Sets the object structure element)
 <max:PERSON> (Object element for primary object)
 <max:PERSONID>Value</max:PERSONID> (Object field element)
 <max:EMPLOYEEType>Value</max:EMPLOYEEType> (Object field element)
```

```

 <max:PHONE> (Child object element)
 <max:PHONENUM>Value</max:PHONENUM> (Child object field element)
 <max:TYPE>Value</max:TYPE> (Child object field element)
 </max:PHONE>
 <max:EMAIL> (Child object element)
 <max:EMAILADDRESS>New value to update</max:EMAILADDRESS>
 <max:TYPE>Value</max:TYPE> (Child object field element)
 </max:EMAIL>

 </max:PERSON>
</max:MXPERSONSet>
</max:SyncMXPERSON>

```

The name of the root element is a concatenation of the operation specified for the channel or service and the name of the object structure. In this example, the **SyncMXPERSON** root element combines the Sync operation and the MXPERSON object structure.

Each element can contain one or more attributes. In this example XML message, the root element includes the namespace attribute.

## Schema generation

To generate the schema and view the generated XML, filter for a specific record and select the Generate Schema/View XML action in any of the following applications:

- Enterprise Services
- Invocation Channels
- Object Structures
- Publish Channels
- Web Services Library

## XML structure

A typical integration XML message has a root element, an object structure element, and elements for the objects that are defined for the object structure. Object elements contain elements for object fields and elements can contain one or more attributes. Attribute names and values are case-sensitive.

- **Root element and attributes**  
The root element of an XML message is based on an object structure and an operation specified for the channel or service used for the communication. The root element can contain one or more attributes.
- **Object structure element**  
The object structure element contains an element for the primary object and elements for any child objects defined for the object structure. This element can support multiple occurrences of the primary object and its child objects.
- **Object elements and attributes**  
An object element contains elements for the object fields. Each object element can contain one or more attributes.
- **Object field elements and attributes**  
If the same field is included in the key for both a parent object and a child object in an object structure, the field is contained in the parent object only. Each object field can include one or more attributes.

## Root element and attributes

The root element of an XML message is based on an object structure and an operation specified for the channel or service used for the communication. The root element can contain one or more attributes.

The following table shows the attributes that can apply to root elements. Attribute names and values are case-sensitive. All attributes are optional.

Attribute	Description	Type	Applicable to
<b>baseLanguage</b>	The base language in which the content values are supplied.	string	All input and output operations
<b>creationDate Time</b>	Date and time when the content is generated.	dateTime	All input and output operations
<b>maximoVersion</b>	The major version, minor version, build, and database build that is generated for all published XML.	MaximoVersionType	All input and output operations
<b>messageID</b>	Unique identifier generated for all messages.	string	All input and output operations
<b>transLanguage</b>	The language in which the values for multilanguage-enabled fields are supplied.	string	All input and output operations

Attribute	Description	Type	Applicable to
<b>event</b>	The origin of an outbound XML message. Valid values are: <ul style="list-style-type: none"> <li>0 (false), indicates that the message is generated by the data export feature.</li> <li>1 (true), indicates that the message is generated by an outbound integration event listener (that is, data entry in an application).</li> </ul>	eventType	All output operations
<b>uniqueResult</b>	Specifies whether a query expects one record or multiple records in a response. If the value is 0, or the attribute is not specified, the query can return multiple records. If the value is 1, the query can return a single record only and, otherwise, an error occurs.	Boolean	Queries (input)
<b>maxItems</b>	If a query can return multiple records, this attribute limits the number of records to be returned at one time. If this attribute is not specified, the response contains the entire result set.	positiveInteger	Queries (input)
<b>rsStart</b>	Specifies the first record to return in the response. If not specified, the response starts with the first record in the result set. If the number of results in the result set is lower than the <b>rsStart</b> value, the response returns no records.  If a <b>maxItems</b> value is specified, the response returns the specified number of records, starting with <b>rsStart</b> value, if one is set.  For example, if maxItems=10 and rsStart is not specified, the response returns results 1 through 10. To receive results 11 through 20, resend the query with rsStart=11.	integer	Queries (input)
<b>rsStart</b>	This value matches the <b>rsStart</b> value in the corresponding query.  If the query contains a <b>maxItems</b> value, the <b>rsStart</b> value in requests for additional records is <b>rsStart + rsCount + 1</b> .  If this attribute is not specified, the response starts with the first record in the result set and includes the number of records specified by the <b>rsCount</b> attribute.	integer	Responses (output)
<b>rsCount</b>	The number of records returned in a message. If the original query specifies a <b>maxItems</b> value, the <b>rsStart</b> value for the subsequent request for additional records is <b>rsStart + rsCount + 1</b> .	integer	Responses (output)
<b>rsTotal</b>	The total number of records in the result set. If the query does not specify a <b>maxItems</b> value, the <b>rsTotal</b> value is the same as the <b>rsCount</b> value.	integer	Responses (output)

## Object structure element

The object structure element contains an element for the primary object and elements for any child objects defined for the object structure. This element can support multiple occurrences of the primary object and its child objects.

The primary object element contains elements for each object field. Child object elements, containing elements for their object fields, are listed after the primary object.

## Object elements and attributes

An object element contains elements for the object fields. Each object element can contain one or more attributes.

The following table lists the attributes that can apply to an object element. Attribute names and values are case-sensitive. All attributes are optional.

Attribute	Description	Type	Applicable to
<b>action</b>	This value is derived from the action attribute of the primary object within the message. For outbound messages, this attribute is for informational purposes only.  For inbound messages, the processing logic uses this value only for the Sync operation. For other operations, this value is ignored.	ProcessingActionType	All input and output operations
<b>relationship</b>	Identifies the relationship that the system uses to retrieve the object using the parent object.	string	All input and output operations
<b>deleteForInsert</b>	Identifies a child object that must be deleted before reinserting. This attribute applies only to inbound messages where the operation is Sync and the action is Change.	string	All input and output operations

## Object field elements and attributes

If the same field is included in the key for both a parent object and a child object in an object structure, the field is contained in the parent object only. Each object field can include one or more attributes.

- Changed field attribute**  
A Boolean value can be set to 1 (True) in outbound XML messages to indicate that the value in the field is changed. The changed attribute is not set in XML generated by the data export feature.

- [General ledger field attribute](#)  
The glorder attribute is set in the GLCOMP elements in fields that identify general ledger (GL) accounts, such as a GLDEBITACCT field. Each GLCOMP element contains part of the account number and the glorder attribute identifies how to combine these elements to construct the GL value.
- [Translatable field attribute](#)  
The langenabled attribute is set to 1 (true) on every field that can be translated in outbound XML messages.
- [Synonym field attribute](#)  
For outbound messages, fields that are associated with a synonym-type domain specify the corresponding internal value using the maxvalue attribute. This value is available for customization or exit processing as required. The attribute is informational only, and is not used for inbound message processing.
- [Encrypted field attribute](#)  
When the data in a field, such as a password field, is encrypted, the Boolean attribute, maxencrypted, is set to 1 (true). External systems use this value to determine whether to apply a decryption process to the information in the field.
- [Action attributes](#)  
An action attribute is an optional attribute that specifies to the receiving system the type of processing to perform on an XML message. Action attributes apply to inbound XML messages that synchronize data, using the Sync operation, and to outbound XML messages that use publish channels.
- [Field value types](#)  
The integration framework specifies the processing behavior for the different data types used to format field values.

---

## Changed field attribute

A Boolean value can be set to 1 (True) in outbound XML messages to indicate that the value in the field is changed. The changed attribute is not set in XML generated by the data export feature.

The changed attribute is set in outbound XML messages only when the transaction satisfies all of the following conditions:

- An outbound, event-based transaction creates the message.
- The Change action attribute or the Replace action attribute is set on the primary object.
- The sending object structure has the same parent-child object relationship as the receiving application.

In the following example, the Replace action attribute is set for the parent object and the changed attribute is set to 1 for the ADDRESSLINE1 field.

```
<MXPERSON>
 <PERSON action="Replace">
 <PERSONID>123</PERSONID>
 <ADDRESSLINE1 changed="1" >1 Main Street</ADDRESSLINE1>
```

For general ledger (GL) type fields, the changed attribute is always set on the name element, which is GLDEBITACCT in the following example:

```
<GLDEBITACCT changed="1">
 <VALUE>6600-800-SAF</VALUE>
 <GLCOMP glorder="0">6600</GLCOMP>
 <GLCOMP glorder="1">800</GLCOMP>
 <GLCOMP glorder="2">SAF</GLCOMP>
</GLDEBITACCT>
```

---

## General ledger field attribute

The glorder attribute is set in the GLCOMP elements in fields that identify general ledger (GL) accounts, such as a GLDEBITACCT field. Each GLCOMP element contains part of the account number and the glorder attribute identifies how to combine these elements to construct the GL value.

In outbound XML messages, the value of a general ledger type field, including delimiters, is set in the VALUE child element within the field. The components of the value, based on the database definition of the components, are included in GLCOMP elements. The glorder attribute in each GLCOMP element identifies the order of the component, starting from 0 (zero), to a maximum of 20. In the following example, the account number has three GL components

```
<GLDEBITACCT>
 <VALUE>6600-800-SAF</VALUE>
 <GLCOMP glorder="0">6600</GLCOMP>
 <GLCOMP glorder="1">800</GLCOMP>
 <GLCOMP glorder="2">SAF</GLCOMP>
</GLDEBITACCT>
```

Inbound XML messages can set a GL account number in the VALUE element or in GLCOMP elements with associated glorder attributes. If the message includes GLCOMP elements, the account number is recreated based on the delimiters defined in the GLCONFIGURE table. If both VALUE and GLCOMP elements are included in the message, the VALUE element is used and the GLCOMP elements are ignored.

---

## Translatable field attribute

The langenabled attribute is set to 1 (true) on every field that can be translated in outbound XML messages.

---

## Synonym field attribute

For outbound messages, fields that are associated with a synonym-type domain specify the corresponding internal value using the maxvalue attribute. This value is available for customization or exit processing as required. The attribute is informational only, and is not used for inbound message processing.

In the following example, a maxvalue of NOLOT is set for the LOTTYPE field.

```
<MXITEM>
<ITEM>
<ITEMNUM>560-00</ITEMNUM>
<DESCRIPTION>Tubing, Copper-1 In ID X .030 In Wall Test
</DESCRIPTION>
<LOTTYPE maxvalue="NOLOT">NOLOT</LOTTYPE>
```

## Encrypted field attribute

When the data in a field, such as a password field, is encrypted, the Boolean attribute, maxencrypted, is set to 1 (true). External systems use this value to determine whether to apply a decryption process to the information in the field.

The following example uses the MXPERSUSER object structure to provide user information, including a password, and the maxencrypted attribute is set on the PASSWORD field in the MAXUSER object.

```
<MXPERSUSER>
<PERSON action="Replace">
<PERSONID>123</PERSONID>
<MAXUSER>
<MAXUSERID>10</MAXUSERID>
<PASSWORD maxencrypted="1"> dmFzdG8=</PASSWORD>
<MAXUSER>
<PERSON>
<MXPERSUSER>
```

## Action attributes

An action attribute is an optional attribute that specifies to the receiving system the type of processing to perform on an XML message. Action attributes apply to inbound XML messages that synchronize data, using the Sync operation, and to outbound XML messages that use publish channels.

The following description describes the processing for inbound messages using the Sync operation. The external system must evaluate the action code that is provided with outbound messages and determine the processing that is appropriate for that external application.

Action attributes can apply to the content of the parent object and child objects in an object structure. An action attribute applied to the parent object specifies the overall processing action for parent and child records. Applied to a child object, an action indicates processing that is specific to that record. An attribute provided for a child object is evaluated only when the primary object has an action value of Change. When the action for the primary object is not Change, actions on the child object are ignored.

Business rules take precedence over action attributes. If a business rule prohibits an action that is specified on an inbound XML message, an error occurs. For example, an inbound transaction that attempts to update a closed purchase order generates an error.

If an XML message contains multiple instances of an object structure, each instance of the object structure can specify a different action attribute. In the following example, the COMPANIES record has multiple child COMPCONTACT records, and each instance has its own action attribute.

```
<MXVENDOR>
 <COMPANIES action="Change">
 <COMPANY>TEST4
 <NAME>test</NAME>
 <ADDRESS1>100 Main Str</ADDRESS1>
 <COMPCONTACT action="Add">
 <NAME>SMITH</NAME>
 <TITLE>MANAGER</TITLE>
 </COMPCONTACT>
 <COMPCONTACT action="Change">
 <NAME>JONES</NAME>
 <TITLE>ENGINEER</TITLE>
 </COMPCONTACT>
 </COMPANY>
 </COMPANIES>
</MXVENDOR>
```

The action attribute can have the following values which are case-sensitive:

- Add
- Delete
- Change
- Replace
- AddChange
- Null

Value	Description
Add	Add records to the database in the receiving system.
Delete	Delete records from the database in the receiving system.
Change	Update existing records in the database in the receiving system.

Value	Description
Replace	Add records or replace records in the receiving system, depending on whether the primary record exists in the database.
AddChange	Add or update existing records in the database in the receiving system.
Null	Add records or replace records in the receiving system, depending on whether the primary record exists in the database.

## Default action processing

When an inbound XML messages does not contain an action attribute, the message is processed as follows:

- If the primary record does not exist in the database, the Add action is applied.
- If the primary record exists in the database, the Replace action is applied.

For a message sourced from a flat file or an interface table, you can provide an action code for the primary object only. There is no support for providing action codes for child objects.

## Add action

The Add action adds records to the database in the receiving system.

For inbound transactions, an error occurs if the data already exists. If the Add action is set on a parent object, the action extends to child objects and it is not necessary to specify the action at the child object level. Outbound transactions contain an Add action when the insert of an object generates the transaction.

## Delete action

The Delete action deletes records from the database in the receiving system.

If the Delete action is set on a parent object, the action extends to child objects and it is not necessary to specify the action at the child object level.

If the Delete action is set on the parent object in an outbound XML message that does not include the child objects, the receiving system is responsible for identifying and deleting child objects.

If the Delete action is set on the parent object in an inbound XML message, the integration framework deletes the related child objects. If the parent object does not exist in the database, no error is reported to the sending system.

## Change action

The Change action updates existing records in the database in the receiving system.

A Change action on the primary object in an XML message indicates that the message contains one or more parent or child records that are added, changed, or deleted. The message always contains the parent of any child record to be updated, even if the parent is unchanged.

The Change action on the primary object is the only case where you can supply an action for a child object. When the primary object in an XML message contains a Change action, each child object in the message can contain one of the following actions.

Action attribute of child object	Processing action
Add	Add the child record. If the child record already exists, an error is generated.
Delete	Delete the child record. If the child record does not exist, an error is generated.
Change	Update the child record. If the child record already exists, an error is generated.
Null or no action specified	If the child record exists, update it. If the child record does not exist, add it.

## Replace action

The Replace action updates existing records in the database in the receiving system.

A Replace action on the primary object in an XML message indicates that the message contains a complete set of objects that represents the result of additions, changes, and deletions to the object structure. These objects replace the existing database records and any record that is not referenced in the XML message is deleted.

For outbound processing, the Replace action is always used, not the Change action.

For inbound processing, any existing child record that is not explicitly mentioned in the message is deleted. External systems must also delete any child records that are not included in the XML message.

The Replace action can apply only to the primary object in an XML message. If a child record in an inbound XML message contains a Replace action when the primary object contains a Change action, the message is not processed. If a child level record contains a Replace action when the parent contains any action other than Change, the action on the child record is ignored.

## AddChange action

The AddChange action adds or updates existing records in the database in the receiving system. The AddChange action is like the Replace action except that the AddChange action does not apply to child objects.

An AddChange action on the primary object adds the primary record and all the sub-records that are specified in the message, if the primary record does not exist in the database. If the primary record does exist, it is updated and any child record that is included in the message. Existing child records that are not specified in the inbound message are not deleted.

The AddChange action is useful when an object structure includes elements that do not exist in the external system. For example, an external system can maintain vendor information but contact information is stored only in the database. An inbound message with a vendor record that has an action value of NULL deletes the contact information in the database. If the action is set to AddChange for this transaction, the vendor information is updated and the contact information remains the same.

## Comparison of Change, Replace, and AddChange actions

The Change, Replace, and AddChange actions differ in the information that they include in the XML message and the processing that they require of the receiving system.

## Action attribute combinations

The following table shows the combinations of action attributes you can include on primary and child records.

Child Record	Add	Delete	Change	Replace	AddChange	No Value	Remarks
Primary Record							
Add	N/A	N/A	N/A	N/A	N/A	N/A	All child values ignored
Delete	N/A	N/A	N/A	N/A	N/A	N/A	All child values ignored
Change	Yes	Yes	Yes	No	No	Yes (insert, update)	Replace and AddChange not allowed at child level
Replace	N/A	N/A	N/A	N/A	N/A	N/A	All child values ignored
AddChange	N/A	N/A	N/A	N/A	N/A	N/A	All child values ignored
No value	N/A	N/A	N/A	N/A	N/A	N/A	All child values ignored

## Field value types

The integration framework specifies the processing behavior for the different data types used to format field values.

## Boolean columns

In inbound transactions, an element that represents a Boolean field must contain a value of 0 (false) or 1 (true). If the element does not contain a 0 or a 1, an error is generated. If the XML does not include an element for a Boolean field, the corresponding database value is updated with the default value (0 or 1) that is defined for that column.

## Encrypted fields

In inbound transactions, the attribute that represents the maxencrypted field must contain a value of 0 (false) or 1 (true). When the attribute value is 1, a decryption process is applied to the received data. When the attribute value is 0, the received data is not decrypted.

If the attribute does not contain a 0 or a 1, the received data is not decrypted. If the XML field does not include an element for an encrypted field, the received data is not decrypted.

## Character encoding

The integration XML uses UTF-8 encoding. If an inbound transaction specifies any other encoding, the entire message must use that encoding. If an error is encountered during the processing of an inbound transaction that uses encoding other than UTF-8, the entire error XML that is written is encoded as UTF-8.

```
<?xml version="1.0" encoding="ISO-8859-2"?>
```

## Date format

The integration XML supports the following ISO 8601 date format:

```
2011-04-06T10:11:58-05:00
```

## Null columns

If an element in an inbound transaction contains no value, the corresponding database column is updated with a null value. If the XML does not include an element for a particular field, that field is not updated in the database.

For inbound data that is sourced from a flat file or an interface table, you can set a field to null by providing ~NULL~ for the field value in the flat file or interface table. Integration processing creates an empty tag in the corresponding XML message for any ~NULL~ values that are provided. This feature does not support numeric or date fields from an interface table source.

## Number format

Regardless of the locale setting of the application server or the database, all decimal fields must use a period (.) as the decimal placeholder. Do not format numbers to the left of the placeholder. This format applies to inbound and outbound data.

---

## Integration XML schemas

XML schemas for channels and services, excluding standard services, are based on the configuration of the objects that are included in the object structure. You can generate schemas in the integration applications.

- [XML schemas overview](#)  
An integration framework schema includes a predefined schema component for metadata as well as schema components based on configured objects, object structures, and standard services
- [Schema structures](#)  
Schema structures include the predefined Metadata schema component and components for objects, object structures, services and standard services, all of which are generated at the time of schema creation

---

## XML schemas overview

An integration framework schema includes a predefined schema component for metadata as well as schema components based on configured objects, object structures, and standard services

Schemas can be generated to support XML-based integration scenarios where the following components are used:

- Object structure service
- Publish channel
- Invocation channel
- Enterprise service
- Standard service

---

## Key fields

XML schema annotation identifies the key fields for a service or channel from the object structure definition and the data dictionary definitions for the corresponding object.

In the following example, the ITEMNUM element is identified as a key field in the schema for the MXITEM object structure.

```
<xsd:element name="ITEMNUM" minOccurs="0" type="MXString">
 <xsd:annotation>
 <xsd:documentation>ITEMNUM is a key field</xsd:documentation>
 </xsd:annotation>
</xsd:element>
```

---

## XML validation

Inbound and outbound XML transactions are not validated against the corresponding XML schema. Integration business rules apply to inbound data regardless of schema validation. For object structures and enterprise services, the integration must comply with the schema format at the point where the message is processed by the object structure layer.

---

## Namespace property

You can change the designation of the XML namespace by updating the `mxe.int.xmlnamespace` property in the System Properties application. The default namespace property value is `http://www.ibm.com/maximo`. If you change the namespace property, the MXMeta.xsd file is regenerated. This file contains the metadata schema information that is used to build all other schemas. The integration framework validates the namespace provided with inbound XML messages.

---

## Schema generation

Whenever you change an object structure or the data dictionary, you must regenerate the affected schemas. You must also regenerate the schemas after the following changes:

- Making a database field required or optional
- Changing the data type of a database field
- Adding or removing fields from an object structure
- Changing the structure of an object structure

Schemas are automatically generated when you deploy a web service.

You can manually generate schemas by selecting a record and selecting the Generate Schema/View XML action in the following applications:

- Enterprise Services
- Invocation Channels
- Object Structures
- Publish Channels
- Web Services Library

To access a generated schema, you can use a URL.

Object structure and enterprise service schemas

Use a URL that is similar to the following example in which MXSR is the object structure name that is associated with the service:

`http://localhost:port/meaweb/schema/service/MXSR`

For compatibility with version 7.5, URLs that are similar to the following example are still supported:

`http://localhost:port/meaweb/schema/service/MXSRSERVICE.xsd`

Standard service schemas

Use a URL that is similar to the following example in which ITEM is the name of the service.

`http://localhost:port/meaweb/schema/service/ss/ITEM`

For compatibility with version 7.5, URLs that are similar to the following example are still supported:

`http://localhost:port/meaweb/schema/service/ss/ITEMSERVICE.xsd`

---

## Schema structures

Schema structures include the predefined Metadata schema component and components for objects, object structures, services and standard services, all of which are generated at the time of schema creation

- [Metadata schema](#)  
The MXMeta.xsd file contains the metadata information that is used to build all other schemas. Do not modify the MXMeta.xsd file because changes can result in incorrect schemas and issues with web services. The system regenerates this schema when someone changes the Namespace property.
- [Object structure schemas](#)  
Object structure schemas define the content of an object structure. Each object structure has its own schema that includes all of the persistent and nonpersistent fields that are defined for each object in the structure. Object structure schemas are used to define input and output types and are not used directly as input or output for any service.
- [Object schemas](#)  
Object schemas define the content of objects. Each object has a distinct schema, which includes all the persistent fields for a persistent object and all nonpersistent fields defined for a nonpersistent object. Object schemas are used to define input and output types and are not used directly as input or output for any service.
- [Multi-noun messages](#)  
An XML message can contain multiple nouns.
- [Service level schemas](#)  
Service level schemas apply to object structure services, enterprise services, and standard services. One schema describes enterprise services and object structure services. A different schema describes standard services.

---

## Metadata schema

The MXMeta.xsd file contains the metadata information that is used to build all other schemas. Do not modify the MXMeta.xsd file because changes can result in incorrect schemas and issues with web services. The system regenerates this schema when someone changes the Namespace property.

In addition to data content, the metadata schema file includes the following additional information about messages:

- Attribute groups
- Content types
- Query data types
- Supporting data types

---

## Attribute groups

The following table lists attributes by group.

Group	Attributes	Applies to
CommonContentGroup	<ul style="list-style-type: none"><li>• baseLanguage</li><li>• creationDateTime</li><li>• maxImoversion</li><li>• messageID</li><li>• transLanguage</li></ul>	The root element of all input and output schema types.
ObjectStructurePropertyGroup	<ul style="list-style-type: none"><li>• action</li><li>• relationship</li><li>• deleteForInsert</li></ul>	The object element of all input and output schema types.
PublishingContentGroup	<ul style="list-style-type: none"><li>• event</li></ul>	The root element of all output schema types.

Group	Attributes	Applies to
QueryContentGroup	<ul style="list-style-type: none"> <li>maxItems</li> <li>rsStart</li> <li>uniqueResult</li> </ul>	The root element of all query input schema types.
ResponseContentGroup	<ul style="list-style-type: none"> <li>rsCount</li> <li>rsStart</li> <li>rsTotal</li> </ul>	The root element of all response output schema types.

## Content types

The following table lists the content types in the metadata schema.

Type	Description	Attributes
MaximoVersionType	Concatenated string that identifies: <ul style="list-style-type: none"> <li>major version</li> <li>minor version</li> <li>build</li> <li>database build</li> </ul> Identifies software version	
MXBooleanType	Extension of integer	changed
MXDateTimeType	Extension of dateTime	changed
MXDomainType	Extension of string; identifies the corresponding Maxvalue for a domain value.	changed maxvalue
MXDoubleType	Extension of double	changed
MXFloatType	Extension of float	changed
MXGLAccountType	Complex type with 2 values, VALUE and GLCOMP; identifies individual GL components and their sequential order for an account.	changed
MXGLComponentType	Extension of string; identifies GL component sequential order within the chart of accounts structure.	glorder
MXIntType	Extension of integer	changed
MLLangStringType	Extension of MXString	changed languageEnabled
MXLongType	Extension of long	changed
MXStringType	Extension of string	changed

## Query types

The following table lists the query types in the metadata schema.

Type	Description	Attribute
MXBooleanQueryType	Extension of integer	operator
MXDateTimeQueryType	Extension of dateTime	operator
MXDomainQueryType	Extension of string	operator maxvalue
MXDoubleQueryType	Extension of double	operator
MXFloatQueryType	Extension of float	operator
MXGLAccountQueryType	Complex type with a value of VALUE	operator
MXGLComponentQueryType	Extension of string	operator
MXIntQueryType	Extension of integer	operator
MXLongQueryType	Extension of long	operator
MXStringQueryType	Extension of string	operator

## Data types

The following table lists the data types in the metadata schema.

Type	Description	Restricted Values
BooleanType	Indicates whether the result of a logical test is true or false.	<ul style="list-style-type: none"> <li>0 (false)</li> <li>1 (true)</li> </ul>
ChangeIndicatorType	Indicates whether a field has a new value.	1 (true)
EventType	Applies only to object structures generated by an event. Indicates whether a published object structure is the result of an event. If the value is 1, the published structure is the	<ul style="list-style-type: none"> <li>0 (false)</li> </ul>

	result of an event. EventType is an extension of BooleanType.	<ul style="list-style-type: none"> <li>• 1 (true)</li> </ul>
<b>ProcessingActionType</b>	Processing actions that the integration services support.	<ul style="list-style-type: none"> <li>• Add</li> <li>• Change</li> <li>• Replace</li> <li>• Delete</li> <li>• AddChange</li> </ul>
<b>QueryOperatorType</b>	Identifies the Query by Example action to be performed on the corresponding field.	<ul style="list-style-type: none"> <li>• =</li> <li>• !=</li> <li>• &lt;</li> <li>• &lt;=</li> <li>• &gt;</li> <li>• &gt;=</li> <li>• SW</li> <li>• EW</li> </ul>

## Object structure schemas

Object structure schemas define the content of an object structure. Each object structure has its own schema that includes all of the persistent and nonpersistent fields that are defined for each object in the structure. Object structure schemas are used to define input and output types and are not used directly as input or output for any service.

## Schema generation

When you generate the following components, the object structure schemas are regenerated:

- The object structure schema by using an action in the Object Structures application
- The enterprise service schema, where the object structure is referenced by the service
- The publish channel schema, where the object structure is referenced by the channel

To access a schema, use a URL that is similar to the following example in which MXPERSON is the object structure name.

**http://localhost:port/meaweb/schema/service/MXPERSON**

For compatibility with version 7.5, URLs that are similar to the following example are still supported:

**http://localhost:port/meaweb/schema/service/MXPERSONService.xsd**

## Schema object structure content

An object structure schema has the following elements:

- Object
- Object set
- Object query

For example, the schema for the MXPERSON object structure has the following elements:

Element	Element name	Type
Object	MXPERSON	MXPERSONType
Object set	MXPERSONSet	MXPERSONSetType
Object query	MXPERSONQuery	MXPERSONQueryType

## Schema object content

The object element has the following content:

- The MXPERSON element has a type of MXPERSONType.
- The MXPERSONType is a complex type and has the PERSON element, which has a type of MXPERSON\_PERSONType.
- The complex type MXPERSON\_PERSONType has elements for all the configured attributes of the PERSON object and elements for the child objects in the object structure.
- Additional objects in the schema have a corresponding complex type, such as the MXPERSON\_PERSONType, that defines the PERSON object.

Element	Type
PERSON (primary object)	MXPERSON_PERSONType
PHONE (child object)	MXPERSON_PHONEType
EMAIL (child object)	MXPERSON_EMAILType
SMS (child object)	MXPERSON_SMSType

The following example shows the structure of the corresponding XML:

```

<MXPERSON>
 <PERSON>
 <PHONE>
 </PHONE>
 .
 .
 <EMAIL>
 </EMAIL>
 .
 .
 <SMS>
 </SMS>
 .
 .
 </PERSON>
</MXPERSON>

```

## Object set content

For the MXPERSON example, the MXPERSONSet element replaces the MXPERSON element and MXPERSONSetType replaces the complex type MXPERSONType. Everything else remains the same. The set element acts as a wrapper for multiple occurrences of the primary object (MXPERSON) and its child objects.

## Object query content

You can use query elements only within the context of a service level schema.

The following content format is in the object query element:

- The MXPERSONQuery element is of type MXPERSONQueryType.
- The MXPERSONQueryType is a complex type and has elements for all the configured attributes of the primary object (PERSON) of the object structure.

The object query and the object set differ in the following ways:

- The query element includes only the primary object of the object structure.
- The query element does not include nonpersistent columns.
- The query element can include two occurrences of the elements to support a query on a range, such as a date range.

Because the query includes only the top object of the structure, it is not possible, for example, to query for a person by phone number. The phone number exists in the child PHONE object.

## Object schemas

Object schemas define the content of objects. Each object has a distinct schema, which includes all the persistent fields for a persistent object and all nonpersistent fields defined for a nonpersistent object. Object schemas are used to define input and output types and are not used directly as input or output for any service.

## File names and location

The naming convention for object schemas is the object name, for example, PERSON.xsd and the files are located in the schema/common/mbo directory.

## Schema generation

Object schema files are generated when you generate the following components:

- An object structure schema that contains the object
- An object structure service or enterprise service schema that references an object structure that includes the object
- A standard service schema that contains the object

All object schemas include the MXMeta.xsd schema file.

## Schema content

The schema has the following elements (using MXPERSON as an example)

Element	Type	Comments
PERSONMbo	PERSONMboType	This type contains one instance of the PERSONMbo element.
PERSONMboSet	PERSONMboSetType	This type contains multiple instances of the PERSONMbo element.

Element	Type	Comments
PERSONMboKey	PERSONMboKeyType	This type contains a single instance of the PERSON element that is PERSONKeyType. The PERSONKeyType contains the attribute that is the primary key of the PERSON object, PERSONID. If multiple attributes make up the primary key of an object, the <i>objectKeyType</i> contains the attributes that make up the primary key. This element is included in the response to a Create operation.
PERSONMboKeySet	PERSONMboKeySetType	This type contains multiple instances of the PERSON element that is PERSONKeyType. The PERSONKeyType contains the attribute that is the primary key of the PERSON object, PERSONID. If multiple attributes make up the primary key of an object, the <i>objectKeyType</i> contains the attributes that make up the primary key. This element is included in the response of a Create operation.
PERSONMboQuery	PERSONMboQueryType	This type contains two instances of the PERSON element. Two instances allow a query to specify a range, for example, From Date and To Date.

## Multi-noun messages

An XML message can contain multiple nouns.

```
<MXPERSON>
 <MXPERSONSET>
 <PERSON>
 .
 <SMS>
 </SMS>
</PERSON>
 <PERSON>
 .
 <SMS>
</SMS>
</PERSON>
 </MXPERSONSET>
</MXPERSON>
```

## Service level schemas

Service level schemas apply to object structure services, enterprise services, and standard services. One schema describes enterprise services and object structure services. A different schema describes standard services.

Object structure services, enterprise services, and standard services use objects and object structures as input and output for the operations they support. Multiple services can perform the same operation using the same input and output.

Predefined input and output for publish channels and invocation channels are used to invoke external services or to map to other output formats.

## File names and location

The naming convention for object structure schemas and enterprise services schemas is *application service name* + Service, for example, PERSONService.xsd where PERSON is the application service name.

The naming convention for service level schemas is *object structure* + Service, for example, MXPERSONService.xsd.

The schema files are located in the `<root>/schema/common/service` directory.

## Schema generation

Predefined service-level schema files are not provided. When you deploy a web service, a service-level schema file is generated for the associated object structure, if one does not exist. You can also generate a service-level schema by using an action in the Web Services Library application

All service level schemas include the metadata schema file and the applicable object structure and object schema files.

## Schema content

One schema file is generated for each object structure with multiple data types within each file. Each data type corresponds to each input and output operation that can be deployed or processed as a service. Different services reuse the data types in these schemas. No one service uses all the data types in a single schema.

Service-level schemas contain the following types, using the MXPERSON example:

- CreateMXPERSON
- CreateMXPERSONResponse
- DeleteMXPERSON

- InvokeMXPERSOn
- InvokeMXPERSOnResponse
- PublishMXPERSOn
- QueryMXPERSOn
- QueryMXPERSOnResponse
- SyncMXPERSOn
- UpdateMXPERSOn
- **Standard service schemas input and output**  
Standard services are provided by applications to perform specific operations on objects and can expose multiple methods as web services. Standard services are available only for methods that are properly annotated within the service.
- **Object structure and enterprise service input and output**  
The object structure contains the content for object structure service and enterprise service schemas. An object structure service supports all defined operations but an enterprise service supports just one specific operation. Multiple enterprise services must be created to support multiple operations even when they reference the same object structure and use the same schema.

## Standard service schemas input and output

Standard services are provided by applications to perform specific operations on objects and can expose multiple methods as web services. Standard services are available only for methods that are properly annotated within the service.

The service-level schemas that are generated for standard services are used only by the corresponding actions.

## Object structure and enterprise service input and output

The object structure contains the content for object structure service and enterprise service schemas. An object structure service supports all defined operations but an enterprise service supports just one specific operation. Multiple enterprise services must be created to support multiple operations even when they reference the same object structure and use the same schema.

Object structure and enterprise service schemas identify the following:

- The input and output types for object structures and enterprise services
- The input and output of an invocation channel
- The output provided by a publish channel

All operations support the following output types:

- The output for the Create, Update, Delete and Sync operations are the primary object keys, the internal ID field and autokey values.
- The output for a Query operation is a result set of object structures.

The following examples, based on the MXPERSOn object structure, describe the content of object structure and enterprise services:

### CreateMXPERSOn element

The CreateMXPersOn element has the following definitions:

- The CreateMXPERSOn element is type CreateMXPERSOnType.
- The CreateMXPERSOnType has element MXPERSOnSet, which is type MXPERSOnSetType. MXPERSOnSet is derived from the object structure schema.
- The MXPERSOnSetType has elements for all the configured attributes of the PERSON object and elements for the child objects (PHONE, EMAIL, and SMS) that are defined in the object structure.

The definitions of the following elements and types are comparable to the CreateMXPERSOn element and type:

Element	Type
UpdateMXPERSOn	UpdateMXPERSOnType
SyncMXPERSOn	SyncMXPERSOnType
InvokeMXPERSOn	InvokeMXPERSOnType
InvokeMXPERSOnResponse	InvokeMXPERSOnResponseType

### Create MXPERSOnResponse element

The CreateMXPERSOnResponse element has the following definitions:

- The CreateMXPERSOnResponse element is type CreateMXPERSOnResponseType.
- The CreateMXPERSOnResponseType has element PERSONMboKeySet, which is type PERSONMboKeySetType.
- The PERSONMboKeySetType has element PERSON, which is type PERSONKeyType.
- The PERSONKeyType contains only the PERSONID attribute of the PERSON object, which is the primary key of the PERSON object.

### PublishMXPERSOn element

The PublishMXPERSOn element has the following definitions:

- The PublishMXPERSO element is type PublishMXPERSOType.
- The PublishMXPERSOType has element MXPERSOSet, which is type MXPERSOSetType. MXPERSOSet is derived from the object structure schema.
- MXPERSOSetType has elements for all the configured attributes of the PERSON object and for the child objects ((PHONE, EMAIL, and SMS) defined in the object structure.

The Publish element is like the Create element but uses an additional attribute, event, that is defined in the PublishingContentGroup in the metadata schema.

## DeleteMXPERSO element

The DeleteMXPERSO element has the following definitions:

- The DeleteMXPERSO element is type DeleteMXPERSOType.
- The DeleteMXPERSOType has element MXPERSODelete, which is type MXPERSODeleteType.
- The MXPERSODeleteType has elements for all the configured attributes of the PERSON object. Delete supports only the top (primary) object of the object structure.

## QueryMXPERSO element

The QueryMXPERSO element has the following definitions:

- The QueryMXPERSO element is type QueryMXPERSOType.
- The QueryMXPERSOType has element MXPERSOQuery, which is type MXPERSOQueryType.
- The MXPERSOQueryType has elements for all the configured attributes of the PERSON object. Query supports only querying against the top (primary) object of the object structure.

The Query element uses the additional attributes uniqueResults, maxItems, and rsStart, which are defined in the QueryContentGroup in the metadata schema.

## QueryMXPERSOResponse element

The QueryMXPERSOResponse element has the following definitions:

- The QueryMXPERSOResponse element is type QueryMXPERSOResponseType.
- The QueryMXPERSOResponseType has element MXPERSOSet, which is type MXPERSOSetType.
- The MXPERSOSetType has elements for all the configured attributes of the PERSON object and elements for child objects defined in the object structure (PHONE, EMAIL, and SMS).
- Although the QueryMXPERSO element restricts queries to the top object of the object structure (PERSON), the response can contain child objects (PHONE, EMAIL, and SMS).

The Query Response element uses the additional attributes rsStart, rsCount, and Total, which are defined in the ResponseContentGroup in the metadata schema.

## Collaboration switches

Collaboration switches use a concept of ownership to help users manage the synchronization of inbound data between the integration framework and an external system. The switches provide the ability to control specific subprocesses within an application, based on the ownership of different data objects within a transaction.

The primary object of the object structure for most master data and document integration objects include an OWNERSYSID attribute. By default, inbound integration processing does not specify any value in the OWNERSYSID field and enterprise services are processed in a standard manner.

- [Format of collaboration switches](#)  
Collaboration switches provide a flexible, user-defined way to control the processing of some inbound transactions through bypassing the default processing for certain types of transactions. Collaboration switches are located in the MXCOLLAB table.
- [Retrieving a collaboration switch](#)  
Each process control ID is associated with at least three collaboration switches, the default switches and any switches that the user adds. The integration framework provides the logic that determines which system ID values to set when retrieving a collaboration switch from the MXCOLLAB table.
- [Configuring collaboration switches](#)  
You can use predefined collaboration switches and you can configure new ones if required.
- [Predefined collaboration switches](#)  
You can use the default collaboration switches and the predefined collaboration switches that are provided.

## Format of collaboration switches

Collaboration switches provide a flexible, user-defined way to control the processing of some inbound transactions through bypassing the default processing for certain types of transactions. Collaboration switches are located in the MXCOLLAB table.

## Switch elements

Each collaboration switch contains four elements, three of which combine to create a unique key. The following table lists these elements and the elements that comprise the unique key are marked with an asterisk (\*).

Element	Corresponding MXCOLLAB field
---------	------------------------------

Element	Corresponding MXCOLLAB field
Process control ID*	PCID
System ID 1*	OWNER1SYSID
System ID 2*	OWNER2SYSID
Process control value	PCVALUE

## Process control ID

The process control ID identifies a business process in an application, such as the validation of an invoice match, the creation of a blanket PO release, and the update of a physical inventory count.

The following table shows the prefix of the process control ID and indicates the application to which it applies.

Prefix of Process Control ID	Corresponding Application
INV	Invoice
ITM	Item
IV	Inventory
LT	Labor
PO	Purchase order
PR	Purchase requisition
WO	Work order

For example, the IVRC, IVRCY, and IVWO collaboration switches are all related to inventory processing.

## System ID values

System ID 1 and System ID 2 identify the internal and external systems. The values in these fields vary, depending on the transaction and the objects in the transaction. In general, System ID 1 identifies the system that creates an object, and System ID 2 identifies the system that creates the record that is being referenced or updated.

## Process control value

The process control value specifies whether the business components bypass default processing for the type of transaction indicated by the process control ID, System ID 1, and the System ID 2. The process control value can be 0 (false) or 1 (true) and can have the following meanings:

Value of process control	Description
0	Performs default processing
1	Bypasses default processing

## Retrieving a collaboration switch

Each process control ID is associated with at least three collaboration switches, the default switches and any switches that the user adds. The integration framework provides the logic that determines which system ID values to set when retrieving a collaboration switch from the MXCOLLAB table.

## Procedure

1. The integration framework determines the values for System ID 1 and System ID 2 based on the process control ID in an inbound transaction.  
For example, if the process control ID is PRDEL, System ID 1 is THISMX, and System ID 2 is the system that owns the PR.
2. If the value in System ID 1 is blank, null, or equal to the value in the MXSYSID row of the MAXVARS table, System ID 1 is set to THISMX.
3. If the value in System ID 2 is blank, null, or is equal to the value in the MXSYSID row of the MAXVARS table, and the process control ID is not PRPAB, System ID 2 is set to THISMX.
4. If the process control ID is PRPAB, the value in System ID 2 is set to null after step 1, and System ID 2 is set to EXT (if a blanket PO does not exist).
5. If both System ID 1 and System ID 2 are now set to THISMX, default processing is used and the remaining logic is not applied.
6. The MXCOLLAB table is checked, to identify if it contains a record with the key.  
If the record exists, the process control value for the record indicates whether to use or bypass standard processing and the remaining logic is not applied.
7. If a matching record does not exist in the database, the key is modified in the following manner:
  - If System ID 1 now equals THISMX and System ID 2 does not equal THISMX, EXT is set as the value for System ID 2.
  - If System ID 1 value does not equal THISMX and System ID 2 equals THISMX, EXT is set as the value for System ID 1.
8. The MXCOLLAB table is checked again, to identify if it contains a record with the modified key.  
If the record exists, the process control value for the record indicates whether to use or bypass standard processing and the remaining logic is not applied.
9. EXT is set as the value for both System ID 1 and System ID 2.
10. The record with the modified key is retrieved from the MXCOLLAB table.  
This record always exists, because every process control value has a default collaboration switch with both system IDs set to EXT.
11. The process control value for the record indicates whether to use or bypass standard processing.

## Configuring collaboration switches

You can use predefined collaboration switches and you can configure new ones if required.

- [Viewing collaboration switches](#)  
Use any database tool to execute a SQL query to see the values in the MXCOLLAB table, or generate a report to view its content.
- [Modifying a collaboration switch](#)  
Authorized users can modify the process control value of a collaboration switch. Do not change the value of PCID, OWNER1SYSID, or OWNER2SYSID values on existing collaboration switches.
- [Adding a collaboration switch to the database](#)  
Authorized users can add collaboration switches to the MXCOLLAB table. New switches must use an existing process control ID, but they can use new system IDs.

---

## Viewing collaboration switches

Use any database tool to execute a SQL query to see the values in the MXCOLLAB table, or generate a report to view its content.

### Procedure

---

1. To view the collaboration switches for a single process control ID, use the following SQL query:

```
select pcid, owner1sysid, owner2sysid, pcvalue
from mxcollab
where pcid = 'PCID'
order by pcid, owner1sysid, owner2sysid;
```

2. To view all collaboration switches, use the following SQL query:

```
select pcid, owner1sysid, owner2sysid, pcvalue
from mxcollab
order by pcid, owner1sysid, owner2sysid;
```

3. To view a short description of the process control IDs, use the following SQL query:

```
select * from mxcollabref order by pcid;
```

---

## Modifying a collaboration switch

Authorized users can modify the process control value of a collaboration switch. Do not change the value of PCID, OWNER1SYSID, or OWNER2SYSID values on existing collaboration switches.

### About this task

---

The values in the MXCOLLAB table are case-sensitive.

### Procedure

---

1. Use a database tool to connect to the Maximo® database.
2. Use the following SQL statement to change the process control value in a collaboration switch :

```
update mxcollab
set pcvalue = PCVALUE
where pcid = 'PCID'
and owner1sysid = 'OWNER1SYSID'
and owner2sysid = 'OWNER2SYSID';
```

3. Restart the application server to refresh the cached values for collaboration switches.

---

## Adding a collaboration switch to the database

Authorized users can add collaboration switches to the MXCOLLAB table. New switches must use an existing process control ID, but they can use new system IDs.

### About this task

---

Only the default collaboration switches can use the values THISMX and EXT in the system ID fields.

### Procedure

---

1. Use a database tool to connect to the Maximo® database.
2. Use the following SQL statement to add a collaboration switch:

```
insert into mxcollab
(pcid, owner1sysid, owner2sysid, pcvalue)
values ('PCID', 'OWNER1SYSID', 'OWNER2SYSID', PCVALUE);
```

## Example

For example, you can configure the integration framework to integrate with an Oracle Financials system and other applications. When Oracle Financials issues system-owned inventory, the integration framework accepts the transaction and updates inventory balances and costs in the Maximo database. When other applications issue system-owned inventory, the integration framework accepts the transaction, but does not update inventory balances or costs in the Maximo database.

Before you modify the MXCOLLAB table to reflect these conditions, the INV collaboration switches have the following values:

Process Control ID	System ID 1	System ID 2	Process Control Value
INV	THISMX	EXT	1
INV	EXT	THISMX	0
INV	EXT	EXT	1

To modify the MXCOLLAB table, to support this scenario:

1. To update the collaboration switch, use the following SQL statement:

```
update mxcollab
set pcvalue = 1
where pcid = 'INV'
and owner1sysid = 'EXT'
and owner2sysid = 'THISMX';
```

This statement changes the value of the INV/ EXT/ THISMX collaboration switches to 1 to bypass normal update processing.

2. Use the following SQL statement to add a new collaboration switch for transactions from the Oracle Financials system:

```
insert into mxcollab
(pcid, owner1sysid, owner2sysid, pcvalue)
values ('INV', 'ORC', 'THISMX', 0);
```

The new collaboration switch sets ORC as the system ID, and sets the process control value to 0 so that normal processing is applied to issue transactions received from Oracle Financials. If the OWNERSYSID is blank, the value in the DEFEXTSYS integration control is used.

After you perform this procedure, the INV collaboration switches have the following values.

Process Control ID	System ID 1	System ID 2	Process Control Value
INV	THISMX	EXT	1
INV	EXT	THISMX	1
INV	EXT	EXT	1
INV	ORC	THISMX	0

For example, when you set the value of the ISUIN integration control to 1, issue transactions are accepted from an external system. The INV collaboration switch controls the update of inventory balance and cost related to issues. You can adjust the setting of this switch, if necessary, to bypass that update process.

The INV/EXT/THISMX collaboration switch controls the processing of inventory (where the Process Control ID = INV) that is issued in the external system (System ID 1 = EXT) and owned by the system (System ID 2 = THISMX).

If the value of the INV/EXT/THISMX collaboration switch is 0, default processing applies and inventory balance and cost values are updated.

If the value of the INV/EXT/THISMX collaboration switch is 1, default processing is bypassed and inventory balance and cost values are not updated.

In the example, ISUIN accepts any issues into the system. The INV/EXT/THISMX collaboration switch determines how the inventory business component processes a specific type of issue.

## Predefined collaboration switches

You can use the default collaboration switches and the predefined collaboration switches that are provided.

- [Default collaboration switches](#)  
Three default collaboration switches are created, with different combinations of system ID values, for each process control ID. Authorized users can create additional switches as needed.
- [Inventory collaboration switches](#)  
Predefined collaboration switches are provided for the Inventory application.
- [Invoice collaboration switches](#)  
Predefined collaboration switches are provided for the Invoice application.
- [Labor transaction collaboration switches](#)  
Predefined collaboration switches are provided for labor transactions.
- [Purchase order collaboration switches](#)  
Predefined collaboration switches are provided for purchase orders.
- [Purchase requisition collaboration switches](#)  
Predefined collaboration switches are provided for purchase requisitions.
- [Receipt collaboration switches](#)  
Predefined collaboration switches are provided for receipts.

- [Work order collaboration switches](#)  
Predefined collaboration switches are provided for work orders.

## Default collaboration switches

Three default collaboration switches are created, with different combinations of system ID values, for each process control ID. Authorized users can create additional switches as needed.

The default switches use various combinations of the following values in the System ID 1 and System ID 2 fields:

System ID value	Meaning
THISMX	The system identified in MAXVARS.MXSYSID The collaboration switches do not use the actual value in MXSYSID.
EXT	Any system other than the one identified in MAXVARS.MXSYSID

Authorized users can update only the process control value in the default collaboration switches. Deleting a default collaboration switch or modifying a field other than the process control value can result in a system failure.

## Inventory collaboration switches

Predefined collaboration switches are provided for the Inventory application.

Process control ID	Description	Value and action		Derivation of system ID 1	Derivation of system ID 2
INV	Update inventory. Used when creating issues, returns, or miscellaneous receipts or adjustments. Inventory must exist in this system.	0 1	Update inventory. Do not update inventory.	INVTRANS or MATUSETRANS	INVENTORY
INVDEL	Delete inventory. Used when deleting externally owned inventory. If value is 1, the item-storeroom will still exist on related open PRs, POs, RFQs, work orders, and so on. This might result in problems receiving/approving these lines.	0 1	Delete item if it passes normal system validations. Delete inventory without any validations and delete INVBALANCES record for the item.	"THISMX"	INVENTORY
INVISS	Enter item issues. Used when issuing material.	0 1	Allow material issues for the inventory. Do not allow material issues for the inventory.	MATUSETRANS	INVENTORY
INVISSR	Enter item issue returns. Used when returning material.	0 1	Allow material returns. Do not allow issue returns for the material.	MATUSETRANS	INVENTORY
INVISSWO	Update work order actual cost, equipment INVCOSTs. Used when processing issues or returns. Meant to handle system to system cases where these updates will be done separately.	0 1	Update work order actual material cost, equipment INVCOST. Do not update work order actual material cost, equipment INVCOST.	MATUSETRANS	WORKORDER
INVPHY	Enter external physical counts. Used when creating physical counts.	0 1	Allow physical count for the inventory. Do not allow physical count for the inventory.	INVTRANS	INVENTORY
INVTR	Update the From storeroom on a transfer or the receipt of internal PO. Used when creating transfers or creating a receipt for an internal POs.	0 1	Update INVBALANCES in the From storeroom. Do not update INVBALANCES in the From storeroom.	MATRECTRANS	LOCATIONS (storeroom for transfer; vendor for internal PO)
ITMDEL	Delete items. Used when deleting items that this system does not own.  Attention: If value is 1, the item will still exist on related open PRs, POs, RFQs, work orders, and so on. This might result in problems receiving/approving these lines.	0 1	Delete item if it passes normal system validations. Delete item without any validation. Also delete INVENTORY, INVBALANCES, and INVENDOR records for the item.	"THISMX"	ITEM

## Invoice collaboration switches

Predefined collaboration switches are provided for the Invoice application.

Process control ID	Description	Value and action		Derivation of system ID 1	Derivation of system ID 2
IVILC	Update inventory last cost. Used when approving invoices.	0 1	Update inventory last cost. Do not update inventory last cost.	INVOICE	INVENTORY
IVINV	Update inventory average cost. Used when approving invoices.	0 1	Update inventory average cost. Do not update inventory average cost.	INVOICE	INVENTORY
IVMATCH	Use and validate invoice match. Used when approving invoices.  If set to 1, IVPO should also be set to 1.	0 1	Validate match. Do not validate any match provided.	"THISMX"	INVOICE
IVPO	Update POs and receipts. Used when approving invoices.	0 1	Update PO status and receipts. Do not update PO status or receipts.	INVOICE	PO
IVPRO	Check and prorate differences between invoice headers and lines. Used when approving invoices.	0 1	Prorate the difference between the header and the line total. Do not prorate the difference between the header and line total.	"THISMX"	INVOICE
IVRC	Create service receipts for invoice lines without a PO reference. Used when approving invoices that contain a line without a PO reference.	0 1	Generate a service receipts for the invoice lines that do not have a PO reference. Do not generate a service receipt for the invoice lines that do not have a PO reference.	"THISMX"	INVOICE
IVRCY	Create service receipts for invoice lines with a PO reference and RECEIPTREQD = N. Used when approving invoices containing a line with a PO reference, when the corresponding POLINE is a service and RECEIPTREQD = N.	0 1	Generate a service receipt for the invoice line. Do not generate a service receipt for the invoice line.	INVOICE	PO
IVTOL	Perform invoice tolerance checking validation. Used when approving invoices.	0 1	Perform all tolerance checks on invoice. Do not perform tolerance checks on invoice.	"THISMX"	INVOICE
IVVLC	Update vendor last cost. Used when approving invoices.	0 1	Update vendor last cost. Do not update vendor last cost.	INVOICE	INVVENDOR
IVWO	Update work orders. Used when approving invoice.	0 1	Update work order. Do not update work order.	INVOICE	WORKORDER

## Labor transaction collaboration switches

Predefined collaboration switches are provided for labor transactions.

Process Control ID	Description	Value and Action		Derivation of System ID 1	Derivation of System ID 2
LTSRC	Generate service receipts for POs. Used when creating labor transactions or changing status. PO must exist in this system.	0 1	Allow setting value of LABTRANS. GENAPPRSERVRECEIPT to Y; configurable in the Application Setup. Leave value of LABTRANS. GENAPPRSERVRECEIPT as N.	LABTRANS	PO

## Purchase order collaboration switches

Predefined collaboration switches are provided for purchase orders.

Process control ID	Description	Value and action		Derivation of system ID 1	Derivation of system ID 2
PODEL	Delete POs. Used when deleting POs. Use only when deleting then subsequently re-adding a PO due to changes in the PO.  If any PRLINES contain a reference to the PO, clear them. If necessary, reopen the PR. When the PO is re-added, the PRLINES will be established again.	0 1	Do not delete PO. Delete PO and PRLINES; do not delete POSTATUS.	"THISMX"	PO

Process control ID	Description	Value and action		Derivation of system ID 1	Derivation of system ID 2
POINV	Do not allow unreferenced external inventory for internal POs. Used when adding or updating PO lines and changing the status of internal POs.	0 1	If the item-vendor combination not in INVENTORY table, error. If item-vendor combination not found in INVENTORY table (where PO.VENDOR = LOCATIONS.LOCATION), ignore error.	PO	LOCATIONS, where vendor is the storeroom
POIVM	Create inventory vendor information for inventory. Used when approving POs.	0 1	Update or create INVENDOR record. Do not create INVENDOR record.	PO	ITEM of POLINE
POPR	Update status of PRs. Used when copying PR lines to POs, creating POs from PRs, reopening PRs.	0 1	Change status of PR (auto close based on MAXVAR setting) or reopen when POLINE containing PR reference is deleted, or other instances of reopen. Do not change PR status.	PO	PR
POREL	Create releases for blanket POs. Used when approving PR and the PR lines contain a blanket references, and when a release is created directly from a PO without a PR.	0 1	Generate PO release. (If PRLINE.AGREEMENTPONUM not in PO, do not generate PO release). Do not regenerate PO releases.	PR	PO of the blanket
PORES	Process material reservations. Used when changing the status of internal POs.	0 1	Generate inventory reservations. If item-vendor combination (where vendor is internal storeroom) not in INVENTORY table, do not generate PO reservations. This might happen if POINV is 0. Do not generate inventory reservations.	PO	INVENTORY
PRREL	Create Purchase Orders. Used to allow Purchase Orders to be created with external contracts. The recommendation is to set the pvalue to zero.	0 1	Create PO. Do not create.	"THISMX"	PO

## Purchase requisition collaboration switches

Predefined collaboration switches are provided for purchase requisitions.

Process control ID	Description	Value and action		Derivation of system ID 1	Derivation of system ID 2
PRDEL	Delete PRs. Used when deleting PRs. Use only when deleting then subsequently re-adding a PR due to changes in the PR.  If WPMATERIAL or MRLINE contain references to the PR, clear them. They will be reestablished when you read PR.	0 1	Do not delete PR. Delete the PR and PRLINES; do not delete PRSTATUS.	"THISMX"	PR
PRINV	Do not allow unreferenced external inventory on internal PRs. Used when storerooms are maintained in an external system. Items are in ITEM master in the system; storeroom is defined as a LOCATION; INVENTORY is not defined for item-storeroom combination because it is not owned by the system.  The owner of the PR is the MXSYSID of the system that creates the PR. Validation occurs when an item-storeroom (INVENTORY) is validated on the PRLINE. The OWNERSYSID of the storeroom is compared with the OWNERSYSID of the PR, and the flag determines if the combination is allowed.	0 1	If the item-vendor combination is not in INVENTORY table, error. If the item-vendor combination (vendor is the internal storeroom) is not in INVENTORY table, where  PR.VENDOR = LOCATIONS.LOCATION, ignore error. LOCATIONS must exist; that is, pass standard validation for the location.	PR	LOCATIONS, where vendor is the internal storeroom
PRPAB	Do not allow unreferenced external purchase agreements / blankets. Used when adding or updating PR lines and changing the status of PRs.	0 1	If PRLINE.AGREEMENTPONUM is not in PO, error. If PRLINE.AGREEMENTPONUM is not in PO, ignore error.	PR	"EXT" Normally this would be from PO of the blanket, but in this case the blanket PO does not exist

## Receipt collaboration switches

Predefined collaboration switches are provided for receipts.

Process control ID	Description	Value and action		Derivation of system ID 1	Derivation of system ID 2
RC	Enter PO receipts. Used when creating receipts.	0	Allow receiving against the PO.	MATRECTRANS or SERVRECTRANS	PO
		1	Do not allow receiving against the PO.		
RCILC	Update inventory last cost. Used when approving receipts.	0	Update inventory last cost.	MATRECTRANS	INVENTORY
		1	Do not update inventory last cost.		
RCINV	Update inventory. Used when receiving, or approving receipts.	0	Update inventory if it exists.	MATRECTRANS	INVENTORY
		1	Do not update inventory.		
RCIV	Generate invoices for PO receipts. Used when approving receipts.	0	Generate invoice if value of PayOnReceipt is set.	MATRECTRANS or SERVRECTRANS	PO
		1	Do not generate invoice, even if value of PayOnReceipt is set.		
RCPO	Update external PO. Used when approving receipt.	0	Update PO.	MATRECTRANS or SERVRECTRANS	PO
		1	Do not update PO.		
RCR	Enter PO receipt return. Used when creating receipt return.	0	Allow receipt returns for the PO.	MATRECTRANS or SERVRECTRANS	PO
		1	Do not allow receipt returns for the PO.		
RCVLC	Update vendor last cost. Used when approving receipt or receiving PO line.	0	Update vendor last cost.	MATRECTRANS	INVENDOR
		1	Do not update vendor last cost.		
RCWO	Update work orders. Used when approving receipts.	0	Update work order.	MATRECTRANS or SERVRECTRANS	WORKORDER
		1	Do not update work order.		

## Work order collaboration switches

Predefined collaboration switches are provided for work orders.

Process control ID	Description	Value and action		Derivation of system ID 1	Derivation of system ID 2
WORES	Process material reservations. Used when changing the status of a work order. Inventory must exist in this system.	0	Generate inventory reservation.	WORKORDER	INVENTORY
		1	Do not generate inventory reservation.		

## Integrating with Maximo Application Suite applications

Maximo® Manage includes features that facilitate integration with other Maximo Application Suite applications.

- [Integrating with Asset Data Dictionary](#)  
The Asset Data Dictionary is a repository of data and metadata that facilitates data sharing and integration between Maximo Manage and other applications. Using pre-defined artifacts in the Maximo Manage integration framework, you can synchronize data in Maximo Manage with the Asset Data Dictionary, which in turn integrates the data into other applications, such as Maximo Monitor.
- [Integrating Maximo Manage with IoT monitoring systems](#)  
You can add metric data that IoT monitoring systems gather from sensor devices to meters in Maximo Manage applications.

## Integrating with Asset Data Dictionary

The Asset Data Dictionary is a repository of data and metadata that facilitates data sharing and integration between Maximo® Manage and other applications. Using pre-defined artifacts in the Maximo Manage integration framework, you can synchronize data in Maximo Manage with the Asset Data Dictionary, which in turn integrates the data into other applications, such as Maximo Monitor.

Pre-defined artifacts are available for integrating data about organizations, sites, assets, asset hierarchies, operating locations, location systems, and location hierarchies.

If you configure event-based synchronization, data in the Asset Data Dictionary can be synchronized across applications. For example, if you configure an event that is based on adding a location, when you can add a location to Maximo Manage, the location is also added to Maximo Monitor.

- [Maximo Manage synchronization with the Asset Data Dictionary](#)  
To support integration with other applications, the Maximo Manage to Asset Data Dictionary synchronization loads organization, site, asset, and location data from Maximo Manage to the data dictionary. It is an on-going integration that can be performed manually when needed, at regularly scheduled intervals, or as event-based updates when data changes.

- [Maximo Monitor to Maximo Manage integration](#)

The Maximo Monitor to Maximo Manage integration is a one-time process that uses the Asset Data Dictionary to add data about organizations, sites, assets, and locations from Maximo Monitor to Maximo Manage.

## Maximo Manage synchronization with the Asset Data Dictionary

To support integration with other applications, the Maximo® Manage to Asset Data Dictionary synchronization loads organization, site, asset, and location data from Maximo Manage to the data dictionary. It is an on-going integration that can be performed manually when needed, at regularly scheduled intervals, or as event-based updates when data changes.

- [Maximo Manage to Asset Data Dictionary synchronization overview](#)  
The IBM® Maximo Manage integration framework provides several artifacts for the Maximo Manage to Asset Data Dictionary synchronization, including an external system, publish channels, endpoints, and query templates.
- [Asset Data Dictionary implementation](#)  
Asset Data Dictionary is installed automatically when a consuming application, such as Maximo Monitor, is installed. However, some initial configuration is also required to fully implement data synchronization.
- [Initial data synchronization from Maximo Manage to Asset Data Dictionary](#)  
The export functions in the External Systems application are used to synchronize data from Maximo Manage to the Asset Data Dictionary.
- [Data synchronization process](#)  
After the initial data synchronization, you can export data from Maximo Manage to the Asset Data Dictionary manually when needed, at regularly scheduled intervals, or when data changes.

## Maximo Manage to Asset Data Dictionary synchronization overview

The IBM® Maximo® Manage integration framework provides several artifacts for the Maximo Manage to Asset Data Dictionary synchronization, including an external system, publish channels, endpoints, and query templates.

Data from Maximo Manage is added to the Asset Data Dictionary by using pre-defined publish channels in the MASDD external system. Query templates specify what data to synchronize. The MASDD endpoint posts data to the Asset Data Dictionary in JSON format.

The following artifacts are designed specifically for integration with the data dictionary:

### MASDD external system

The MASDD external system includes publish channels for outbound data synchronization from Maximo Manage to the Asset Data Dictionary.

### Publish channels

The following table describes the publish channels, object structures, and query templates that are associated with the MASDD external system in Maximo Manage:

Table 1. Publish channels for the data dictionary

Publish Channel	Data that the channel publishes	Object Structure	Query Template
MASDDORG	Organizations and sites	MXAPIORGANIZATION	MASDDORG
MASDDMETER	Meters	MXAPIMETER	MASDDMETER
MASDDLOCSYS	Location systems	MXAPILOCSYSTEM	MASDDLOCSYSTEM
MASDDOPERLOC	Locations of type OPERATING	MXAPIOPERLOC	MASDDOPERLOC
MASDDLOCHIER	Location hierarchies	MXAPILOCATION	MASDDLOCHIER
MASDDASSET	Assets	MXAPIASSET	MASDDASSET
MASDDASSETHIER	Asset hierarchies	MXAPIASSET	MASDDASSETHIER
MASDDMEASUREUNIT	Units of measurement	MXAPIMEASUREUNIT	MASDDMEASUREUNIT

Publish channels are configured to publish data in JSON format. An object structure can belong to more than one publish channel, and a different template can be assigned to each publish channel.

Processing uses an outbound queue, which can be JMS or Kafka.

### Query templates

To improve efficiency and performance, publish channels have query templates that limit the number of fields to serialize.

### Endpoints

Publish channels in the MASDD external system are configured to export data by using the MASDD endpoint. Data is posted in JSON format to the Asset Data Dictionary.

Endpoint properties are configured in Red Hat® OpenShift® and are stored as server bundle properties.

The following properties are added to the endpoints:

- URL
- GRAPH
- USERNAME
- PASSWORD
- TENANT

The Allow Override checkbox must be selected to allow the properties to be overwritten.

After you configure the external system, you can perform an initial export of data from Maximo Manage to the Asset Data Dictionary.

To synchronize the data after the initial data load, you can select one of the following options:

- Export data from Maximo Manage manually using the Data Export or Bulk Data Export actions in the External Systems application.

- Schedule a cron task to export data automatically at regular intervals, such as once a day.
- Enable event listener to initiate processing for a publish channel when a change occurs. To use this option, you must enable event listener on all MASDD publish channels except the MASDDASSETHIER asset hierarchy publish channel. Asset hierarchies are synchronized as part of the MASDDASSET asset integration.

## Asset and location status assignment

Statuses for assets and locations in Maximo Manage might not match the statuses of the target application. The following table describes how statuses are mapped from Maximo Manage to the Asset Data Dictionary:

Table 2. Status assignments for the integration

Status in Maximo Manage	Status that is assigned in Asset Data Dictionary
DECOMMISSIONED	DECOMMISSIONED
NOT READY	NOT READY
ARCHIVED (external value)	ARCHIVED
All other values	ACTIVE

## Asset Data Dictionary implementation

Asset Data Dictionary is installed automatically when a consuming application, such as Maximo® Monitor, is installed. However, some initial configuration is also required to fully implement data synchronization.

When another application requires data synchronization, the operator for Maximo Manage detects the presence of the Asset Data Dictionary dynamically. You do not have to restart Maximo Manage after the Asset Data Dictionary is installed.

Before you can synchronize your data by using the Asset Data Dictionary, you must also complete the following configurations:

- Configure authorization for the following object structures:
  - MXAPIORGANIZATION
  - MXAPIMETER
  - MXAPILOCSYSTEM
  - MXAPIOPERLOC
  - MXAPIASSET
  - MXAPIMEASUREUNIT
- Configure the outbound queue and an inbound queue for the external system.  
For more information about Kafka queues, see [Message processing by using a Kafka provider](#). For more information about JMS queues, see [JMS queue configuration](#).
- Enable the MASDD external system.
- If you are using Asset Data Dictionary with Maximo Monitor, create instances of the IOTCONNECTOR cron task for managing the Maximo Monitor metric to Maximo Manage meter updates. You must create a cron task instance for each type of update and in the instance, set both a **FILTER** value and a **METERLIST** value.
- To synchronize Manage data with the data dictionary when any changes occur, enable event listeners.
- Do not enable an event listener on the MASDD external system until your initial data load is complete. Ensure that, before you complete the initial data load, that the event listener is disabled. The initial data export must occur in a specific sequence. Enabling an event listener before initial data is exported might interfere with the ordered loading of the data. For more information, see [Initial data synchronization from Maximo Manage to Asset Data Dictionary](#).

## Initial data synchronization from Maximo Manage to Asset Data Dictionary

The export functions in the External Systems application are used to synchronize data from Maximo® Manage to the Asset Data Dictionary.

The following options are available for initial data synchronization:

Export data one publish channel at a time

Use the Data Export action for publish channels on the Publish Channels tab in the External Systems application.

To limit what data is exported, you can set export conditions on each publish channel. The following list contains examples of export conditions. Each condition results in data exported for only the specified object, such as asset number or location name. You can specify multiple objects. For example, the **assetnum in**

**('asset\_number', 'asset\_number', 'asset\_number')** export condition results in data exported for only the three specified assets.

- **systemid in ('system\_ID')**
- **location in ('location\_name')**
- **assetnum in ('asset\_number')**
- **orgid in ('organization\_ID')**
- **metername in ('meter\_name')**

Export multiple publish channels sequentially in batches

To export multiple channels sequentially, select the Bulk Data Export action from the More Actions menu in the External Systems application.

Data is synchronized in the following order:

1. Organizations and sites
2. Unit of measure

3. Location systems
4. Operating locations
5. Location hierarchies
6. Assets
7. Asset hierarchies

You can verify the state of messages by enabling message tracking. When message tracking is enabled, the messages appear in the Message Tracking application. For more information, see [Message tracking](#).

You can use the Message Reprocessing application to ensure that messages are not blocking other messages for processing. In the Message Reprocessing application, click Refresh to refresh the table and retrieve any blocking messages.

- [Organization and site synchronization](#)  
Organizations and sites are synchronized using the the MASDDORG publish channel.
- [Unit of measure synchronization](#)  
Unit of measure is synchronized by using the MASDDMEASUREUNIT publish channel.
- [Meter synchronization](#)  
Data for meters is synchronized using the locations and assets integrations. Only meters that are used by assets or locations are synchronized.
- [Location systems synchronization](#)  
Location systems are synchronized by using the MASDDLCSYS publish channel.
- [Operating locations synchronization](#)  
Operating locations and location meters are synchronized using the MASDDOPERLOC publish channel. An operating location is a location with the type OPERATING.
- [Location hierarchy synchronization](#)  
Operating location hierarchies are synchronized by using the MASDDLOCHIER publish channel. An operating location is a location with the type OPERATING.
- [Asset synchronization](#)  
Assets and asset meters are synchronized by using the MASDDASSET publish channel.
- [Asset hierarchy synchronization](#)  
Asset hierarchies are synchronized by using the MASDDASSETHIER publish channel.

---

## Organization and site synchronization

Organizations and sites are synchronized using the the MASDDORG publish channel.

The following artifacts are used to synchronize organizations and sites:

- Publish Channel: MASDDORG
- Object Structure: MXAPIORGANIZATION
- Query Template: MASDDORG

You can synchronize all organizations, or you can synchronize a subset. Synchronizing an organization also synchronizes all sites for the organization.

The following table describes how statuses are mapped for the organizations and sites when Maximo® Manage is synchronized with the Asset Data Dictionary.

Table 1. Status assignments for Maximo Manage to Asset Data Dictionary synchronization

Status in Maximo Manage	Status that is assigned in Asset Data Dictionary
ISACTIVE = 1	ACTIVE
ISACTIVE = 0	INACTIVE Data that is inactive is not integrated with Maximo Monitor.

To validate that data was successfully sent to the Asset Data Dictionary, you can use a REST API call that is similar to the following call:

**`https://host:port/maximo/oslc/masdd/organization`**

You can create queries using primary keys, as shown in the following example:

**`https://host:port/maximo/oslc/masdd/organization?orgid=EAGLENA`**

---

## Unit of measure synchronization

Unit of measure is synchronized by using the MASDDMEASUREUNIT publish channel.

The following artifacts are used to synchronize units of measure:

- Publish Channel: MASDDMEASUREUNIT
- Object Structure: MXAPIMEASUREUNIT
- Query Template: MASDDMEASUREUNIT

Although in Maximo® Manage you can specify different units of measurement for different organizations or sites, in the Asset Data Dictionary, the unit of measure is unique and does not vary from organization to organization or site to site. Importing an organization also imports all sites for the organization.

You can synchronize all units of measure, or you can synchronize a subset.

To validate that data was successfully sent to the Asset Data Dictionary, you can use a REST API call that is similar to the following call:

**`https://host:port/maximo/oslc/masdd/measureunit`**

You can create queries by using primary keys, as shown in the following example:

```
https://host:port/maximo/oslc/masdd/measureunit?measureunitid=LBS
```

---

## Meter synchronization

Data for meters is synchronized using the locations and assets integrations. Only meters that are used by assets or locations are synchronized.

The following artifacts are used to synchronize meters:

- Publish Channel: MASDDMETER
- Object Structure: MXAPIMETER
- Query Template: MASDDMETER

You can use the meters integration to delete meters from the Asset Data Dictionary.

To validate that data was successfully sent to the Asset Data Dictionary, you can use a REST API call that is similar to the following call:

```
https://host:port/maximo/oslc/masdd/meter
```

You can create queries for meters using primary keys, as shown in the following example:

```
https://host:port/maximo/oslc/masdd/meter?metername=TEMP-F
```

---

## Location systems synchronization

Location systems are synchronized by using the MASDDLOCSYS publish channel.

The following artifacts are used to synchronize location systems:

- Publish Channel: MASDDLOCSYS
- Object Structure: MXAPILOCSYSTEM
- Query Template: MASDDLOCSYSTEM

You can synchronize all location systems, or you can synchronize a subset.

To validate that data was successfully sent to the Asset Data Dictionary, you can use a REST API call that is similar to the following call:

```
https://host:port/maximo/oslc/masdd/locsystem
```

You can create queries that use primary keys, as shown in the following example:

```
https://host:port/maximo/oslc/masdd/locsystem?systemid=PRIMARY&siteid=BEDFORD
```

---

## Operating locations synchronization

Operating locations and location meters are synchronized using the MASDDOPERLOC publish channel. An operating location is a location with the type OPERATING.

The following artifacts are used to synchronize operating locations:

- Publish Channel: MASDDOPERLOC
- Object Structure: MXAPIOPERLOC
- Query Template: MASDDOPERLOC

You can synchronize all operating locations, or you can synchronize a subset. When you synchronize locations, location meters that have a metric ID are also synchronized.

The following table describes how statuses are mapped for the LOCASSETSTATUS domain when Maximo® Manage is synchronized with the Asset Data Dictionary:

Table 1. Status assignments for synchronization

Status in Maximo Manage	Status that is assigned in Asset Data Dictionary
DECOMMISSIONED	DECOMMISSIONED
NOT READY	NOT READY
ARCHIVED (external value)	ARCHIVED
Any internal value other than DECOMMISSIONED, NOT READY, or ARCHIVED (external value)	ACTIVE

Location hierarchies are not synchronized using this integration. Hierarchies are synchronized using the location hierarchy integration.

To validate that operating location data was successfully sent to the Asset Data Dictionary, you can use a REST API call that is similar to the following call:

```
https://host:port/maximo/oslc/masdd/locations
```

You can create queries for operating locations using primary keys, as shown in the following example:

```
https://host:port/maximo/oslc/masdd/locations?location=TEST1&siteid=BEDFORD
```

---

## Location hierarchy synchronization

Operating location hierarchies are synchronized by using the MASDDLOCHIER publish channel. An operating location is a location with the type OPERATING.

The following artifacts are used to synchronize location hierarchies:

- Publish Channel: MASDDLOCHIER
- Object Structure: MXAPILOCATION
- Query Template: MASDDLOCHIER

You can synchronize all operating location hierarchies, or you can synchronize a subset.

To validate that data was successfully sent to the Asset Data Dictionary, you can use a REST API call that is similar to the following call:

**`https://host:port/maximo/oslc/masdd/locations`**

You can also create queries by using primary keys, as shown in the following example:

**`https://host:port/maximo/oslc/masdd/locations?location=TEST1&siteid=BEDFORD`**

---

## Asset synchronization

Assets and asset meters are synchronized by using the MASDDASSET publish channel.

The following artifacts are used to synchronize assets:

- Publish Channel: MASDDASSET
- Object Structure: MXAPIASSET
- Query Template: MASDDASSET

You can synchronize all assets, or you can synchronize a subset.

Assets that are not associated with a location are synchronized. Assets that are associated with locations are synchronized only if the location type is OPERATING.

When you synchronize assets, asset meters that have a metric ID are also synchronized.

The following table describes how statuses are mapped for the LOCASSETSTATUS domain when Maximo® Manage is synchronized with the Asset Data Dictionary:

Table 1. Status assignments for synchronization

Status in Maximo Manage	Status that is assigned in Asset Data Dictionary
DECOMMISSIONED	DECOMMISSIONED
NOT READY	NOT READY
ARCHIVED (external value)	ARCHIVED
Any internal value other than DECOMMISSIONED, NOT READY, or ARCHIVED (external value)	ACTIVE

Asset hierarchies are not synchronized by using this integration. Hierarchies are synchronized by using the asset hierarchy integration.

Assets that are associated with storeroom locations are not synchronized.

To validate that asset data was successfully sent to the Asset Data Dictionary, you can use a REST API call that is similar to the following call:

**`https://host:port/maximo/oslc/masdd/asset`**

You can create queries for assets by using primary keys, as shown in the following example:

**`https://host:port/maximo/oslc/masdd/asset?assetnum=TEST1&siteid=BEDFORD`**

To validate that meter data was successfully sent to the Asset Data Dictionary, you can use a REST API call that is similar to the following call:

**`https://host:port/maximo/oslc/masdd/meter`**

You can create queries for meters by using primary keys, as shown in the following example:

**`https://host:port/maximo/oslc/masdd/meter?metername=TEMP-F`**

---

## Asset hierarchy synchronization

Asset hierarchies are synchronized by using the MASDDASSETHIER publish channel.

The following artifacts are used to synchronize asset hierarchies:

- Publish Channel: MASDDASSETHIER
- Object Structure: MXAPIASSET
- Query Template: MASDDASSETHIER

You can synchronize all asset hierarchies, or you can synchronize a subset. Asset hierarchies are moved after assets are moved to ensure that hierarchies are accurately correlated with the assets.

To validate that data was successfully sent to the Asset Data Dictionary, you can use a REST API call that is similar to the following call:

`https://host:port/maximo/oslc/masdd/asset`

You can create queries that use primary keys, as shown in the following example:

`https://host:port/maximo/oslc/masdd/asset?assetnum=TEST1&siteid=BEDFORD`

## Data synchronization process

After the initial data synchronization, you can export data from Maximo® Manage to the Asset Data Dictionary manually when needed, at regularly scheduled intervals, or when data changes.

The following synchronization options are available:

- Export data from Maximo Manage manually using the Data Export or Bulk Data Export actions in the External Systems application.
- Schedule a cron task to export data automatically at regular intervals, such as once a day.
- Enable event listener to initiate processing for a publish channel when a change occurs. To use this option, you must enable event listener on all MASDD publish channels except the MASDDASSETHIER asset hierarchy publish channel. Asset hierarchies are synchronized as part of the MASDDASSET asset integration.

Processed data is added to the outbound queue. You can configure a cron task to specify how often messages are sent to the data dictionary.

The following table describes the events that trigger data synchronization:

Table 1. Events that trigger data dictionary synchronization

Synchronization	Events that trigger updates to the data
Organizations and sites	An organization becomes active. An organization is deleted. A site is added, deleted, or becomes active.
Location systems	A location system is added. A location system is deleted.
Locations, locations of type OPERATING or any synonyms for OPERATING in the LOCTYPE domain	A location is added. A location is deleted. Location type is changed. A location status is changed. A location meter with a metric ID is added or deleted.
Location hierarchies	A location hierarchy is added. A location hierarchy is deleted.
Assets	An asset is added. An asset is deleted. An asset's parent, location, site ID or asset type is modified. An asset status is changed. An asset meter with a metric ID is added or deleted.
Asset hierarchies	The MASDDASSETHIER publish channel publishes the asset hierarchy for export scenarios. Do not enable an event listener for this publish channel.

Data synchronization must occur in the following order:

1. Organizations and sites
2. Location systems
3. Operating locations
4. Location hierarchies
5. Assets
6. Asset hierarchies

## Maximo Monitor to Maximo Manage integration

The Maximo® Monitor to Maximo Manage integration is a one-time process that uses the Asset Data Dictionary to add data about organizations, sites, assets, and locations from Maximo Monitor to Maximo Manage.

Use this integration only for a one-time, initial load of data into Maximo Manage. After the initial data is loaded, Maximo Manage takes ownership of the data and manages any subsequent changes to the data.

- [Maximo Monitor to Maximo Manage integration overview](#)  
Maximo Manage provides several artifacts for the Maximo Monitor to Maximo Manage integration, including an external system, enterprise services, and endpoints.
- [Maximo Monitor to Maximo Manage organization and site integration](#)  
The External Systems application provides an enterprise service for integrating organization and site data from Maximo Monitor to Maximo Manage.

- [Location integration](#)  
The External Systems application provides an enterprise service for integrating location system, operating location, and location hierarchy data from Maximo Monitor to Maximo Manage.
- [Asset integration](#)  
The External Systems application provides an enterprise service for integrating asset and asset hierarchy data from Maximo Monitor to Maximo Manage.
- [Maximo Monitor to Maximo Manage integration process](#)  
Integration of data from Maximo Monitor to Maximo Manage is performed by using the Get External Data option that is available on the Enterprise Services tab in the External Systems application.

## Maximo Monitor to Maximo Manage integration overview

Maximo® Manage provides several artifacts for the Maximo Monitor to Maximo Manage integration, including an external system, enterprise services, and endpoints.

You can use the following artifacts to add data from Maximo Monitor to Maximo Manage:

### MASDD external system

The MASDD external system includes enterprise services for inbound data integration from Maximo Monitor to Maximo Manage.

To integrate data from Maximo Monitor into Maximo Manage, you use the MASDD external system and the MASDDLLOAD endpoint. Processing uses an inbound queue, which can be JMS or Kafka.

### Enterprise services

The following table describes the object structures and enterprise services that are associated with the MASDD external system in Maximo Manage:

Table 1. Enterprise services for Maximo Monitor to Maximo Manage integration

Object structure	Enterprise service
MXAPIORGANIZATION	MASDDORG
MXAPILOCSYSTEM	MASDDLOCSYS
MXAPIOPERLOC	MASDDOPERLOC
MXAPIOPERLOC	MASDDLOCHIER
MXAPIASSET	MASDDASSET
MXAPIASSET	MASDDASSETHIER

To synchronize data, use the Get External Data option, which is available on the External Service tab for an external system.

### Endpoints

Enterprise services in the MASDD external system are configured to export data by using the MASDDLLOAD endpoint. Data is posted in JSON format to Maximo Manage.

Endpoint properties are configured in Red Hat® OpenShift® and are stored as server bundle properties.

The following properties are added to the endpoints:

- URL
- GRAPH
- USERNAME
- PASSWORD
- TENANT

The Allow Override check box must be selected to allow the properties to be overwritten.

## Maximo Monitor to Maximo Manage organization and site integration

The External Systems application provides an enterprise service for integrating organization and site data from Maximo® Monitor to Maximo Manage.

The following artifacts are used to integrate organizations and sites:

- Enterprise Service: MASDDORG
- Object Structure: MXAPIORGANIZATION

You can integrate all organizations. Synchronizing an organization also integrates all sites for the organization.

To create an organization in Maximo Manage, you must supply an ITEMSETID, COMPANYID, and BASECURRENCY, which Maximo Monitor does not have. You have two options for providing organizations and sites for Maximo Manage:

- You can manually create an organization in Maximo Manage and then integrate only sites.
- You can add default values for item set, company ID, and base currency by using the following system properties:

Table 1. System properties for organization and site synchronization

Property	Description
mxe.int.masdddfltitemset	Default item set ID.
mxe.int.masdddfltcompset	Default company set ID.
mxe.int.masdddfltbasecurrency	Default currency code.

After you add the default values, you can integrate organization data from Maximo Monitor into Maximo Manage.

Before you can activate an organization, you must specify a clearing account. If you want to disable GL validation, you can set the `mxe.int.disableglvalidation` property to true by specifying 1. If you disable the validation, an organization is created as active with the clearing account set to ?. The following MAXVARS are set to bypass GL validation:

- DISABLEGLSWITCH
- GLVALIDATEFP
- GLCHECKCOA

Before attempting to synchronize organizations and sites, check that the correct permissions are set:

- If the `mxe.int.propagateuser` property is set to 0, it means that the MXINTADM user runs the transactions and therefore, must have access to Inactive Sites, which are set in the Users application.
- If the `mxe.int.propagateuser` property is set to 1, it means that the user executing the Get External Data action must have access to Inactive Sites.

Mismatches in field lengths between Maximo Monitor and Maximo Manage can prevent accurate synchronization.

Integration fails when a field length in Maximo Monitor is greater than the maximum field length in Maximo Manage.

When you integrate data from Maximo Monitor to Maximo Manage, adjustments are sometimes required for field lengths. Except for the descriptions, attributes in Maximo Monitor have a length of 30. Consequently, you must reconfigure attributes in Maximo Manage to a length of 30.

The following tables describe the default field lengths and data types that Maximo Manage uses for the organization and site attributes:

Table 2. Data types and lengths for organization attributes

Attribute	Data type	Length
ORGID	UPPER	8
ORGANIZATIONID	BIGINT	19
DESCRIPTION	ALN	100
ACTIVE	INTEGER	1

Table 3. Data types and lengths for site attributes

Attribute	Data type	Length
ORGID	UPPER	8
SITEID	UPPER	8
SITEUID	BIGINT	19
DESCRIPTION	ALN	100
ACTIVE	ALN	1

The following table describes how organization and site statuses are mapped from Maximo Monitor to Maximo Manage:

Table 4. Organization and site status assignments for the integration from Maximo Monitor to Maximo Manage

Status in Maximo Monitor	Status that is assigned in Maximo Manage
ACTIVE	The ACTIVE flag is set to 1.
ARCHIVED	The ACTIVE flag is set to 0.

---

## Location integration

The External Systems application provides an enterprise service for integrating location system, operating location, and location hierarchy data from Maximo® Monitor to Maximo Manage.

## Location systems integration

---

The following artifacts are used to integrate location systems:

- Enterprise Service: MASDDLOCSYS
- Object Structure: MXAPILOCSYSTEM

You can integrate all location systems.

Mismatches in field lengths between Maximo Monitor and Maximo Manage can prevent accurate integration. Integration fails when a field length in Maximo Monitor is greater than the maximum field length in Maximo Manage.

When integrating from Maximo Monitor to Maximo Manage, adjustments are sometimes required for field lengths. The following table describes the default field lengths that Maximo Manage uses for the location system attributes:

Table 1. Data types and lengths for location systems attributes

Attribute	Data type	Length
SYSTEMID	UPPER	12
SITEID	UPPER	8
LOCSYSTEMID	BIGINT	19
DESCRIPTION	ALN	100

## Operating Locations integration

The following artifacts are used to integrate operating locations:

- Enterprise Service: MASDDOPERLOC
- Object Structure: MXAPIOPERLOC

You can integrate all operating locations, or you can integrate a subset.

If Maximo Monitor uses a location type that does not exist in the Maximo Manage LOCTYPE domain, the location type is created in Maximo Manage as a synonym of the OPERATING type.

The following table describes how statuses are mapped for the LOCASSETSTATUS domain from Maximo Monitor to Maximo Manage:

Table 2. Status assignments for the integration

Status in Maximo Monitor	Status that is assigned in Maximo Manage
ACTIVE	The default external value for the OPERATING internal value.
ARCHIVED	A synonym of the OPERATING internal value.

If the imported description from Maximo Monitor exceeds the maximum length that is allowed in the Description field in Maximo Manage, the text is truncated. However, the full description is provided in the Long Description field.

Location hierarchies are not integrated using this integration. Hierarchies are integrated using the location hierarchy integration.

Mismatches in field lengths between Maximo Monitor and Maximo Manage can prevent accurate integration for operating locations. Adjustments are sometimes required for field lengths. The following table describes the default field lengths and data types that Maximo Manage uses for the operating location attributes:

Table 3. Data types and lengths for operating location attributes

Attribute	Data type	Length
LOCATION	UPPER	12
SITEID	UPPER	8
LOCATIONSID	BIGINT	19
TYPE	UPPER	16
STATUS	ALN	20
DESCRIPTION	ALN	100

## Location hierarchies integration

The following artifacts are used to integrate location hierarchies:

- Enterprise Service: MASDDLOCHIER
- Object Structure: MXAPIOPERLOC
- Query template: MASDDLOCHIER

You can integrate all location hierarchies. Location hierarchies are moved after locations are moved to ensure that hierarchies are accurately correlated with the locations.

Mismatches in field lengths between Maximo Monitor and Maximo Manage can prevent accurate integration of location hierarchies. Adjustments are sometimes required for field lengths. The following table describes the default field lengths and data types that Maximo Manage uses for the location hierarchy attributes:

Table 4. Data types and lengths for location hierarchy attributes

Attribute	Data type	Length
LOCATION	UPPER	12
SYSTEMID	UPPER	12
PARENT	UPPER	12
SITEID	UPPER	8

## Asset integration

The External Systems application provides an enterprise service for integrating asset and asset hierarchy data from Maximo® Monitor to Maximo Manage.

## Assets integration

The following artifacts are used to integrate assets:

- Enterprise Service: MASDDASSET
- Object Structure: MXAPIASSET

All assets can be integrated.

If Maximo Monitor uses an asset type that does not exist in the Maximo Manage ASSETTYPE domain, the asset type is created in Maximo Manage as a synonym of the PRODUCTION type. This value is configurable. You can change it by changing the mxe.int.masdddfktassettype property.

The following table describes how statuses are mapped for the LOCASSETSTATUS domain from Maximo Monitor to Maximo Manage:

Table 1. Status assignments for the integration

Status in Maximo Monitor	Status that is assigned in Maximo Manage
ACTIVE	The default external value for the OPERATING internal value.
ARCHIVED	A synonym of the OPERATING internal value.

If the imported description from Maximo Monitor exceeds the maximum length that is allowed in the Description field in Maximo Manage, the text is truncated. However, the full description is provided in the Long Description field.

Asset hierarchies are not integrated by using this integration. Hierarchies are integrated by using the asset hierarchy integration.

Mismatches in field lengths between Maximo Monitor and Maximo Manage can prevent accurate integration. Integration fails when a field length in Maximo Monitor is greater than the maximum field length in Maximo Manage.

When you integrate data from Maximo Monitor to Maximo Manage, adjustments are sometimes required for field lengths. The following table describes the default field lengths and data types that Maximo Manage uses for the asset attributes:

Table 2. Data types and lengths for asset attributes

Attribute	Data type	Length
ASSETNUM	UPPER	25
SITEID	UPPER	8
ASSETUID	BIGINT	19
ASSETTYPE	UPPER	20
STATUS	ALN	20
DESCRIPTION	ALN	100

## Asset hierarchies integration

The following artifacts are used to integrate asset hierarchies:

- Enterprise Service: MASDDASSETHIER
- Object Structure: MXAPIOPERLOC
- Query template: MASDDASSETHIER

You can integrate all asset hierarchies. Asset hierarchies are moved after assets are moved to ensure that hierarchies are accurately correlated with the assets.

Mismatches in field lengths between Maximo Monitor and Maximo Manage can prevent accurate integration of asset hierarchies. Adjustments are sometimes required for field lengths. The following table describes the default field lengths and data types that Maximo Manage uses for the asset hierarchy attributes:

Table 3. Data types and lengths for asset hierarchy attributes

Attribute	Data type	Length
ASSETNUM	UPPER	25
PARENT	UPPER	25
SITEID	UPPER	8

## Maximo Monitor to Maximo Manage integration process

Integration of data from Maximo® Monitor to Maximo Manage is performed by using the Get External Data option that is available on the Enterprise Services tab in the External Systems application.

Data must be integrated in the following order:

1. Organizations and sites
2. Location systems
3. Operating locations
4. Location hierarchies
5. Assets
6. Asset hierarchies

After the data is loaded into Maximo Manage, Maximo Manage owns the data and manages any subsequent changes to the data.

## Integrating Maximo Manage with IoT monitoring systems

You can add metric data that IoT monitoring systems gather from sensor devices to meters in Maximo® Manage applications.

- [IoT device data integration overview](#)  
Data that Internet of Things (IoT) monitoring systems collect from sensor devices can be imported into Maximo Manage by using the Asset Data Dictionary integration features.
- [Associating device metrics to asset and location meters](#)  
Metrics data from IoT sensor devices, such as data that is gathered by Maximo Monitor, can be integrated with asset and location meters in Maximo Manage.

You can associate device metrics with asset and location meters directly in the Assets, Locations, and Object Structures applications. You can associate data in bulk for large numbers of devices by importing files that pair the IoT devices with the assets and locations by using a metrics ID.

## IoT device data integration overview

Data that Internet of Things (IoT) monitoring systems collect from sensor devices can be imported into Maximo® Manage by using the Asset Data Dictionary integration features.

Metrics are time-based groupings of sensor data that is associated with IoT devices. In IoT monitoring systems, devices can be associated with assets and locations. When a device is associated with an asset or location, the metrics that are associated with the device can be added to the meter data that Maximo Manage maintains for assets and locations.

In Maximo Manage, in the Assets and Locations applications, on the Meters tab, the Metric ID field associates an asset or location meter to a metric that is collected by IoT monitoring systems.

The metrics data can be added to Maximo Manage by using the Asset Data Dictionary artifacts in the integration framework and the IOTCONNECTOR cron task.

The IOTASSET and IOTLOCATIONS enterprise services in the MASDD external system are used to import metrics data into Maximo Manage.

You can create one or more cron task instances and run the IOTCONNECTOR cron task to pull data from IoT monitoring systems into meter readings for assets and locations.

To accommodate the large variety of sensor devices that gather data, Maximo Manage provides various configuration options for the IOTCONNECTOR cron task. For example, you can apply filters to select specific assets or locations. Because some sensors need to be monitored more frequently than others, you can also specify how often to poll for data. If no filter or meter list is specified, the cron task selects all assets and locations and also selects the meters that are associated with a metric ID.

The following table describes the parameters that you can use to configure the IOTCONNECTOR cron task:

Table 1. IOTCONNECTOR cron task parameters

Parameter	Description	Default
FILTER	WHERE clause that filters the assets and locations that are selected when the cron task runs.	Does not apply.
METERLIST	Comma-separated list of meter names for the cron task to process. The meter list is added to the WHERE clause that filters the data.	Does not apply.
PROCESSOR	IoT processor class that implements the <code>com.ibm.tivoli.maximo.iotf.processor.IoTProcessor</code> interface.	<code>com.ibm.tivoli.maximo.iotf.processor.IoTProcessor</code>
BATCHSIZE	Page size to use for the metric data request. For example, if the page size is 100, the cron sends a bulk request for 100 metrics to the Asset Data Dictionary.	100
ASSETBASED	Specifies whether the task processes assets or locations. <ul style="list-style-type: none"><li>For asset-based metrics, specify 1.</li><li>For location-based metrics, specify 0.</li></ul>	1
QUEUEBASED	Specifies whether the response goes through a queue or not.	1
HISTDAYS	Number of days in the past to retrieve metrics if meter readings were never synchronized with metrics. This parameter is used when meter readings were not synchronized for one of the following reasons: <ul style="list-style-type: none"><li>The cron task is run for the first time.</li><li>The cron task processes data for a meter that does not have any readings that are registered with Maximo Manage. That is, the <code>lastreadingdate</code> parameter is null in the asset meter or the location for that meter.</li></ul> It is important to determine how many days in the past to request data for metrics that have no meter readings in Maximo Manage. For example, in some monitoring systems, such as Maximo Monitor, metrics might be configured many days before the metric is associated with an asset or location meter. You must specify whether the cron task collects all available historical data or limits the historical data to the number of days that is specified in the HISTDAYS parameter. This parameter is used only when no prior readings exist for a meter. When readings exist, the cron task always uses the value that is specified for the <code>lastreadingdate</code> parameter as a starting point for retrieving the meter data.	7
USELASTREADINGS	Specifies whether to use the last reading that was taken for the metric device. <ul style="list-style-type: none"><li>To use the last reading for the asset or location meter, specify 1.</li><li>To use the last run time for the cron task, specify 0.</li></ul>	1

The ASSETBASED parameter in the cron task determines whether asset or location data is integrated. For example, if the value of the ASSETBASED parameter is 1, the cron task imports all asset metrics by using the FILTER and METERLIST parameters and sends one or more REST API calls to the Asset Data Dictionary by using the batch size that is specified. The Asset Data Dictionary connects with a provider of the metrics data such as Maximo Monitor to retrieve the data.

If the value for the QUEUEBASED parameter is 1, the data is broken into individual transactions before it is added to the queue. For example, if the batch size is 100, a call to the Asset Data Dictionary returns 100 records for a transaction, and the records are broken into 100 separate transactions before they are written to the queue. This process facilitates parallel processing. If the value of the QUEUEBASED parameter is 0, the data is imported directly by using the IOTASSET enterprise service.

Depending on the number of metrics that you select and the batch size that you configure for the cron task, the IOTCONNECTOR cron task might make several requests in a single run. For example, if the data set has 1000 metrics and the batch size is set to 100, which is the default, the cron task attempts to make 10 requests for 100 records each to fetch data for 1000 metrics. If the third request encounters an error for any reason, such as a network, Asset Data Dictionary, or monitoring system issue, the cron task stops the run and does not attempt the remaining seven runs. When the cron task runs next, it uses the `lastreadingdate` from

the asset meter or location meter tables to determine when the last reading for an individual meter was taken. The timestamp is used in the subsequent query to the Asset Data Dictionary for the associated metric. This process ensures that even if errors prevent the cron task from fetching data for a specific metric in one run, the data can be captured in the next successful run.

# Associating device metrics to asset and location meters

Metrics data from IoT sensor devices, such as data that is gathered by Maximo® Monitor, can be integrated with asset and location meters in Maximo Manage. You can associate device metrics with asset and location meters directly in the Assets, Locations, and Object Structures applications. You can associate data in bulk for large numbers of devices by importing files that pair the IoT devices with the assets and locations by using a metrics ID.

## Before you begin

Before you can associate metrics from IoT devices with asset and location meters in Maximo Manage, you must complete the following tasks:

- Ensure that the IoT devices for your monitoring system are registered in the Asset Data Dictionary.
- In Maximo Manage, ensure that the MXASSET and MXOPERLOC object structures are enabled for flat files by selecting the Support Flat File Structure check box for the object structures.
- Resolve any alias conflicts for field names in the object structures.
- Ensure that the appropriate authorizations are assigned for the object structures.

## Associating metrics to meters in the Maximo Manage user interface

In the Assets and Locations applications, you can select an asset or location and then associate metrics data from IoT devices by using the Metric ID field on the Meters tab.

### About this task

This task describes how to associate metrics that are collected by IoT devices with meter data in the Assets application in Maximo Manage. In the Locations application, you can perform the same steps to associate metrics data with locations.

### Procedure

1. In the Assets application, locate the asset for which you want to import device metrics.
2. On the Meters tab for the asset, select the meter for which you want to import metrics.
3. In the Metric ID field, click the search icon.
4. In the Select Value window, select the metric that you want to associate with the meter.
5. Save the record.

## Associating metrics to meters in bulk

You can associate large numbers of metrics with asset and location meters in bulk by importing flat files that pair the IoT devices with the assets and locations by using a metrics ID.

### About this task

This task describes how to associate in bulk the metrics that are collected by IoT devices with meter data in the Assets application in Maximo Manage. In the Locations and Object Structures applications, you can perform similar steps to associate metrics data with location meters.

To complete this task, you specify which assets you want to associate metrics with and download a compressed file that contains the following two CSV files that you can use to associate metrics from IoT devices with the corresponding asset meters in Maximo Manage:

- asset\_metric\_<file ID>.csv

The spreadsheet lists data for IoT devices that are associated with the asset or assets that you selected, including metric ID, metric name, device name, and device type. If a metric already is associated with an asset, the meter is listed in the METERNAME cell.
- asset\_meter\_<file ID>.csv

The spreadsheet lists the meters that are associated with the Maximo Manage asset or assets that you selected. If an asset meter is already associated with a metric ID, the metric ID is displayed in the METRICID cell.

You must select one of the files and update it to associate a metric ID with an asset meter. For each meter that you want to associate with a metric ID, you can add the metric ID to the METRICID column to the asset\_meter\_<file ID>.csv file. Or you can choose to add the meter that corresponds to the metric ID that is listed for the asset in the asset\_metric\_<file ID>.csv file.

### Procedure

1. In the Assets application, choose one of the following options to specify which assets to associate with imported metric data:
  - On the List tab, select the check box for the assets for which you want to import metrics data.
  - Select a single asset for which you want to import metrics data.
2. From the Select Action menu, choose IoT Metric List.
3. In the IoT Metric List window, enter the following information to retrieve data for the metrics:

Table 1. IoT Metric List field descriptions

Field	Description	Default
-------	-------------	---------

Field	Description	Default
Where clause	A valid SQL WHERE clause for the MXASSET and MXOPERLOC object structures. If no WHERE clause is entered, all data is processed. Note: In the Assets and Locations applications, this field is prepopulated with values that are based on the assets or locations that you selected on the List tab or the individual record that you selected.	None
Delimiter	The character to use to separate one cell in the spreadsheet from another.	The default value is specified in the <code>mxe.int.flatfiledelimiter</code> system property.
Text Qualifier	If a delimiter is used in one of the cells, text qualifiers are used to enclose each value.	The default value is specified in the <code>mxe.int.textqualifier</code> system property.
Unmapped Only	If this check box is selected, the spreadsheet includes only assets or locations that are not associated with a metric ID. If the check box is cleared, asset or location meters are included whether they have a metric ID or not. If any asset or location is associated with a metric, the metric is displayed in the spreadsheet.	
Add Header	Specifies whether to add a header row that contains the external system name, enterprise service name, action, and language code. Select this check box if you use the Data Import action for an enterprise service in the External Systems application. A header is not needed when you load by using object structures.	

4. Click OK. After you click OK, a compressed file is downloaded to the default download folder on the computer.
5. Extract the compressed file.
6. Determine which file to update for import into Maximo Manage and select one of the following options to prepare data in the spreadsheet for import.
  - Update the `asset_metric_<file ID>.csv` file.  
For each metric ID that you want to associate with a meter, add the meter name to the `METERNAME` column in the `asset_metric_<file ID>.csv` file and save the file. Rows with no meter name are ignored when data is imported into Maximo Manage.
  - Update the `asset_meter_<file ID>.csv` file.  
For each meter that you want to associate with a metric ID, add the metric ID to the `METRICID` column in the `asset_meter_<file ID>.csv` file and save the file.
7. After you update the spreadsheet, select one of the following options to import the spreadsheet:
  - Import data by using the `MXASSETInterface` and `MXOPERLOCInterface` enterprise services in the MASDD external system. If you select this option, use a header in the CSV file.
  - In the Assets or Locations application, select the Application Import action. Then, select the MXASSET or MXOPERLOC object structure and synchronize the objects. If you select this option, no header is needed in the CSV file.
  - Make a REST API call by using the MXASSET and MXOPERLOC object structures. If you select this option, no header is needed in the CSV file.
  - In the Object Structures application, select the MXASSET or MXOPERLOC object structure and then use the Data Import action. If you select this option, no header is needed in the CSV file.

## Integrating with Cognos Analytics server

From Maximo® Manage 8.6, an integration to IBM® Cognos® Analytics is available. The integration provides an extra suite of Business Intelligence (BI) tools.

- [Installing Cognos Analytics](#)  
Installing Cognos Analytics enables features including enabling your authorized users to access Cognos Analytics reporting, synchronization of the Maximo Application Suite security groups to Cognos Analytics, and publishing of Maximo Application Suite object structures as Cognos metadata packages.
- [Configuring Cognos Analytics server](#)  
Configure Cognos Analytics server to use it for reporting.

## Installing Cognos Analytics

Installing Cognos® Analytics enables features including enabling your authorized users to access Cognos Analytics reporting, synchronization of the Maximo® Application Suite security groups to Cognos Analytics, and publishing of Maximo Application Suite object structures as Cognos metadata packages.

- [Cognos Analytics entitlement for Maximo Application Suite](#)  
IBM Cognos Analytics on IBM Cloud Pak® for Data is a supporting program in Maximo Application Suite 8.10 Long Term Support Release (LTSR).
- [Prerequisites for Cognos Analytics](#)  
Before you configure IBM Cognos Analytics to work with Maximo Manage, there are certain things you must check for.
- [Collecting key information from Cloud Pak for Data for Cognos Analytics configuration](#)  
It is important to collect some key information for Cognos Analytics.

## Cognos Analytics entitlement for Maximo Application Suite

IBM® Cognos® Analytics on IBM Cloud Pak® for Data is a supporting program in Maximo® Application Suite 8.10 Long Term Support Release (LTSR).

The usual Supporting Program license terms apply to Cognos Analytics along with the following restrictions specific to creating and editing reports or dashboards:

- Cognos Analytics requires IBM Administrative Base User license. Maximo Application Suite customers must have at least one license.
- It is limited up to three Administrative Base users who can do Cognos Analytics Administrative creating or editing.

- No separate installation AppPoint consumption takes place on installing Cognos Analytics cartridge.
- User AppPoint consumption is based on Limited, Base, or Premium license types.

---

## Prerequisites for Cognos Analytics

Before you configure IBM® Cognos® Analytics to work with Maximo® Manage, there are certain things you must check for.

You must ensure that you have installed the following software before you install Cognos Analytics:

- Red Hat® OpenShift® Container Platform
- IBM Cloud Pak® for Data
- IBM Common Services

To install Cloud Pak for Data and Cognos Analytics, you must follow the instructions in the Ansible playbook. For more information, see [cp4d](#).

---

## Collecting key information from Cloud Pak for Data for Cognos Analytics configuration

It is important to collect some key information for Cognos® Analytics.

### Procedure

---

1. Log on to Red Hat® OpenShift® Container Platform.

Collecting Cloud Pak for Data namespace

2. Go to Administration > Namespaces and check if the ibm-cpd namespace exists.

Collecting Cloud Pak for Data URL

3. Go to Networking > Routes and in the ibm-cpd project you can see a URL in the Location column. Note the URL.

Collecting default admin credentials

4. Use the user name "admin" and go to Workloads > Secrets and select admin-user-details in the Name column. Copy the initial\_admin\_password in the Data section and note it down.

Collecting the project folder path

5. After you create an instance, come back to Red Hat OpenShift Container Platform and in Workloads > Pods select the reporting pod and create a project folder. Note the project folder path.

Collecting Cognos Analytics administrator details

6. After you create the Cognos Analytics administrator and add the administrator to your instance, note down the user name and password.

Collecting the team content folder name

7. After you create a team content folder for publishing packages, note down the name of the folder.

Collecting data source name

8. After you create a data source, go to Cognos Analytics and note down the data source name.

---

## Configuring Cognos Analytics server

Configure Cognos® Analytics server to use it for reporting.

You must set up platform connections in Cloud Pak for Data. For more information, see [Configuring the content store for Cognos Analytics](#)

- [Creating Cognos Analytics instances](#)  
Create a Cognos Analytics instance to manage users.
- [Cognos Analytics system properties](#)  
There are eight system properties that apply to Cognos Analytics.
- [Cognos Analytics end point properties](#)  
The MXCOGNOS end point has seven end point properties.
- [Creating a Cognos Analytics administrator for publishing packages](#)  
You must run a CURL command to create a Cognos Analytics administrator for publishing packages and then create a team content folder where you can configure the endpoint to publish framework packages.
- [Creating a data source in Cognos Analytics](#)  
Create a data source for publishing and running reports.

- [Configuring Maximo Manage user synchronization to Cloud Pak for Data](#)  
You must check whether the user synchronization is correct by going to the Cloud Pak for Data interface.

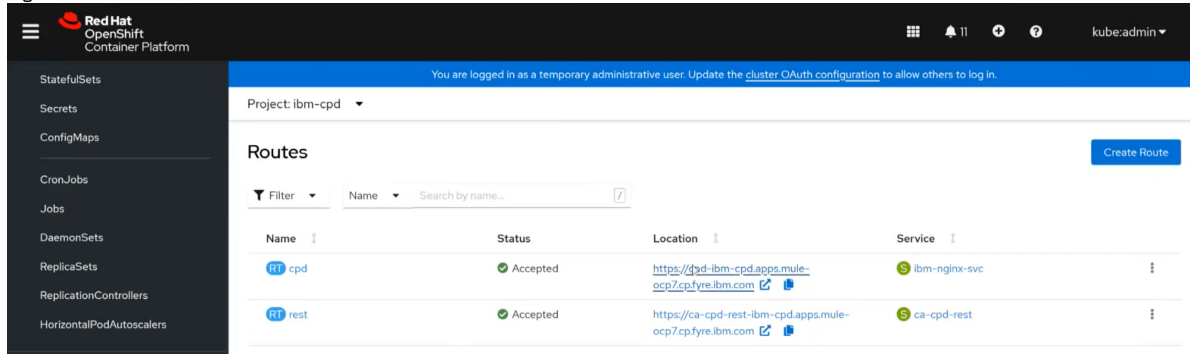

## Creating Cognos Analytics instances

Create a Cognos® Analytics instance to manage users.

### Procedure

1. Log on to Red Hat® OpenShift® Container Platform and access the IBM Cloud Pak® for Data pod.
2. From the menu, select Networking > Routes and open the cpd route.

Figure 1. CPD route

3. Log on as admin to Cloud Pak for Data by using your IBM® provided credentials.
4. To create a platform connection, go to Platform connections from the navigation menu and click New connection +.  
The platform connection is used as a Cognos Analytics content store.  
Note: Supported databases are IBM Db2®, Oracle, and Microsoft SQL Server only. IBM Db2 Warehouse is not a supported database.
5. From the menu, select Services catalog.
6. In the Analytics section, verify whether the Cognos Analytics tile is enabled.
7. Go to Instances and select New instance.
8. Select Cognos Analytics and click New instance.
9. In the wizard, select an Instance Name Space, which is ibm-cpd.
10. Select the Shared File Volume Storage, Shared Block Volume Storage, and Plan size and click Next.
11. Select a Content Manager Database and an Audit Database and click Next.
12. Complete the wizard to finish creating a new instance.
13. Go to Instances from the navigation menu to check for the newly created instance.  
Note: Check the Status column to see whether it displays Running Instance that is created.

### What to do next

Add users or go to Cognos Analytics.

## Cognos Analytics system properties

There are eight system properties that apply to Cognos® Analytics.

### Cognos Analytics system properties and values

Note: Maximo® Manage user interface does not support configuring system properties.

Property name	Description	Used for
mxe.report.cognos.serverURL	Cognos Analytics Dispatcher or Gateway URL. It is used to launch Cognos Analytics reports or admin.	Report execution
mxe.report.cognos.cpdnamespace	Cognos Analytics project namespace, where Cognos Analytics services are installed. For example, ibm-cpd.	Report execution
mxe.report.cognos.content.store.package.location	Cognos Analytics Team Content folder where the Cognos Analytics package is published. For example, PUBLIC.	Package creation
mxe.report.cognos.datasource	The name of the Cognos Analytics data source name for the Maximo Manage database. For example, MXDB.	Package creation
mxe.report.cognos.db.schemaName	The Maximo Manage database schema name that relates to the Cognos Analytics data source.	Package creation
mxe.report.cognos.db.type	Maximo Manage database type that relates to the Cognos Analytics data source.	Package creation and report execution
mxe.report.cognos.db.sql.name	The SQL Server database name if the database type is SQL Server.	Access to Cognos Analytics outside

		of Maximo Manage
mxe.report.cognos.namespace	Cognos Analytics namespace which holds information on users, security groups, and roles. For example, jwtin lowercase always.	Report execution

## Cognos Analytics end point properties

The MXCOGNOS end point has seven end point properties.

## MXCOGNOS end point properties and values

You can change and configure the values for each property.

Property	Value	Description
CONTENT_STORE_PACKAGE_LOCATION	PUBLIC	Cognos® Analytics Team Content folder where the Cognos Analytics package is published.
DATA_SOURCE_NAME	MXDB	Cognos Analytics data source name for the Maximo® Application Suite database.
NAMESPACE_ID	jwt	Cognos Analytics namespace, which holds information on users, security groups, and roles.
USERNAME	cpdadmin	Cognos Analytics administrator user name used for publishing reporting object structures.
PASSWORD	<i>encrypted value</i>	Cognos Analytics administrator password used for publishing reporting object structures.
PROJECT_BASE_DIR	/opt/ibm/cognos/analytics/projects	File path location on the Cognos Analytics reporting pod where Framework Manager model files are published.
URL	https://cpd-ibm-cpd.apps.mule-ocp9.cp.fire.ibm.com	Cognos Analytics dispatcher or gateway URL. It is used to publish reporting object structures.

## Creating a Cognos Analytics administrator for publishing packages

You must run a CURL command to create a Cognos® Analytics administrator for publishing packages and then create a team content folder where you can configure the endpoint to publish framework packages.

## Procedure

1. Run the following CURL commands:

[illegible]

```

"email": "<admin_email>",
"user_roles": [
 "User",
 "Administrator"
]
},

```

2. Log on to Cloud Pak for Data and confirm that the Cognos Analytics administrator is created by going to Access control from the navigation menu.
3. In your Cognos Analytics instance, select Manage access and click Add users +
4. In the Grant access to users and user groups dialog, select the Cognos Analytics administrator you created and select Analytics Administrator as the role from the list.
5. Click Add
6. On the IBM® Cognos Analytics page, select Content from the menu.
7. On the Team content tab, click the Add a folder icon.
8. Specify a name for the folder and click Add.  
On the Content page, you can see your new folder.

---

## Creating a data source in Cognos Analytics

Create a data source for publishing and running reports.

### Procedure

---

1. In the Cognos® Analytics instance, click the Overflow menu and select Open.
2. From the menu, click Manage > Administration console
3. Click Configuration.
4. Click the New Data Source icon.
5. Specify a name for the data source and click Next.
6. Select the type from the list, ensure that the Configure JDBC connection checkbox is selected, and click Next.
7. In the User ID, Password, and Confirm password fields, specify the login credentials. Click Next.
8. In the Server name field, specify a JDBC server and in the Port number , specify a port number.
9. In the Database name field, specify a database and JDBC connection parameters.
10. Click Test the connection and click Test.  
If the configuration works, the status is Succeeded.
11. Click Close twice and click Finish.

---

## Configuring Maximo Manage user synchronization to Cloud Pak for Data

You must check whether the user synchronization is correct by going to the Cloud Pak for Data interface.

### About this task

---

Check whether the user is synchronized from Maximo® Manage to Cognos® Analytics.

### Procedure

---

1. Log on to Cloud Pak for Data by using the URL specified in the End Points application in Maximo Manage.  
Note: If you configured a cron task for the synchronization, you must wait for the time interval you specified before you check it in Cloud Pak for Data. The default time interval is 5 minutes.
  2. Click the Manage users tile.  
You can see one or more users that you synchronized in the Access control page.  
Note: Removing the user from the COGNOSUSERS security group does not remove the synchronization with Cognos. You must delete the user from the table in the Access control page to remove the synchronization.
- [Configuring MXCOGNOS end point](#)  
Configure MXCOGNOS end point to synchronize users from Maximo Manage to Cognos Analytics.
  - [Adding users to security group](#)  
You must add a user to the right security group for user synchronization with Cognos to work correctly.

---

## Configuring MXCOGNOS end point

Configure MXCOGNOS end point to synchronize users from Maximo® Manage to Cognos® Analytics.

### About this task

---

You must configure the end point before you can synchronize users between Maximo Manage to Cognos Analytics.

## Procedure

---

1. From the navigation menu, go to Integration > End Points.
2. Specify MXCOGNOS as the search criteria in the End Point field.
3. From the search results, select MXCOGNOS and a list of properties for the end point is displayed.  
For more information on MXCOGNOS, see [End point system properties](#).
4. Check that the URL for the CPD\_ROUTE property has a value. User synchronization cannot happen without this property configured.

---

## Adding users to security group

You must add a user to the right security group for user synchronization with Cognos to work correctly.

### About this task

---

You can add an existing user to the COGNOSUSERS group to synchronize with Cognos.

## Procedure

---

1. From the navigation menu, go to Security > Users.
2. Search for an existing user and select the username from the search results.  
Note: You can only search for existing users. New users are created at the Maximo® Application Suite level and migrated to Maximo Manage.
3. Go to the Groups tab and click Select Groups.
4. In the Select Groups dialog, select the COGNOSUSERS group and click OK.
5. Click Save to save your changes to the user.

---

## Using Maximo Manage

The IBM® Maximo® Manage applications are grouped into modules. You can access the modules from the Go To menu in the Navigation toolbar of the user interface.

- [Administration module](#)  
You use the applications in the Administration module for system administration tasks. You can perform functions such as creating communication templates and setting up organizations.
- [Analytics module](#)  
You use the applications in the Analytics module to view scheduled reports and KPIs to analyze and understand information about the lifecycle and the maintenance of your assets.
- [Assets module](#)  
The Assets module contains applications that are designed to manage the assets that are owned or leased by your company from purchase to salvage, from the beginning to the end of the life cycle for an asset.
- [Building Information Models \(BIM\) module](#)  
You use the applications in the Building Information Models (BIM) module to import building model data in Construction-Operations Building information exchange (COBie) format and then manage and view building models in 3D. You can inspect assets and locations of the building, create work orders and service requests, and search for and create systems from the model.
- [Change module](#)  
You use the Activities and Tasks application, located in the Change module, to plan, to review, and to manage activities and tasks.
- [Contracts module](#)  
You use the applications in the Contracts module to manage contracts for labor rates, purchases, leases, warranties, and software. You can create different types of contracts and define the rules that govern each type of contract.
- [Financial module](#)  
You use the applications in the Financial module to define and manage currency codes, exchange rates, general ledger accounts and resource codes. You can also track project management costs.
- [Integration module](#)  
The Integration module contains a set of applications that help you to integrate the system with your enterprise applications. You also can create business flows between the system and your other enterprise applications.
- [Inventory module](#)  
You use the applications in the Inventory module to manage your inventory of spare parts. You can maximize the availability of items for upcoming work tasks, and also reduce excess inventory balances and related carrying costs.
- [IT Infrastructure module](#)  
The IT Infrastructure module (configuration process manager) applications enable management of the configuration items in your IT environment. They provide a logical model of the IT infrastructure by helping you to identify, control, maintain, and verify the versions of all configuration items in the environment and their attributes and relationships.
- [Planning module](#)  
You use the applications in the Planning module to plan how work should be performed, such as creating job plans that outline the steps that must be performed for each type of job.
- [Preventive Maintenance module](#)  
You use the applications in the Preventive Maintenance module to manage the work performed on a regular schedule to keep assets running efficiently. The applications can help you to plan and budget for regular maintenance work by planning the labor, material, service, and tool needs of your regularly scheduled maintenance and inspection work orders.

- **[Purchasing module](#)**  
You use the applications in the Purchasing module to manage the purchasing process, including obtaining requests for quotations (RFQs), purchasing the materials and services, and then receiving and invoicing them. The applications also help you to maintain information about the companies from which you purchase, and to integrate legal terms and conditions into the purchasing process.
- **[Release module](#)**  
You use the Activities and Tasks application to plan, review, and manage activities and tasks. When you create an activity, you initiate the work process and create a historical record of the work being performed.
- **[Security module](#)**  
You use the applications in the Security module to implement and manage security for users and groups.
- **[Self Service module](#)**  
Self-Service users (with proper permissions) can register themselves in the system and use the applications in the Self-Service modules (Desktop Requisitions and Service Requests) to create records without the assistance of an administrator or a service desk agent.
- **[Service Desk module](#)**
