IBM Maximo Manage documentation	1
Maximo Manage overview	1
Introduction to Maximo Manage	2
What's new in Maximo Manage	3
... in 8.6	3
... in 8.5	4
... in 8.4	6
... in 8.3	7
... in 8.2	8
... in 8.1	9
... in 8.0	10
What's new in Maximo Mobile	11
... in 8.10	12
... in 8.9	13
... in 8.8	14
Maximo Manage components	15
Accessibility features for Maximo Manage	15
Documentation conventions	17
Getting started with Maximo Manage	18
Start Center	18
Start Center portlets	18
Favorite Applications portlet	19
Inbox/Assignments portlet	19
KPI Graph portlet	19
KPI List portlet	19
Quick Insert portlet	20
Report List portlet	20
Result Set portlet	20
Managing Start Center templates	20
Creating a start center template	21
Changing start center templates	21
Changing existing Start Center templates	21
Creating Start Center templates in multiple languages	22
Configuring Result Set portlets	22
Applying colors to result set rows	22
Displaying related attributes in Result Set portlets	23
Changing the content and layout of the Start Center	23
Specifying a default Start Center	23
Editing portlets in the Start Center	24
Updating Start Centers	24
Operational dashboard	24
My profile information	25
Changing my default information	25
Changing my password information	25
Changing my personal information	26
Specifying the electronic signature key	26
Navigation	27
Bookmarks	27
Navigation bar	27
Keyboard shortcuts	27
Searching	29
Basic searches	29
Advanced searches	29
Searching by using examples	30
SQL WHERE clause searches	30
Wildcards and operators for searching	30
Navigation in location and asset hierarchies	31
Entering data and dates in fields	32
Specifying values	32
Keyboard shortcuts for dates	32
Printing documents	33
Printing individual attachments	33
Printing all attachments	33
Running, scheduling, and printing reports within an application	34
Planning for multiple sites	34
Multisite capability	35
Sites	35
Organizations	36
Product settings	36

Site settings	36
Organization settings	36
System settings	37
Security settings	37
When to create multiple organizations and sites	38
Levels in the hierarchy	38
Data storage levels	39
Applications and their data storage levels	40
Data sharing between organizations	44
Item sets and data sharing between organizations	44
Company sets and vendors shared between organizations	45
Selective data sharing	46
Transactions involving multiple sites in site-level applications	46
Limitations when setting up options in the Organizations application	47
Examples of using the multisite capability	48
Example: Multisite configuration with separate general ledger accounts	48
Example: Multisite configuration with separate maintenance and IT operations	49
Deploying Maximo Manage	50
Planning and preparing to deploy	51
System requirements	52
Configuring an internal image repository	52
Setting up your database	53
Database deployment planning	53
Preparing your database for deployment	54
Creating a database instance	54
Configuring Db2	55
Configuring IBM Cloud Pak for Data	57
Configuring Db2 Warehouse	57
Configuring Oracle Database	61
Configuring Microsoft SQL Server	62
Database encryption	63
Database encryption overview	63
Database encryption scenarios	64
Viewing database encryption history	65
Disabling automatic generation of encryption keys	66
Resetting the crypto and cryptox fields in the database	66
Troubleshooting database deployment	66
Demo data	67
Deployment of industry solutions and add-ons	67
Language support	68
Server bundle overview	69
Provisioning storage	70
Ephemeral storage overview	70
Configuring ephemeral storage	70
Persistent storage overview	71
Configuring persistent volume claims	71
Configuring persistent volume claims during deployment	72
Configuring persistent volume claims for server bundles	72
Monitoring agent for Maximo Manage	72
Monitoring metrics	73
Configuring Grafana dashboards	75
Prerequisites	76
Configuring Red Hat OpenShift monitoring service	76
Configuring PodMonitor for Maximo Manage	77
Verifying the monitoring data	78
Installing and configuring Grafana	78
Loading Maximo Manage dashboard into Grafana for Maximo Manage	80
Troubleshooting monitoring issues	80
Backing up and restoring Maximo Manage	81
Storing images in an external registry	81
Configuring Java Message Service (JMS) servers	82
Configuring JMS servers for Maximo Manage	82
Scaling JMS servers	84
Deployment planning worksheet	85
Deploying and activating Maximo Manage	85
Deploying the Manage application	86
Configuring the database	87
Selecting Manage components	88
Expanding the advanced configurations	89
Selecting languages	90
Setting the server bundles	90
Setting customizations	91

Setting server mode	92
Setting Persistent Volume Claims (PVC)	92
Setting build data interpreter (BDI)	92
Setting build tag	93
Setting certificates for integration	93
Setting server time zone	93
Setting asset investment optimization	93
Monitoring Manage application deployment by using the Maximo Application Suite interface	93
Activating Maximo Manage	94
IBM Maximo Manage tool	95
Monitoring Maximo Manage activation	95
Configuring Maximo Manage after deployment	96
Administering users	96
Configuring initial data	97
Changing database credentials	98
Upgrading from IBM Maximo Enterprise Asset Management to IBM Maximo Manage	98
Overview	99
Enterprise Asset Management to IBM Maximo Manage summary	99
Architecture and deployment models	100
IBM Maximo Application Suite architecture	100
Maximo Manage deployment model	101
Maximo Asset Management deployment	101
Maximo Manage deployment in Red Hat OpenShift Container Platform	102
Upgrading the Maximo environment	104
Upgrade prerequisites	104
Working with on-premises deployment calculator	105
Upgrade process overview	105
Authentication, security, and SMTP configuration	106
Upgrading to IBM Maximo Application Suite	107
Checking IBM Maximo Manage deployment status	107
Migrating users to IBM Maximo Application Suite	108
Migrating users - troubleshooting	108
Accessing Manage and troubleshooting	109
Validating customization archive	109
Managing users post upgrade	110
Viewing user synchronization information	111
Configuring Maximo Manage for upgrade	111
Overview of changes	112
Security and user management	112
Integration	114
Migrating to JMS provider	114
Migrating to Kafka	115
Supported JMS provider	115
Moving from JMS to Kafka	115
RMI replaced by REST API	115
Maximo properties	115
Changes in Maximo Application Suite	116
Configuring Maximo Manage for deployment	116
Customizing IBM Maximo Manage	119
Creating customization archives	120
Deployment descriptors	121
Using certificates	121
Configuring Oracle Connector	121
Configuring SAP Connector	122
Viewing Maximo Manage Logs	122
Monitoring	123
IBM Maximo Manage tool	95
Useful information	124
Maximo Application Suite licensing model	124
Manage Admin Docker image	125
Installing Docker	125
Getting the Manage admin docker image	125
Adding third-party JAR files	126
Debugging Maximo Manage application	127
Maximo Manage facts	128
Connecting to Red Hat OpenShift cluster from Windows	128
Useful links	130
Administering	130
Administrative tasks for IBM Maximo Application Suite	132
APIs for administrative utilities	132
Sending log output to S3 Cloud Object Storage	134
S3 buckets	135
Adding trusted certificates	135
Configuring databases	136

Database design	137
Relational database structure	137
Data dictionary tables	138
Integrity checker	138
Storage partitions	138
Business objects	139
User-defined objects	139
Configuration levels for objects	139
Database relationships	140
Business object attributes	140
Attribute data types	141
Views	141
Indexes	142
Primary keys	142
Defining objects for applications	142
Creating objects	142
Adding views to databases	143
Creating applications from imported database views	144
Specifying attributes for objects	144
Descriptions and long descriptions	144
Adding attributes to objects	144
Changing attributes	145
Creating restrictions on attributes	145
Excluding user-defined attributes when duplicating objects	146
Enabling autonumbering for attributes	146
Adding tax types to database tables	146
Adding indexes	147
Adding primary keys	147
Creating relationships between parent and child tables	148
Configuration of general ledger accounts	148
General ledger account codes	148
General ledger account components	149
Sequence of components	149
Length of components	149
Configuring the database	149
Modes of configuring the database	150
Configuring the database in administration mode	150
Database changes without administration mode	151
Configuring the system for regulatory compliance	151
Electronic signatures, audit records, and login tracking	152
Login tracking	152
Electronic audit records	152
Enabling electronic audits	152
Database updates for electronic audit	153
Electronic signature verification	153
Configuring electronic signature verification	154
Configuring email address for signature key resets	154
Configuring email subject lines and body text	155
Creating a drop-down list for the Reason for Change field	155
Adding electronic signature requirements	156
Resetting the electronic signature key	156
Controlling changes to objects	156
Defining lookup maps	157
Adding system messages	157
Query definitions	157
Search option configuration for performance optimization	158
Text search function	158
Search type configuration	158
Migration Manager	159
Getting started with Migration Manager	159
Migration environments	160
Migration process	161
Applications used in the migration process	162
What content you can migrate	162
Database configuration content	163
Compiled sources	163
Package definitions and packages	164
Snapshot packages	165
Change packages	165
Collection packages	166

Package definition status	166
Package status	166
Deletion of package definitions	167
Deletion of packages	167
Migration collections	167
Planning for migration	167
Migration participants and roles	168
Validation of database integrity	168
Migration and database backups	168
Migration scheduling	169
Determining the configuration content to migrate	169
Predefined migration objects and migration groups	169
Data Dictionary migration group	170
Document Library migration group	172
Application migration group	173
Resources migration group	174
Functional migration group	174
Application Security migration group	175
Reporting migration group	176
System migration group	176
Integration migration group	177
Business Process Management migration group	178
Migration migration group	180
Ticket Template Data migration group	181
Classification Data migration group	182
Interaction System Objects migration group	182
Interaction Artifacts migration group	183
Scripting System Objects migration group	184
OSLC migration group	185
Creating migration objects	185
Migration object processing sequences	186
Creating migration groups	186
Deletion of migration groups	186
Comparing source and target databases	187
Setting inbound restrictions	187
Migration limitations	187
Migration reports	190
Migrating your configuration content	190
Setting up migration collections	191
Exporting and importing configuration records to and from external systems	191
Exporting migration collection records	191
Downloading exported migration collection records	192
Importing migration collection records	192
Creating migration collections	192
Capturing events in migration collections	192
Defining the related configuration records in migration collections	193
Validating migration collections	193
Enabling users to add records to migration collections	194
Setting up package definitions	194
Defining target environments and their distribution types	194
Creating package definitions	195
Attribute replacements	195
Selecting attributes to replace during deployment	195
Creating package definitions from a migration collection	196
Creating packages	196
Distributing packages	196
Deploying packages	197
Deployment overview	197
Deployment previews	198
Deployment steps and package content	199
Deployment to an environment that has different products or versions	199
Deployment of a package to its source environment	200
Attribute replacement rules	200
Defining attribute replacement rules in a target environment	200
Uploading packages to a target environment	200
Increasing the package size upload limit	201
Deploying a package	201
Downloading compiled sources	202
Deployment data errors	202

Correcting deployment data errors	202
Post-deployment activities	202
Migration troubleshooting	203
Migration logger	203
Package creation errors	204
Package distribution errors	204
Package deployment errors	204
Migration error messages	205
Managing communication templates	207
Communications template overview	207
Communication templates and escalations	207
Communication templates and the service desk	208
Communication templates and workflow	208
Substitution variables for communication templates	208
Predefined communication templates	208
Recipients of communication templates	209
Attachments for communication templates	209
Communication logs	209
Working with communication templates	209
Creating communication templates	209
Adding email addresses as communication template recipients	210
Adding person groups as communication template recipients	210
Adding persons as communication template recipients	211
Adding roles as communication template recipients	211
Attaching documents to communication templates	211
Attaching document folders to communication templates	211
Attaching files to communication templates	212
Attaching web pages to communication templates	212
Linking records to communication templates	212
Copying communication templates	212
Changing communication templates	213
Deleting communication templates	213
Changing the status of communication templates	213
Managing escalations	213
Escalations overview	214
Escalation engine	214
Escalation logs	214
Structured Query Language Expression Builder	215
Escalation points	215
Actions associated with escalation points	215
Predefined escalations	216
Escalations and service level agreements	216
Communication templates and notifications	217
Escalation record fields	217
Deletion rules for escalations	217
Working with escalations	218
Creating escalations	218
Defining escalation points	218
Defining actions for escalation points	219
Defining notifications for escalation points	219
Validating escalations	219
Activating escalations	220
Modifying escalations	220
Deactivating escalations	221
Enabling email updates for objects and workflows	221
Email interaction overview	221
Simple and advanced email formats	221
Email variables in email interaction	222
Examples of email interaction	222
Example: Enabling email updates to purchase orders	222
Example: Enabling email updates to workflow assignments	223
Configuring updates by using email interaction	224
Managing cron tasks	224
Cron task setup overview	224
Preexisting cron tasks	225
Access levels for cron tasks	225
Cron task parameters	225
Instances of cron tasks	226
Owner and Issuer for cron task instance	226
Working with cron tasks	227

Creating cron task definitions	227
Deleting cron task definitions	227
Working with instances of cron tasks	227
Creating cron task instances	228
Copying cron task instances	228
Changing cron task instances	228
Reloading cron task instances	229
Deleting cron task instances	229
Disabling cron tasks for a server bundle	229
Viewing hidden cron tasks	230
Managing domains	230
Domains overview	230
Types of domains	230
ALN domains	231
Numeric domains	231
Numeric range domains	231
Crossover domains	232
Synonym domains	232
TABLE domains	233
Foreign keys and TABLE domains	233
Domains and organizations or sites	233
Working with domains	233
Adding alphanumeric domains	234
Adding numeric domains	235
Adding numeric range domains	235
Adding table domains	236
Adding crossover domains	237
Associating domain values with conditions	238
Creating synonyms of internal values	238
Deleting synonyms of internal domain values	239
Deleting domains	239
Applications associated with domains	239
Linear assets management	240
Linear components	241
Linear referencing	241
Features application	242
Relationships and linear assets	242
Linear asset classifications	242
Linear segment details	243
Configuring security	243
Enabling application components	244
Configuring a linear reference	244
Creating units of measure	244
Configuring conversion factors	245
Creating a linear referencing method	245
Configuring a linear asset segment	246
Creating linear assets	246
Classifying a linear asset	247
Creating features	247
Associating features with linear assets	248
Example of reference points that are outside the span of a linear asset feature	248
Creating relationships	248
Retrieving related assets	249
Creating a route based on relationships	249
Linear segment label and balloon tip formatting	249
Configuring balloon tips and label messages for Linear Visual Control segments	250
Customizing the default label and balloon tip information for new organizations	250
Locating Linear features on the map from the Linear Visual table	250
Deleting Linear segments on maps	251
Managing data by using the Linear Visual Control grid on the map	251
Configuring the appearance of Linear object symbols in the Linear Visual Control display	251
Configuring the appearance of Linear object symbols in maps	252
Organizing work on a linear asset	252
Creating start and end features	252
Creating a work order with multiple assets	252
Searching for work orders using linear measures	253
Creating a work order on an asset feature	253
Tracking the progress of work on a linear asset	253
Importing linear assets from an external system	254
Import of linear assets from an external application	254

Performing the import	254
Configuring the asset object structure	254
Creating import files	254
Running the import	255
Configuring features and relationships for import	255
Creating an object structure	256
Creating an enterprise service	256
Reference information for linear asset controls	256
Conditional components	257
Linear components in the Assets application	257
Linear components in the Classifications application	258
Linear components in the Condition Monitoring application	258
Linear components in the Features application	258
Linear components in the Preventive Maintenance application	258
Linear components in the Quick Reporting application	258
Linear components in the Routes application	258
Linear components in the Work Order Tracking application	259
Linear components in the Create Service Request application	259
Linear components in the View Service Request application	259
Linear components in the Service Requests application	259
Nonlinear components used by the product	259
Visual control tools	260
Linear asset terminology	260
Planning and scheduling work	261
Scheduling roles	262
Scheduling terms	263
Rolling schedules	263
Date calculation and display	263
Date constraints in schedules	264
Best practices: Data preparation for scheduling	264
Performance considerations for scheduling work	265
Graphical view	265
Graphical view navigation	266
Record movement in the graphical view	266
Sorting columns in the graphical view	267
Filtering data in the graphical view	267
Quick filter	268
Zoom options in the graphical view	268
Refreshing data in the graphical view	268
Uncommitted work	269
Graphical view tips	269
Graphical view customization	270
Defining shift colors	271
Configure Tooltips application	272
Configuring tooltips	272
Configuring default settings in the graphical view	272
Managing schedules	272
Schedules overview	273
Graphical view for schedules	273
Resource planning in schedules	273
Scheduling Alternate Resources application	274
Defining alternate resource availability	274
Asset and location availability	275
Status of schedules	275
Schedule duplication	275
Time zones in the graphical view	276
CPM in schedules	276
Percent complete display and calculations	276
Displaying percent complete in the graphical view	277
Schedule compliance calculation	277
Viewing costs associated with scheduled work	278
Forecast costs for preventive maintenance	278
Evaluating project performance	278
Evaluating maintenance planning	279
Evaluating resource load and availability	279
Calculating schedule compliance with a cron task	279
Scheduling work in the graphical view	280
Creating schedules	280
Sample queries	281
Scheduling work based on resource availability	282

Managing precedence constraints in the Graphical Scheduling application	282
Predecessor relationships	282
Interruptible and uninterruptible tasks	283
Committing schedule and work list data	283
Scenarios	283
Comparing scenarios	284
Published schedules	284
Snapshots	284
Graphical Scheduling application	285
Graphical Scheduling - Large Projects application	285
Scheduling dashboard	285
Adding schedules to the Scheduling dashboard	286
Viewing resource utilization on the Scheduling dashboard	286
Viewing resource leveling on the Scheduling dashboard	286
Fixing scheduling issues on the Scheduling dashboard	287
Monitoring optimization progress on the Scheduling dashboard	287
Removing schedules from the Scheduling dashboard	287
Managing assignments	287
Assignments overview	288
Assigning work	288
Splitting work between people and shifts	289
Rescheduling assignments	289
Assigning emergency work	289
Exporting assignment calendars	289
Resource availability for assignments	290
Graphical Assignment application	290
Creating work lists	291
Dispatching work	291
Preparing to dispatch labor and crews	292
Responding to labor and crews unavailability	292
Responding to emergency work	292
Geolocation of labor and crews	293
Street level route cron task	293
Work zones	293
Graphical Assignments - Repair Facility application	293
Repair facilities	293
Creating work lists	294
Assigning work to repair facilities	294
Asset availability in repair facilities	294
Checking asset availability in repair facilities	295
Managing short term work	295
Graphical Work Week application	295
Creating work lists in the Graphical Work Week application	295
Modifying availability in the Graphical Work Week application	296
Balancing resource loads and assigning work	296
Managing resources	297
Graphical Resource View application	297
Creating resource lists	297
Modifying availability in the Graphical Resources View application	297
Managing crews graphically	298
Resources in the Graphical Crew Management application	298
Creating crew lists	298
Adjusting crew assignments	299
Validating data	299
Scheduler Data Manager application	299
Validating schedule data	300
Troubleshooting data validations	300
Calendar validations	301
Query validations	302
Work validations	302
Dependency validations	303
Assignment validations	303
Resource validations	303
Managing appointment books	304
Appointment Book Manager application	304
Creating appointment books	304
Viewing appointments in an appointment book	305
Modifying available appointments in an appointment book	305
Managing access to appointment books	305

Graphical Appointment Book application	305
Scheduling appointments	306
Rescheduling appointments	306
Canceling appointments	306
Enabling communication templates for appointments	306
Managing weather	307
Configure Weather Forecast application	307
Enabling weather panels in applications	307
Configuring weather panels	308
Weather data customization	308
Configuring Weather Alerts application	308
Configuring weather alerts	309
Enabling weather alerts by using cron tasks	309
Optimizing schedules	309
IBM® Maximo® Optimizer optimization models	310
Optimization templates	311
Running optimization	311
Monitoring optimization processes	311
Example of comparing optimization scenarios	312
Managing calibration assets and standards	312
Documenting instrument specifications by using data sheets	312
Data sheets	313
Asset functions	314
Asset function parameters	314
Calibration points	315
Dynamic checks	315
Functional checks	315
Uncertainty measurement for calibration	315
Non-linear instruments in data sheets	316
Tolerance limits on data sheets	316
Creating data sheets	316
Revising the version of a data sheet	317
Associating work assets with data sheets	317
Duplicating the asset function of a data sheet	317
Calibration calculations	318
Symbols used in calibration formulas	318
Tolerance criteria for calibration calculations	319
Single tolerance for calibration calculations	319
Summed tolerance for calibration calculations	320
Square root tolerance for calibration calculations	320
Reverse flow calculation for calibration calculations	321
Defining calibration procedures, assets, tools, and locations	321
Calibration procedures	322
Calibration job plans	322
Revising calibration job plans	322
Associating data sheets to a work asset on a job plan	322
Calibration assets	323
Rotating and nonrotating measuring and test equipment	323
Creating an asset record for measuring and test equipment	323
Tools used for calibration	324
Creating a tool record	324
Adding alternate tools to a tool record	324
Associating data sheets to a tool record	324
Loop locations	325
Adding a location to a loop calibration	325
Attaching data sheets to a location record	325
Configuring calibration features	325
Configuring options for organizations	326
Configuring calibration options for organizations	326
Configuring edit rules for calibration work orders	326
Configuring calibration features for uncertainty data	326
Creating the data sheet template object structure	326
Source object information: Data sheet template object structure	327
Creating the work order data sheet object structure	327
Source object information: Work order data sheet object structure	328
Creating publish channels for the object structures	329
Creating enterprise services for the object structures	329
Configuring the external system	329
Recording calibration data in work orders	330
Work order tracking in calibration	330

Associating data sheets to a work order	330
Viewing the calibration history of data sheets	331
Checking the status of a tool	331
Recording tool spot check results	331
Entering calibration results on a work order data sheet	331
Adding a calibration point to a work order data sheet	332
Extending due dates of calibration PM records	332
Overriding extended dates of calibration PM records	332
Viewing PM extended dates	333
Administering and configuring attached documents	333
Configuring attached documents	333
Preparing storage repositories	333
Adding persistent storage parameters to deployments	334
Configuring system properties for persistent storage	334
Configuring system properties for S3	335
Converting file-based storage to S3 storage	335
Administering attached document libraries	336
Adding document folders	336
Associating document folders with applications	337
Adding file attachments to the library	337
Adding URLs to the library	337
Modifying existing documents	337
Attaching documents to records	338
Enabling edit mode	338
Edit mode for records that are used frequently by multiple users	338
Configuring edit mode	339
Releasing records from edit mode	339
Log management	339
Log output locations	339
Sending log output to S3 Cloud Object Storage	134
Managing log files	341
Logging application components	341
Application of logger settings	342
Working with log files	342
Specifying local log file locations	342
Managing appenders	343
Automation scripts loggers	343
Log control of individual scripts	343
Cron task loggers	343
Adding a rolling logger for the PMWoGen cron task	344
Escalation loggers	344
Integration framework loggers	345
Enabling the EventTracker filter	345
Logging events for specific applications or users	346
Enabling logging for application server security synchronization	346
Stopping the logging of events	346
Correlation of related events in logs	347
Configuring custom log messages to help with debugging	348
Enabling thread logs	348
Scenario: Interpreting log file statements to resolve errors	348
Viewing Maximo Manage Logs	122
Managing bulletin boards	350
Bulletin board overview	351
Communication logs for bulletin board messages	351
Working with bulletin boards	351
Viewing bulletin board messages	351
Creating bulletin board messages	352
Specifying audiences for bulletin board messages	352
Changing the status of bulletin board messages	352
Copying bulletin board messages	352
Viewing communication logs for bulletin board messages	353
Viewing the history of bulletin board messages	353
Deleting expired bulletin board messages	353
Working with sets	353
Creating item sets or company sets	353
Changing item or company sets	354
Managing organizations	354
Organizations overview	354
Application levels and data storage	355
Sites and organizations	355
Activation and deactivation of organizations and sites	356

Item sets	356
Autonumbering	356
ABC breakpoints and organizations	357
Enablement of repair facilities	357
Customization options for applications	357
Taxes for organizations	358
Drilldown options	358
Working with organizations	359
Creating organizations	359
Activating organizations	359
Deleting organizations	360
Clearing material reservations for work orders	360
Specifying options for work orders and ticket owners	360
Setting purchasing options	360
Associating properties with contracts for organizations	361
Associating terms and conditions with contracts for organizations	361
Specifying options for invoices	361
Specifying autonumbering for applications	362
Specifying autonumbering for special order items	362
Displaying user messages	362
Managing calendars	362
Calendars overview	363
Shift patterns for calendars	363
Exceptions to the standard calendar	363
Working with calendars	363
Creating calendars	364
Specifying shifts in calendars	364
Applying shifts to calendars	364
Specifying shift patterns in calendars	365
Specifying shift breaks in calendars	365
Copying calendars	365
Deleting calendars	366
Establishing work periods	366
Creating work periods	366
Changing work periods	366
Specifying non-working time for work periods	367
Managing classifications	367
Classifications overview	367
Classification paths and hierarchies	368
Generate Description option	368
Associations of records with classifications	369
Classification searches	369
Actual and authorized configuration item classifications	369
Actual configuration items	369
Authorized configuration items	370
Actual configuration item classifications and authorized configuration item classifications	370
Attributes of classifications	370
Groupings of attributes	370
Apply Down Hierarchy option	371
Classifications planning	371
Types of records to be classified	371
Categories of items for reporting	371
Industry codes	371
Working with classifications	372
Creating classifications	372
Associating attributes with records	372
Modifying classifications	373
Modifying attributes	373
Adding attributes	373
Searching for classifications from application records	374
Defining associations between actual and authorized configuration item classifications	374
Adding units of measure	374
Configuring the signature option to enable classification images	375
Managing charts of accounts	375
Chart of accounts overview	375
General ledger account codes	375
Organizational default accounts for general ledgers	376
Merge of general ledger accounts	376
Resource codes for general ledgers	376
Inactive component values	376

Working with chart of accounts	377
Working with general ledger accounts	377
Creating general ledger account codes	377
Changing general ledger account codes	378
Deleting general ledger account codes	378
Creating general ledger component values	378
Changing component values in general ledger accounts	379
Deleting general ledger component values	379
Changing general ledger account structures	379
Updating databases for general ledger accounts	380
Setting up accounts	380
Setting up organization default accounts	380
Specifying company-related accounts for general ledgers	381
Specifying external labor control accounts for general ledgers	381
Specifying financial periods for general ledgers	381
Closing financial periods	382
Specifying resource codes for general ledgers	382
Specifying validation options	382
Working with cost management	383
Creating cost management projects	383
Managing currency codes	383
Creating currency codes	383
Changing currency codes	384
Setting system properties	384
Global properties	384
Options for system properties	384
Values for system properties	385
System properties that contain password information	385
Memory errors	385
Automating routine tasks with automation scripts	386
Automation scripts	387
Creating automation scripts	387
Example: Automating assigning service requests	388
Example: Result of automating the assignment of service requests	388
Example: Assigning the service group to the service request	388
Example: Creating the action launch point and script	389
Example: Creating the escalation	389
Example: Testing the configuration	389
Example: Actions performed by the example script	390
Example: Work log creation by using MBO APIs	390
Example: Automating communication by using a custom role	391
Launch points	391
Script with an object launch point	392
Script with an attribute launch point	393
Script with an action launch point	393
Script with a custom condition launch point	394
Script without a launch point	394
Examples of MBR scripts	395
Variables in automation scripts	396
Launch point variables	396
Implicit variables	397
Service.log() method	399
Data retrieval by using variable bindings	399
Relationship notation and path	399
Single value retrieval	400
Multiple value retrieval	400
Array notations as filters	400
Example: Array notations in automation scripts	401
Gathering user input by using choice messages in automation scripts	401
Example: Configuring choice messages	402
Reusable library scripts in automation scripts	403
Scheduling automation scripts to run as part of cron tasks	403
Creating cron tasks that run automation scripts	403
Variables in automation scripts that run as cron tasks	404
Adding scripts that run as asynchronous jobs	404
Automation scripts for integration	405
Debugging with automation scripts	405
Log statements in the application framework	405
Print statements	405
Finding debug files	405
Testing automation scripts	406

Error messages for users	406
Error messages created with automation scripts	406
Displaying error messages	407
Creating scripts to manage attachments	407
Interface methods	408
Managing building information model data	408
Building information modeling (BIM)	409
COBie standard data	409
Classifications for building information models	410
Configuring Maximo Manage for Building Information Models (BIM) applications	410
Signature options for Building Information Models applications	411
Configuring building information model data	412
Defining system settings for building information modeling (BIM) data	412
Importing OmniClass classifications	412
Configuring BIM projects	413
Defining filters	413
Creating maps from COBie attributes to Maximo business objects specifications and fields	414
Creating projects	414
Creating system maps for COBie systems	414
Configuring data for building models	415
Configuring data for Maximo Manage	415
Importing model data into Maximo Manage	415
Validating data	416
Importing validated data	416
Updating imported data	417
Merging design data with existing data	417
Exporting data from Maximo Manage to COBie	418
Commissioning buildings	418
Managing building models	418
Configuring the Building Information Modeling (BIM) viewer	419
Associating building models with locations	419
Building models viewer	419
Attribute maps for COBie data	420
Contacts	420
Facility	421
Floor	422
Space	422
Component	422
Zone	423
System	423
Job	423
Attributes	424
Document	424
Resource	425
Assembly	425
Monitoring maintenance budgets	425
Budget Monitoring	425
Configuring budget monitoring	426
Creating budget records	426
Predefined focal points and calculation rules	426
Removing personal information from records	427
Removal of personal information	427
Deleting personal information	428
Example: Deleting transactional references	428
Customizing the application	429
Customization archive guidelines	429
Adding customizations to the application	431
Configuring server bundle properties	432
Configuring the application server	433
Configuring JVM options	433
Retrieving administrative images	434
Setting up a local Maximo Manage development environment	434
Installing Podman and exposing the default route	435
Preparing a development environment	435
Pulling and tagging base images	435
Building and deploying development images	436
Configuring the Help menu	437
Managing Maximo Mobile	437
Introduction to Maximo Mobile	438
Overview of Maximo Mobile authentication and data flow	440
Device requirements for Maximo Mobile	441
Defining security privileges for Maximo Mobile role-based applications	441

Installing the Maximo Mobile app on mobile devices	441
Configuring self-signed certificates for the Maximo Application Suite server on iOS devices	442
Configuring self-signed certificates for Maximo Application Suite on Android devices	442
Configuring self-signed certificates for the Maximo Mobile Windows application	442
Setting the URL of the Maximo Application Suite server in the Maximo Mobile app	443
Configuring Map Manager	444
Offline areas	445
Creating replicas and downloading to mobile devices	445
Creating and downloading vector tile packages	446
Map toolbar functions	446
Creating a service address with map location	447
Preloaded data on mobile devices	447
Creating preloaded data for mobile devices	448
Refreshing data	448
Troubleshooting Maximo Mobile	449
Troubleshooting applications on Android	449
Configuring Maximo Mobile	449
Configuring default bar code formats	450
Configuring properties that affect mobile apps	450
Push notifications	452
Integrating Apache Kafka queues with Maximo Manage	452
Integrating JMS queues with Maximo Manage	453
Creating and configuring API keys for push notifications	453
Configuring Maximo Application Suite notifications	454
Recording physical signatures	455
Recording e-signature keys	455
Configuring application links	456
Enabling photo analysis by IBM Maximo Visual Inspection	456
Configuring and customizing applications with the Maximo Application Framework (MAF) Configuration application	457
Prerequisites	457
Component reference	458
Deprecated Maximo Application Framework components	458
container	458
Serviceability	459
Removing Docker containers through the command line	459
Command variable legend	459
Configuration and customization summary	460
Maximo Application Framework Configuration application deployment	460
Environment configuration	460
Downloading the Docker container image	461
Running the Docker image	461
Maximo Application Framework Configuration application use	462
Authorizing with the Maximo Manage server	462
Connect to the Maximo Manage server	462
Modifying applications	462
Application revisions	463
Application preview	463
Duplicating applications	463
Redownloading applications	464
Deleting applications	464
Application upgrade	464
Upgrade example	465
Configuring an application	465
Creating a delta file	466
Applying the delta file	467
Upgrading duplicated applications	467
Anatomy of an application XML file	468
Datasources	470
Maximo Mobile Queries	471
Filtering records returned from a query	473
Changing a query	473
Adding an owner group reference on a work order	473
Maximo Mobile REST APIs	474
Maximo Mobile application object structures, query information, and security authorization	475
Security and user management	477
User creation, authentication, and synchronization	477
Security group synchronization and default assignments	478
User processing by the integration framework	479
License type updates	479
Upgraded users	480
Configuring security groups	480
Security groups overview	480
Combination of security groups	481

Authorizations for security groups	482
Security profiles	484
Creating security groups	484
Creating Work Center and Tool security groups	484
Security access for inventory clerks	485
Example: Specifying security access for technicians	485
Application templates	486
Granting administrative login authorization for database configuration	486
Authorizing standard services for security groups	486
Authorizing security group reassignments for users	487
Setting user defaults	487
Deleting users from security groups	488
Deleting security groups	488
Managing users	489
Users overview	489
Administrative users	489
Database users	490
System users	490
Self service users	490
Security controls	491
Security profiles for users	491
Resending multiple users from Maximo Manage to Maximo Application Suite	491
Database access for users	491
Default insert sites for users	491
Working with users	492
Assigning users to security groups	492
Authorizing users to assign other users to security groups	492
Changing persons associated with users	493
Configuring user settings	493
Deleting security groups from user profiles	493
Setting signature key requirements	494
Configuring user authorizations	494
Specifying security groups for users	494
Specifying security profiles for users	494
Specifying security profiles for multiple users	495
Granting user access to Oracle and Structured Query Language server databases	495
Changing user access to Oracle and Structured Query Language server databases	495
Removing user access to Oracle and Structured Query Language server databases	496
Setting user defaults	487
Implementing additional security	497
Login tracking	497
Enabling and disabling login tracking	497
Work Centers	497
Introduction to Work Centers	498
Administering Work Centers	498
Enabling tasks as work orders	499
Enabling technicians to create work orders	500
Disabling access to learn more links	500
Managing notifications	501
Creating notification message templates	501
Creating notification events	501
Consuming notification events	502
Changing the deletion frequency of notifications	502
Configuring service requests	502
Configuring service request properties	503
Configuring categories for service requests	503
Configuring integration	503
Analyzing data	504
Business Analysis Work Center	504
Data Set Designer	504
Managing inventory	504
Items	505
Importing item data	506
Item statuses	506
Condition-enabled items	506
Adding condition codes and rates to items	507
Storeroom management	507
Issuing items	508
Transferring rotating items	509
Managing reorder rules	509
Cycle counting	509

Reconciling inventory balances	510
Inventory reservations	510
Issuing items	511
Returning issued items	511
Issuing, transferring, or deleting reservation batches	511
Picking and staging inventory	512
Inventory pick and stage	512
Creating and processing pick lists	513
Managing assets and locations	514
Assets	514
Adding asset types	515
Importing assets	515
Asset import guidelines	515
Moving assets	516
Locations	516
Defining locations	517
Systems	517
Location import guidelines	518
Adding locations to systems	518
Adding location types	519
Location import guidelines	518
Configuring autonumbering for assets and locations	520
Managing work	520
Work order management	521
Work orders and job plans	522
Work orders and inspections	522
Creating work orders	522
Reviewing service requests	523
Completing work orders	523
Creating work orders	524
Configuring Work Centers	524
Configuring header information	524
Configuring subheader information	525
Configuring panel or tab information	525
Configuring cards	525
Saving and publishing configurations	526
Viewing revision history	527
Managing inspection forms	527
Creating inspection forms	528
Revising inspection forms	528
Adding conditions to inspection form responses	529
Duplicating inspection forms	529
Associating inspections with work records	529
Configuring actions for inspections	529
Enabling voice-guided inspections	530
Conducting inspections	531
Conducting inspections	531
Creating unscheduled inspections	531
Submitting service requests	532
Creating service requests	532
Example: Responding to a user problem	532
Developing applications	533
Application framework	533
Preparing the development environment	534
Setting up the environment	535
Exploring the workspace	535
Design guidelines	535
Data validation	536
Server-side validation	536
Client-side validation	537
Autofill properties	537
Configuring autofill properties	537
Example: Configuring autofill for the Affected Person field in service requests	538
Error notification for client-side validation	538
Best practices for data validation types	538
Property configurations	539
Developing applications	539
Creating and modifying applications	540
Duplicating applications	540
Creating applications	540
Deleting an application	541
Creating restrictions	541
Creating application restrictions	542

Restricting data	542
Restricting the data returned from the database	542
Examples of restrictions on the data that users see	542
Defining signature options	544
Arranging the layout of controls	544
Laying out a new tab	544
Merging classification attribute values into one column	544
Controlling the size of fields	545
Specifying size ranges for data types	545
Specifying the size of single fields	545
Adding images	546
Adding images to the images directory	546
Adding a record image to an application	546
Configuring default values for controls	547
Assigning a default label to an attribute	547
Saving changes to the database	547
Overriding a value in the default label field	548
Assigning a default value to an application field	548
Setting default filters for a table window	548
Adding a value list to a text field	548
Moving application controls	549
Moving controls across tabs	549
Moving controls across applications	550
Moving components and applications across servers	550
Exporting multiple applications	550
Adding navigation components	551
Navigation components	551
Linking to an external URL	552
Linking to an application from a text field	552
Adding buttons to the application toolbar or Common Actions menu	552
Adding buttons next to text boxes	553
Example: Adding buttons next to a multipart text box	553
Adding options to the Select Action menu or More Actions menu	554
Modifying links in a self-service application	554
Configuring related information for fields	554
Example: Enabling an existing hover window	554
Example: Creating hover windows	555
Providing user information	555
Adding messages to the messages table	556
Linking to user information	556
Configuring dialog windows for an application	556
Modifying an application dialog window	557
Modifying a system dialog window	557
Creating a dialog window	557
Transferring data between applications	558
Data transfer options	558
Linking objects to share data between applications	558
Adding a comment attribute to an asset	558
Linking objects in different applications	559
Adding a text box for comments	559
Using crossover domains to share data between applications	560
Adding a comment attribute to an asset	558
Adding a comment attribute to a work order	560
Creating a crossover domain	561
Applying a crossover domain	561
Adding a text box for comments	559
Configuring conditional components	562
Conditional user interface	562
Hierarchy of restrictions	563
Creating conditions	563
Conditions	564
Creating conditional expressions and classes	564
Conditional expression syntax	564
Sample conditional classes	565
Applying conditional security	565
Conditional security	566
Defining signature options	544
Removing a signature option from a UI control	566
Applying signature options to show UI controls	567
Showing controls to some users	567

Applying conditional data restrictions	567
Conditional data restrictions	568
Specifying data restrictions for security groups	568
Specifying global data restrictions for security groups	568
Adding conditions to the properties of UI fields	569
Adding conditions to determine access to UI controls	569
Adding conditions to hide user interface controls	569
Application developer properties	570
Control properties	570
Application bar control	571
Attachments control	572
Blank line control	572
Breadcrumbs control	572
Button group control	573
Check box control	573
Combo box control	574
Data source control	575
Default value control	576
Help grid control	576
Hover window control	577
Hyperlink control	577
Icon menu control	577
Image control	578
Include control	578
List box control	578
Menu bar control	579
Multiline text box control	579
Multipart text box control	580
Parameter value control	582
Parameter values control	582
Presentation control	582
Push button control	583
Radio button control	584
Radio button group control	584
Record image control	585
Rich text editor control	585
Rich text viewer control	586
Section control	587
Section column control	588
Section header control	588

Operating location GL account	604
Preventive maintenance GL account	604
Resource codes	604
Inventory resource code	604
Labor resource code	604
Tool resource code	604
Resource control accounts	604
External labor control account	605
External tools control account	605
Internal labor control account	605
Internal tools control account	605
Tax accounts	605
Paid tax GL account	606
Unpaid tax GL account	606
Financial processes common information	606
GL account transaction processes	606
GL account tracking	608
Displayed fields	608
Database fields	609
Financial processes in the Assets module	609
Financial processes in the Assets application	609
Move/Modify Assets action	610
Move and modify assets between operating or other non-storeroom locations	610
Move rotating assets from non-storeroom location to storeroom or inventory control location	610
Move rotating assets from non-storeroom location to storeroom or other inventory-type location	611
Swap Assets action	611
Financial processes in the Locations application	612
Financial processes in the Inventory module	612
Financial processes in the Item Master application	612
Change status from non-capitalized to capitalized	612
Change status from capitalized to non-capitalized	613
Financial processes in the Inventory application	614
Inventory costing	615
Insert Item action	616
Adjust Current Balance actions	616
Adjust Physical Count action	616
Reconcile Balances action	617
Adjust Standard Cost action	618
Adjust Average Cost action	618
Issue Current Item action	619
Return an Item action	619
Transfer Current Item action	620
Assemble and Disassemble Kit actions	620
Receipt adjustment transactions	621
Financial processes in the Inventory Usage application	622
Issue an item within one site	622
Issue an item between sites within the same organization	622
Return a previously issued item	623
Transferring items	623
Transferring items via shipments	624
Database transactions	624
Financial processes in the Tools application	626
Financial processes in the Issues and Transfers application	626
Issue an item within one site	626
Issue an item between sites within the same organization	627
Return a previously issued item	627
Transfer out	627
Transfer in	628
Database transactions	629

Financial processes in the Preventive Maintenance module	631
Financial processes in the Preventive Maintenance application	631
Financial processes in the Purchasing module	631
Financial processes in the Companies application	632
Financial processes in the Purchase Requisitions application	632
Material requisitions for a storeroom	632
Material requisitions for a direct issue	632
Material requisitions from an internal vendor	633
Material requisitions from an internal vendor in a different organization	633
Service purchase requisitions	633
Standard service purchase requisitions	634
Rotating asset purchase requisitions	634
Financial processes in the Purchase Orders application	634
Material orders from an external vendor	634
Receiving application	635
External material receipts into a storeroom	635
External material receipts issue on receipt	635

Importing workflow processes	681
Workflow/Inbox Assignments portlet	681
Configuring the Workflow Inbox	681
Configuring administrator email notifications	682
Reassigning workflow assignments	682
Sending reassignment notifications	682
Completing workflow assignments	682
Deleting assignments	683
Integrating data with external applications	683
Integration framework overview	684
Architecture	684
Integration framework components	685
Message provider enablement	686
Framework for operational management product integration	686
Framework for user interface integration	686
Integration with Apache Kafka	686

Specifying a Kafka provider	687
Registering Kafka topics as Maximo Manage queues	688
Configuration of the Kafka cron task	688
Guidelines for Kafka cron task configuration	689
Kafka message processing	689
Error processing with an Apache Kafka provider	691
Expired message cleanup	691
Managing Kafka offset values in Maximo Manage	692
API requests for browsing Kafka queues	692
Enabling data export and import through message queues	693
Configuring system properties for JMS queues	693
Activating the cron task for JMS queues	693
Exporting data to a test file	694
Importing data from a test file	694
Configuring Java Message Service (JMS) servers	82
Configuring JMS servers for Maximo Manage	82
Scaling JMS servers	84
Integration components	697
Object structures	697
Identification of object structure data	698
Alternate keys	698
Object fields	698
Interface table and flat file considerations	698
Modification of a predefined object structure	699
Configuring an object structure	699
Creating object structures	699
Configuring an alternate key	700
Including nonpersistent fields in the object structure	700
Excluding persistent fields from the object structure	701
Resolving alias conflicts	701
Setting restrictions on fields for inbound messages	701
Setting advanced configurations for an object structure	702
Message templates that specify outbound data	702
Publishing channels and services	702
Publish channels	702
Creating publish channels	703
Enabling publish channel listeners	703
Invocation channels	704
Creating invocation channels	704
Configuring an action to call an invocation channel	704
Invoking an external system from an application	705
Object structure services	705
Enterprise services	705
Configuring an enterprise service	706
Creating an enterprise service	706
Configuring additional object structures for an enterprise service	707
Adding gateway properties to an enterprise service	707
Standard services	707
Endpoints and handlers	708
Configuring an endpoint	708
Creating endpoints	708
Adding a handler to an endpoint	709
Writing custom handlers	709
Predefined endpoint handlers and properties	709
Enterprise bean handler	710
Flat file handler	711
Kafka handler and properties	712
HTTP handler	712
S3 handler and properties	714
IFACETABLE handler	714
JMS handler	714
Web service handler	716
Web service handler (JAX-WS)	717
XML file handler	718
Command line handler	718
Configuring OAuth access	719
Web services	720
Web service sources	720
JMS queue settings for enterprise web services	721
Implementing SOAP 1.1 and 1.2 with JAX-WS web services	721
Web service deployment options	722

Web service deployment actions	723
Schema generation	723
Generation of a Web Services Description Language file	723
UDDI registration	724
Creating and deploying web services	724
Creating a web service	724
Deploying a web service to the product web service container	725
Deploying a web service to the application server web service container	725
Updating schema information	725
Web service interactions overview	725
Creating interactions	726
Configuring an external system	726
Creating an external system	727
Specifying a Kafka provider	728
Enabling an external system	728
Enabling a publish channel	728
Associating a publish channel with an external system	729
Selecting publish channels for the external system	729
Adding an endpoint to a publish channel	729
Importing file-based data	730
Enabling an enterprise service	730
Associating an enterprise service with an external system	731
Selecting enterprise services for the external system	731
Selecting an enterprise service queue type	731
Exporting data	732
Exporting data in sequential batches	732
Importing file-based data	730
Importing data by using a REST API call	734
Registering Kafka topics as Maximo Manage queues	688
Adding JMS queues to an external system	735
Creating interface tables	736
Working with integration controls	736
Setting up a Boolean control	736
Setting up a cross-reference control	737
Setting up a list control	737
Setting up a value control	738
Overriding values for a cross-reference control	738
Overriding values for a list control	739
API keys application	739
Searching for API keys	740
Sorting API keys	740
Adding API keys	740
Copying API keys	741
Deleting API keys	741
Changing the layout	741
Managing columns	741
Viewing APIs with filters	741
Predefined integration content	741
Master data objects	742

Integration data processing	777
Planning to process data for integration	777
Inbound data processing	778
Asynchronous processing of inbound messages	778
Synchronous processing of inbound messages	779
Initiation of asynchronous processing of inbound data	779
Initiation of synchronous processing of inbound data	780
Processing sequences	780
Enterprise service processing sequences	781
Synchronous integration with an object structure service	781
Synchronous integration with a standard service	782
Enterprise service processing sequences	781
Synchronous integration with an object structure service	781
Synchronous integration with a standard service	782
Outbound data processing	783
Asynchronous integration with a publish channel	783
Data export feature	784
Event-based integration	784
Synchronous integration with an invocation channel	784
Customization of metadata properties in an invocation channel	785
Configuring integration processing	785
Configuring asynchronous processing of inbound messages	785
Configuring asynchronous processing of outbound messages	785
Rule-based customization	786
Rule definitions for objects and records	786
Processing rule definitions	787
Processing rule initiation	787
Processing rule actions	787
Message processing actions	787
Field transformation actions	788
Processing sequence	789
Conditions and evaluations	789

Condition specifications	789
Evaluation category specifications	789
Field to evaluate	790
Type of evaluation	790
When to evaluate a field	790
Comparison field specifications	791
Integration controls	791
Control levels	791
Control types	791
New controls	792
Configuring processing rules	792
Defining integration control or system control evaluations	793
Defining object field evaluations	793
Defining object set evaluations	794
Defining XML field evaluations	794
Defining processing rules	795
Enabling processing rules	795
Adding controls	795
Adding Boolean controls	796
Adding cross-reference controls	796
Adding list controls	797
Adding value controls	797
Associating integration controls with enterprise services or publish channels	798
Managing data in sub-record fields	798
Setting sub-record field values	798
Combining sub-record field values	799
Splitting sub-record field values	800
Replacing sub-record field values	800
Code-based customization	801
Customization Java classes and methods	801
External exit classes	801
User exit classes	802
Preprocessing method for outbound transactions	802
Postprocessing method for outbound transactions	802
Preprocessing method for inbound transactions	802
Postprocessing method for inbound transactions	803
Business object processing on inbound transactions	803
Event filter classes	803
Handler exit classes	803
Enterprise bean processing user exit class	804
HTTP processing user exit class	804
JMS processing user exit class	805
Web service processing user exit class	805
Customization with automation scripts	805
Creating automation scripts for integration	806
Customization of object structure processing	806
Customization points for object structure processing	806
Outbound processing of object structures	807
Functions for outbound processing of object structures	807
Skip processing of business objects	807
Skip processing of columns in business objects	808
Set values in fields	808
Java definition classes and automation scripts	809
Inbound processing of object structures	809
Functions for inbound processing of object structures	810
Skip or change message processing	810
Create business object sets	810
Change business objects or business object sets	811
Change processing of rules	811
Set values in fields	811
Add business objects and change values in fields	811
Change the transaction before saving to the database	812
Change status or status date	812
Context APIs for the inbound processing of object structures	812
Customization of channel and service processing	813
Customization points during publish channel processing	814
Customization points during enterprise service processing	814
Customization points during invocation channel processing	815
Examples of using automation scripts during processing by channels and services	816

XSL mapping	817
Interface table user exit class	817
Configuring the integration framework	818
JMS queue configuration	818
Creating and configuring a queue	819
Queue properties	819
Sequential queues	819
Continuous queues	820
Continuous queue performance	820
Configuring message beans	820
Message caching	820
Configuring an error queue for the continuous queue	821
Queue message format	821
Messages in text format	821
Queue selectors	822
Viewing and deleting messages in a JMS queue	822
Configuring queues with WebSphere MQ	823
Configuring JMS endpoints and handlers	823
Configuring integration queues and WebSphere MQ provider	823
Error management	823
Non-queue error management	824
Queue-based error management	824
Configuring error management	824
Configure notification properties	824
Error processing with an Apache Kafka provider	691
Error notification	825
Message reprocessing	826
Message status values	826
Error messages	826
Critical errors	827
Correcting errors	827
Reprocessing an edited message	827
Deleting messages	828
Refresh messages	828
Error management with file-based data import	828
File-based error management	828
Configuring error management in data import cron tasks	829
Information extracted by file-based error management	829
Downloading reprocessable files	829
Reprocessable file format	829
Deleting reprocessable files	830
Interface table error management	830
Common causes of errors	831
Error research	831
Message tracking	831
Message details	832
Message status values	832
Message events	833
Message tracking configuration	833
Enabling message tracking	834
Cluster configuration	834
JMS queues in a server cluster	834
Continuous queue on an application server cluster	835
Sequential queue on an application server cluster	836
Configuring the cron task	837
Configuring a message processing server	837
Global directory configuration	837
Access to services by inbound messages	838
Integration security	838
Authentication security	839
Configuring J2EE security	839
Configuring J2EE restrictions for JMS queues	839
Securing enterprise bean access	840
Securing the HTTP servlet	841
Securing web services	843
Interface table security	843
Securing remote integration APIs	843
Outbound router handler security	844
Authorization security	844

Language support	845
Default processing of multiple languages	845
Multilanguage attributes	846
Bidirectional language support	846
Bidirectional language formats	846
Configuring bidirectional language support for external systems	846
Exporting and importing file-based data	847
Exporting and importing data in the External Systems application	847
Exporting data	732
Exporting data in sequential batches	732
Importing file-based data	730
Importing data by using a REST API call	734
Importing S3 data by using cron tasks	850
Cron tasks for processing inbound data	851
XMLFILECONSUMER cron task	851
FLATFILECONSUMER cron task	851
LOADFLATOBJECT cron tasks	852
LOADXMLJSONOBJECT cron task	852
Configuring applications for data export and import	852
Defining the object structure content	853
Enabling data import and export in an application	853
Initiating data export and import in an application	854
Exporting application data	854
Importing application data	854
Federated MBO integration	854
Integration APIs	855
REST JSON API enhancements	855
Data import and export with REST API	855
REST API as replacement for RMI	856
Communication with external applications through REST API	857
Integration queries	858
Query services	858
Creating an enterprise service query	858
Web service queries	858
Query XML structure	859
Query selection criteria	860
Field selection	860
Field evaluation	861
Range selection	862
Where clause selection	862
Interface tables	864
Creation of interface tables	864
Regeneration of interface tables	865
Deletion of interface tables and records	865
Format of interface tables	865
Interface table polling	867
Interface table polling cron task	867
Advanced interface table polling	867
Processing interface tables on an external system	868
Enabling inbound processing	868
Enabling outbound processing	868
Integration modules	869
Integration module components	869
Integration module definitions	870
Operational management products	870
Logical management operations	870
Implementation prerequisites	871
Implementation properties	871
Integration module parameters	871
Integration module process flow	872
Endpoints	872
Invocation channel or Java class implementation	872
Invocation channel and Java class comparison	872
Invocation channel implementation	873
Java class implementation	874
Integration module processing	874
Identification of integration components	875
Integration module invocation	875
Service invoker property map	875
Invoke methods	876
Operational management product service method	876
Service invoker utility methods	876

Integration module response processing	877
Configuring integration modules	877
Creating integration modules	877
Selecting logical management operations for integration modules	878
Selecting logical management operations for operational management products	878
Associating a logical management operation with an integration module	879
Associating an operational management product with an integration module	879
Configuring logical management operations	880
Creating logical management operations	880
Adding attributes to logical management operations	880
Launch in Context feature	881
Preparation of the external application	881
Launch entry URL into an external application	881
Launch entry URL into a product application	881
Enabling launch-in-context	882
Creating a launch entry	882
Properties specific to operational management products	883
Configuring a signature option for a launch point	883
Adding a launch point to an application menu	883
Adding a button as a launch point	884
Adding a condition to a launch point	884
Signature option conditions	884
Integrating with Workday Connector	884
Workday Human Capital Management (HCM) overview	885
Workday worker integration	886
Workday Time Tracking integration	886
Workday Financials overview	887
Workday Account integration	888

Envizi ESG Suite and TRIRIGA Application Suite Connectors	889
Integrating with Maximo Connector for Envizi	889
Overview	890
App Connect	891
Installing App Connect	891
App Connect flows	891
Installing Maximo Connector for Envizi	892
Installing Maximo Connector for Envizi in Maximo Application Suite 8.10	892
Installing Maximo Connector for Envizi in Maximo Application Suite 8.9	892
Configuring Maximo Connector for Envizi	892
Configuring App Connect	893
Adding account for S3 server and HTTP connectors	893
Importing and configuring App Connect flows	893
Authenticating on-premises and cloud based App Connect	893
Check data and add App Connect certificate	894
Check the data correctness	894
Adding unit of measurement	894
Adding service address	895
Adding the App Connect certificate in Maximo Application Suite 8.9 and later	895
Adding the App Connect certificate in Maximo Asset Management 7.6.1.2 and later	895
Configuring Maximo Application Suite for integration	896
Deploying the Maximo Application Suite build	896
Configuring artifacts	896
Meter groups configuration	897
Configuring endpoints	897
Cron tasks	897
Basic cron task parameters	897
Advance cron task parameters	898
Configuring Cron Task	898
Using the connector	898
Starting or stopping cron task instance	898
Starting or stopping App Connect flows	899
Testing the configuration	899
Troubleshooting connection errors	899
Integrating with Maximo Connector for TRIRIGA	899
Overview	899
App Connect	901
Installing App Connect	901
App Connect flows	901
Installing Maximo Connector for TRIRIGA	902
Installing Maximo Connector for TRIRIGA in Maximo Application Suite 8.10 and later	902

Installing Maximo Connector for TRIRIGA in Maximo Application Suite 8.8 and 8.9	902
Installing Maximo Connector for TRIRIGA in Maximo Asset Management 7.6.1.2 and later	903
Configuring Maximo Connector for TRIRIGA	903
Configure App Connect	904
Authenticating App Connect	904
Importing App Connect flows	904
by using App Connect Enterprise (CP4I) and App Connect SaaS (AWS)	904
by using App Connect SaaS (IBM Cloud)	905
Add App Connect certificate	905
Adding the App Connect certificate in Maximo Application Suite 8.9 and later	905
Adding the App Connect certificate in Maximo Asset Management 7.6.1.2 and later	905
Adding the App Connect certificate in TRIRIGA Application Suite	906
Configuring TRIRIGA Application Suite for integration	906
Importing object migration packages	906
Configuring an integration object	907
Running in production	907
Configuring Maximo Application Suite for a new organization	907
Creating the TRIRIGA organization	907
Creating a clearing account in the chart of accounts	908
Creating the TRIMAIN site	908
Generating API keys	908
Creating integration controls	909
Enabling object structure security	909
Setting definitions in Application Designer	910
Testing the configuration	911
Troubleshooting connection errors	911
Integration reference information	912
System properties for integration	912
Integration XML	915
XML message overview	915
XML structure	916

Synonym field attribute	918
Encrypted field attribute	919
Action attributes	919
Field value types	921
Integration XML schemas	922
XML schemas overview	922
Schema structures	923
Metadata schema	923
Object structure schemas	925
Object schemas	926
Multi-noun messages	927
Service level schemas	927
Standard service schemas input and output	928
Object structure and enterprise service input and output	928
Collaboration switches	929
Format of collaboration switches	929
Retrieving a collaboration switch	930
Configuring collaboration switches	930
Viewing collaboration switches	931
Modifying a collaboration switch	931
Adding a collaboration switch to the database	931
Predefined collaboration switches	932
Default collaboration switches	933
Inventory collaboration switches	933
Invoice collaboration switches	933
Labor transaction collaboration switches	934
Purchase order collaboration switches	934
Purchase requisition collaboration switches	935
Receipt collaboration switches	936
Work order collaboration switches	936
Integrating with Maximo Application Suite applications	936

Integrating with Asset Data Dictionary	936
Maximo Manage synchronization with the Asset Data Dictionary	937
Overview	937
Implementation	938
Initial data synchronization	938
Organization and site synchronization	939
Unit of measure synchronization	939
Meter synchronization	940
Location systems synchronization	940
Operating locations synchronization	940
Location hierarchy synchronization	941
Asset synchronization	941
Asset hierarchy synchronization	941
Data synchronization process	942
Maximo Monitor to Maximo Manage integration	942
Overview	943
Organization and site integration	943
Location integration	944
Asset integration	945
Integration process	946
Integrating Maximo Manage with IoT monitoring systems	946
IoT device data integration overview	947
Associating device metrics to asset and location meters	948
Integrating with Cognos Analytics server	949
Installing Cognos Analytics	949
Cognos Analytics entitlement for Maximo Application Suite	949
Prerequisites for Cognos Analytics	950
Collecting key information from Cloud Pak for Data for Cognos Analytics configuration	950
Configuring Cognos Analytics server	950
Creating Cognos Analytics instances	951
Cognos Analytics system properties	951
Cognos Analytics end point properties	952
Creating a Cognos Analytics administrator for publishing packages	952
Creating a data source in Cognos Analytics	953
Configuring Maximo Manage user synchronization to Cloud Pak for Data	953
Configuring MXCOGNOS end point	953
Adding users to security group	954
Using Maximo Manage	954
Administration module	955
Sets	956
Organizations	956
Calendars	956
Resources	957
Labor	957
Labor overview	957
Labor records and person records	958
Assignment of calendars to labor	958
Status of qualifications	958

Qualifications	960
Qualifications overview	960
Status changes	960
Working with qualifications	961
Creating qualifications	961
Associating labor with qualifications	961
People	961
People overview	962
Person statuses	962
Deletion of person records	962
Working with people	963
Creating person records	963
Changing the status of multiple persons	963
Changing availability for assigned work	964
Viewing the history of persons	964

Viewing related assets and locations for persons	964
Person Groups	964
Person group overview	965
Person groups	965
Deletion rules for person groups	965
Working with person groups	965
Creating person groups	965
Specifying alternate persons for notifications and workflows	966
Crafts	966
Crafts overview	966
Standard rates and premium pay codes	966
Disassociation of labor records from craft records	967
Deletion rules for crafts	967
Working with crafts	967
Creating crafts	967
Associating labor with crafts	967
Crew Types	968
Defining crew types	968
Crews	968
Crews	969
Crew tools	969
Crew statuses	969
Crew availability	969
Creating crews	969
Assigning crews and labor to work	970
Reporting crew work hours	970
Bulletin Board	970
Communication Templates	971
Report Administration	971
Report development	971
Administering reports	971
Adding reports	972
Report management	972
Importing reports	972
Importing library files	973
Adding data sources	973
Setting report file security	973
Setting application security	973
Setting all application security	974
Running reports using request pages	974
Creating browser shortcuts for reports	974
Creating printing shortcuts for reports	975
Creating a printing shortcut for reports with attached documents	975
Enabling the printing of attached documents	975
Ad hoc report administration	976
Ad hoc report creation	976
Conditional Expression Manager	976
Creating conditional expressions and classes	564
Conditional expression syntax	564
Sample conditional classes	565
Classifications	978
CI Types	978
Configuration items management	978
Status of configuration item types	979
Work View	979
Working with work view queries	980
Editing work view queries	980
Changing default work view queries	980
Deleting work view queries	980
Service Address	980
Service addresses	981
Address systems	981
Adding service addresses to records	981
Creating address systems for sites	982
Configuring service addresses	982
Map Manager	982
Enabling maps	982
Developing maps and routes for applications	983
Configuring map tips	983
Map feature tips	983

Map feature tip templates	983
Adding additional information to map records	984
Creating dialog boxes for map tip menu items	984
Assigning map markers to work types and work order priorities	984
KPI	985
KPI Manager	985
Historical trends and values for key performance indicators	985
Creating key performance indicators	985
Example: Creating KPI templates to generate KPIs	985
Record Release	986
Time Zone Rules	986
Creating time zone rules	986
Maximo Visual Inspection models	987
Analytics module	987
Viewing scheduled reports	987
Monitoring performance	987
Assets module	987
Assets	988
Assets overview	988
Rotating assets and non-rotating assets	988
Asset depreciation	988
Working with assets	989
Creating assets	989
Applying item assembly structures	989
Associating users and custodians with assets	990
Associating services with assets	990
Associating safety information with assets	990
Associating tag out procedures with assets	991
Associating hazards with assets	991
Associating hazardous materials with assets	991
Associating safety-related issues with assets	992
Adding assets to collections	992
Adding relationships to assets	992
Granting access to asset relationship functions	993
Viewing related assets	993
Issuing items from a storeroom	993
Modifying assets	993
Changing the status of assets	994
Adding depreciation schedules to assets	994
Swapping depreciation schedules between assets	995
Reporting asset downtimes	995
Changing downtime asset status	995
Managing downtime history	995
Adding meters to assets	996
Specifying meter readings	996
Assigning meter groups to assets	997
Updating meter history	997
Resetting meter readings	998
Deleting asset records	998
Updating historical meter readings	999
Replacing meters	999
Moving assets	999
Swapping assets	1000
Changing item numbers	1000
Zeroing out asset costs	1001
Rolling up maintenance costs	1001
Rolling up maintenance costs by using an automation script	1001
Importing asset-related digital data	1002

IBM® Maximo® Manage documentation

Maximo Manage overview

IBM® Maximo® Manage is an asset lifecycle and workflow process management application that manages your asset operations and business processes and integrates with your existing enterprise applications.

Maximo Manage delivers a comprehensive view of all asset types, their conditions and locations, and the work processes that support them, to provide you with optimal planning, control, audit, and compliance capability.

Maximo Manage can help your organization optimize many aspects of your business.

Optimize asset efficiency

Manage and optimize the efficiency and use of all assets to maximize asset availability and performance, reduce downtime, and extend the life of the asset.

Increase productivity

Organize planned and unplanned work for assets and locations based on priority, urgency, and available resources to streamline work for increased productivity.

Improve inventory processes

Plan and manage inventory across multiple storerooms, providing visibility and availability of materials to meet and support maintenance operations.

Optimize schedules

Lower maintenance costs and optimize the use of your resources by scheduling maintenance work in a single graphical view.

Improve business intelligence

View scheduled reports and KPIs to analyze and understand information about the lifecycle and the maintenance of your assets.

Capture information at the right time

Optimize your workforce and data by using mobile solutions and device-specific capabilities, such as, photos and voice-to-text features that capture the right information at the right time.

Integrate applications and systems

Integrate enterprise applications and create business flows with external systems.

Overview video

Check out the video to learn more about Maximo Manage:

IBM Maximo Manage overview

The video thumbnail features a solid blue background. In the top left, the text 'IBM® Maximo® Manage' is displayed in white. Below it, the word 'Overview' is also in white. To the right of the text is a white circle, and further right is a white icon of a person with a gear, representing maintenance or operations. At the bottom of the video player, a progress bar shows '0:00 / 1:31' and a volume icon with '1x'.

When you deploy and activate IBM Maximo Manage, you can optionally include additional components, such as add-ons and industry solutions during the deployment and activation process.
- [Accessibility features for Maximo Manage](#)
Accessibility features for Maximo Manage assist users who have disabilities, such as restricted mobility or limited vision, to use information technology content successfully.
- [Documentation conventions](#)
The following table describes the conventions that are used in this documentation.

Introduction to Maximo Manage

IBM® Maximo Manage is an asset management life cycle and workflow process management system. With Maximo Manage, you can manage your asset operations and business processes. You can also integrate with your existing applications.

Streamline, customize, and integrate

Maximo Manage provides insight for all your enterprise assets, their conditions and work processes, for better planning and control. With Maximo Manage you can:

- Manage which users can log in to the system and which sites, applications, and menu options each user can access.
- Transfer product configurations and customizations from development to test to production environments. Migration Manager facilitates management of regulatory compliance efforts.
- Integrate Maximo Manage with your external financial applications to use your financial application to access and track Maximo Manage data and transactions.
- Develop and implement workflow to automate your business and management processes.
- Maximo Manage is highly customizable and both the user interface and the help can be adapted to suit your business requirements. You can change applications to meet your specific business needs. The Application Designer provides a graphical user interface for configuring applications without editing a line of code.
- Integrate enterprise applications and create business flows between Maximo Manage and your framework applications.

Choose your database and application server

Maximo Manage uses multiple software servers. You can install the servers on the same server or on a different server. System requirements depend on your operating system, database platform, and site configuration.

Maximo Manage comprises features that have different purposes but function in a similar way. Information that you enter into an application is stored as data in the Manage database. The relational structure of the database means that you can view the same data in different ways, from different applications.

Maximo Manage supports the following database servers:

- Db2®
- Oracle
- Microsoft SQL Server

The application server manages the Maximo Manage JavaServer Pages (JSPs), XML, and business logic components. Maximo Manage uses a Java™ 2 Platform, Enterprise Edition (J2EE) application server:

Maximo Manage supports the J2EE server, WebSphere® Application Server.

Select standard or custom reports

BIRT (Business Intelligence and Reporting Tools) is the embedded reporting tool in Maximo Manage. BIRT has standard reports that cover many applications.

- BIRT report types are analysis, detail, hierarchical, and drill down reports.
- Reports can update the database, hyperlink to one another to enable more detailed analysis, and refresh data dynamically.
- You can customize the BIRT reports or develop new reports to suit your business needs.

With ad hoc reporting, you can quickly create your own custom reports from any application. You can select what type of report you want to create, which fields to include, and whether to group and sort the results. You can also define unique report parameters, and specify whether you want the report to run on the records of the application. You can then save and share the reports with others, or run the report only once. If you save a report, it can be scheduled and automatically emailed to other users. You can also download the contents of the report to other file formats for additional analysis.

New applications

IBM® Cognos® Analytics integration

Maximo Manage 8.6 includes integration with Cognos Analytics to provide Business Intelligence tools. For more information, see [Integrating with Cognos Analytics server](#).

Operational dashboard enhancements

KPIs

You can now track overdue preventive maintenance and emergency work, the rate of closure of preventive maintenance work orders, and the number of work orders that are awaiting approval. You can also see trend information for each KPI and whether your organization is over or under your target.

Favorites and Quick actions

You can now use the Favorites card to quickly access other applications. You can also use the Quick actions card to create a work order, service request, job plan, and more.

Workflow assignment actions

You can now accept, reject, route, and reassign workflow assignments on the Workflow assignments due soon card on the Operational dashboard.

Work Orders application enhancements

Rich text support

You can now add images, links, and text formatting to the long description of each work order.

Scheduling dashboard enhancements

Resource leveling tab

Use the Resource leveling tab to view resource allocation and planned work by craft. For more information, see [Viewing resource leveling on the Scheduling dashboard](#).

Optimization report

Use the optimization report to view optimization progress and to see details of the last run optimization. For more information, see [Monitoring optimization progress on the Scheduling dashboard](#).

Calendar and shift breaks

New shift break options are available in the Calendars application that update labor and crew availability to more accurately reflect calendar and shift information. For more information, see [Specifying shift breaks in calendars](#).

IBM Maximo Optimizer updates

Scheduling enhancements

Optimization rules were updated to support high priority work, work records locked by date or time, and modified availability from shift breaks. New constraints were added to support custom fields in the Graphical Scheduling and Graphical Scheduling-Large Projects applications.

Dispatching enhancements

New optimization rules were introduced for the Graphical Assignment application, including the support of global routing breaks, assigning related work records to the same technician, and allowing for uninterruptible tasks to be scheduled across shift breaks.

Technical updates

New interface for Java™ or automation scripts

Maximo Manage now has an interface that you can implement with Java™ or automation scripts. This interface accesses the store and reads, writes, or deletes documents from the store. For more information, see [Creating scripts to manage attachments](#).

Rolling upgrade

You can complete a rolling upgrade from a previous version of Maximo Manage to a later version of Maximo Manage. With a rolling upgrade, the interruption to Maximo Manage is minimal when you upgrade both operators and operands and has zero downtime when you upgrade only the operators but not the operands.

Advanced search added to the Work Orders and Workflow Assignments applications

You can now click the Filter icon to see extra search fields including target start, target finish, priority, job plan, and more.

User assistance improvements

Documentation for integrating with IBM Maximo Connector for Envizi

Topics added to learn about integrating the Maximo Manage with the Envizi ESG Suite. For more information, see [Integrating with Maximo Connector for Envizi](#).

Documentation for integrating with IBM Maximo Connector for TRIRIGA®

Topics added to learn about integrating the Maximo Manage with the TRIRIGA Application Suite. For more information, see [Integrating with Maximo Connector for TRIRIGA](#).

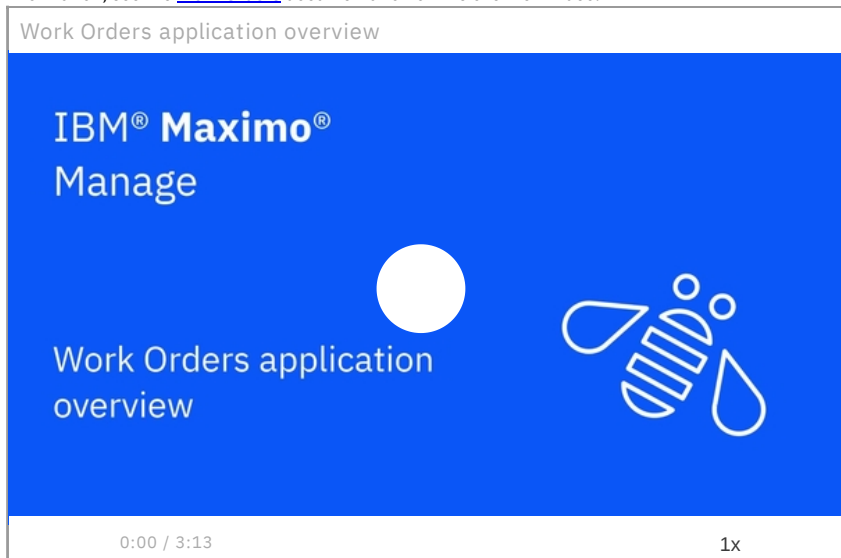

What's new in Maximo Manage 8.5

Learn more about what's new and changed in Maximo Manage.

New applications

Work Orders application

The Work Orders application contains a modernized, simplified view of the most important work order actions and information. You can also organize your work orders into custom views, track the status of each work order in the status bar, and enhance your productivity with type-ahead search. For more information, see the [Work Orders](#) documentation or this overview video.

Workflow Assignments application

You can use the Workflow Assignments application to monitor KPIs, such as the number of overdue assignments, and organize your assignments into custom views. You can also take advantage of productivity enhancements, such as type-ahead search and the ability to accept, reject, or reassign multiple assignments at once. For more information, see [Workflow Assignments](#).

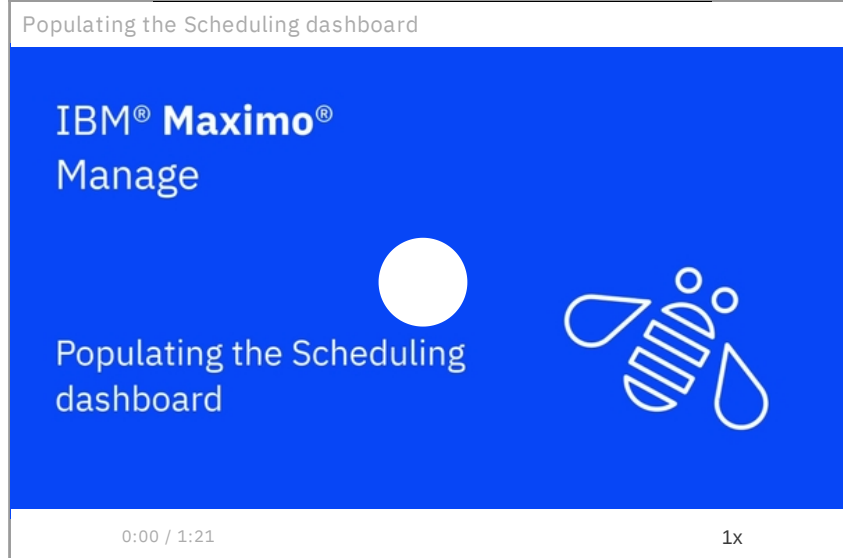

Manage Monitoring Information application

The Manage Monitoring Information application replaces the Maximo Management Interface tool that was available in previous versions. This application, which is in the System Configuration module, provides information about your system's database, MBO counts, memory, JVMs, threads, and operating system. It also includes details about queues, object structures, the user who is logged in, classes, crontasks, and appservices. For more information, see [Manage Monitoring Information](#).

New dashboards

Scheduling dashboard

On the Scheduling dashboard, you can see all your schedules at a glance and conveniently view all upcoming work. KPIs show important information, including scheduling problems and resource utilization. You can update work records, view resource allocation, fix scheduling problems, and run optimization from one convenient location. You can publish your changes when your adjustments are complete. For more information, see the [Scheduling dashboard](#) documentation. For information on setting up your Scheduling dashboard, see [Adding schedules to the Scheduling dashboard](#) or this video.

Operational dashboard

The Operational dashboard is a modernized landing page that is similar to the Start Center. You can use the Operational dashboard to see your workflow assignments that are due soon. For more information, see [Operational dashboard](#).

IBM Maximo Optimizer

The Maximo Optimizer includes an integration with the new Scheduling dashboard and includes an SRE metrics dashboard. The SRE dashboard reports the following metrics:

- Execution services CPU and memory usage
- API services CPU and memory usage
- Job creation rate by model
- In progress job count

The Graphical Scheduling optimization model detects and reports infeasible work records and generates a partial schedule, which minimizes unscheduled work. The model extracts critical path information to identify bottlenecks in schedules, including limited resource capacity. For more information, see [Optimizing schedules](#).

Monitoring metrics added

The monitoring agent provides metrics for application usage and performance. More metrics are available in Maximo Manage.

For more information, see [Monitoring metrics](#).

Ability to require electronic signatures based on record status

You can now require electronic signatures based on the status of a record. For example, you can require an electronic signature for a work order only when it is completed. For more information, see [Electronic signatures, audit records, and login tracking](#).

Technical updates

Swagger interface for API integrations

To access the Swagger interface, enter the URL for the interface into a browser or an API client, such as Postman, as shown in the following example:

<https://<host>:<port>/toolsapi/oas3/api.html>

For more information, see [Integration APIs](#).

Stored procedures for text searches in Microsoft SQL Server databases

Because Microsoft deprecated the `sp_fulltext_table` stored procedure that is related to indexing in Microsoft SQL Server databases, that stored procedure is removed in this release. This programming update does not affect the user experience, and full text search continues to function as it did in previous releases. For more information, see [Searching](#).

KafkaErrorsCleanup cron task removed

The KafkaErrorsCleanup cron task is no longer used for reprocessing expired messages that have errors.

New integrations

There are two new integrations, ENVIZI and IBM® TRIRIGA® Application Platform integration. You can now view documentation for these Maximo Manage components. For more information, see [Maximo Manage components](#).

User assistance improvements

Onboarding assistance

Onboarding assistance is available to help you find your way around the Maximo Manage Start Center. You can also watch an overview video for Manage. Click Take a tour to get started.

Documentation improvements

To optimize and improve content retrievability, the documentation is now organized and streamlined to identify information by product and version. For more information, see [Documentation conventions](#).

What's new in Maximo Manage 8.4

Learn more about what's new and changed in Maximo Manage.

Support for Java Servlet Specification 3.1

To enhance security, Maximo Manage now uses Java™ Servlet Specification 3.1 for all web modules.

Database encryption updates

The following features are added for database encryption:

Ability to view encryption history

When you encrypt or reencrypt the database, an entry is logged in the syschangetracker table, and you can view the history for database encryption. For more information, see [Viewing database history](#).

Automatic generation of encryption keys

By default, if encryption keys are not specified when you activate Maximo Manage with a fresh database, new encryption keys are automatically generated. If you do not want to automatically generate encryption keys, you can set the `autoGenerateEncryptionKeys` property to `false`. For more information, see [Disabling auto-generation of encryption keys](#).

Ability to reset fields with crypto and cryptox encryption

If you inadvertently lose your crypto and cryptox encryption keys, you can run a reset script that clears the fields with crypto and cryptox encryption. Then, you can then restart the server and reset your data. For more information, see [Resetting encryption keys](#).

User management updates

In Maximo Application Suite 8.7 and earlier, users were created with a single username. Effective with Maximo Application Suite 8.8, when a user is created in Maximo Application Suite, a display name and a user ID are created. The user ID is a primary key that identifies a user, and it cannot be changed after the user is created. An option is also available to make a user's login ID be the same as the unique user ID or to create a custom login ID such as an email address. Login IDs can be updated if necessary. When user synchronization occurs, the Login ID that is specified in Maximo Application Suite becomes the login ID in Maximo Manage. The user ID in Maximo Application Suite becomes the user ID and the person ID in Maximo Manage.

New Count Books application

You use the new Count Books application to select inventory for periodic counting and to record the results of physical counts. You can then reconcile discrepancies between expected and actual quantities. For more information, see [Count Books application](#).

Ability to stream WebSphere Application Server Liberty logs

You can stream WebSphere® Application Server Liberty logs for server bundles by constructing a URL that you can use in a browser or other tool that you use for REST API calls. For more information, see [Sending log output to S3 Cloud Object Storage](#).

Ability to scale Java Message Service (JMS)

You can now configure multiple JMS servers and add custom message queues as needed. For more information, see [Configuring JMS server](#).

Documentation for automation scripting

Scripting allows you to customize the product without going through system downtime and a steep learning curve. You can customize Maximo using the Maximo scripting framework. For more information, see [Maximo autoscripting](#).

Ability to test automation scripts

You can test automation scripts after you create them. It is possible to test different types of scripts like object launch scripts, attribute launch scripts, integration scripts, and REST scripts. For more information, see [Testing automation scripts](#).

Ability to configure requests and limits for ephemeral storage

By default, ephemeral storage is allocated for the administrative and server bundle builds when Maximo Manage is deployed. Effective with this release, administrators can modify the requests and also limit the amount of ephemeral storage that is provisioned. For more information, see [Configuring ephemeral storage](#).

Metrics are added to the monitoring dashboard

The monitoring agent provides metrics for application usage and performance. Additional metrics were added in Maximo Manage 8.5. For more information, see [Monitoring metrics](#).

OAuth access is supported for the WEBSERVICE-JAX-WS web service handler

If you use the WEBSERVICE-JAX-WS web service handler, you can configure an OAuth authentication service to provide secure delegated access to Maximo Manage data. For more information, see [Configuring OAuth access](#).

Ability to provide Java virtual machine (JVM) options when you deploy Maximo Manage

You can now specify JVM options when you specify additional configurations for a server bundle in the Maximo Manage workspace. For more information, see [Configuring JVM options](#).

Documentation for configuring Grafana dashboards

Maximo Manage includes a monitoring agent that collects statistics about application usage and performance. Administrators can configure the Prometheus monitoring service and then use Grafana visualization software to view usage data that the agent collects. For more information, see [Configuring Grafana dashboards](#).

What's new in Maximo Manage 8.3

Learn more about what's new and changed in Maximo Manage.

New Asset Data Dictionary for integrating and synchronizing data across applications

The Asset Data Dictionary repository of data and metadata facilitates data sharing and integration between Maximo Manage and other applications. Using predefined artifacts in the Maximo Manage integration framework, you can synchronize data in Maximo Manage with the Asset Data Dictionary, which in turn integrates the data into other applications, such as Maximo Monitor. Synchronization can be performed manually when needed, at regularly scheduled intervals, or as event-based updates when data changes.

[Learn more about the Asset Data Dictionary.](#)

Support for initial data loads from Maximo Monitor to Maximo Manage

You can use the Asset Data Dictionary to load data for organizations, sites, assets, and locations from Maximo Monitor into Maximo Manage. Use this integration only for a one-time, initial load of data into Maximo Manage. After the initial data is loaded, Maximo Manage takes ownership of the data and manages any subsequent changes to the data.

[Learn more about adding Maximo Monitor data to Maximo Manage.](#)

New process for integrating metrics data from IoT sensor devices

You can add metric data that IoT monitoring systems gather from sensor devices to meters in Maximo Manage applications.

[Learn more about integrating metrics data from IoT sensor devices.](#)

Ability to use OAuth access standards

If you want to use an OAuth authentication service to provide secure delegated access to Maximo Manage data, you can configure OAuth access in the End Points application.

[Learn more about configuring OAuth access.](#)

Integration framework support for OR and AND operators in the same OSLC WHERE clause

You can now use both AND and OR operators in the same OSLC WHERE clause. For more information, see the Maximo Manage REST API documentation.

Upgrade to Business Intelligence and Reporting Tools (BIRT) 4.8

Maximo Manage 8.3 uses BIRT version 4.8.0. To design your reports, use version 4.8 of the report designer tools for BIRT.

[Learn more about BIRT 4.8 in Maximo Manage 8.3.](#)

Update feature is removed from inventory analysis reports

Effective with Manage 8.3, the Update button is removed from the following inventory analysis reports:

- Inventory ABC Analysis
- Inventory EOQ Analysis
- Inventory ROP Analysis
- Inventory ABC Transaction Date Analysis
- Inventory EOQ Transaction Date Analysis
- Inventory ROP Transaction Date Analysis

Although you can still run the reports to obtain an analysis of your inventory, you cannot update the Manage database with the analytic values that the reports calculate.

Support for configuring Grafana dashboard visualization software for monitoring services

Maximo Manage 8.3 includes new features to help you configure Grafana dashboards. You can use Grafana to display data that is collected from the Prometheus monitoring service.

[Learn more about configuring Grafana dashboards for Maximo Manage.](#)

Ability to add multiple customization archive files

You can now add multiple customization archive files to customize Maximo Manage.

[Learn more about adding customization archive files.](#)

New server bundle type for deploying a JMS server

You can use the new standalonejms server bundle type to configure and deploy a Liberty server for JMS messaging.

[Learn more about deploying a JMS server.](#)

Enhanced features for persistent volume storage

The following enhancements are added for configuring persistent storage:

Dynamic provisioning for persistent volume claims

When a persistent storage volume is declared, if you do not specify a persistent volume claim, the workspace operator creates a persistent volume claim that is dynamically provisioned based on the storage class.

[Learn more about persistent storage.](#)

Ability to configure persistent volume storage for specific server bundles

You can now create persistent volume claims for specific server bundles. For example, you can deploy a server for processing JMS messages and create a persistent volume claim to provide persistent storage just for that server.

[Learn more about configuring persistent volume claims for storage bundles.](#)

What's new in Maximo Manage 8.2

Learn more about what's new and changed in Maximo Manage.

Ability to add files to IBM® WebSphere Application Server Liberty

Administrators can now customize the WebSphere® Application Server Liberty application server for a server bundle by adding directories and files to the customization archive for the bundle. For example, if you use an IBM MQ service for messaging, you can add an RAR file for your IBM MQ resource adapter to the additional-server-files directory in the customization archive for a server bundle. The file is added to the application server for that bundle when Maximo Manage is deployed.

[Learn more about adding files to the application server.](#)

External certificates can be imported using API calls

Administrators can now issue an API call to import external certificates. This feature is useful if you do not have access to the Maximo Application Suite user interface.

[Learn more about importing external certificates.](#)

JDBC driver options can be added when you configure the Manage database

When you deploy Maximo Manage, you can now configure more JDBC driver options using the Maximo Application Suite user interface.

[Learn more about adding JDBC driver options.](#)

Bulk export feature is added to the integration framework

To export multiple batches of message data to an external system, you can use the new Bulk Data Export action in the External Systems application. When you use this feature, exports are processed in order based on the sequence that you specify for the publish channels.

[Learn more about bulk data exports.](#)

SMTP configurations in Maximo Application Suite apply to Maximo Manage

The SMTP configurations that you define in Maximo Application Suite are now also automatically applied to Maximo Manage. No additional configuration is required in the Manage application.

[Learn more about configuring SMTP for Maximo Application Suite.](#)

What's new in Maximo Manage 8.1

Learn more about what's new and changed in Maximo Manage.

Maintenance cost rollup in the Assets application

A new feature is added to the Assets application to help you calculate maintenance costs for your assets. After you close a work order that is associated with an asset, you can roll up costs that you incur for labor, materials, tools, and services to the top-level asset in the hierarchy that the asset belongs to. You can roll up costs manually or configure a system property to roll up costs automatically when work orders are closed.

In previous releases, the Maintenance Cost Rollup Report was used to calculate maintenance costs for assets. Use the new rollup feature in the Assets application instead of the report. The report is still available to allow existing users to roll up pending maintenance costs. If you upgrade to Maximo Manage 8.1, run the report to roll up pending maintenance costs before the upgrade.

[Learn more about asset cost rollup.](#)

APIs for administrative utilities

APIs to run script commands for administrative utilities are now available. The API requests can run the integrity checker utilities, start and stop the Maximo Manage pods, download log files or a list of log files, and upload logs to Simple Storage Service (S3) Cloud Object Storage. [Learn more about APIs for administrative utilities.](#)

Adding trusted external certificates

Administrators can add trusted external certificates for Maximo Manage in the Suite administration panel of Maximo Application Suite. [Learn more about adding trusted external certificates](#)

Log output to S3 Cloud Object Storage

You can send server bundle logs for Maximo Manage to your provisioned Simple Storage Service (S3) Cloud Object Storage. You also can redirect logs from the administrative server to S3 Cloud Object Storage. [Learn more about sending log output to S3 Cloud Object Storage](#)

External registry for build images

You can now configure Maximo Manage to send the images that are created when you deploy or update the application to an external repository. The external build images are useful if you want to test or review the application before you deploy it in the Maximo Application Suite. [Learn more about configuring an external registry.](#)

Deploying Maximo Manage on a local computer

After you configure Maximo Manage to send build images to an external registry, you can deploy the images to a Docker container on a local computer. You can use these images to review content or to customize the application. [Learn more about deploying Maximo Manage on a local computer.](#)

Configuring JVM options

You can now configure JVM configuration options for the WebSphere Application Server Liberty server on which a server bundle runs. For example, you can specify memory options to improve performance or specify logging options for the server bundle. You configure JVM options by adding them to the custom resource definition in the Red Hat® OpenShift® console. [Learn more about configuring JVM options.](#)

Parts Identifier add-on for Maximo Mobile

Parts Identifier is an IBM Cloud® service add-on for Maximo Mobile that enables technicians to search for and identify industrial parts from their mobile device by using a combination of visual and text-based search approaches. You add the Parts Identifier add-on in IBM Maximo Application Suite. After you add Parts Identifier in Maximo Application Suite, you must integrate it with Maximo Manage.

[Learn more about configuring the Parts Identifier integration with Maximo Manage.](#)

What's new in Maximo Manage 8.0

Learn more about what's new and changed in Maximo Manage.

Product name change

In Maximo Application Suite, IBM® Maximo Asset Management is renamed IBM Maximo Manage. The industry solutions and add-ons that are included in Maximo Application Suite are also renamed. For more information, see [Maximo Manage components](#).

Deploying and activating Maximo Manage

Maximo Manage is an application in Maximo Application Suite. Maximo Application Suite is a suite of asset management and data analytic offerings. Maximo Application Suite is offered as a customer-managed product on Red Hat® OpenShift® and as an IBM Managed solution.

To access and use Maximo Manage, you deploy and activate Maximo Manage in Maximo Application Suite. For more information, see [Deploying in Maximo Application Suite](#).

Upgrading to Maximo Manage 8.0

You can upgrade to Maximo Manage 8.0 from Maximo Asset Management. Before you upgrade, you must have Maximo Asset Management 7.6.1.2 installed. For more information, see [Upgrading from IBM Maximo Enterprise Asset Management to IBM Maximo Manage](#).

Maintaining calibration assets and standards

Calibration is included in the base entitlement for Maximo Manage and no longer requires an additional license or install. When you deploy Maximo Manage, calibration functionality is also included. For more information, see [Managing calibration assets and standards](#).

Maintaining linear assets

Linear is included in the base entitlement for Maximo Manage and no longer requires an additional license or install. When you deploy Maximo Manage, linear functions is also included. For more information, see [Linear assets management](#).

Planning and scheduling work

Scheduler is included in the base entitlement for Maximo Manage and no longer requires an additional license or install. When you deploy Maximo Manage, scheduler functionality is also included. For more information, see [Planning and scheduling work](#).

Maximo Mobile

Maximo Mobile is a next-generation mobile application platform that is supported by Maximo Manage. Maximo Mobile allows users use mobile devices to securely access Maximo Manage functionality. The Maximo Mobile apps provide a mobile user with capabilities to manage work and conduct inspections both when the app is connected and disconnected. For more information, see [Managing Maximo Mobile](#).

User management

Users are added and authenticated in Maximo Application Suite. Users who have an entitlement to Maximo Manage are synchronized to Maximo Manage.

If you are upgrading from Maximo Asset Management to Maximo Application Suite, user records in the Maximo database are imported by Maximo Application Suite if they do not exist there or if they are not managed by an identity provider.

License type updates can be sent to Maximo Application Suite when authorizations change or when the calculated license type has a different entitlement value in Maximo Manage.

Security groups

Authorization enables access to applications, application actions, and data in Maximo Manage. Authorization is provided by assigning users to one or more security groups in Maximo Manage. You can create security groups in Maximo Manage. If you manage users in an LDAP user registry, you create groups in the user registry

and synchronize the data to Maximo Application Suite so that it can be synchronized to Maximo Manage. Map your LDAP groups to Maximo Manage security groups before you synchronize them to the suite. For more information, see [Security group synchronization and default assignments](#).

Logging

Maximo Manage server logs are written to standard output. You can view or process log output using various tools, such as an aggregation of logs in an Red Hat OpenShift cluster-level logging stack.

Electronic signature

Electronic signature keys must conform to the same rules as product passwords. Any key that is manually created or automatically generated from a reset action is validated by using the rules for user passwords, such as password length or excluded words. For more information, see [Electronic signature verification](#).

Kafka updates

You can browse message content in a Kafka queue using a REST API that the product provides. Browse message content to analyze it or to troubleshoot processing. For more information, see [Sample REST API requests for browsing Kafka queues](#).

To reduce the possibility of duplicate message processing, Maximo Manage attempts to keep its offsets synchronized with the offsets that are managed by Kafka. You can reset offsets in Maximo Manage if they are not synchronized with the offsets that are managed by Kafka. For more information, see [Managing Kafka offset values in Maximo Manage](#).

To use Kafka features in the product, you must obtain and configure a Kafka server instance of the provider. The Kafka server that you obtain must be compatible with the Kafka 2.5.0 client libraries.

Other integration updates

Use REST API instead of RMI

You use REST API instead of Remote Method Invocation (RMI) for interactions with the product from custom extensions or external applications. RMI is not supported in the product.

For more information, see [Communication with external applications through REST API](#).

API key authentication for REST API and integration features

API keys for user and group synchronization are generated for you. If you interact with REST API or machine-to-machine integration activities, you must configure an API key. The API key is configured in the Administration Work Center of Maximo Manage.

Added support for the JSON schema in OAS 3.0 documentation

Complete JSON schema content was added to the OAS 3.0, or Swagger, documentation for the Maximo Manage APIs. The existing non-OAS 3.0 JSON schema is still supported.

Support Simple Object Access Protocol (SOAP) 1.1 and SOAP 1.2 in same web server instance for a WebSphere® Application Server Liberty environment

You can use SOAP 1.1 and SOAP 1.2 with the Java™ API for XML Web Services (JAX-WS) endpoint handler to exchange messages in a WebSphere Application Server Liberty environment.

For more information, see [Implementing SOAP 1.1 and 1.2 with JAX-WS web services](#).

New batch parameter to support processing large outbound messages

You can set a batch size parameter to break up large outbound messages into multiple transactions of the size that you specify. Set the batch size in the Data Export window of the publish channel.

New location for REST API documentation

The documents and videos about REST API are now in the Internet of Things community.

[See and bookmark the new location for REST API documentation](#).

API key support for legacy APIs

API keys are supported if you are working with legacy APIs. Legacy APIs are APIs that became available in product versions before Maximo Asset Management 7.1.

Form data support using the HTTP handler

In the integration framework, the HTTP handler now supports a POST of form data, in addition to existing support for JSON and XML data.

Support for nested representation of hierarchical object structures in messages

You can export a nested JSON representation of an object structure and all of its descendant objects by selecting the Complete Hierarchy option for outbound messages. Object structures that were exported as complete hierarchies can be imported as complete hierarchies.

Scripting point for Maximo Manage roles

A scripting point is available to define custom roles and automate communications to users who are associated with the roles.

For more information, see [Example: Automating communication by using a custom role](#).

Sequences for SQL Server

Sequences are database objects that automatically generate unique key values or caches of multiple values. Sequence caches might improve system performance.

For more information, see [Modifying sizes of sequence caches](#).

Redundant Maximo properties

The Maximo properties file is now redundant in Maximo Manage.

For more information, see [Maximo properties](#)

What's new in Maximo Mobile

- [What's new in Maximo Mobile 8.10](#)
Learn more about what's new and changed in Maximo Mobile 8.10.
- [What's new in Maximo Mobile 8.9](#)
Learn more about what's new and changed in Maximo Mobile 8.9.
- [What's new in Maximo Mobile 8.8](#)
Learn more about what's new and changed in Maximo Mobile 8.8.

Related concepts

- [Managing Maximo Mobile](#)
- [Introduction to Maximo Mobile](#)

What's new in Maximo Mobile 8.10

Learn more about what's new and changed in Maximo Mobile 8.10.

Work orders

- In the work log, you can now expand the Note field to add a summary for your note. You can also add much longer notes than before.
- As you complete the tasks on a work order, you can record observations and measurements.
- You can include comments when you report failures so that you can better describe the details.
- You can now view classifications on a work order.

Assets

- You can now create and edit assets in the app and change the status of the asset.

Inspections

- During an inspection, you can upload a photo and select Analyze photo. You can continue the inspection while the photo is analyzed to detect anomalies. When the analysis is complete, you can review and edit the results. This feature is configured in the Manage Inspection Forms tool. For more information, see [Enabling photo analysis by Maximo Visual Inspection](#)

Onboarding tour

- A short overview tour of the navigator is available to help new users get started with the app.

Data updates

- The Data update page now shows the status of uploads and downloads. The information is divided into four sections: Transaction upload, Configuration data, Functions, and Record data. The four sections are processed in sequence, with each section starting the update only when the previous category is complete.
- Errors are also shown inline on the Data update page instead of a separate page so that users can troubleshoot in context.
- Transactions are grouped by object and an error in one transaction blocks all other transactions that belong to the same object. To continue the upload, you can retry the transaction, go to the object and fix the error, or you can delete the transaction.
- Tap the refresh icon on the Data update page to update data. You can specify the record data to update by tapping the options icon on the Data update page. To fully update your record data, open the navigator and tap Settings.

For more information, see [Refreshing data](#)

Inventory receiving

In the Inventory Receiving function, storeroom clerks can receive materials from purchase orders. As part of the receiving activity, the storeroom clerk can inspect and return items and view or void receipts.

Service requests

Creating service requests is improved in this release. You can select a location by searching and the Asset page has a better layout and search option.

Troubleshooting

The debugging capabilities of Maximo Mobile applications on Android are improved.

For more information, see [Troubleshooting applications on Android](#).

E-signatures

E-signature keys capture and validate work order status changes in the My Schedule function of the Technician application. For more information, see [Recording e-signature keys](#).

Documentation

Documentation developed for application development and upgrade.

For more information, see [Anatomy of an application XML file](#) and [Application upgrade](#)

What's new in Maximo Mobile 8.9

Learn more about what's new and changed in Maximo Mobile 8.9.

Navigation

- When technicians complete the final task in the task list, the Report work page opens automatically. This behavior is controlled by the `maximo.mobile.gotoreportwork` system property.
- When technicians tap Start work, the Work order details page opens automatically, but tapping Stop travel no longer opens another page.

Usability

- To prevent errors, the work order number is displayed when a technician edits a work order.
- Technicians can now specify a name and add a description when they add attachments to a work order.
- The icons for Start work, Start travel, and Start travel with timer are now visually different so that technicians can easily distinguish them on a small mobile screen.

Data

- When a work order specifies both an asset and a location, the Asset and location history page displays any closed and completed work orders for the asset and the location.
- The list of related records now shows the status and type of record, such as work order or service request.
- The asset or location of a task is now displayed when the parent work order has a different asset or location.
- When mobile users are offline, requests are processed on the device by using data that was retrieved during online operations. When connectivity is restored, local data is automatically synchronized. For more information, see [Overview of Maximo Mobile authentication and data flow](#).
- You can create a preloaded database that contains all supporting data to save mobile application users time when they are onboarding. For more information, see [Preloaded data on mobile devices](#).

Approvals

- You can require a physical signature when a user approves work. Specify one or more work order statuses for the `maximo.mobile.statusforphysicalsignature` system property.

Maps

- Technicians can now select a building from the map, then review individual floor plans to see the position of their work orders in the building. Indoor maps are available only to Maximo Spatial customers. For more information, see [Indoor maps](#).

Assets

- Technicians can go to the Assets function in the Maximo Mobile app or on desktop go to Work Orders > Role Based Applications > Asset Manager to see the details of all their assets, including their specifications and associated meters.

Defects

- In the Defects function, customers who have Maximo Civil Infrastructure can now view confidence scores to suggest how close the detected anomalies are to a defect. You can also select one or more anomalies and use the new menu with options such as change the category, show, hide, and delete the anomalies.

Inspection forms

- Inspection supervisors can now review an inspection and update it before the inspection is completed. Use the `mxe.mobile.inspection.features.enablereview` system property to set a review status between the In progress and Complete statuses.
- Inspection supervisors can now see whether a field was hidden or visible when an inspector completed an inspection form.

Inspections

- Inspectors can group inspections to report them as a batch and can open and preview an inspection without starting it.

- Inspectors can search for questions or groups of questions and jump to that part of the inspection form.

Service Requests

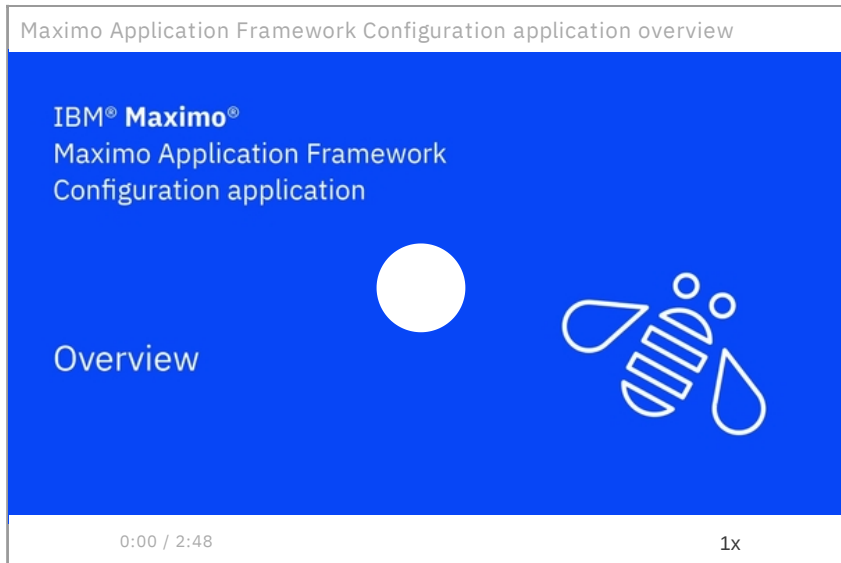

- Users who create service requests can now search through a hierarchy to find the correct location, capture their GPS location on the service request, and can add service address information.

Troubleshooting

- Users can troubleshoot mobile application issues by contacting IBM Support to download the debug version of Maximo Mobile. For more information, see [Troubleshooting applications on Android](#).

Configuration

- Use the Maximo Application Framework Configuration application to configure non-mobile, role-based applications, such as Workflow Assignments. For more information, see the [Configuring and customizing applications with the Maximo Application Framework \(MAF\) Configuration application](#) documentation or this overview video.

What's new in Maximo Mobile 8.8

Learn more about what's new and changed in Maximo Mobile 8.8.

Inventory counting

In the new Inventory Counting function, storeroom clerks can use count books, ad hoc counts, and reconciliation to ensure valid inventory balances.

Work orders

Supervisors can specify relationships between work orders and tasks so that only when a task is completed, the next task in the flow can be started. The sequence can be defined in a work template at the job plan level.

Safety

Safety plan information, including hazards and precautions, is now included on the work order so that technicians can review the details and be fully prepared for their work.

Defects

IBM® Maximo Civil Infrastructure customers can use the new Defects function to create defects and attach photos that can be automatically analyzed to detect anomalies. You can create defects from the new Defects function or from an inspection record. For more information, see [Creating defects](#).

Inspection forms

- In the Manage Inspection Forms tool, inspection supervisors can add validation rules for numeric fields. For example, a supervisor might specify that the number the inspector enters must be within a range, and if the entered value is outside of the range, the value is rejected.

- Inspection supervisors can now link from an existing domain to a single choice field or a multiple choice field. Supervisors configure the link in the Manage Inspections Forms tool. When a supervisor creates an inspection form, they choose Lookup Domain Value - Single Choice or Lookup Domain Value - Multiple Choice as the response type. An inspector can then complete the field by selecting values from a list.

Inspections

- Inspectors can now complete hands-free inspections on their mobile device. The inspection form is read aloud, and verbal responses are recorded on the form. For more information, see [Enabling voice inspections](#).
- When unexpected work arises, inspectors can now create unscheduled inspections to track work.
- When GPS is enabled on their mobile device, the geographical location is saved every time that an inspector updates a field in the inspection form. This feature is controlled by the `mxe.mobile.inspection.features.savegeolocation` system property.

Maximo Manage components

When you deploy and activate IBM® Maximo® Manage, you can optionally include additional components, such as add-ons and industry solutions during the deployment and activation process.

Add-ons

An add-on is a component that extends the capabilities of Maximo Manage.

Industry solutions

An industry solution is a component that provides additional, industry-specific functionality to Maximo Manage.

Maximo Manage components

Table 1 lists the additional components that you can deploy with Maximo Manage, and links to documentation for each component.

Table 1. Maximo Manage components

Component name	Component type	Name in version 7.6	Documentation link
IBM Maximo Anywhere Available only in Maximo Application Suite 8.8 and earlier.	Add-on	IBM Maximo Anywhere	Maximo Anywhere documentation
IBM Maximo Asset Configuration Manager	Add-on	IBM Maximo Asset Configuration Manager	Maximo Asset Configuration Manager documentation
IBM Maximo Aviation	Industry solution	IBM Maximo for Aviation	Maximo for Aviation documentation
IBM Maximo Civil Infrastructure	Industry solution	IBM Maximo for Civil Infrastructure	Maximo Civil Infrastructure documentation
IBM Maximo Connector for SAP Applications	Add-on	IBM Maximo Enterprise Adapter for SAP Applications	Maximo Enterprise Adapter for SAP Applications documentation
IBM Maximo Connector for Oracle applications	Add-on	IBM Maximo Enterprise Adapter for Oracle Applications	Maximo Enterprise Adapter for Oracle Applications documentation
IBM Maximo Connector for Workday Applications	Add-on	Not applicable	Integrating with Workday Connector
IBM Maximo Health, Safety and Environment	Add-on	IBM Maximo Health, Safety and Environment Manager	Maximo Health, Safety, and Environment Manager documentation
IBM Maximo Nuclear	Industry solution	IBM Maximo for Nuclear Power®	Maximo for Nuclear Power documentation
IBM Maximo Oil & Gas	Industry solution	IBM Maximo for Oil and Gas	Maximo for Oil and Gas documentation
IBM Maximo Service Provider	Add-on	IBM Maximo for Service Providers	Maximo for Service Providers documentation
IBM Maximo Spatial	Add-on	IBM Maximo Spatial Asset Management	Maximo Spatial Asset Management documentation
IBM Maximo Transportation	Industry solution	IBM Maximo for Transportation	Maximo for Transportation documentation
IBM Maximo Utilities	Industry solution	IBM Maximo for Utilities	Maximo for Utilities
IBM Maximo Connector for Envizi	Add-on	Not applicable	Integrating with Maximo Connector for Envizi
IBM Maximo Connector for TRIRIGA®	Add-on	Not applicable	Integrating with Maximo Connector for TRIRIGA

Accessibility features for Maximo Manage

Accessibility features for Maximo® Manage assist users who have disabilities, such as restricted mobility or limited vision, to use information technology content successfully.

Accessibility features

For information about IBM accessibility and to view Accessibility Conformance Reports, see [IBM Accessibility](#).

Maximo Manage includes the following major accessibility features:

- Supports interfaces that are commonly used by screen readers.
- Can be operated by using only the keyboard.
- Allows the user to access the interfaces without inducing seizures due to photo-sensitivity.

Maximo Manage uses the latest W3C Standard, [WAI-ARIA 1.0](http://www.w3.org/TR/wai-aria/) (<http://www.w3.org/TR/wai-aria/>), to ensure compliance with [US Section 508](https://www.access-board.gov/ict/about/) (<https://www.access-board.gov/ict/about/>) and [Web Content Accessibility Guidelines \(WCAG\) 2.0](http://www.w3.org/TR/WCAG20/) (<http://www.w3.org/TR/WCAG20/>). To take advantage of accessibility features, use the latest release of your screen reader in combination with the latest web browser that is supported by this product.

Maximo Manage contains a screen reader check box. The Use Screen Reader check box is in the User tab of the Users application. When you select the check box, the user interface is optimized to work with a screen reader. The Accessibility Help window provides details on general navigation, menu navigation, and hot keys. Click Accessibility Help from the toolbar of the product to access the help window. To use the accessibility tools to read reports, you must access the reports in Microsoft Excel. In the reports applications, select the Run Reports option. With this option, you can email an .xls file version of a report to yourself at a scheduled time.

Keyboard navigation

Maximo Manage uses the following keyboard shortcuts.

Table 1. Keyboard shortcuts for general navigation

Action	Keyboard shortcut
Move from one interface element to the next.	Tab key
Select buttons, links, and menu options.	Enter key
Select or clear a check box.	Spacebar
Display field help for the field that is in focus.	Alt+F1

Table 2. Keyboard shortcuts for global navigation

Link name	Keyboard shortcut
Bulletins	Alt+B
Go To	Alt+G
Reports	Alt+R
Start Center	Alt+C
Profile	Alt+P
Sign Out	Alt+S
Help	Alt+H
Return	Alt+R
Return with Value	Alt+W

Table 3. Keyboard shortcuts for application-specific actions

Action	Applications	Keyboard shortcut
Assign Labor	Assignment Manager	Ctrl + Alt + L
Finish Assignment	Assignment Manager	Ctrl + Alt + F
Interrupt Assignment	Assignment Manager	Ctrl + Alt + U
Select Work Date	Assignment Manager	Ctrl + Alt + W
Start Assignment	Assignment Manager	Ctrl + Alt + T
Start Timer	Activities, Changes, Incidents, Problems, Releases, and Service Requests	Ctrl + Alt + B
Stop Timer	Activities, Changes, Incidents, Problems, Releases, and Service Requests	Ctrl + Alt + E

Table 4. Keyboard shortcuts for toolbar actions

Action	Keyboard shortcut
Insert New Record	Ctrl+Alt+I
Save Record	Ctrl+Alt+S
Clear Changes	Ctrl+Alt+C
Previous Record	Ctrl+Alt+P
Next Record	Ctrl+Alt+N
Change Status	Ctrl+Alt+A
Create KPI	Ctrl+Alt+K
Put record in edit mode or release record from edit mode	Ctrl+Alt+L

Table 5. Keyboard shortcuts for tables

Action	Keyboard shortcuts
Next Row	Ctrl+down arrow
Previous Row	Ctrl+up arrow
Open/Close Table Window Filter	Ctrl+Z
Next Page	Ctrl+right arrow
Previous Page	Ctrl+left arrow

Table 6. Keyboard shortcuts for dates

Action	Keyboard shortcuts
Insert today's date	Ctrl+SHIFT+7
Move forward one day	ALT+up arrow
Move back one day	ALT+down arrow
Move forward one month	Ctrl+SHIFT+0
Move back one month	Ctrl+SHIFT+9
Move forward one year	Ctrl+SHIFT+up arrow
Move back one year	Ctrl+SHIFT+down arrow

Table 7. Non-standard keyboard shortcuts

UI element	Action	Standard UI response	Deviation
Radio buttons	To move between radio buttons, press the Right and Left arrows.	The radio buttons are selected as the user moves through them.	The radio buttons are highlighted but not selected as the user moves through them. A radio button is selected only when the user presses Spacebar or Enter on the highlighted radio button.
Tree view	To select a node, press Enter.	When the user presses Enter, the default action is performed for a node.	Nodes might have zero, one, or two actions. If a node has 2 actions and a user navigates to an element by using the arrows, when the user presses Enter the default action is performed. When the user presses Enter a second time, the secondary action is performed.

Interface information

Maximo Manage has the following accessibility characteristics:

- If PDF files are included, the files have limited accessibility support. With PDF documentation, you can use optional font enlargement, high-contrast display settings, and you can navigate by keyboard alone. All PDF documentation is also available in HTML format.
- Maximo Manage online product documentation is available in IBM® Documentation, which is viewable from a standard web browser.
- Maximo Manage does not have audio features in its interface.
- You can use supported screen readers with the user interface.
- You use the Go To menu to navigate to any of the applications that you have access to. The Go To menu is a cascading menu that is three levels deep at its deepest point. You can use the screen reader with the Go To menu.

The following instructions apply to both the standard navigation and the side navigation menu and describe how to get started with the screen reader:

1. To get to the Go To menu press Alt+G.
 2. When you open the menu, the screen reader reads the first application in the menu. If the screen reader does not read the entry, restart the screen reader.
 3. Navigate the list of applications in the menus by using the arrow keys.
 4. The screen reader indicates whether a menu item has submenus. To get to a submenu, press the right arrow or enter.
 5. Press the left arrow to move up a level in the hierarchy. If you press the left arrow at the highest level of the Go To menu, you leave the menu completely.
 6. Press the Enter key to enter an application.
- The Maximo Manage user interfaces do not have content that flashes 2 - 55 times per second.

The Maximo Manage web user interfaces rely on cascading style sheets to render content properly and to provide a usable experience. The application provides an equivalent way for low-vision users to use a user's system display settings, including high-contrast mode. You can control font size by using the device or web browser settings.

The Maximo Manage web user interface includes WAI-ARIA navigational landmarks that you can use to quickly navigate to functional areas in the application.

Related accessibility information

In addition to standard IBM help desk and support websites, IBM has established a TTY telephone service for use by deaf or hard of hearing customers to access sales and support services:

TTY service 800-IBM-3383 (800-426-3383) (within North America)

IBM and accessibility

For more information about the commitment that IBM has to accessibility, see [IBM Accessibility](#).

Documentation conventions

The following table describes the conventions that are used in this documentation.

Icon	Description
	Identifies IBM® Maximo® Manage that is offered as a customer-managed product on Red Hat® OpenShift®.
	Identifies Maximo Manage that is offered as a cloud-based product on Amazon Web Services (AWS).
No icon	For both Maximo Application Suite and (SaaS).

Getting started with Maximo® Manage

After you sign in, you see your start center. The start center contains links to actions, applications, and data records for you to begin the tasks that are relevant to your job.

- [Start Center](#)
A Start Center is a page that gives you quick access to the tools and key performance indicators (KPIs) that you use most frequently. You can change the appearance of the Start Center and can have multiple Start Centers. All your Start Centers are accessible from the main Start Center page.
- [Operational dashboard](#)
The Operational dashboard is a modernized landing page that is similar to the Start Center. You can use the Operational dashboard to monitor KPIs, see your workflow assignments that are due soon, quickly complete tasks, and access other applications.
- [My profile information](#)
Your profile contains the user information specific to you such as your password, electronic signature key, contact details, and time zone. You can change your profile information and default settings. For example, you can modify your default information to ensure that you see records for your site only.
- [Navigation](#)
To navigate the user interface, you use the links on the navigation bar and can use keyboard shortcuts for many actions. You can also navigate location and asset hierarchies.
- [Searching](#)
The search method that you use depends on how much you know about the record that you want to find. For example, you must know the exact record ID to search by using the Find field but need only a partial value to search by using wildcards.
- [Entering data and dates in fields](#)
When you create or edit a record, you can enter values in fields by using different methods depending on the type of field and what you need to enter. You can also use classifications to retrieve historical data.
- [Printing documents](#)
You can print the documents attached to a record or work pack. You can also schedule and print reports in an application.

Start Center

A Start Center is a page that gives you quick access to the tools and key performance indicators (KPIs) that you use most frequently. You can change the appearance of the Start Center and can have multiple Start Centers. All your Start Centers are accessible from the main Start Center page.

To see the most up-to-date data in your key performance indicators (KPI), click Update in the KPI section.

Each Start Center is based on a template. Each security group is assigned a Start Center template. When you log on to the system, you see a Start Center that is based on the template for the security group to which you are assigned. If you belong to more than one security group, you might see more than one tab. Each tab is a Start Center for a different security group.

A user with administrative rights can create and change templates, update portlets, and change the appearance of the Start Center. A user with administrative rights can also control which portlets you see and can configure.

By default, Start Center templates are shown in English. However, a user with administrative rights can create Start Center templates that are shown in languages other than English.

- [Start Center portlets](#)
A portlet is a configurable window that provides quick access to applications and actions, and an at-a-glance view into data specific to the job function of an individual.
- [Managing Start Center templates](#)
The portals and content that users see in the Start Center depends on the Start Center template that is assigned to their security group. A user with administrative rights can create Start Center templates, modify or delete existing templates, and create templates that can be shown in multiple languages.
- [Configuring Result Set portlets](#)
You can specify that rows in a Result Set portlet are colored if they meet a condition. For example, the rows for the incidents with a priority of 1 are colored in red. You can also include related attributes in the result set. For example, you can display the given name and surname of a user, rather than their user ID.
- [Changing the content and layout of the Start Center](#)
You can change the content and layout of Start Center pages. For each Start Center, you can specify the column layout, the portlets that you want to display in each column, the order of those portlets, and which portlets to remove from the columns. You can also specify a name for the Start Center, and this name will appear on the Start Center tab.
- [Specifying a default Start Center](#)
When you have more than one Start Center page available to you, the system displays tabs for each page. You can set which Start Centers appear as tabs on the Start Center page, and which you want to open by default when you navigate to the Start Center.
- [Editing portlets in the Start Center](#)
You can change the contents of a portlet in the Start Center to make the information more useful to you. Changes can include adding information to a portlet, removing information from a portlet, changing the order of information in the portlet, and renaming the portlet.
- [Updating Start Centers](#)
When a system administrator notifies you that changes have been made to your start center template, you can update the Start Center page.

Start Center portlets

A portlet is a configurable window that provides quick access to applications and actions, and an at-a-glance view into data specific to the job function of an individual.

- [Favorite Applications portlet](#)
Use the Favorite Applications portlet in your Start Center to display the applications that you use frequently. Clicking an application in the portlet takes you directly to the application.
- [Inbox/Assignments portlet](#)
Inbox/Assignments is one of the portlets that you might see on your Start Center. The portlet lists your task assignments. You use the inbox to review assignments, to route assignments, and to complete assignments.
- [KPI Graph portlet](#)
Key Performance Indicators (KPIs) provide the means to track critical performance variables over time. The KPI Graph portlet displays graphical representations of KPIs.
- [KPI List portlet](#)
Key Performance Indicators (KPIs) provide the means to track critical performance variables over time. You use the KPI List Setup Portlet to create a table of KPIs that can be viewed in the Start Center.
- [Quick Insert portlet](#)
You can add actions to the Start Center in the Quick Insert portlet. Clicking an item in the portlet list takes you to the application to carry out the task. In addition, you can associate templates with some actions. When you click an action link that has an associated template, the template is applied to the action.
- [Report List portlet](#)
The Report List portlet displays the reports that you use frequently. Clicking a report in the portlet runs the report.
- [Result Set portlet](#)
The Result Set portlet displays the results of a saved query in either list format or chart format.

Favorite Applications portlet

Use the Favorite Applications portlet in your Start Center to display the applications that you use frequently. Clicking an application in the portlet takes you directly to the application.

A Start Center can have one or more Favorite Applications portlets so that you can organize applications into logical groups. You can change the title of the portlet to one that makes sense to you.

Inbox/Assignments portlet

Inbox/Assignments is one of the portlets that you might see on your Start Center. The portlet lists your task assignments. You use the inbox to review assignments, to route assignments, and to complete assignments.

A task assignment is a record that is routed to you for action, based on information in a workflow process. You must complete the assignments before a record can move to the next step in a workflow process.

KPI Graph portlet

Key Performance Indicators (KPIs) provide the means to track critical performance variables over time. The KPI Graph portlet displays graphical representations of KPIs.

The KPI Graph portlet displays the Actual, Target, and Variance values for each KPI. When one KPI is selected for the portlet, it is shown as a gauge on the Start Center. When more than one KPI is selected, a bar chart is displayed.

Tip: To avoid skewing the graphical presentation, add graphs of only one type, either decimal or percentage.

Colors are used for an at-a-glance estimate of the value, and caution and alert values can be set. When the value of the KPI is in the safe zone, it is green. When the value of the KPI is between the caution and alert values, it is yellow. And when the value of the KPI is above the alert value, it is red.

There is also a status indicator of the directional trend since the last reading. For example, if a KPI is yellow but was previously red, then this trend is good. But if it is yellow and was previously green this trend is cause for concern.

Tip: Consider changing the name that is displayed on the Start Center if you create more than one KPI Graph group. You can use display names to reflect how you work. For example, the display name can indicate how often you perform actions, such as daily, weekly, or monthly. Or a display name can indicate the category to which actions belong, such as personnel or equipment.

The same information is displayed in the KPI List portlet, but in text format. You can display different KPIs in KPI List and KPI Graph.

KPI List portlet

Key Performance Indicators (KPIs) provide the means to track critical performance variables over time. You use the KPI List Setup Portlet to create a table of KPIs that can be viewed in the Start Center.

The KPI List displays the Actual, Target, and Variance values for each KPI.

Colors are used for an at-a-glance estimate of the value. When the KPI is set up, caution and alert values can be set. When the value of the KPI is in the safe zone, it is green. When the value of the KPI is between the caution and alert values, it is yellow. And when the value of the KPI is above the alert value, it is red.

There is also a status indicator of the directional trend since the last reading. For example, if a KPI is yellow but was previously red, then this trend is good. But if it is yellow and was previously green this trend is cause for concern.

Tip: Consider changing the name that is displayed on the Start Center if you create more than one KPI List group. You can use display names to reflect how you work. For example, the display name can indicate how often you perform actions, such as daily, weekly, or monthly. Or a display name can indicate the category to which actions belong, such as personnel or equipment.

The same information is displayed in the KPI Graph portlet, but in graphical format. You can display different KPIs in KPI List and KPI Graph.

Quick Insert portlet

You can add actions to the Start Center in the Quick Insert portlet. Clicking an item in the portlet list takes you to the application to carry out the task. In addition, you can associate templates with some actions. When you click an action link that has an associated template, the template is applied to the action.

Templates associated with actions

You can associate a template with an action by specifying a template. For example, associate a template named `I need to reset my password` with the New Service Request action. When you click the link for that action in the Start Center, a new Service Request record opens with the appropriate fields completed.

Tip: Consider replacing the default description for actions with templates. An action can have several templates associated with it. So change the description to match the template and identify the action in the Start Center. In this example, consider changing the description from New Service Request to Reset Password.

Report List portlet

The Report List portlet displays the reports that you use frequently. Clicking a report in the portlet runs the report.

Use the Report List portlet to run reports from the Start Center. You can add any report to the portlet that you have rights to run. A Start Center can have one or more Report List portlets so that you can organize applications into logical groups. You can change the title of the portlet to one that makes sense to you.

Result Set portlet

The Result Set portlet displays the results of a saved query in either list format or chart format.

If you frequently run the same searches, you can save time by creating saved queries. You can display the results of those queries on the Start Center in the Result Set portlet. A Start Center can have one or more Result Set portlets.

You can interact with the result set from within the portlet:

- Alternate between a list view and a chart view by clicking either List View or Graphical View. The link depends on which view you are in. If you have not set up a chart, you see Set Graph Options instead of Graphical View.
- Display graphical information as a bar chart or a pie chart by clicking the Chart type link.
- View the results of the entire result set in the List tab of the application by clicking the Open result set in the application icon.
- View a subset of the results in the List tab of the application by clicking a bar or a slice of pie graph.
- View a specific record in an application from the list view by clicking the record in the Result Set portlet. For example, if the query involves purchase orders, when you click a list item you are taken to the Purchase Orders application.

Options available from the Result Set portlet

You can change how the portlet is displayed by clicking the Edit Portlet icon:

- Change the default display format of a chart or a list.
- Set the number of rows in the portlet.
- Apply colors to rows in a list view using the Condition Attribute on the Color Options tab.
- Change the fields in a list view on the Field Configuration tab.
- Change details in a graphical view on the Chart Options tab.

Managing Start Center templates

The portals and content that users see in the Start Center depends on the Start Center template that is assigned to their security group. A user with administrative rights can create Start Center templates, modify or delete existing templates, and create templates that can be shown in multiple languages.

- [Creating a start center template](#)
To create a Start Center, you create a template that specifies the column layout, information portlets, and name for the Start Center.
- [Changing start center templates](#)
You can change start center templates to change the column layout, the portlets in the columns, and the name of the Start Center.
- [Changing existing Start Center templates](#)
You can use this window to open an existing template to change it, or you can delete a template.

- [Creating Start Center templates in multiple languages](#)

The Start Center that users see when they log in depends on their security group. By default, Start Center templates are in English. An administrator can create a Start Center template that can be viewed in multiple languages. Then, the administrator can assign the template to the security group whose users require non-English languages.

Creating a start center template

To create a Start Center, you create a template that specifies the column layout, information portlets, and name for the Start Center.

About this task

You must have system privileges to create a template for your Start Center.

Procedure

1. At the top of the Start Center page, click New Template.
2. Select the column layout for the Start Center page.

Option	Description
Equal Width	Divides the page into two equal columns
Narrow-Wide	Places a narrow column on the left and a wide column on the right
Wide-Narrow	Places a wide column on the left and a narrow column on the right

3. In the Description field, type the name that you want to appear on the tab for this Start Center.
4. Select the portlets that you want to appear in the left and right columns of the Start Center, as follows:
 - a. In the section for the column (left or right) to which you want to add portlets, click Select Content.
 - b. In the Available Portlets window, select the check box beside the portlets that you want to add. Although you can add portlets to either column, use the Suggested Format information as guidance.
 - c. Click OK.
5. Click Finished. You are returned to the Start Center where the template is added as a tab at the top of the page.
6. Select the new template tab.
7. Save the new template, delete it, or cancel any changes you made to it. When you save the template, it possibly can disappear from your Start Center. This behavior is determined by the group the new template is assigned to.

What to do next

When the new Start Center page opens, the portlets are shown in the appropriate column but with no content. Click the Edit Portlet icon in the new portlet to specify content for it.

Changing start center templates

You can change start center templates to change the column layout, the portlets in the columns, and the name of the Start Center.

Procedure

1. At the top of any Start Center page, click Modify Existing Template to open the Modify a Template window.
2. Click the link for the template that you want to change to open that template in a tab on your Start Center page.
3. You can now modify the template in the same manner as you would any other Start Center page.
4. Select Save Template when finished.

Changing existing Start Center templates

You can use this window to open an existing template to change it, or you can delete a template.

About this task

The template list contains all of the templates that you have authorization to modify. If the template that you want to modify is not displayed in the list, click Update List to reload the list of available templates.

Procedure

1. To delete a template, click the Delete Template icon in the row containing the template you want to delete.
2. In the template list, click the name of the template that you want to modify to open the template as another tab in your Start Center.

Creating Start Center templates in multiple languages

The Start Center that users see when they log in depends on their security group. By default, Start Center templates are in English. An administrator can create a Start Center template that can be viewed in multiple languages. Then, the administrator can assign the template to the security group whose users require non-English languages.

Before you begin

You must have an administrator account whose default language is the language that you want to use in the Start Center. If you require templates in several languages, you must have an administrator account for each language.

About this task

The content and structure of Start Center templates are stored in .xml files. However, any editable description labels are stored in a separate database table and are referenced in the .xml files by using the contentuid attribute. The description labels in English are stored in the MAXLABELS table, and description labels in other languages are stored with their language codes in L_MAXLABELS table.

To reduce the number of changes that are required in Start Center templates, create the template after you verify that all portlets and content are required.

Procedure

1. Log in as an administrator whose default language is English and create a Start Center template.
2. In the new English-language template, add portlets.
3. Configure the portlets to include the necessary content and provide labels for the editable descriptions.
4. Save the template.
The template is saved in English. The labels in the XML are inserted into the MAXLABELS table.
5. In the Security Groups application, open the relevant group for your users and specify the new template as the Start Center template.
6. Save the record and log out.
7. Log in as an administrator whose default language is not English, click Modify Existing Template, and select the English-language template that you created.
All editable description labels are in English. If a portlet does not provide editable description labels, then those labels are shown in the default language. For example, your default language is Russian and your template includes the KPI Graph portlet and the Inbox portlet. The KPI Graph portlet is entirely in English, but the labels for the Inbox portlet are in Russian.
8. Edit each portlet to include editable description fields in the non-English language.
9. Save the template.
10. To apply the changes for the non-English language, update the Start Center.
The editable description labels are now shown in the non-English language. The description labels are also saved in the L_MAXLABELS table with the language code.

Results

Any user whose default language is the same as the language code in the L_MAXLABELS table can log in and see that language used in the Start Center labels. Users whose default language is English can see the English version of the Start Center.

If the Start Center template requires the addition or removal of portals, you must log in as an administrator whose default language is English and change the English language version of the template.

Configuring Result Set portlets

You can specify that rows in a Result Set portlet are colored if they meet a condition. For example, the rows for the incidents with a priority of 1 are colored in red. You can also include related attributes in the result set. For example, you can display the given name and surname of a user, rather than their user ID.

- [Applying colors to result set rows](#)
You can apply colors to rows in the Result Set portlet to highlight set-points and implement user-defined standards. For example, for all work orders with a status of WAPPR, you can change the row color to blue. You can apply color to only one condition attribute in a result set.
- [Displaying related attributes in Result Set portlets](#)
A number of report object structures are available to provide the data for related attributes in Result Set portlets. However, you might require a new object structure, or you might need to add attributes to an existing object structure.

Applying colors to result set rows

You can apply colors to rows in the Result Set portlet to highlight set-points and implement user-defined standards. For example, for all work orders with a status of WAPPR, you can change the row color to blue. You can apply color to only one condition attribute in a result set.

Procedure

1. From the Result Set portlet, click the Edit Portlet icon.

2. In the Query field, ensure that the relevant query is specified.
3. In the Color Options tab, specify a condition attribute and click Add Color Alert.
4. Complete the fields and click Finished.

Displaying related attributes in Result Set portlets

A number of report object structures are available to provide the data for related attributes in Result Set portlets. However, you might require a new object structure, or you might need to add attributes to an existing object structure.

Procedure

1. Make the attributes available for display in the Result Set portlet:

Option	Description
If the object structure does not exist	Create an object structure or select the action to duplicate an existing report object structure and modify as necessary.
If the object structure exists but does not include the attributes you want	Open the object structure and select the Exclude/Include Fields action.

2. Configure security for the report object structure so that users can see the related attributes in the Result Set portlet and so that you can specify the object structure when you configure the result set.

Changing the content and layout of the Start Center

You can change the content and layout of Start Center pages. For each Start Center, you can specify the column layout, the portlets that you want to display in each column, the order of those portlets, and which portlets to remove from the columns. You can also specify a name for the Start Center, and this name will appear on the Start Center tab.

Procedure

1. On the Start Center that you want to update, click the Change Content/Layout link.
2. Complete a task in the following table to change the content and layout of the Start Center page, as needed. If you want to complete multiple tasks while on the Layout and Configuration page, only click Finished when you have completed all tasks.

Option	Description
Change the column layout of the Start Center page	<ol style="list-style-type: none">a. In the Layout field, specify the column layout that you want to use. Selecting Equal Width divides the Start Center into two equal columns. Wide-Narrow places the wide column on the left of the Start Center page, and Narrow-Wide places the narrow column on the left.b. Click Finished.
Change the Start Center name that is displayed on the tab	<ol style="list-style-type: none">a. In the Description field, specify the name of the current Start Center. This name appears on the tab for the current Start Center.b. Click Finished.
Add portlets to the Start Center page	<ol style="list-style-type: none">a. In the section for the column (left or right) to which you want to add portlets, click Select Content.b. In the Available Portlets window, select the check box beside the portlets that you want to add. Although you can add portlets to either column, use the Suggested Format information as guidance.c. Click OK.d. Click Finished.e. When the Start Center page opens, the portlets are shown in the appropriate column but with no content. Click the Edit Portlet icon in the new portlet to specify content for it.
Change the order of the portlets on the Start Center page	<ol style="list-style-type: none">a. Enter a sequential number in the Order column for any portlets that you want to display in order. Any portlets that you do not order, will be listed after the ones you do order.b. Click Finished.
Remove a portlet from the Start Center page	<ol style="list-style-type: none">a. Click the Trash icon for the portlet that you want to remove. A line is drawn through the portlet.b. Click Finished to return to the Start Center page where the portlet is no longer displayed.

Specifying a default Start Center

When you have more than one Start Center page available to you, the system displays tabs for each page. You can set which Start Centers appear as tabs on the Start Center page, and which you want to open by default when you navigate to the Start Center.

Procedure

1. Click Display Settings to open the Display Settings window.
2. Select the check the box next to each Start Center that you want to display or clear the check box next to each Start Center that you want to hide.
3. Select the check box next to the Start Center that you want to open by default when you navigate to the Start Center. You can check only one default Start Center.
4. Click OK.

Editing portlets in the Start Center

You can change the contents of a portlet in the Start Center to make the information more useful to you. Changes can include adding information to a portlet, removing information from a portlet, changing the order of information in the portlet, and renaming the portlet.

Procedure

1. From the Start Center portlet for which you want to make content changes, click the Edit Portlet icon.
2. On the portlet setup page, specify your changes to the portlet content.
3. Click Finished. The portlet is updated with the content changes you made.

Updating Start Centers

When a system administrator notifies you that changes have been made to your start center template, you can update the Start Center page.

Before you begin

You must have access to the Update Start Center option to update a Start Center page.

About this task

You can choose a language when you are logging in but you click Update Start Center to translate the Start Center. When you update the Start Center page, you lose any configurations that you made, for example, specific quick inserts or result sets. If you update the Start Center page and there are no changes to your original template, the latest changes you have made to the Start Center are discarded. Also, the template on which the Start Center was originally based on is reapplied.

Procedure

1. Click Update Start Center on the Start Center page that you want to update.
2. Click Yes in the message that opens.
The new Start Center page displays.

Results

The current Start Center page is deleted and replaced with a page that uses the same template as the deleted page.

Operational dashboard

The Operational dashboard is a modernized landing page that is similar to the Start Center. You can use the Operational dashboard to monitor KPIs, see your workflow assignments that are due soon, quickly complete tasks, and access other applications.

KPIs

The Operational dashboard includes the following KPIs:

Overdue Emergency Work

The number of emergency work orders that are overdue.

Overdue PM Work

The number of preventive maintenance work orders that are overdue.

PM Performance

The rate of closure of preventive maintenance work orders.

Open Work Orders Waiting Approval

The number of work orders with a status of Waiting for approval.

Each KPI includes trend information, so you can see how much it as increased or decreased since the last time the data was refreshed. You can also see how much each KPI is over or under the target that is set by your organization.

You can use KPI Manager to either refresh these KPIs manually, or schedule automatic refreshes by using the preexisting **KPICronTask**. For more information, see [Managing cron tasks](#).

Favorites and Quick actions

The Favorites card contains links to other applications, including Work Orders, Workflow Assignments, Work Order Tracking, and Service Requests.

The Quick actions card contains links to forms for common tasks, such as creating a work order, creating a service request, and creating a purchase request.

Workflow assignments due soon

On the Workflow assignments due soon card, you can see your workflows assignments that are due in the next 24 hours or overdue. You can select one or more of these assignments to accept, reject, route, or reassign them. Clicking a workflow assignment opens it in the application in which it was created.

My profile information

Your profile contains the user information specific to you such as your password, electronic signature key, contact details, and time zone. You can change your profile information and default settings. For example, you can modify your default information to ensure that you see records for your site only.

- [Changing my default information](#)
You can customize several aspects of working with the system that are specific to your user. You can specify the application that opens when you log onto the system, the records that display when you open an application, and the values that are inserted by default on records that you create.
- [Changing my password information](#)
You use the Password Information dialog box to change your password, password hint, or both. The system administrator must enable the password hint question and answer for you to reset your password. If the fields are disabled, the system administrator did not enable the feature.
- [Changing my personal information](#)
You use the Personal Information dialog box to add or change workplace and credit card information that the system uses on certain kinds of records.
- [Specifying the electronic signature key](#)
If your organization requires electronic signature verification, you must create an electronic signature password key for verification.

Changing my default information

You can customize several aspects of working with the system that are specific to your user. You can specify the application that opens when you log onto the system, the records that display when you open an application, and the values that are inserted by default on records that you create.

Procedure

1. From the toolbar, click Profile and select Default Information.
2. In the Default Information window, edit the following fields as needed:

Field name	Description
Default Insert Site	Specify the site from which you most often insert records. When you insert a record, if the Site field is not determined by some other relationship, the system enters the site you specified as the default value. Similarly, if an Organization field is not determined by some other relationship, the system enters the Organization owning this site in the field.
Use Default Insert Site as a Display Filter?	Select this check box to ensure that the system displays records for only the default insert site. If the application is defined at the organization-level, the system displays the records for the organization to which the site belongs. You can clear the check box in applications where you can view records for all the sites for which you have access.
Use Side Navigation?	Select this check box to move the queries, Select Action options, and toolbar actions to a navigation menu on the side of the UI. On the Start Center, the side navigation menu shows the items that are typically in the Go To menu.
Storeroom Site for Self-Service Requisitions	Specify the site and storeroom from which you most often request material. When you create a material requisition in a self service application and the site is not determined by another relationship, the system inserts this site and the default storeroom.
Default Storeroom for Self-Service Requisitions	Specify the storeroom from which you most often request material. You can enter a value for the storeroom site only, but if you specify a default storeroom, you must also specify the storeroom site.
User Default Application	Specify the application that displays when you log on to the system.
Language	Specify the language in which you want to use the system.
Locale	Specify a locale and use this field to configure several system settings such as the currency and date formats.
Calendar Type	Specify the calendar that you use such as Gregorian or Islamic.
Time Zone	Specify the time zone where you are based.
Default Repair Facility	Specify the location that is the default repair facility.
Repair Facility Site	Specify the site where the default repair facility is located.

3. Click OK.

Changing my password information

You use the Password Information dialog box to change your password, password hint, or both. The system administrator must enable the password hint question and answer for you to reset your password. If the fields are disabled, the system administrator did not enable the feature.

Before you begin

If you did not specify a password hint question and answer for your user, you must contact your system administrator and request that your password is reset.

About this task

The system administrator must configure the SMTP property and then enable the property in the System properties application to enable the password, password hint, or both.

Procedure

1. From the toolbar, click Profile and select Password Information.
2. In the Current Password field, enter your current password. The other password fields become editable only after the system validates your current password.
3. Edit the following fields as needed:

Field	Action
New Password	Specify a password that is at least 6 characters long. Your company might have other requirements, such as a longer password or the use of numeric or symbol characters. If the value you enter is not valid, an error message is displayed.
Verify New Password	Reenter your new password.
Password Hint Question	Click Select Value to select from a list of possible questions.
Password Hint Answer	Specify your answer to the question. If you become blocked from using the system, an administrator can use the password question and answer to verify your identity. Answers are case-sensitive.

4. Click OK.

Changing my personal information

You use the Personal Information dialog box to add or change workplace and credit card information that the system uses on certain kinds of records.

Procedure

1. From the tool bar, click Profile and select Personal Information.
2. In the Personal Information dialog box, edit the following fields as needed:

Field name	Description
Primary Phone	List the phone number or numbers where you can be reached. To list multiple phone numbers, click Show/Manage Values and add rows in the dialog box that opens. Specify the Type, for example Home or Work, and select the Primary check box to indicate the number with which you can best be reached. If the Primary Phone field contains more than one phone number, it becomes read-only and you must click Show/Manage Values to see all of them or edit the field.
Primary E-mail	List your e-mail address or addresses. To list multiple addresses, click Show/Manage Values and add rows in the dialog box that opens. Specify the Type, for example Home or Work, and select the Primary check box to indicate the address with which you can best be reached. If the Primary E-mail field contains more than one address, it becomes read-only and you must click Show/Manage Values to see all of them or edit the field.
Primary SMS	List your short message service address or addresses for receiving short text messages. To list multiple addresses, click Show/Manage Values and add rows in the dialog box that opens. Specify the Type, and select the Is this the Primary SMS Address check box to indicate the address where you can best be reached. If the Primary SMS field contains more than one address, it becomes read-only and you must click Show/Manage Values to see all of them or edit the field.
Person's Site	Specify the site where you work.
Person's Location	The specific location where you work may be part of your company's location structure. Click Select Value to select from a list.
Ship to Address	If you specified a site in the Person's Site field, specify the appropriate shipping address.
Drop Point	Specify a drop point for deliveries.
Card #	If you have a company credit card, specify its number.
Card Type	Click the drop down button to select from a list.
Verification Value	Specify the three- or four-digit code on the credit card.
Expiration Date	Specify the date on which the card expires.

3. Click OK.

Specifying the electronic signature key

If your organization requires electronic signature verification, you must create an electronic signature password key for verification.

About this task

To comply with regulatory requirements, some organizations require that users provide credentials and give a reason for changes before they can change records. If your organization requires electronic signature verification, you must create an electronic signature key when you set up your profile. When you perform an action or change a field that requires authentication, enter the key that you created.

Administrators can configure security controls to require that electronic signature keys conform to rules for product passwords.

Procedure

1. From the toolbar in the Start Center, click Profile and select Set or Modify E-Signature Key.
2. In the Set or Modify E-Signature Key window, select from the following options:
 - If you are a first-time user, specify a new key in the New E-Signature Key field and confirm the key in the Verify New E-Signature Key field.
 - If you are modifying an existing key, edit the following fields as needed:

Field name	Description
Current E-Signature Key	Specify the current electronic signature key.
New E-Signature Key	Specify a new electronic signature key.
Verify New E-Signature Key	Specify the new electronic signature key again to confirm its accuracy.

Navigation

To navigate the user interface, you use the links on the navigation bar and can use keyboard shortcuts for many actions. You can also navigate location and asset hierarchies.

- [Bookmarks](#)
If you frequently view the same records, you can save time by creating bookmarks. You click a bookmark to be taken directly to a record.
- [Navigation bar](#)
The Navigation bar identifies the current application, shows messages, and has links so you can move among applications.
- [Keyboard shortcuts](#)
You can use a combination of keys to perform an action without using a mouse. Some of the combinations are standards and adhere to the Web Content Accessibility Guidelines (WCAG) version 2.0 and the Web Accessibility Initiative - Accessible Rich Internet Applications (WAI-ARIA) specification.

Bookmarks

If you frequently view the same records, you can save time by creating bookmarks. You click a bookmark to be taken directly to a record.

There are two ways to add a record to your list of bookmarks. You can click the Add to bookmarks icon from the list tab or you can use the menu item.

The bookmarks you create are saved in My Bookmarks which you can access from the Search toolbar of the list tab. When you delete a bookmark, it is only removed after you close My Bookmarks. Deleting a bookmark does not delete the corresponding record.

Each application has separate bookmarks, for example, work orders bookmarked in Work Order Tracking are not bookmarked in Quick Reporting.

Navigation bar

The Navigation bar identifies the current application, shows messages, and has links so you can move among applications.

Sections of the navigation bar

The Navigation bar has three sections:

- The application icon and name identify the current application.
- The message area shows informational messages. For example, when you create and save a record, a message indicates that the record was saved.
- The navigation links vary depending on the application, but some are common to most applications.

Table 1. Navigation links common to most applications

Navigation link	Function
Bulletins	Shows the bulletin board and broadcast messages
Go To	Shows a menu of modules and applications that you can move to
Reports	Shows a menu of modules so that you can select an application to run reports on
Start Center	Returns you to the start center
Profile	Opens your personal information so you can manage it
Sign Out	Signs you out
Help	Shows a help menu

Keyboard shortcuts

You can use a combination of keys to perform an action without using a mouse. Some of the combinations are standards and adhere to the Web Content Accessibility Guidelines (WCAG) version 2.0 and the Web Accessibility Initiative - Accessible Rich Internet Applications (WAI-ARIA) specification.

Standard keyboard shortcuts

You can navigate among and within the applications by using a combination of keys. You can use the following keyboard shortcuts to navigate the application screens.

Table 1. Keyboard shortcuts for general navigation

Action	Keyboard shortcut
Move from one interface element to the next.	Tab key
Select buttons, links, and menu options.	Enter key
Select or clear a check box.	Spacebar
Display field help for field in focus.	Alt+F1

Table 2. Keyboard shortcuts for global navigation

Link name	Keyboard shortcut
Bulletins	Alt+B
Go To	Alt+G
Reports	Alt+R
Start Center	Alt+C
Profile	Alt+P
Sign Out	Alt+S
Help	Alt+H
Return	Alt+R
Return with Value	Alt+W

Table 3. Keyboard shortcuts for application-specific actions

Action	Applications	Keyboard shortcut
Assign Labor	Assignment Manager	Ctrl + Alt + L
Finish Assignment	Assignment Manager	Ctrl + Alt + F
Interrupt Assignment	Assignment Manager	Ctrl + Alt + U
Select Work Date	Assignment Manager	Ctrl + Alt + W
Start Assignment	Assignment Manager	Ctrl + Alt + T
Start Timer	Activities, Changes, Incidents, Problems, Releases, and Service Requests	Ctrl + Alt + B
Stop Timer	Activities, Changes, Incidents, Problems, Releases, and Service Requests	Ctrl + Alt + E

Table 4. Keyboard shortcuts for toolbar actions

Action	Keyboard shortcut
Insert New Record	Ctrl+Alt+I
Save Record	Ctrl+Alt+S
Clear Changes	Ctrl+Alt+C
Previous Record	Ctrl+Alt+P
Next Record	Ctrl+Alt+N
Change Status	Ctrl+Alt+A
Create KPI	Ctrl+Alt+K
Put record in edit mode or release record from edit mode	Ctrl+Alt+L

Table 5. Keyboard shortcuts for tables

Action	Keyboard shortcuts
Next Row	Ctrl+↓
Previous Row	Ctrl+↑
Open/Close Table Window Filter	Ctrl+Z
Next Page	Ctrl+→
Previous Page	Ctrl+←

Table 6. Keyboard shortcuts for dates

Action	Keyboard shortcuts
Insert today's date	Ctrl+SHIFT+7
Move forward one day	ALT+↑
Move back one day	ALT+↓
Move forward one month	Ctrl+SHIFT+0
Move back one month	Ctrl+SHIFT+9
Move forward one year	Ctrl+SHIFT+↑
Move back one year	Ctrl+SHIFT+↓

Non-standard keyboard shortcuts

There are two keyboard shortcuts that do not conform to standards. It is important that you are aware of these deviations from the standard action so you are aware of the Maximo® Manage UI response.

Table 7. Non-standard keyboard shortcuts

UI element	Standard action	Standard UI response	Maximo Manage UI response
Radio buttons	To move between radio buttons, press the Right and Left arrows.	The radio buttons are selected as the user moves through them.	The radio buttons are highlighted but not selected as the user moves through them. A radio button is selected only when the user presses Spacebar or Enter on the highlighted radio button.
Tree view	To select a node, press Enter.	When the user presses Enter, the default action is performed for a node.	Nodes might have 0, 1 or 2 actions. If a node has 2 actions and a user has navigated to an element by using the arrows, when the user presses Enter the default action is performed. When the user presses Enter a second time, the secondary action is performed.

Searching

The search method that you use depends on how much you know about the record that you want to find. For example, you must know the exact record ID to search by using the Find field but need only a partial value to search by using wildcards.

- [Basic searches](#)
You search for a single record or for a set of records by using the search toolbar. You can also save your queries.
- [Advanced searches](#)
You might want to specify your search by using Structured Query Language (SQL) or by providing examples of the type of records you are searching for. The Advanced Search menu on the search toolbar provides these options.
- [Wildcards and operators for searching](#)
You can use special characters to search when you do not know the entire value that you want to search for or when you want to specify the type of information that you are searching for. The type of value that is used in a field, such as a numeric or string value, determines which operators can be used to filter for values in the field. If you want to change how values are searched for in a specific field, you can edit the SQL where clause for a field.
- [Navigation in location and asset hierarchies](#)
Locations and assets are often defined in hierarchies. When you need to specify a value from one of these hierarchies, you can view a graphical representation of the items to select from.

Basic searches

You search for a single record or for a set of records by using the search toolbar. You can also save your queries.

Searching for single records

You must know the exact record ID to search using the Find field. Entering a partial record ID does not return any results. For example, to search for a work order, enter the exact work order number in the Find field and press enter.

Filtering tables

The table filter is a row of editable fields at the top of the table. If the filter is not visible, click the Filter icon. You can filter one or all of the columns in a table and then press Enter to see the results of your search.

Saving queries

If you frequently perform the same searches, you can save time by creating saved queries. You can also define a default saved query to display every time you open an application. Saved and default queries are specific to each application. For example, a query created in Work Order Tracking is not available in Quick Reporting, unless you also create and save it in Quick Reporting.

The Save Query menu lists saved query options:

Save Current Query

Click to name and save your query so that you can reuse it at a later time.

View/Manage Queries

Click to view and manage your saved queries for your current application.

Advanced searches

You might want to specify your search by using Structured Query Language (SQL) or by providing examples of the type of records you are searching for. The Advanced Search menu on the search toolbar provides these options.

You use the WHERE Clause dialog box to conduct advanced queries of the Maximo® database by using Structured Query Language (SQL). SQL is a language that is commonly used by system administrators to request information from databases. To perform advanced queries, you must be familiar with both SQL and the Maximo database.

You can query by example by clicking Advanced search, > More search fields. You do not need to be familiar with any specialized language to perform this kind of search. Querying by example (QBE) means that you enter values in the fields to provide the system with an example of the type of records you are searching for. For example, if you want to find all work orders with a status of waiting for approval, you would enter WAPPR in the Status field. You can give examples of records you want to find by entering values in one or more fields in the dialog box. You can also enter more than one value in a field. The values must be separated by commas,

and cannot exceed the length that is allowed for the field. For example, to find work orders that list either pumps or motors you enter "pump, motor" in the Description field.

- [Searching by using examples](#)
You enter values in the fields of the More Search Fields window to give an example of the type of records you are searching for.
- [SQL WHERE clause searches](#)
A WHERE clause is used to filter records and extracts only those records that fulfill a certain criterion. You can search using the WHERE clause if you know Structured Query Language (SQL).

Searching by using examples

You enter values in the fields of the More Search Fields window to give an example of the type of records you are searching for.

Procedure

1. On the toolbar of the List tab, click Advanced Search.
2. Click More Search Fields.
3. Optional: Click Change Query on the Revise button to open a new window with the same contents as View/Manage Queries window. You can select a query against which the More Search Fields parameters will be applied.
4. Specify the values to search for. Enter more than one value in a field separated by commas. For example, to find work orders that list either pumps or motors, enter `pump, motor` in the Description field.
5. Click Find.

SQL WHERE clause searches

A WHERE clause is used to filter records and extracts only those records that fulfill a certain criterion. You can search using the WHERE clause if you know Structured Query Language (SQL).

To perform queries using the WHERE clause, you must be familiar with both SQL and the database. If you know SQL you can modify the WHERE clause to change your search parameters. Constructing SQL queries is something that is more commonly performed by system administrators and database administrators. The WHERE Clause window shows the SQL where clause for your current query. The Current Query field shows the current query whether you searched using the View/Manage Queries window or the More Search Fields window. The WHERE Clause window is accessed from the Advanced Search menu.

Wildcards and operators for searching

You can use special characters to search when you do not know the entire value that you want to search for or when you want to specify the type of information that you are searching for. The type of value that is used in a field, such as a numeric or string value, determines which operators can be used to filter for values in the field. If you want to change how values are searched for in a specific field, you can edit the SQL where clause for a field.

Rules for Wildcards and Operators

The following rules apply to fields that contain numbers, such as the Priority field or the Work Order Number field:

- By default, commas can be used only to separate numbers that have more than three digits. To use commas as separators for multiple numeric values, in the System Properties application, set the `mxe.system.IntegerQBESearchCommaAsOr` property to 1. If the property is set to 1, commas can be used only as separators for whole numeric values. For example, `1,245` returns records that contain a value of 1 and records with a value of 245.
- You cannot search for a range of numeric values. To search for more than one value, you must separate each individual value by using a comma, use an operator, or use a wildcard.

The following rules apply to fields that contain dates, such as the Target Delivery Date field or the Shipped Date field:

- If you specify a date without a time, the records that are returned have values for times during the date.
- If you specify a date with a time and specify the minute, the records that are returned have values for the 12 hours after the date and time or until the end of the day.
- If you specify a date with a time and do not specify a minute, the records that are returned have values from the specified time until the end of the day.
- You cannot specify a range of dates, and you cannot specify more than one date in a field.
- You can use the TODAY and YTD (Year to Date) keywords to query for information. YTD lists all records with dates for the present year. TODAY lists all records with the present date. You can use operators with the TODAY keyword to determine what times from the present day are shown.

The following rules apply to fields that contain strings, such as the Name field and the Type field:

- Searches are case sensitive.
- If the equal sign (=) is not used, wildcards are added to the beginning and end of the string so that any record that includes the string in the field is found. However, if you add a wildcard to a string, additional wildcards are not automatically added.
- You can use commas to search for more than one term. For example, you could search for `rails, generators` to find all records that have `rails` or `generators` in that field.

The WHERE Clause

You can edit the WHERE clause to change how values are searched for in a specific field. To edit the WHERE clause, add a value to a field and then select Advanced Search > Where Clause. If you are searching for null values by editing the WHERE clause, you use the SQL comparison values IS NULL and IS NOT NULL to select and compare null values.

Wildcards

A wildcard character is used to search for a partial value in a field when you do not know the entire value. You place the wildcard where the unknown characters occur. You can use more than one wildcard character in a single search.

Table 1. Wildcard characters

Wildcard	Use
%	Substitute for a string of characters. For example, 123% find records that start with 123, such as 123, 12345, and 123ABC.
? or _	Substitutes for a single character. For example, 123? or 123_ find any four-character records that start with 123, such as 1234 or 1239.

Operators

An operator is used to specify the type of information that you are searching for. You can only use operators in fields that have a search type of text, such as Description fields.

Table 2. Operator characters

Operator	Use
ampersand (&)	Find records that contain at least one occurrence of all of your query terms. For example, Rail&Line returns records that include both Rail and Line.
hyphen (-)	Find records that contain at least one query term in a set of two or more, and prioritize the results based on the order of terms with the operator. For example, Rail-Line returns records that only include Rail, records that include only Line, and records that include both, but the records that include only Rail are ranked higher on the results page.
pipe ()	Find records that contain at least one occurrence of any of your query terms. For example, Rail Line returns records that include only Rail, records that include only Line, and records that include both.
tilde (~)	Find records that contain one query term and not another. For example, Rail~Line returns records that include Rail, but does not return records that include Line.
equals (=)	Find records that are an exact match to your query. For example, filtering records with a status of APPR also returns records that have a status of WAPPR unless you type =APPR in the status field. If you are searching for a set of exact values, separate the values with commas. For example, filtering records with priorities =1, =2, and =3 returns records that have a 1, 2, or 3 priority.
~null~	Find records that do not include a value in a specific field. When using the List tab, the Advanced Search action, or the More Search Fields dialog box to search for records that contain null values, use the following syntax: <ul style="list-style-type: none">To search for records that contain a null value for a field, enter ~null~To search for records that do not contain a null value for a field, enter !=~null~ You cannot use the ~null~ or !=~null~ operator in fields that have date values.
<	Find values that are less than the value that is in the field. For example, <3 returns records with values that are less than 3, such as 2 or 1. You cannot use the less than symbol (<) for fields that have string values.
!=	Find all values except for the value that is in the field. For example, !=7 returns records with values such as 4, 5, 6, and 8. You cannot use the not equal operator (!=) for fields that have date values.
>=	Find values that are greater than or equal to the value that is in the field. For example, >=7 returns records with values such as 7, 8, and 9. You cannot use the greater than or equal to symbol (>=) operator for fields that have string values.
<=	Find values that are less than or equal to the value that is in the field. For example, <=3 returns records with values such as 3, 2, or 1. You cannot use the less than or equal to symbol (<=) for fields that have string values.
>	Find values that are greater than the value that is in the field. For example, >3 finds records with values that are greater than 3, such as 4, 5, or 6. You cannot use the greater than symbol (>) for fields that have string values.

Navigation in location and asset hierarchies

Locations and assets are often defined in hierarchies. When you need to specify a value from one of these hierarchies, you can view a graphical representation of the items to select from.

The Drilldown window is available from the DetailMenu on the Asset, Location, and some Belongs To fields. You can use the drill-down feature to complete some fields when you create records. For example, when you create an asset record, you can complete the Parent and Location fields by selecting Detail Menu...>Open Drilldown.

The Drilldown window is also available from the More Actions menu.

The location hierarchies that are shown in the Drilldown window are created in the Locations application, and the asset assembly structures are built in the Assets application.

Standard Drilldown window

You use the Drilldown window to view the assets at a particular location or to view the location of an asset.

In the standard Drilldown window, you can select a location, then switch tabs to view the assets at that location. Alternatively, you can drill down to an asset and then switch tabs to see its location and the systems that location belongs to.

Optional single hierarchy view

Administrators have the option to enable a drill-down view that displays both assets and locations in a single hierarchy. The option offers additional features, including the ability to display the following data about assets and locations:

- Locations, which are organized by systems
- Assets
- Spare parts of assets
- Preventive maintenance items for locations
- Preventive maintenance items for assets

You can use drag-and-drop for asset or location nodes in the hierarchy to complete the following actions:

- Move an asset to a new parent asset
- Move an asset to a new location
- Move a location to another location that is in the same system

You can also select an asset or location and right-click to copy and paste it in a different spot in the hierarchy. Only assets and locations can be moved. You cannot move spare parts or preventive maintenance nodes.

When you select a location node, all systems that are associated with the location are displayed. When you select a location node and select a specific system, the hierarchy displays all ancestors of that location in the system that you selected.

When you select the Open Drilldown option from the More Actions menu, you can select an object. Then, in the Drilldown window, you can click OK and choose to go to the selected object. This option is not available when you select Open Drilldown from the Detail Menu for fields.

The optional, single hierarchy view is available only if your administrator configured the system property that implements this option.

Entering data and dates in fields

When you create or edit a record, you can enter values in fields by using different methods depending on the type of field and what you need to enter. You can also use classifications to retrieve historical data.

- [Specifying values](#)
In addition to typing a value in a field, you can select single or multiple values, or you can go to other applications to retrieve values.
- [Keyboard shortcuts for dates](#)
Many records contain more than one date field. Keyboard shortcuts can be used to quickly enter dates in these fields.

Specifying values

In addition to typing a value in a field, you can select single or multiple values, or you can go to other applications to retrieve values.

You perform the following actions to select values:

Table 1. Specifying values for fields

Action	Description	Example of usage
Select a value from a list of valid values	Click the Select value button next to the field.	In an asset, the Type, Bin, Condition Code, Usage, Calendar, and Shift fields have a select value button.
Find a value by using classifications	1. Click the Detail Menu button and select Classification. 2. Click the value you want to insert.	In an asset, the Parent, Location, and Rotating Item fields have a Detail Menu button with a Classification option.
Find a value in another application	1. Click the Detail Menu button and select Go To <i>application_name</i> . 2. Select the value you want to insert. 3. Click Return With Value.	In an asset, the Location, Rotating Item, Failure Class, Vendor, Manufacturer, and PO fields have a Detail Menu button with an option to go to another application.

You can define data as the default in any table that has a default data section. Values you enter as default table data are used as field defaults when you insert new rows into the table.

Keyboard shortcuts for dates

Many records contain more than one date field. Keyboard shortcuts can be used to quickly enter dates in these fields.

Table 1. Keyboard shortcuts to enter a date in any date field

Action	Keyboard shortcut
Insert today's date	Ctrl+SHIFT+7
Move forward one day	ALT+ ↑

Action	Keyboard shortcut
Move back one day	ALT+↓
Move forward one month	Ctrl+SHIFT+0
Move back one month	Ctrl+SHIFT+9
Move forward one year	Ctrl+SHIFT+↑
Move back one year	Ctrl+SHIFT+↓

Printing documents

You can print the documents attached to a record or work pack. You can also schedule and print reports in an application.

About this task

Note:

The ".ppt, .pptx" attachment formats are not supported for direct printing with attachments in Linux® or Liberty deployments. You can add a ".ppt" or ".pptx" format attachment, but you cannot print it.

- **[Printing individual attachments](#)**
You can select and print an individual document that is attached to a record.
- **[Printing all attachments](#)**
You can print all documents included in the work pack of a current record using the Reports application. By default, all attached documents are included in the work pack of a record. A work pack includes all documents attached to the current record as well as all documents attached to associated application records. For example: When you print a work pack for a Work Order record that has an associated Job Plan, you will also print the documents attached to that Job Plan.
- **[Running, scheduling, and printing reports within an application](#)**
When you are in an application and you need report information, there are several report actions from which you can choose to get that information. For example, you can run a report and then view its table of contents, print the report, and export the report data. You can open and view a report in a browser. You can directly print out a report, with or without attachments. You can schedule a report and send it using e-mail, and you can view and edit scheduled reports.

Printing individual attachments

You can select and print an individual document that is attached to a record.

Procedure

1. Display the record for which you want to print an attached document.
2. Click the Attachments icon to open the Attachments menu.
3. Click View Attachments to open the View Attachments dialog box.
4. Click the underlined document name in the Document column of the View Attachments table window.
5. The system displays the document in a new browser instance. You might need additional software to view some file types. If you cannot view a document in the Internet browser, you cannot print it.
6. Print the document from the new browser instance.

Printing all attachments

You can print all documents included in the work pack of a current record using the Reports application. By default, all attached documents are included in the work pack of a record. A work pack includes all documents attached to the current record as well as all documents attached to associated application records. For example: When you print a work pack for a Work Order record that has an associated Job Plan, you will also print the documents attached to that Job Plan.

Before you begin

You can preview the attached documents for the record before you print by clicking the Attachments icon and selecting View Documents. You might need additional software to view some file types. If you cannot view a document in the Internet browser, you cannot print it. Only documents that have the Print with a work pack? option selected will print when the system generates a report. If you add an attachment using Manage Library the default for Print with a work pack is one, but if you add an attachment using the paperclip icon, the default is zero.

Procedure

1. In any application that has Attached Documents actions, display the record whose attachments you want to print.
2. From the Navigation Bar, select Reports to access the Reports application. See the Reports application topic for detailed instructions about using the Reports application.
3. Optional: To print all documents that are attached to a group of records, use the List tab to select the records and then click Reports in the Navigation Bar from the List tab.

Running, scheduling, and printing reports within an application

When you are in an application and you need report information, there are several report actions from which you can choose to get that information. For example, you can run a report and then view its table of contents, print the report, and export the report data. You can open and view a report in a browser. You can directly print out a report, with or without attachments. You can schedule a report and send it using e-mail, and you can view and edit scheduled reports.

About this task

Attached document files with the following file extensions cannot be printed:

- .ppt
- .pptx

Procedure

Complete a report-action task in the following table to select, view, print, or export report information, as needed.

Option	Description
Run a report and optionally print it, export report data, and toggle the table of contents view	<ol style="list-style-type: none">Select the Reports Menu in the application toolbar and select an application, or select the Run Reports action, to open the Reports dialog box to the On Demand Reports tab.In the Reports to Run table window, click the report that you want to run.In the Request Page dialog box, specify any parameters to define the report, and then click Submit to run the report and open it in your browser.From the Reporting toolbar, perform any of the following actions:<ul style="list-style-type: none">Click the Print Report as PDF icon to print the report. Due to spacing default settings, the page length of your report in .PDF print format can exceed the page length in your report browser.Click the Export Data icon to export the data in .CSV format.Click the Toggle table of contents icon to see the table of contents for the report that you selected.
Open a report in browser view	<ol style="list-style-type: none">Click the Browser View icon in the application toolbar to open the report in a report browser.From Browser View, print the report or export the report data in .CSV format.
Direct-print a report in .pdf form using the default printer of the browser	<ol style="list-style-type: none">Click the Direct Print icon on the application toolbar.
Direct-print a report and all its attachments in .pdf form using the default printer of the browser	<ol style="list-style-type: none">Click the Direct Print with Attachments icon on the application toolbar to view the number of printable attachments that are attached to the report. Printable attachments have a supported file extension.Click Yes to print all printable attachments.
Schedule a report and send the report as PDF in e-mail	<ol style="list-style-type: none">Click the Reports Menu in the application toolbar and select an application, or select the Run Reports action, to open the Reports dialog box.Click the Scheduling Status tab and select one of the following scheduling options:<ul style="list-style-type: none">Once - The report runs on a specific date and time in the future. Use this option to schedule complex or lengthy reports to run during off-peak hours. Specify a date in the format (M or MM) / (D or DD) / YY format. Specify a time in HH:MM format and specify a.m. or p.m.Recurring - The report runs at regular intervals. Four fields let you determine when the report runs. In the first field, enter a number from 1 through 365. In the second field, enter the interval (day, week, or month). In the third field, enter the day of the week or date of the month. In the fourth field, enter the time in HH:MM format, along with AM or PM. The following examples show the use of these fields: To run a report every day at 6:00 AM, select 1, and then Day. Leave the third field blank and then 6:00 AM. To run a report every other Friday at 5:00 PM, select 2, then Weeks, then Friday, and then 5:00 PM. To run a report every three months at 11:00 PM, on 15th of the month, select 3, then Months, then Day 15, and then 11:00 PM.Specify one or more e-mail addresses of the recipients for the report. Enter any comments you want to include in the e-mail message.Specify a subject for the report, or use the report name which defaults to this field.Click Submit to run the report and send it to the e-mail address at the scheduled time.
View and edit scheduled reports	<ol style="list-style-type: none">Click the Reports Menu in the application toolbar and select an application, or select the Run Reports action, to open the Reports dialog box.Click the Scheduling Status tab to open the Scheduling Status dialog box.In the Schedules You Can Edit section, you can view the type of report (once or recurring) and the next run time. You can delete a scheduled report and change schedule information.

Planning for multiple sites

You can use a multisite setup to categorize the facilities in your company into sites and organizations. A multisite setup enables sites to share data from a single database while keeping their operations separate. Before you create multiple sites, you must determine what types of operations are performed at each location

and what data can be shared by each location.

- **Multisite capability**
The multisite capability provides a way to standardize and share certain kinds of data between facilities while keeping other kinds of data, such as work management records, unique to a particular site. The multisite capability also can selectively give users access to data at different sites.
- **Data storage levels**
Application data is stored at the following four levels: enterprise, set, organization, and site. The data that a user can see and use depends on the level at which the data is stored and whether the user is part of an organization or site that can access the data.
- **Data sharing between organizations**
Sets allow for the sharing of data between organizations. An item set allows organizations to share item data, such as inventory. A company set allows organizations to share vendor information.
- **Selective data sharing**
Applications that can store data at the enterprise, organization, and site levels typically store data at the enterprise level by default. Storing data at the organization level means that all sites in the organization can use the data. Storing data at the site level restricts data to just the specified site.
- **Transactions involving multiple sites in site-level applications**
Applications that store data at the site level require that the identifier field for each record is unique within the site. However, an identifier can be used within other sites and organizations. Only users who have security permission for the site and the application can view the records.
- **Limitations when setting up options in the Organizations application**
Except for system settings and autonumber settings, options apply at either the organization or site level, regardless of the level at which the application stores data. Even if an application stores data at the application level, it can have settings that are applied at the organization level.
- **Examples of using the multisite capability**
The multisite capability provides flexibility when you are setting up your implementation. You can create item sets, company sets, organizations, and sites to reflect the structures of your business.

Multisite capability

The multisite capability provides a way to standardize and share certain kinds of data between facilities while keeping other kinds of data, such as work management records, unique to a particular site. The multisite capability also can selectively give users access to data at different sites.

Why the multisite capability is needed

Separate facilities often have common business practices or share common data, which results in the duplication of information in the separate databases. The multisite capability provides a single Manage database while maintaining both data sharing and data separation, depending on your business needs.

You are not required to use the multisite capability. If your business is relatively small and has a single general ledger accounting system, you might consider whether you have a specific reason for using the multisite capability, such as multiple facilities with separate maintenance operations. The minimum implementation requirement is to create a single organization with a single site, one company set, and one item set.

How the multisite capability works

The basic units of a multisite implementation are organizations and sites. An enterprise can have multiple organizations; each organization can have multiple sites. Organizations and sites are virtual entities that can accommodate many different kinds of business practices. Organizations and sites do not necessarily correspond to physical sites or facilities.

To use the multisite capability, the administrator installs the application software once and sets up multiple sites that can access the software and the Manage database. Although a single database is used, the multisite capability provides site-specific independence for certain kinds of data. For example, different sites can share the same vendor list but still keep their work order and inventory records separate.

The multisite capability creates an environment that has the following characteristics:

- All sites use the same Manage database.
- All sites use the same product instance, which runs on an application server.
- Users at any site can access applications by using a Web browser.
- Different sites can keep certain operations separate, according to their business needs and the constraints of the application architecture.
- **Sites**
A site is typically a facility in an organization where work is managed. These activities include managing assets and physical locations by using preventive maintenance schedules and work orders, managing inventory in storerooms, processing stock replenishment, and other supply chain-related activities.
- **Organizations**
An organization is typically a financial entity in an enterprise in which all financial transactions are maintained in one base currency. Each organization maintains its own general ledger account, which is available to all sites that belong to that organization.
- **Product settings**
You must plan the settings you define in the product. Settings can be stored at the system level, the organization level, the site level, or the security level. Depending on where you define settings within the hierarchy, product settings affect the functioning of many applications.
- **When to create multiple organizations and sites**
When using the multisite capability, you must first decide whether you want to set up multiple organizations. Then, for each organization, you must decide whether to set up multiple sites. You can set up multiple sites even if your implementation has only a single organization.
- **Levels in the hierarchy**
Systems, organizations, and sites form a hierarchy that guides how you use and configure the product to fit your organization. When you create an organization, you create at least one site.

Sites

A site is typically a facility in an organization where work is managed. These activities include managing assets and physical locations by using preventive maintenance schedules and work orders, managing inventory in storerooms, processing stock replenishment, and other supply chain-related activities.

A site is not required to be a physical location. For example, you can use sites in any of the following ways:

- Two sites can correspond to two different facilities in two different countries.
- Two sites can correspond to two subdivisions that you want to keep separate for business reasons, even if the sites are located within the same facility.
- Several facilities can correspond to a single site because they all use the same data that the application software treats as site-level data. For example, the facilities all use the same work order data.

Organizations

An organization is typically a financial entity in an enterprise in which all financial transactions are maintained in one base currency. Each organization maintains its own general ledger account, which is available to all sites that belong to that organization.

In a large enterprise, multiple business functions can also be configured as separate organizations. For example, a company can define two organizations: one to maintain its own assets, and another to maintain the assets of its clients.

Product settings

You must plan the settings you define in the product. Settings can be stored at the system level, the organization level, the site level, or the security level. Depending on where you define settings within the hierarchy, product settings affect the functioning of many applications.

- [Site settings](#)
Settings enable each site in your organization to use different business rules, depending on the requirements of each organization.
- [Organization settings](#)
You can create organizations and sites in the Organizations application. You can further configure your organizations using the Organizations, Chart of Accounts, Exchange Rates, and Calendars applications.
- [System settings](#)
You configure system-wide settings based upon your business requirements. At this level, you can create at least one organization, currency code, item set, and company set.
- [Security settings](#)
You can set up user records and security groups to define different levels of access.

Site settings

Settings enable each site in your organization to use different business rules, depending on the requirements of each organization.

You define most site settings in the Organizations application. Most options have default values. You must verify that the defaults correspond to your business rules and change them if necessary.

Table 1. Configuration of site settings

Action in the Organizations application	Function
Work order options	Configure the site settings for work orders, such as numbering for tasks.
Inventory options	Configure the site-level settings for inventory, such as determining how costs are calculated at issue.
PM options	Configure how your sites schedule planned maintenance. For example, scheduling by priority or frequency, or specifying how far in advance to generate work orders.
SLA options	Specify how you want to match service level agreements (SLAs) to records for example, one or multiple SLAs.
Autonumber setup	Configure auto-numbering for items that are numbered at the site level, such as work orders. For example, you can configure starting numbers and prefixes.

Organization settings

You can create organizations and sites in the Organizations application. You can further configure your organizations using the Organizations, Chart of Accounts, Exchange Rates, and Calendars applications.

Several of the organization options have default values. Be sure to verify that the default values correspond to your business rules and change them if necessary.

Table 1. Configuration tasks by application

Application	Tab or action	Function
-------------	---------------	----------

Application	Tab or action	Function
Chart of Accounts		<p>Define general ledger accounts and configuring rules surrounding general ledger account code validation.</p> <p>Most companies import their general ledger account codes and use this application to view the import and configure the validation rules.</p> <p>Configure additional chart of accounts options through database configuration.</p>
Exchange Rates		Configure and administer exchange rates for currencies you and your vendors use.
Calendars		<p>Define calendars, holidays, shifts, and work periods for your company.</p> <p>This data is used to schedule in other areas within the system.</p>
Organizations	Addresses tab	Configure addresses for your company.
	Sites tab	Create sites. You must have at least one site to use the system. You can set additional administrative options for each site in a different part of the application.
	Work order options action	Configure the options that your organization uses for work orders. For example, configure editing rules and configure prompts for failure and downtime reporting.
	Inventory options action	Configure the options that your organization uses for inventory. For example, specify options for breakpoints, negative balances, and reorder rules.
	Drill down options action	Configure the appearance of drill down menus.
	Safety plan options action	Specify that the system displays the hazards of a work asset in the select hazards dialog box.
	PO options action	Configure purchase order options for your organization. For example, specify the options for converting purchase requisitions to purchase orders.
	Contract options action	Associate terms and conditions with contract types.
	Tax options action	Configure tax options for your organization, including how multiple taxes are calculated.
	PO labor options action	Configure options for the rules of your organization for outside labor costs, including reporting of actuals and requirements for purchase orders.
	Labor options action	Configure options for labor costs in your organization, including reporting of actuals and requirements for purchase orders.
	Workflow options action	Configure options for workflow processes in your organization, including reporting automated generation of work orders and purchase orders.
	Autonumber setup action	Configure auto-numbering for items that are numbered at the organization level, such as assets. For example, you can configure starting numbers and prefixes. This action facilitates moves from one site to another.

System settings

You configure system-wide settings based upon your business requirements. At this level, you can create at least one organization, currency code, item set, and company set.

Table 1. System settings

Application	Tasks
Database Configuration	<p>Create objects and associate attributes with objects. You can create objects or import objects into the database.</p> <p>Configure the database in administration mode or in command line mode.</p>
Organizations	<p>Define organizations and sites. You must define at least one organization and site. Many organizations and sites can share a single database.</p> <p>Set up the Autonumber feature: Specify autonumber seeds and prefixes for record IDs that are unique at the system level.</p>
Sets	<p>Create item sets and company sets.</p> <ul style="list-style-type: none"> Item sets are groups of items that are shared between organizations to enable features such as inventory sharing. Company sets are groups of vendors that are shared between organizations.
Currency Codes	Define the codes to represent currencies that you and your vendors use. One currency code is the base currency. Define exchange rates if needed.

Security settings

You can set up user records and security groups to define different levels of access.

Table 1. Applications with security settings

Application	Description
Security Groups	A security group defines levels of access to system applications and data.

Application	Description
Users	<p>A user record defines how the system looks and behaves for a user. The record must have an associated person record. You can maintain both records from the Users application.</p> <p>A user must be a member of at least one group to access system applications. Users do not need to be given access to any sites in their groups to access data in system-level applications.</p>

When to create multiple organizations and sites

When using the multisite capability, you must first decide whether you want to set up multiple organizations. Then, for each organization, you must decide whether to set up multiple sites. You can set up multiple sites even if your implementation has only a single organization.

When to create multiple organizations

You create an organization to identify a unique business entity to which one or more sites can belong.

Table 1. Situations in which you can create multiple organizations

Situation	Example	Recommendation
An enterprise has multiple legal entities, each of which maintains its own general ledger account.	An aerospace company has two legal entities: International and North American.	Create an organization for each legal entity.
An enterprise has multiple businesses. The maintenance operations are independent of each other and have their own general ledger accounts.	A large multinational company has two businesses: a utilities operation and a fleet of vehicles.	Create an organization for each business.
An enterprise has two different departments, one of which manages IT assets while one manages general assets. Each department has a unique set of general ledger accounts and cost centers.	A manufacturing company has a facilities department for managing general assets and an information technology department for managing IT assets.	Create an organization for each department.

When to create multiple sites

You typically create multiple sites within an organization when you want to have separate work management practices. When you create multiple sites, each site can maintain its own work orders, assets, inventory, and preventive maintenance orders.

Table 2. Situations in which you can create multiple sites

Situation	Example	Recommendation
An enterprise has a North American organization with facilities in multiple cities, each with independent maintenance operations.	An aerospace company has facilities in Boston, Chicago, and Denver.	Create a site for each facility.
A service enterprise maintains assets in facilities that are located in several countries. The enterprise deals in multiple currencies, but uses one general ledger system with a single base currency.	A large multinational company has facilities in Peru, Chile, and Argentina.	Create a single organization, and then create a site for each facility.
An enterprise has maintenance operations that occur in multiple facilities, but only some of the facilities use the same inventory and work orders.	A manufacturing company has three locations in the state of Ohio, all which share the same inventory and work orders. Two other facilities in another state do not use the same data as the Ohio facilities and also do not use the same data as each other.	Create a site for the three facilities in Ohio, then create a separate site for each of the other facilities.

Levels in the hierarchy

Systems, organizations, and sites form a hierarchy that guides how you use and configure the product to fit your organization. When you create an organization, you create at least one site.

Applications store data at different levels in a multiple site implementation. The following definitions describe the types of levels that can occur in an implementation with more than one site:

System level

A system is a single instance of a database. A single system can contain one or more sets, organizations, and sites.

Set

Sets exist below the system level, but above the organization level. This configuration enables multiple organizations to share company and item data. Each organization can have only one company set and one item set. Each set can be shared by more than one organization.

Organization

An organization identifies a unique legal entity. A large corporation can have different organizations for different companies. A corporation can also group the facilities that exist in a continent or country into an organization. There can be many organizations in a single database.

Site

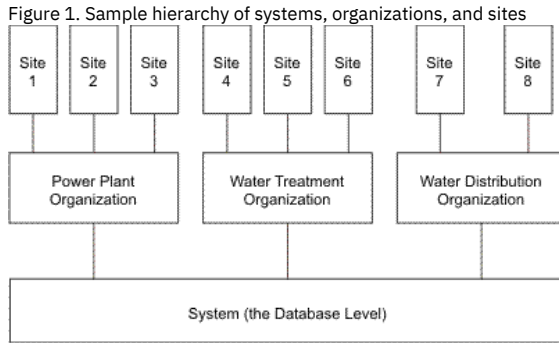

A site identifies a work location, such as a plant or a facility. A site is a division within an organization that maintains certain data independently from other sites. You can also use sites to administer security, and give users different rights at different sites.

Example of a utility company

A utility company owns several power plants, three water treatment plants, and two water distribution systems

- System-level refers to the entire utility company.
- The organizations of the company are grouped into power plants, water treatment, and water distribution facilities.
- Each organization has several sites that track inventory separately. The sites are the individual power plants, the treatment plants, and the water distribution systems.

The following figure shows a sample hierarchy of systems, organizations, and sites at a utility company.

Data storage levels

Application data is stored at the following four levels: enterprise, set, organization, and site. The data that a user can see and use depends on the level at which the data is stored and whether the user is part of an organization or site that can access the data.

Enterprise level

An enterprise represents a single instance of the Manage database. Data that is stored at the enterprise level, which is sometimes referred to as the system level, is available to all organizations and sites in the enterprise. An enterprise can have multiple organizations, and each organization can have multiple sites.

When an application stores data at the enterprise level, the data is unique for the entire implementation. An identifier for a record in an enterprise-level application can be used only once for that application. For example, in the People application, if a person record exists with the identifier 12345, then no other person record in any organization or site can use the identifier 12345.

Set level

The set level is a category below the enterprise level, but above the organization level. The set level allows multiple organizations to use the same item data and vendor data. Item data is stored in an item set. Vendor data is stored in a company set.

An enterprise can have multiple item sets and company sets, but each organization can use only one company set and one item set. Multiple organizations can use the same item set or company set.

For example, a utilities company owns several power plants and several water treatment facilities. The business practices of the power plants are similar, but different from the water treatment facilities. You can create an item set and a company set for use by the power plant organizations. Then you can create a different item set and company set for use by the water treatment organizations.

Organization level

Organizations and sites correspond to logical divisions in the company. An organization contains one or more sites.

If an application stores data at the organization level, then all sites in that organization access and use the same data from that application. For organization-level applications, different organizations can maintain separate data.

For example, the Chart of Accounts application is an organization-level application. Two organizations can each maintain separate general ledger accounts. The corollary is that different organizations can use the identical general ledger account code to refer to different accounts. For example, the account code 2000-300-400® might identify a tax debit account in one organization and an expense account in another organization.

Site level

A site is a division in an organization that maintains certain kinds of data independently from other sites. For example, the Assets application is a site-level application. The same asset number might identify a pump at one site and a computer at another site. Site-level applications primarily involve work management activities.

You can also use sites in administering security. You can give users different rights at different sites. For example, a user with management responsibility at one site might need full rights to the Work Order Tracking application at that site. The same user might only need to view work order data at another site.

- **Applications and their data storage levels**

Records must be unique within the data storage level. For example, the Automation Scripts application stores data at the enterprise level, so you could not have two scripts with the same identifiers in an enterprise. Some applications, such as the Job Plans application, are able to store data at multiple levels.

Applications and their data storage levels

Records must be unique within the data storage level. For example, the Automation Scripts application stores data at the enterprise level, so you could not have two scripts with the same identifiers in an enterprise. Some applications, such as the Job Plans application, are able to store data at multiple levels.

Table 1. Applications and the levels at which they store data

Application	Enterprise level	Set level	Organization level	Site level	Notes
Actions	X				
Activities and Tasks				X	
Application Designer	X				
Asset Templates			X		
Assets				X	Assets are defined at the site level. However, a user can issue items from a storeroom located in one site to an asset located in another site. The user must have access to both sites, and the two sites must belong to the same organization.
Assignment Manager				X	
Automation Scripts	X				
Bulletin Board	X				
Calendars			X		
Catalogs		Item set			
Catalog Orders				X	
Catalog Purchase Requisitions				X	
Chart of Accounts			X		
CI Types	X				
Classifications	X		X	X	Classifications exist at the enterprise level but can be restricted to a particular organization or site.
Cognos® Reporting	X				
Commodity Codes		Item set			Menu item
Company Master		Company set			Company master records are defined at the company set level and are unique at that level.
Companies			X		Company records are defined at the organization level. However, they are unique at the company set level. A company record must exist in the Company Master application before it can be defined for an organization.
Communication Templates	X				
Condition Codes		Item set			All condition enabled items in an item set can use the codes.
Condition Monitoring				X	Condition monitoring points are defined against an asset or location and hence are accessible only in the site where the asset or location is defined.
Conditional Expression Manager	X				
Configuration Items	X				
Conversion Values		Item set			All condition enabled items in an item set can use the codes.
Create Interactions	X				
Crews			X		
Crew Types			X		

Application	Enterprise level	Set level	Organization level	Site level	Notes
Cost Management				X	
Crafts			X		
Create Requisitions				X	Transactions can reside at enterprise, organization, or site level.
Create Service Requests	X		X	X	Transactions can reside at enterprise, organization, or site level.
Cron Task Setup	X				
Currency Codes	X				All sites and organizations can access currency codes.
Database Configuration	X				
Database Information	X				
Domains	X		X	X	Domains are defined at the enterprise level, but individual values can be restricted to an organization or site.
Email Interaction Setup	X				
Email Listeners	X				
End Points	X				
Enterprise Services	X				
Escalations	X				
Exchange Rates			X		Exchange rates are accessible to all sites in the organization in which the exchange rates were defined.
External Systems	X				
Failure Codes			X		The problems, causes, and remedies associated with failure codes are also defined at the organization level and are unique at that level.
Features	X				
Fulfillment Options		Item set		X	
Global Search	X				
Hazards			X		The precautions associated with the hazards are defined at the site level.
Interactions	X				
Inventory				X	Items in a storeroom are defined at the site level. Items can be transferred from a storeroom in one site to a storeroom in another site, provided the two sites belong to the same organization or the organizations of the two sites use the same item set.
Inventory Usage				X	
Incidents	X				Incidents are defined at the enterprise level. The incident can specify an asset or location that belongs to any site. The incident can also be handled at any site, not just the site specified for the asset or location.
Integration Modules	X				
Invocation Channels	X				
Invoices				X	
Issues and Transfers				X	
Item Master		Item set			Items are defined at the item set level and the identifiers are unique at that level. An organization can use only one item set, and all sites in that organization can access all the items defined in that item set.
Job Plans	X		X	X	Job plans can be defined at the enterprise level, organization level, or site level. When a job plan is defined at the enterprise level, the identifier is unique at that level. No other job plan at the site level or the organization level can have the same identifier. When a job plan is defined at the organization level, the identifier is unique at the organization level. No other job plan at the site level within that organization can have the same identifier.
KPI Manager	X				
KPI Viewer	X				
Labor			X		
Labor Rate Contracts			X		Labor rate contracts are accessible to all the sites in the organization in which the contract was created.
Labor Reporting				X	

Application	Enterprise level	Set level	Organization level	Site level	Notes
Launch in Context	X				
Lease/Rental Contracts			X		Though lease/rental contracts are defined at the organization level, you must explicitly specify the sites to which a lease/rental contract applies using the Authorize Sites action. The sites must belong to the organization in which the contract is created or to an organization that uses the same item set and company set as the organization in which the contract is created.
Locations				X	Though locations are defined at the site level, a user can issue items from a storeroom located in one site to a location in another site. The user must have access to both sites, and the two sites must belong to the same organization.
Lock Out/Tag Out				X	
Logging	X				
Logical Management Operations	X				
Master Contracts			X		Though master contracts are defined at the organization level, you must explicitly specify the sites to which a master contract applies using the Authorize Sites action. The sites must belong to the organization in which the contract is created or to an organization that uses the same item set and company set as the organization in which the contract is created.
Master PM	X				PM records from any site can be associated with a master PM.
Maps			X		
Message Reprocessing	X				
Message Tracking	X				
Meter Groups	X				Defined items, assets, and locations can access all the meters defined in the Meter Groups application. Defined items, assets, and locations can access all the meters defined in the Meters application.
Meters	X				Defined items, assets, and locations can access all the meters defined in the Meter Groups application. Defined items, assets, and locations can access all the meters defined in the Meters application.

Data sharing between organizations

Sets allow for the sharing of data between organizations. An item set allows organizations to share item data, such as inventory. A company set allows organizations to share vendor information.

- [Item sets and data sharing between organizations](#)
Item sets group information about assets, materials, spare parts, service items, and tools. Records created in the Item Master application are stored at the set level. You can specify a unique identifier, assign properties, and add the item to the inventory of one or multiple sites.
- [Company sets and vendors shared between organizations](#)
The Company Master application, in which you maintain a master list of vendors, stores data in the company set. The vendors that you do business with are unique within the company set. One or more organizations can share the same company set.

Item sets and data sharing between organizations

Item sets group information about assets, materials, spare parts, service items, and tools. Records created in the Item Master application are stored at the set level. You can specify a unique identifier, assign properties, and add the item to the inventory of one or multiple sites.

Assets and inventory items shared between organizations

When you create an item master record, it becomes part of the item set of the organization to which your default site for new records belongs. The items are unique within the set. Because you can assign the same item set to multiple organizations, you can use the same item definitions for all sites within those organizations.

Using item sets provides the following benefits:

- You can transfer items between organizations.
- You can standardize your item definition so that all organizations and their sites share the same item catalog and item assembly structure.
- The Item Master application provides an item catalog from which to set up inventory at multiple sites.

If more than one organization in your enterprise requires its own item definition, you can create multiple item sets. You can assign a separate item set to each organization, or to each group of organizations that you want to share the same item definition.

The following figure illustrates an example of an enterprise with three organizations and eight sites. Two organizations and their six sites share the same item set. The third organization has its own item set.

Figure 1. Two organizations can share one item set

Service items and tools shared between organizations

Service items and tools records are also stored at the item set level. Service items and tools are unique to the item set. Any organization assigned to the item set can use the service items and tools records in the item set.

Some of the data on a service item record may be specific to a single organization or site. For example, the companies listed in the Vendors window are at the organization level.

Company sets and vendors shared between organizations

The Company Master application, in which you maintain a master list of vendors, stores data in the company set. The vendors that you do business with are unique within the company set. One or more organizations can share the same company set.

Using company sets provides the following benefits:

- You can standardize your list of approved vendors.
- You can create global contracts that can be shared by multiple organizations.

The relationship between the Company Master application and the Companies applications is like the relationship between the Item Master application and the Inventory application. In the Company Master application, you create a catalog of companies and you associate individual companies with specific organizations. In the Companies application, which stores data at the organization level, users can access the vendor information associated with their organization.

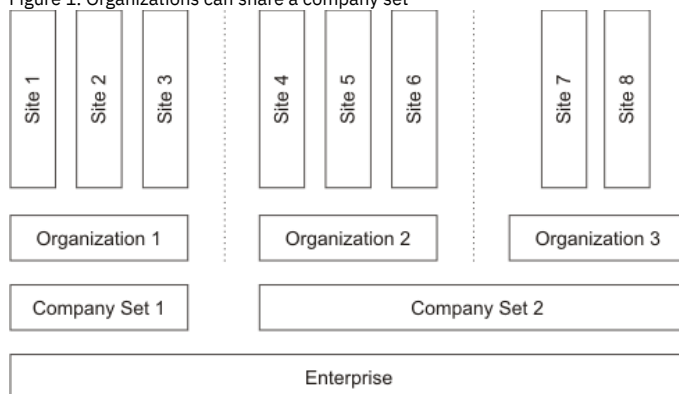

The companies records and company master records have many fields in common. A user can edit these fields in the Companies application without changing the values in the Company Master application. For example, while the Ship Via field in the Company Master record might be one shipping vendor, one of the organizations using that company set might want to specify a different vendor.

When you create a company set in the Sets application, you have the option of automatically adding the companies to the Company Master application. By default, this option is not enabled, which means that users must manually enter new companies in the Company Master application. However, you can enable the options so that the record is automatically added in the Company Master application.

You apply a company set to one or more organizations. If an organization requires its own list of vendors and contracts, you can create a separate company set for it.

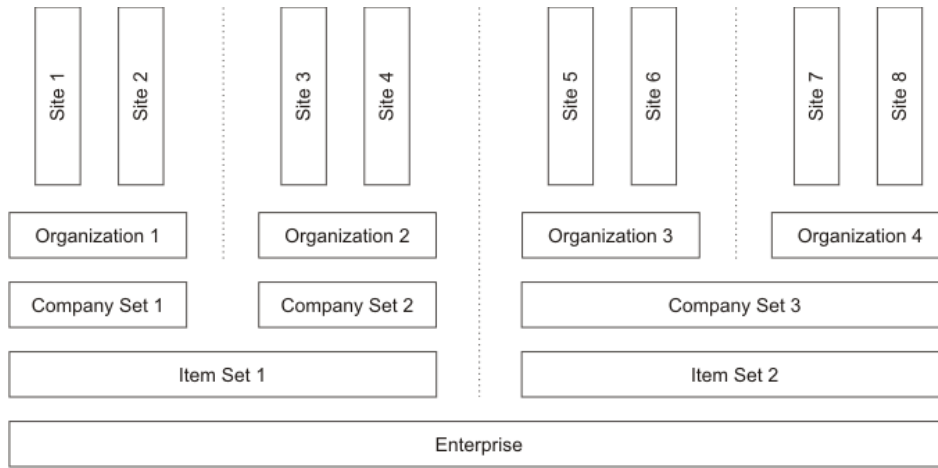

The following figure illustrates an example of an enterprise with three organizations and eight sites. Two organizations, and their five sites, share the same company set. The third organization has its own company set.

Figure 1. Organizations can share a company set

Item sets and company sets are independent of each other. The following figure illustrates such an example. There are four organizations and eight sites. Organizations 1 and 2 share Item Set 1; Organizations 3 and 4 share Item Set 2. Organizations 1 and 2 each have their own company set. Organizations 3 and 4 share Company Set 3.

Figure 2. Organizations can share an item set while having separate company sets

Selective data sharing

Applications that can store data at the enterprise, organization, and site levels typically store data at the enterprise level by default. Storing data at the organization level means that all sites in the organization can use the data. Storing data at the site level restricts data to just the specified site.

Job Plans application

When you create a job plan, you can specify an organization, a site, or neither. If you specify neither, the job plan is stored at the enterprise level, which makes it available to all sites and organizations. If you specify an organization, the job plan is available to all sites within the organization but cannot be accessed by other organizations. If you specify a site, the job plan is available only to that site and cannot be accessed by other sites.

When you create enterprise-level job plans, you also have the option of specifying organization-specific or site-specific tasks, labor, materials, services, and tools. Organization-specific tasks, such as labor records, are copied only to those work orders that are created in a site belonging to that organization. Site-specific tasks are copied only to those work orders created at that site.

Classifications application

By default, classification records are at the enterprise level and can be accessed by all organizations and sites. However, when you add a new classification record, you have the option of specifying an organization or site, but only if the Items check box in the Use With section is not selected. Any classification used with items must be at the enterprise level.

You can similarly add child classifications. If the parent classification is stored at the enterprise level, you can restrict the child classification to an organization or site. But if the parent classification is restricted to an organization or site, then all the children must be restricted to the lowest level of the parent classification. For example, if the parent classification is restricted to an organization, a child classification can be further restricted to a specific site. If the parent classification is restricted to a site, then all the children must be restricted to that site.

Domains application

The Domains application enables you to create several kinds of domains, including value lists and crossover fields. By default, domains apply at the enterprise level and all sites can access them. You have the option of applying domain values to a particular organization or site.

The synonym domain works differently from other domain types when you specify an organization or site for a domain value:

- For a synonym domain, if you add a new value and specify an organization or site, the records in that organization or site that access that domain show the new value as well as the existing enterprise-level values. This behavior occurs because synonym domains are part of the product and have existing business rules. You cannot add new synonym domains, only new synonym values.
- For other domain types, after you specify an organization or site for one value in a domain, records in that organization or site no longer have access to values in that domain that have no organization or site specified. Therefore, the best practice for non-synonym domains is either to leave the Organization and Site fields empty for all values in a domain or to specify an organization or site for all values in the domain.

Person Groups application

Person groups apply at the enterprise level and can be accessed by all sites, but you can restrict individual persons in the group to particular organizations or sites. When you add a person to a person group, you can specify an organization or site for that person. You can add multiple rows for the same person to specify multiple sites or organizations. If you add multiple rows, you must use multiple sites or multiple organizations. You cannot use a mixture of sites and organizations.

Transactions involving multiple sites in site-level applications

Applications that store data at the site level require that the identifier field for each record is unique within the site. However, an identifier can be used within other sites and organizations. Only users who have security permission for the site and the application can view the records.

Transactions that involve multiple sites can be performed in applications that store data at the site level.

Purchase requisitions

You can create a purchase requisition at one site that requests items from a storeroom at a different site. The storeroom site must belong to the same organization as the requesting site, or the requesting site and the supplying site must belong to organizations that share the same item set.

Purchase orders

You can create an internal purchase order at one site that requests parts from a storeroom at a different site. The storeroom site must belong to the same organization as the requesting site, or the requesting site and the supplying site must belong to organizations that share the same item set.

To facilitate centralized purchasing, the system allows you to create a purchase order at one site that requests items from a storeroom at a different site. The storeroom must belong to a site that is in the same organization as the site in which you create the purchase order.

Asset transfers

You can transfer assets from one site to another. The destination site can belong to a different organization if the asset is not a rotating asset.

If the asset is rotating, the organizations for the originating and destination sites must share the same item set. If the site to which you want to move an asset already has an asset with the same asset identifier, the system prompts you to assign a new asset identifier to the asset you are moving.

Issues

You can issue an item from a storeroom in Site A, for example, to a work order created in Site B. When performing this transaction you must have access to both sites and the storeroom. The two sites must belong to the same organization.

If you need to issue an item to a site in a different organization, you must use the internal transfer capability to transfer the item and then issue the item.

Work planning

You can specify the storeroom from which to obtain an item. The storeroom site can be different than the work order site if both sites belong to the same organization and you have access to both sites.

Limitations when setting up options in the Organizations application

Except for system settings and autonumber settings, options apply at either the organization or site level, regardless of the level at which the application stores data. Even if an application stores data at the application level, it can have settings that are applied at the organization level.

For example, the Work Order Tracking application stores data at the application level. However, edit rules for the Work Order Tracking application apply at the organization level. All the sites in an organization use the same edit rules. The Preventive Maintenance application stores data at the application level and its options are also applied at the application level.

If you are able to select or specify a site in an option dialog box, then the settings apply at the site level. When you see a list of sites in a dialog box, the sites all belong to the organization that you selected on the List tab. For settings that apply at the site level, you can specify different settings for different sites. For example, you can apply different inventory cost options for different sites.

If you do not see a list of sites in an options dialog box, then the settings apply at the organization level, specifically to the organization you selected on the List tab. The settings you make apply to all the sites in the selected organization. You can select a different organization on the List tab to specify option settings for that organization.

The following table shows the options and the levels to which they apply.

Table 1. Options that apply at the organization level or the site level

Menu action	Menu sub-action	Organization	Site	Options description
Work Order Options	Work Type	X		Define work order class and type including a description and the prompts for failure or downtime.
	Edit Rules	X		Specify which fields on the work order are editable for each work order status.
	Other Organization Options	X		Set default start for downtime, the actual start date, the prompts that are displayed, when material reservations are cleared, and when duplicate warnings are displayed.
	Site Options		X	Specify default starting number and increment for task numbering.
Inventory Options	Inventory Defaults	X		Set ABC breakpoint options.
	Reorder	X		Specify when external and internal requests are created and also the maximum number of reorder lines on each purchase order or purchase requisition.
	Inventory Costs		X	Set whether issue cost is standard or average and whether non-capitalized rotating is an issue cost or an asset cost.
Asset Options		X		Specify when the asset history is recorded.

Menu action	Menu sub-action	Organization	Site	Options description
Drilldown Options		X		Set order for the top-level asset on the Asset tab.
PM Options			X	Specify how preventive maintenance work orders are issued.
Safety Plan Options			X	Determine whether the hazards appear in the Select Hazards action for an asset.
Purchasing Options	PO Options	X		Specify purchasing options such as whether purchase requisitions require approval, when purchase requisitions are closed, whether standard service costs are added to direct issue lines, and whether the generation of special order items is allowed.
	Contract Options	X		Add and modify contract types.
	Tax Options	X		Specify the general ledger options for tax, such as the rate and effective date.
	PO Labor Options	X		Determine whether a purchase order is required to approve inside labor.
Labor Options		X		Specify whether inside and outside labor transactions are automatically approved, whether mismatched craft and labor are permitted when reporting actuals, whether invoices from labor transactions are automatically approved, and the number of hours for future labor transaction tolerance.
Service Desk Options	Global Ticket Solution Options	X		Specify whether solutions are applied to related global tickets.
SLA Options			X	Specify whether multiple service level agreements are allowed and, if so, how multiple are ranked.
Ownership Assignment Options			X	Specify whether person availability is checked.
Workflow Options			X	Determine which workflow processes are initiated automatically.

The following table shows the levels for the autonumber settings and the system settings.

Table 2. Levels for the autonumber settings and system settings

Menu action	Menu sub-action	Enterprise	Company Set	Item Set	Organization	Site
Autonumber Settings	System Level	X				
	Set Level		X	X		
	Organization Level				X	
	Site Level					X
System Settings		X				

Examples of using the multisite capability

The multisite capability provides flexibility when you are setting up your implementation. You can create item sets, company sets, organizations, and sites to reflect the structures of your business.

- [Example: Multisite configuration with separate general ledger accounts](#)
You can create two organizations that share a company set but maintain separate item sets. This example illustrates a way to reflect the structure of your enterprise with sites, organizations, and sets.
- [Example: Multisite configuration with separate maintenance and IT operations](#)
The multisite capability allows you to create organizations with sites in different locations. These organizations can share an item set and a company set.

Example: Multisite configuration with separate general ledger accounts

You can create two organizations that share a company set but maintain separate item sets. This example illustrates a way to reflect the structure of your enterprise with sites, organizations, and sets.

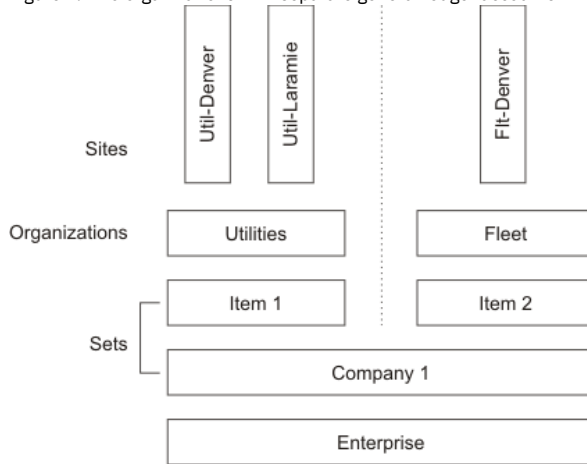

Your enterprise has two distinct business operations: a utilities operation and a fleet of vehicles. Both are run from a central location in Denver, Colorado, and both use the same list of vendors. Each operation has its own general ledger accounts.

The utilities operation also has a facility in Laramie, Wyoming. All operations and locations use the same vendors, although the utilities and fleet operations maintain different items and storerooms.

You can accommodate your enterprise structure by doing the following:

- Create two organizations: Utilities and Fleet.
- Create two sites for the Utilities organization: Util-Denver and Util-Laramie.
- Create one site for the Fleet organization: Flt-Denver.
- Create one company set for use by both organizations.
- Create an item set for the Utilities organization.
- Create an item set for the Fleet organization.

Figure 1. Two organizations with separate general ledger accounts

Example: Multisite configuration with separate maintenance and IT operations

The multisite capability allows you to create organizations with sites in different locations. These organizations can share an item set and a company set.

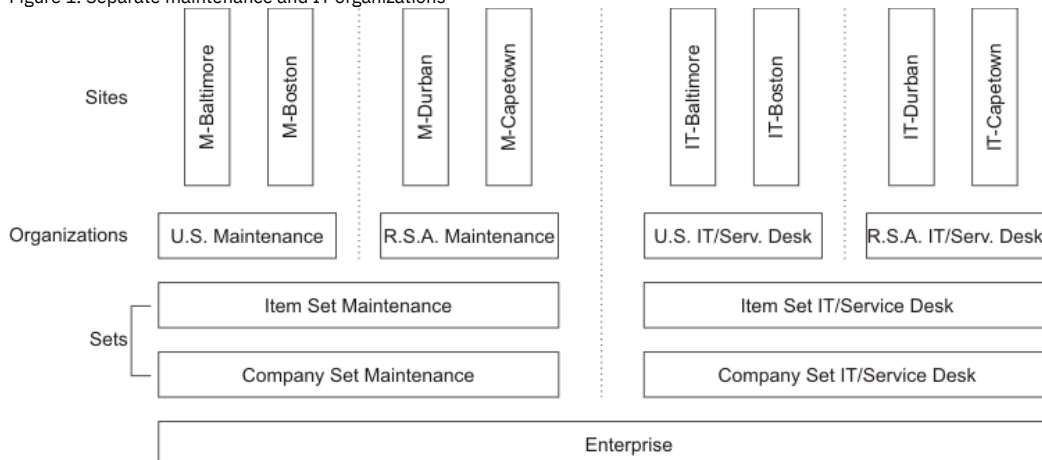

Your enterprise has production facilities in the United States (U.S.) and in the Republic of South Africa (R.S.A.). Both production facilities have separate maintenance and service desk operations, each with its own general ledger account. Both production facilities also have two locations that maintain separate work orders.

You want to maintain two item sets: one for maintenance operations and one for the service desk departments.

You also use different sets of vendors for maintenance and for service desk. You want to be able to create global contracts so that, for example, the South African and United States maintenance facilities can buy from the same vendors.

- Create four organizations:
 - U.S. Maintenance
 - U.S. Service Desk
 - R.S.A. Maintenance
 - R.S.A. Service Desk
- Create two sites in the U.S. Maintenance organization:
 - M-Baltimore
 - M-Boston
- Create two sites in the U.S. Service Desk organization:
 - IT-Baltimore
 - IT-Boston
- Create two sites in the R.S.A. Maintenance organization:
 - M-Capetown
 - M-Durban
- Create two sites in the R.S.A. Service Desk organization:
 - IT-Capetown
 - IT-Durban
- Create an item set for use by both maintenance organizations.
- Create an item set for use by both service desk organizations.
- Create a company set for use by both maintenance organizations.
- Create a company set for use by both service desk organizations.

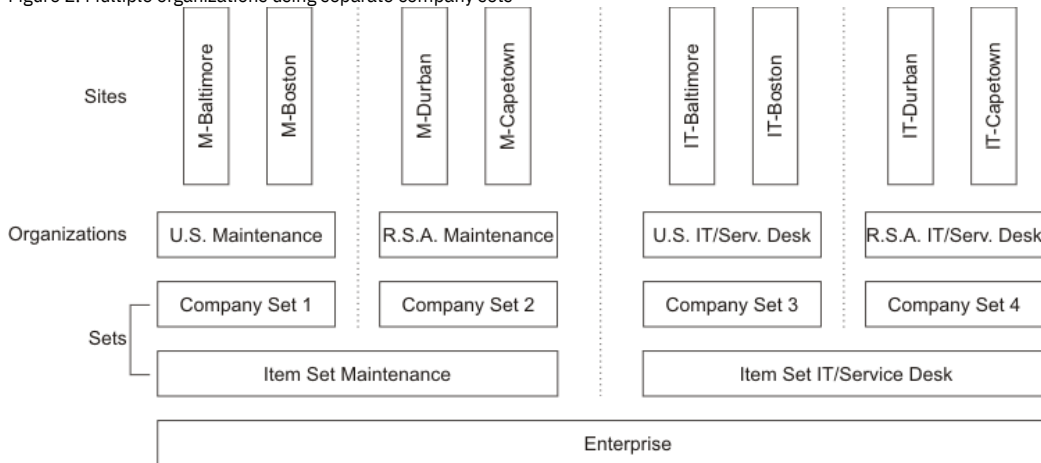

Figure 1. Separate maintenance and IT organizations

Local vendors

If each organization uses separate vendor lists, then you can create separate company sets for each organization.

Figure 2. Multiple organizations using separate company sets

Deploying in Maximo Application Suite

By deploying and activating Maximo Manage, Maximo Manage is available for use in IBM® Maximo Application Suite.

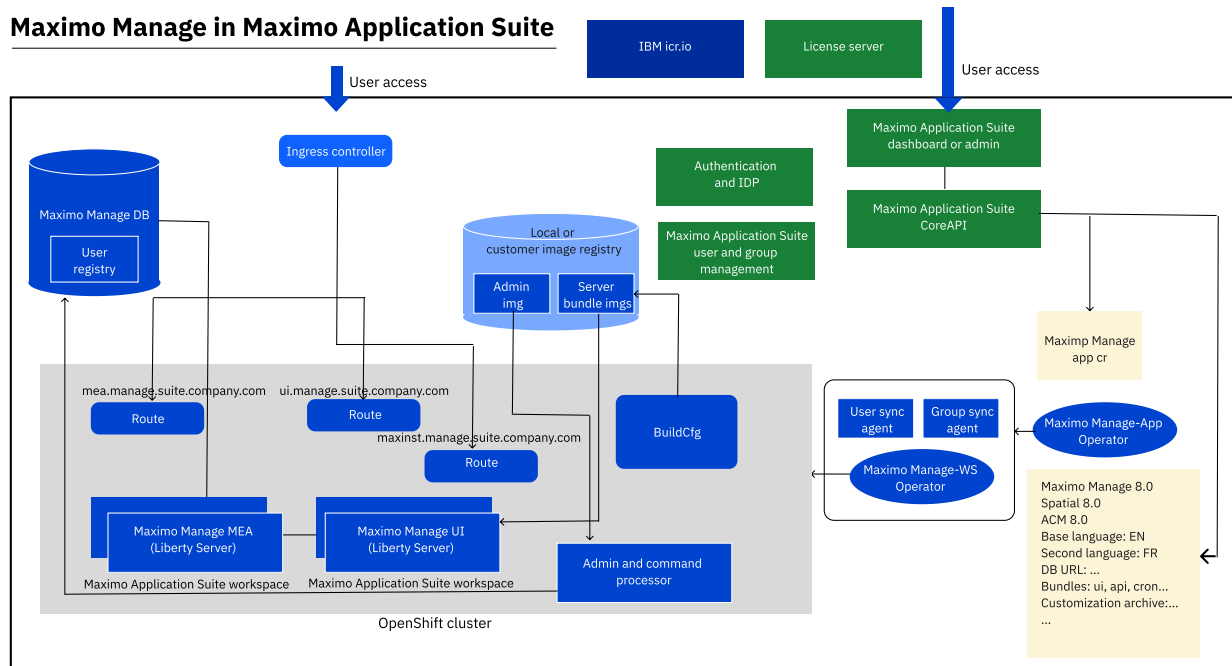

A system administrator can do the following tasks:

- Configure your database for Maximo Manage
- Select and deploy industry solutions and add-ons with Maximo Manage
- Set up additional configurations.
- Grant users access permission to use Maximo Manage after the deployment is completed.
- Complete additional post deployment and administration tasks.

Maximo Application Suite is a suite of asset management and data analytic offerings. Maximo Application Suite is offered as a customer-managed product on Red Hat® OpenShift® and as an IBM Managed solution. It is also available as a SaaS offering.

As a system administrator, you can deploy and activate Maximo Manage and related industry solutions and add-ons in Maximo Application Suite. After you install Maximo Manage, the architecture is as shown in the following figure.

Figure 1. Maximo Manage in Maximo Application Suite

When you want to connect to a particular database or install an add-on, a customer resource is generated to specify exactly what you want to do. The Maximo Manage operator generates the admin image and the server bundle images. The server bundle images are the Liberty servers because, for example, if you want to install industry solutions, the server must be deployed there. The operator completes these tasks. Then, those finalized images are placed in the local image

registry or a customer-provided image registry. The operator issues commands to the Admin pod and the database to configure the database. When the configuration is done, the operator starts the Liberty servers and makes the routes available, so users can start to connect to it. The operator automates the whole deployment.

Before you deploy, verify that the following tasks are complete:

- Verify that your environment meets the [system requirements](#).
- Verify that Maximo Application Suite is installed and configured according to your requirements. For more information about planning and installing, see the [Maximo Application Suite online product documentation](#).

Complete the following tasks to deploy and access a in Maximo Application Suite:

1. Review the [Plan and prepare Maximo Manage](#) for the deployment section. It provides instructions, such as preparing your database, provisioning persistent storage if you want to, configuring your customization archive, and other tasks.
2. Review the [Deploying and activating Maximo Manage](#) section, which provides the necessary steps to deploy and activate Maximo Manage and how to monitor its deployment progress. The following steps are a summary:
 - a. Deploy Maximo Manage application.
 - b. Configure Maximo Manage to connect to your database and for example, select industry solutions and add-ons to co-deploy with Manage, set the languages, configure the customization archive, configure external file storage, and other tasks.
 - c. Activate Maximo Manage for use in Maximo Application Suite.
 - d. Monitor the Maximo Manage deployment and when completed, do the [Post-deployment configurations](#).

Note:

You can also upgrade to Maximo Manage from Maximo Asset Management. Before you upgrade, you must have and 7.6.1.10 or 7.6.1.2 installed. [Learn more about upgrading to Maximo Manage](#).

- **[Planning and preparing to deploy](#)**
To prepare for deployment, you must complete several tasks, such as configuring the database for IBM Maximo Manage, determining the compatibility of the industry solutions and add-ons in case you want to deploy, and other preparation steps. If you are deploying in multiple languages, review the support languages that are available.
- **[Deploying and activating Maximo Manage](#)**
As a system administrator, you deploy and activate Maximo Manage in Maximo Application Suite by selecting the application version, connecting to the configured database and applying the Java database connectivity (JDBC) configurations.
- **[Configuring Maximo Manage after deployment](#)**
You must give users access to the and application. Application administrators can configure the application to set up the required data structure for managing assets, including an organization, general ledger account structure, and configuring email notifications. You can also perform other post-deployment configurations.

Planning and preparing to deploy

To prepare for deployment, you must complete several tasks, such as configuring the database for IBM® Maximo® Manage, determining the compatibility of the industry solutions and add-ons in case you want to deploy, and other preparation steps. If you are deploying in multiple languages, review the support languages that are available.

- **[System requirements](#)**
To deploy in Maximo Application Suite, your environment must meet all of the hardware and software requirements for Maximo Manage and Maximo Application Suite.
- **[Configuring an internal image repository](#)**
You must create a repository for storing images.
- **[Setting up your database](#)**
Before you can deploy, you must configure your database and determine how your database is encrypted.
- **[Deployment of industry solutions and add-ons](#)**
When you deploy Maximo Manage, you can also include industry solutions and add-ons for deployment.
- **[Language support](#)**
Maximo Manage is available in a number of languages. You can specify languages when you activate the application.
- **[Server bundle overview](#)**
The application can be deployed in one or more workloads called server bundles. A server bundle isolates the workload processes so that they can be independently managed.
- **[Provisioning storage](#)**
Maximo Manage supports both ephemeral storage and persistent storage.
- **[Monitoring agent for Maximo Manage](#)**
Maximo Manage includes a monitoring agent that collects statistics about application usage and performance. Administrators can configure Prometheus service monitoring and then use visualization software, such as Grafana, to view usage information that the agent collects.
- **[Backing up and restoring Maximo Manage](#)**
To avoid disruptions to service and unplanned downtimes, create regular Maximo Manage backups that you can restore as needed.
- **[Storing images in an external registry](#)**
When Maximo Manage is deployed or updated, the build process generates an administrative image and a server bundle image for each bundle type. Bundle types are specified in the custom resource for the workspace. Images are stored in an internal registry. In some cases, you might want to store the build images in an external repository. For example, you might want to run security scans on images that have customizations, or you might want to test builds independently before you deploy the application in Maximo Application Suite. Administrators can configure Maximo Manage to store images in an external repository.
- **[Configuring Java Message Service \(JMS\) servers](#)**
If you use Java™ Messaging Service (JMS) to integrate data, you can deploy one or more server bundles with a Liberty server that supports JMS messaging.
- **[Deployment planning worksheet](#)**
Use the planning worksheet to record the information that you need when configuring and during the deployment process, such as database parameters, server bundle files, and customization archive location.

System requirements

To deploy in Maximo® Application Suite, your environment must meet all of the hardware and software requirements for Maximo Manage and Maximo Application Suite. For more information, see [IBM® Maximo Application Suite system requirements](#).

Check the detailed system requirements. For more information, see [Software Product Compatibility Reports](#).

Configuring an internal image repository

You must create a repository for storing images.

Procedure

1. Log in to a Bastion host.
2. Create an NFS file system for the image repository.

```
mkdir /disk1/nfs/image-registry && chmod 777 /disk1/nfs/image-registry/
```

3. Edit the /etc/exports file and add an export statement.

```
/disk1/nfs/image-registry 10.176.245.0/24(rw,no_subtree_check,sync,no_wdelay,insecure,no_root_squash)
```

4. Restart the server.

```
systemctl restart nfs-server
```

5. Create the image-storage.yaml file.

```

  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: 500Gi
```

6. Apply the image-storage.yaml file.

```
oc apply -f image-storage.yaml
```

7. Edit the operator.

```
oc edit configs.imageregistry.operator.openshift.io
```

8. Change the *spec.managementState* value from *Removed* to *Managed*
9. Update the *spec.storage* value.

```
storage:
  managementState: Managed

pvc:
  claim: image-registry-storage
```

10. Save and quit.
11. Verify that the image repository is available.

```
oc get co image-registry
```

12. Enable the route.

```
oc patch configs.imageregistry.operator.openshift.io/cluster --patch '{"spec":{"defaultRoute":true}}' --type=merge
```

Setting up your database

Before you can deploy, you must configure your database and determine how your database is encrypted.

- [Database deployment planning](#)
Guidelines to consider when you create and configure your database.
- [Preparing your database for deployment](#)
Maximo Manage supports IBM Db2®, IBM Db2 Warehouse, Microsoft SQL Server, and Oracle Database. You must configure your database and gather the information that is needed when you deploy the application.
- [Database encryption](#)
When you deploy Maximo Manage, the fields that require security, such as passwords and API keys, are encrypted or re-encrypted to provide security.
- [Troubleshooting database deployment](#)
When you deploy the Maximo Manage application, issues that are related to database deployment might cause the deployment process to fail.
- [Demo data](#)
When you deploy Maximo Manage, you can add sample data to a demo database.

Database deployment planning

Guidelines to consider when you create and configure your database.

General

Use hard disks that have over 200 MB/second throughput.

If you are using IBM® cloud storage, choose a custom performance block storage of 100+ IOPS.

Configure separate system, data, and backup storage when you create a Db2® instance.

If you are using AWS cloud storage and EFS for your database, consider Provisioned mode for the constant throughput. For more disk options, see [Amazon EFS performance](#).

IBM Db2 and IBM Db2 Warehouse

Increase the maxsequence cache to 50.

Consider running **REORG INDEXERS/TABLES** and **RUNSTATS** daily.

Separate system storage, user storage, back up storage, transaction logs storage, and temporary table space storage on different disks.

Maximo® Manage requires row-organized tables. The IBM Db2 Warehouse database setting used column-based table organization by default. Update the setting if needed.

Maximo Manage does not support MMP or table partitioning. Consider archiving records that are over a year old. InfoSphere® Optim™ Data Growth Solution can be used for archiving. For more information, see [IBM Maximo Archiving 7.5.1 for IBM Maximo Asset Management 7.6](#).

An issue can occur when you load a large amount of data by using Maximo Integration Framework. Increase the concurrently running statements that are allowed for a Db2 application. For more information about tuning, see [How many concurrently running statements allowed for a Db2 Java™ application and how to increase it?](#)

If you use IBM Cloud Pak® for Data, consider the following configuration and deployment options:

- Avoid the IBM operator catalog to install IBM Cloud Pak for Data.
- Use storage services, such as Portworx or OCS, for improved performance.
- Secure operator versions and disable autoupdate for all components.
- Use the IAM and LDAP service instead of the default authentication methods.

For more information, see [Maximo 7.6.x Best practice](#) and [DB2® Performance Insight®](#).

Oracle Database

For more information, see [Best practices for system performance](#).

Microsoft SQL Server

If the original database was created in a version earlier than Microsoft SQL Server 2019, set the compatibility level to the older version to maintain the execution plan.

Set the transactions isolation level by using the following commands:

```
ALTER DATABASE MyDatabase  
SET ALLOW_SNAPSHOT_ISOLATION ON
```

```
ALTER DATABASE MyDatabase  
SET READ_COMMITTED_SNAPSHOT ON
```

For more information, see [Best practices for system performance](#).

Sizing

The storage class that you select can affect the size of your database. For example, if you plan to use OCS, it increases the storage space that you need for your database.

Be aware of space requirements for services, such as IBM Cloud Pak for Data. IBM Cloud Pak for Data space requirements change if you deploy it in a clustered environment.

Managed versus on-premises services, such as MongoDB and Kafka, impact your disk space needs.

All-in-one POD bundles have different disk space requirements when compared to configuring separate resources for UI, Report, Cron, Maximo Integration Framework, and Mobile.

The number of concurrent users affect resource needs. For example, for the UI resource, configure a JVM that has two cores to support 50–75 concurrent users.

Preparing your database for deployment

Maximo® Manage supports IBM® Db2®, IBM Db2 Warehouse, Microsoft SQL Server, and Oracle Database. You must configure your database and gather the information that is needed when you deploy the application.

Before you begin

Tip: Set up your database at the same site as your IBM Maximo Application Suite to reduce chances of database failures because of connection issues and data latency. However, if you have issues to set up the database during Maximo Manage deployment, see [Troubleshooting database deployment](#).

Procedure

1. Confirm that one of the following databases is configured.
 - [Configuring IBM Db2](#)
 - [Configuring IBM Db2 Warehouse](#)
 - [Configuring Oracle Database](#)
 - [Configuring Microsoft SQL Server](#)
 2. Gather the following information for your database:
 - The host and hostname.
 - The port.
 - The database name.
 - The username and password for the database user. These values are created as part of configuring the database.
 - The table space, index space, and schema values. These values are created as part of configuring the database.
- [Creating a database instance](#)
Create a database instance.

Creating a database instance

Create a database instance.

Before you begin

If you intend to use the database instance for production, you can select Deploy database on dedicated nodes and adjust the number of nodes as needed in the Configure page.

About this task

Depending on the type of database, you must configure one of the following:

- [Configuring IBM® Db2®](#)
- [Configuring IBM Db2 Warehouse](#)
- [Configuring Oracle Database](#)
- [Configuring Microsoft SQL Server](#)

- [Configuring Db2](#)
You must configure Db2 for use by Maximo Manage before you deploy Maximo Manage in Maximo Application Suite.
- [Configuring Db2 Warehouse](#)
You must create a new Db2 Warehouse database for exclusive use by Maximo Manage. You cannot reuse the Db2 Warehouse database on Cloud Pak for Data where you already deployed another application from Maximo Application Suite.
- [Configuring Oracle Database](#)
To configure Oracle Database for use with Maximo Manage, you create table spaces, create a database user, and configure database settings.
- [Configuring Microsoft SQL Server](#)
To configure Microsoft SQL Server for Maximo Manage, you create table spaces, create a database user, and configure database settings.

Configuring Db2

You must configure Db2 for use by Maximo® Manage before you deploy Maximo Manage in Maximo Application Suite.

Before you begin

Before you configure the database, install and deploy it. For installation instructions, see [Creating a database instance](#).

For information about supported database versions, generate a [Software Product Compatibility Report](#). Search for IBM® Maximo Application Suite and select the suite version to generate the report. Check for the supported database versions in the Supported Software tab of the report.

Configure your database with the following Operating System (OS):

- Linux® or UNIX
- Microsoft Windows

About this task

The commands in this task can be used to configure a Db2 database outside of the Red Hat® OpenShift® cluster (not Db2 Warehouse), by using different Operating Systems such as Microsoft Windows, Linux , or UNIX .

The commands in this task are examples of the commands that you must run. For example, maxdb80 is the name of the database. If maxdb80 is not your database name, ensure that you replace all instances with the correct database name.

Procedure

1. Log in to the system as a user that has administrative permissions on the system.
2. If system users do not exist on the system, create the system users.
 - Windows
 - db2admin
 - maximo
 - Linux or UNIX
 - maximo (Maximo db user)
 - ctgfenc1 (Db2 fenced user)
 - ctginst1 (Db2 instance owner)

The administrative user being used most is assigned the primary group of the instance owner to perform some of the following steps.
3. At the Db2 installation directory, run the following command to set up the command line environment:
 - Windows

```
db2cmd
```
 - Linux or UNIX

Ensure that the /opt/ibm/db2/V11.5/bin, /opt/ibm/db2/v11.5/instance, and /opt/ibm/db2/V11.5/adm directories are added to your PATH.
4. Run the following commands to create the database instance.
 - Windows

Tip: Replace the variable <administrator_password> with the Db2 administrator password.

```
db2icrt -s ese -u db2admin,<administrator_password> -r 50005,50005 ctginst1
set db2instance=ctginst1
db2start
db2 update dbm config using SVCENAME 50005 DEFERRED
db2stop
db2set DB2COMM=tcpip
db2start
```
 - Linux or UNIX

```
db2icrt -s ese -u ctgfenc1 -p 50005 ctginst1
. /home/ctginst1/sqllib/db2profile
db2start
db2 update dbm config using SVCENAME 50005 DEFERRED
db2stop
db2set DB2COMM=tcpip
db2start
```

5. Run the following commands to create the database:

```
db2 create db 'maxdb80' ALIAS 'maxdb80' using codeset UTF-8 territory US pagesize 32 K
db2 connect to 'maxdb80'
db2 GRANT DBADM ON DATABASE TO USER db2admin (windows only)
db2 GRANT SECADM ON DATABASE TO USER db2admin (windows only)
db2 connect reset
```

6. Run the following commands to configure the database:

```
db2 update db cfg for maxdb80 using SELF_TUNING_MEM ON
db2 update db cfg for maxdb80 using APPGROUP_MEM_SZ 16384 DEFERRED
db2 update db cfg for maxdb80 using APPLHEAPSZ 2048 AUTOMATIC DEFERRED
db2 update db cfg for maxdb80 using AUTO_MAINT ON DEFERRED
db2 update db cfg for maxdb80 using AUTO_TBL_MAINT ON DEFERRED
db2 update db cfg for maxdb80 using AUTO_RUNSTATS ON DEFERRED
db2 update db cfg for maxdb80 using AUTO_REORG ON DEFERRED
db2 update db cfg for maxdb80 using AUTO_DB_BACKUP ON DEFERRED
db2 update db cfg for maxdb80 using CATALOGCACHE_SZ 800 DEFERRED
db2 update db cfg for maxdb80 using CHNGPGS_THRESH 40 DEFERRED
db2 update db cfg for maxdb80 using DBHEAP AUTOMATIC
db2 update db cfg for maxdb80 using LOCKLIST AUTOMATIC DEFERRED
db2 update db cfg for maxdb80 using LOGBUFSZ 1024 DEFERRED
db2 update db cfg for maxdb80 using LOCKTIMEOUT 300 DEFERRED
db2 update db cfg for maxdb80 using LOGPRIMARY 20 DEFERRED
db2 update db cfg for maxdb80 using LOGSECOND 100 DEFERRED
db2 update db cfg for maxdb80 using LOGFILSIZ 8192 DEFERRED
db2 update db cfg for maxdb80 using SOFTMAX 1000 DEFERRED
```

7. Run the following command according to your operating system and bit size:

Operating system	Command
32-bit Microsoft Windows	db2 update db cfg for maxdb80 using MAXFILOP 32768 DEFERRED #32-bit Windows
64-bit Windows	db2 update db cfg for maxdb80 using MAXFILOP 65335 DEFERRED #64-bit Windows
32-bit UNIX	db2 update db cfg for maxdb80 using MAXFILOP 30720 DEFERRED #32-bit UNIX
64-bit UNIX	db2 update db cfg for maxdb80 using MAXFILOP 61440 DEFERRED #64-bit UNIX

8. Run the following commands to continue to configure the database:

```
db2 update db cfg for maxdb80 using PCKCACHESZ AUTOMATIC DEFERRED
db2 update db cfg for maxdb80 using STAT_HEAP_SZ AUTOMATIC DEFERRED
db2 update db cfg for maxdb80 using STMTHEAP AUTOMATIC DEFERRED
db2 update db cfg for maxdb80 using UTIL_HEAP_SZ 10000 DEFERRED
db2 update db cfg for maxdb80 using DATABASE_MEMORY AUTOMATIC DEFERRED
db2 update db cfg for maxdb80 using AUTO_STMT_STATS OFF DEFERRED
db2 update db cfg for maxdb80 using STMT_CONC LITERALS DEFERRED
db2 update alert cfg for database on maxdb80 using db.db_backup_req SET THRESHOLDSCHECKED YES
db2 update alert cfg for database on maxdb80 using db.tb_reorg_req SET THRESHOLDSCHECKED YES
db2 update alert cfg for database on maxdb80 using db.tb_runstats_req SET THRESHOLDSCHECKED YES
db2 update dbm cfg using PRIV_MEM_THRESH 32767 DEFERRED
db2 update dbm cfg using KEEPFCED NO DEFERRED
db2 update dbm cfg using NUMDB 2 DEFERRED
db2 update dbm cfg using RQRIOLBK 65535 DEFERRED
db2 update dbm cfg using HEALTH_MON OFF DEFERRED
db2 update dbm cfg using AGENT_STACK_SZ 1000 DEFERRED
db2 update dbm cfg using MON_HEAP_SZ AUTOMATIC DEFERRED
db2set DB2_SKIPINSERTED=ON
db2set DB2_INLIST_TO_NLJN=YES
db2set DB2_MINIMIZE_LISTPREFETCH=Y
db2set DB2_EVALUNCOMMITTED=YES
db2set DB2_FMP_COMM_HEAPSZ=65536
db2set DB2_SKIPDELETED=ON
db2set DB2_USE_ALTERNATE_PAGE_CLEANING=ON
```

9. For Linux or UNIX, log in to the system, for example as the `ctginst1` user, and then restart the Db2 command line environment:

```
su - ctginst1
db2
```

10. Run the following command to stop the database:

```
db2stop force
```

11. Run the following command to start the database:

```
db2start
```

12. Run the following command to reconnect to the database:

```
db2 connect to 'maxdb80'
```

13. Run the following commands to create a buffer pool:

```
db2 CREATE BUFFERPOOL MAXBUFFERPOOL IMMEDIATE SIZE 4096 AUTOMATIC PAGESIZE 32 K
db2 CREATE REGULAR TABLESPACE MAXDATA PAGESIZE 32 K MANAGED BY AUTOMATIC STORAGE INITIALSIZE 5000 M BUFFERPOOL
MAXBUFFERPOOL
db2 CREATE TEMPORARY TABLESPACE MAXTEMP PAGESIZE 32 K MANAGED BY AUTOMATIC STORAGE BUFFERPOOL MAXBUFFERPOOL
db2 CREATE REGULAR TABLESPACE MAXINDEX PAGESIZE 32 K MANAGED BY AUTOMATIC STORAGE INITIALSIZE 5000 M BUFFERPOOL
MAXBUFFERPOOL
db2 GRANT USE OF TABLESPACE MAXDATA TO USER MAXIMO
```

14. Run the following command to create the schema:

```
db2 create schema maximo authorization maximo
```

15. Run the following commands to grant authority to the Maximo user:

```
db2 GRANT  
DBADM,CREATETAB,BINDADD,CONNECT,CREATE_NOT_FENCED_ROUTINE,IMPLICIT_SCHEMA,LOAD,CREATE_EXTERNAL_ROUTINE,QUIESCE_CONNE  
CT,SECADM ON DATABASE TO USER MAXIMO  
db2 GRANT USE OF TABLESPACE MAXDATA TO USER MAXIMO  
db2 GRANT CREATEIN,DROPIN,ALTERIN ON SCHEMA MAXIMO TO USER MAXIMO
```

16. Run the following command to break the database connection:

```
db2 connect reset
```

- [Configuring IBM Cloud Pak for Data](#)

Configuring IBM Cloud Pak for Data

About this task

If you select Db2® as your database, you must configure Cloud Pak for Data.

Procedure

1. Open the Red Hat® OpenShift® console to log in to IBM Cloud Pak® for Data.

If you do not have the Cloud Pak for Data `admin` password the first time you log in, you can get it through the Red Hat OpenShift console:

- a. In the Red Hat OpenShift console, go to Workloads/Secrets.
- b. Select a Cloud Pak for Data namespace from the Project field.
For Amazon Web Services, the customer-managed, automated deployment, the Cloud Pak for Data namespace is `cpd-services-uniqueid`
- c. Filter by `admin-user-details`.
- d. In the Secrets list, click the name of the administrator account.
- e. Copy the value of the `initial_admin_password` field.

2. In the Red Hat OpenShift console, go to Networking/Routes.
3. Select a Cloud Pak for Data namespace from the Project field.

For Amazon Web Services, the customer-managed, automated deployment, the Cloud Pak for Data namespace is `cpd-services-uniqueid`

4. Click the Location link to open the Cloud Pak for Data login page in a new browser tab.

5. Log in to Cloud Pak for Data as `admin`.

6. Select Databases and then click Create Database.

7. From the Select a database page, click Next.

8. From the Configure page, select Single location for all data, and then click Next.

9. From the Advanced page, click Next.

10. From the Storage page, select the storage class and then Next.

For Amazon Web Services customer-managed Red Hat OpenShift clusters that are provisioned through an automated deployment offering, select `oc-storagecluster-cephfs`.

11. From the Finalize page, update the Display name if needed, and then click Create.

Results

After the instance is created, a green icon appears with the display name of the database tile.

Configuring Db2 Warehouse

You must create a new Db2® Warehouse database for exclusive use by Maximo® Manage. You cannot reuse the Db2 Warehouse database on Cloud Pak for Data where you already deployed another application from Maximo Application Suite.

Before you begin

Create a Db2 Warehouse database on IBM Cloud Pak® for Data. For more information, see [Creating Db2 instance by using IBM Cloud Pak for Data console](#).

After Db2 Warehouse databases are provisioned, a parameter is configured to specify user table organization on creation set as a column-organized table. However, to successfully deploy Maximo Manage on Db2 Warehouse, you must change this parameter so that the tables are created as row-organized tables.

Db2 Warehouse can have more than one database instance provisioned. You must ensure that you choose the one that is used by Maximo Manage to set this configuration and the remaining along this document. If your Db2 Warehouse was installed through Cloud Pak for Data, you can follow these steps to find the Db2 administrator pod:

1. Log in to the Cloud Pak for Data interface as an administrator.
2. Select Databases.
3. On the tile of the Db2 Warehouse database instance that you provisioned for Maximo Manage, select Details from the menu.
4. Search for the deployment ID value, for example, `db2wh-1652220906500619`.

5. Copy the suffix of the deployment ID, for example, 1652220906500619.
6. Search for the database name. The name of the database is the value that you use in place of *\$DB_NAME* variables in command-line examples.
7. Open the Red Hat® OpenShift® console, and then open Workloads > Pods.
8. From the Project menu, select your Cloud Pak for Data namespace.

For Amazon Web Services, the customer-managed, automated deployment, the Cloud Pak for Data namespace is *cpd-services-uniqueid*.

9. In the Filter field, enter the portion of the deployment ID you that copied and append it to the administrator pod value, for example, 1652220906500619-db2u-0. The pod that is displayed is the db2u administrator pod where you run the **db2inst1** command.

Note: The following commands use the variable *\$DB_NAME* to indicate the name of the database that you defined. Before you run the commands, ensure that you replace the *\$DB_NAME* with the name of your database at least in the **export** command available in the list of the commands.

```
su - db2inst1
export DB_NAME=$DB_NAME
db2 connect to $DB_NAME
db2 update db cfg for $DB_NAME using dft_table_org row
db2 terminate
db2 deactivate db $DB_NAME
db2stop
db2start
db2 activate db $DB_NAME
db2 connect to $DB_NAME
db2 get db cfg | grep DFT_TABLE_ORG
```

About this task

The following information is an example of the steps that you must complete and applies only to Cloud Pak for Data. If you complete different steps, ensure that a database schema, and table spaces are configured and that the *ddl_constraint_def* parameter is set to yes.

The following steps and commands also use the variable *\$DB_NAME* to indicate the name of the database that you defined. Before you run the commands, ensure you replace the *\$DB_NAME* with the actual name of your database.

Procedure

1. Confirm that the database is created.
 - a. As an administrator, log in to Red Hat OpenShift and from the Red Hat OpenShift cluster, from the navigation menu, click Workloads > Pods .
 - b. Locate and open the db2wh-string-db2u-0 pod. *string* is a randomly generated set of numbers.
 - c. On the Terminal tab, run the following commands:

```
su - db2inst1
export DB_NAME=$DB_NAME
db2 connect to $DB_NAME
```

If the database is configured, the database connection information is returned. The following text is an example of this information, where BLUDB is the name of the database. You need these values later in the configuration.

```
sh-4.2$ su - db2inst1
Last login: Tue May 26 14:29:55 UTC 2020
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$ db2 connect to BLUDB

Database Connection Information

Database server = DB2/LINUX8664 11.5.2.0
SQL authorization ID = DB2INST1
Local database alias = BLUDB
[db2inst1@db2wh-1589293563350-db2u-0 - Db2U db2inst1]$
```

2. Create an administrative Cloud Pak for Data user.

To set Maximo Manage to connect to the database, you can use the db2inst1 user that comes by default with Db2 Warehouse or you can create a different administrative user.

If you installed Db2 Warehouse without Cloud Pak for Data, you can create a different administrative user. For more information, see [Authentication options for Db2U](#).

If you installed Db2 Warehouse through Cloud Pak for Data, you can create a new administrative user through Cloud Pak for Data.

- a. As an administrator, log in to Cloud Pak for Data and from the navigation menu, click Administration > User management.
- b. Create a user by specifying the following information:
 - Specify a *user* and *username*.
 - Specify an email address and password.
 - Select the Administrator role.
- c. From the navigation menu, click Data > Databases.
- d. Open the three-dot menu for your Maximo Manage database and then click Details.
- e. From the drop-down menu, click Manage access.
- f. In the Maximo user row, click the edit icon.
- g. In the Role field, select Admin and then click Save.

Note: Take note of this *username* because it is used as the value of the *\$DB_USERNAME* variable in commands in this procedure.

3. Prepare the database for the **maxinst** program. Run the following commands from a database browser or command-line:
 - a. Run the following command to connect to the database as the db2inst1 user:

```
su - db2inst1
```

- b. Run the following command to connect to the database:

```
export DB_NAME=$DB_NAME
db2 connect to $DB_NAME
```

- c. Optional: For administrators who connect from outside Red Hat OpenShift, run the following command to connect to the Db2 pod. Replace the variable with the string value for your db2wh-string-db2u-0 pod, which was accessed during step 1.

```
oc rsh -n <db2wh namespace> c-db2wh-*<string>*-db2u-0 /bin/bash
```

Note: The name of the `c-db2wh-*<string>*-db2u-0` pod can be different if you installed Db2 Warehouse without Cloud Pak for Data. For example, if you installed the `DB2u` operator through [Db2](#), the name of the pod is similar to `c-$DB2_INSTANCE_NAME-db2u-0`.

4. Run the following commands.

- a. Run the following commands to configure the database:

Note: Choose the `APPHEAPSZ` db2 value to use in the following commands and replace the value of the `$HEAPVALUE` variable by at least 2048 in its specific `export` command line. If you intend to install many Manage extensions at the same time, set the `$HEAPVALUE` variable to 16384 to prevent failure of the `maxinst` or `updated` processes.

```
su - db2inst1
export DB_NAME=$DB_NAME
export HEAPVALUE=$HEAPVALUE
db2 connect to $DB_NAME
db2 update db cfg for $DB_NAME using "APPHEAPSZ $HEAPVALUE AUTOMATIC DEFERRED"
db2 update db cfg for $DB_NAME using "AUTO_MAINT ON DEFERRED"
db2 update db cfg for $DB_NAME using "AUTO_TBL_MAINT ON DEFERRED"
db2 update db cfg for $DB_NAME using "AUTO_RUNSTATS ON DEFERRED"
db2 update db cfg for $DB_NAME using "AUTO_REORG ON DEFERRED"
db2 update db cfg for $DB_NAME using "AUTO_DB_BACKUP ON DEFERRED"
db2 update db cfg for $DB_NAME using "CATALOGCACHE_SZ 800 DEFERRED"
db2 update db cfg for $DB_NAME using "CHNGPGS_THRESH 40 DEFERRED"
db2 update db cfg for $DB_NAME using "DBHEAP AUTOMATIC"
db2 update db cfg for $DB_NAME using "LOCKLIST AUTOMATIC DEFERRED"
db2 update db cfg for $DB_NAME using "LOGBUFSZ 1024 DEFERRED"
db2 update db cfg for $DB_NAME using "LOCKTIMEOUT 300 DEFERRED"
db2 update db cfg for $DB_NAME using "LOGPRIMARY 20 DEFERRED"
db2 update db cfg for $DB_NAME using "LOGSECOND 100 DEFERRED"
db2 update db cfg for $DB_NAME using "LOGFILSIZ 8192 DEFERRED"
db2 update db cfg for $DB_NAME using "SOFTMAX 1000 DEFERRED"
db2 update db cfg for $DB_NAME using "MAXFILOP 61440 DEFERRED"
db2 update db cfg for $DB_NAME using "PCKCACHESZ AUTOMATIC DEFERRED"
db2 update db cfg for $DB_NAME using "STAT_HEAP_SZ AUTOMATIC DEFERRED"
db2 update db cfg for $DB_NAME using "STMTHEAP AUTOMATIC DEFERRED"
db2 update db cfg for $DB_NAME using "UTIL_HEAP_SZ 10000 DEFERRED"
db2 update db cfg for $DB_NAME using "DATABASE_MEMORY AUTOMATIC DEFERRED"
db2 update db cfg for $DB_NAME using "AUTO_STMT_STATS OFF DEFERRED"
db2 update db cfg for $DB_NAME using "STMT CONC LITERALS DEFERRED"
db2 update alert cfg for database on $DB_NAME using "db.db_backup_req SET THRESHOLDSCHECKED YES"
db2 update alert cfg for database on $DB_NAME using "db.tb_reorg_req SET THRESHOLDSCHECKED YES"
db2 update alert cfg for database on $DB_NAME using "db.tb_runstats_req SET THRESHOLDSCHECKED YES"
db2 update dbm cfg using "PRIV MEM THRESH 32767 DEFERRED"
db2 update dbm cfg using "KEEPFENCED NO DEFERRED"
db2 update dbm cfg using "NUMDB 2 DEFERRED"
db2 update dbm cfg using "RQRIOLBK 65535 DEFERRED"
db2 update dbm cfg using "HEALTH_MON OFF DEFERRED"
db2 update dbm cfg using "AGENT_STACK_SZ 1000 DEFERRED"
db2 update dbm cfg using "MON_HEAP_SZ AUTOMATIC DEFERRED"
db2 update db cfg using "DDL_CONSTRAINT_DEF YES"
db2set DB2_SKIPINSERTED=ON
db2set DB2_INLIST_TO_NLJN=YES
db2set DB2_MINIMIZE_LISTPREFETCH=Y
db2set DB2_EVALUNCOMMITTED=YES
db2set DB2_FMP_COMM_HEAPSZ=65536
db2set DB2_SKIPDELETED=ON
db2set DB2_USE_ALTERNATE_PAGE_CLEANING=ON
```

- b. Run the following command to create the buffer pool:

```
db2 CREATE BUFFERPOOL MAXBUFFPOOL IMMEDIATE SIZE 4096 AUTOMATIC PAGESIZE 32 K
```

- c. Run the following commands to create the table spaces:

```
db2 CREATE REGULAR TABLESPACE MAXDATA PAGESIZE 32 K MANAGED BY AUTOMATIC STORAGE INITIALSIZE 5000 M BUFFERPOOL MAXBUFFPOOL
db2 CREATE TEMPORARY TABLESPACE MAXTEMP PAGESIZE 32 K MANAGED BY AUTOMATIC STORAGE BUFFERPOOL MAXBUFFPOOL
db2 CREATE REGULAR TABLESPACE MAXINDEX PAGESIZE 32 K MANAGED BY AUTOMATIC STORAGE INITIALSIZE 5000 M BUFFERPOOL MAXBUFFPOOL
```

- d. Run the following command to create the schema:

Note:

- The `DB_SCHEMA` variable is defined by user.
- The `DB_USERNAME` variable is the user with administrative rights that was created in step 2.

```
export DB_SCHEMA=$DB_SCHEMA
export DB_NAME=$DB_NAME
export DB_USERNAME=$DB_USERNAME
db2 CREATE SCHEMA $DB_SCHEMA AUTHORIZATION $DB_USERNAME
```

- e. Run the following commands to grant authority to the database user:

```
db2 GRANT
DBADM,CREATETAB,BINDADD,CONNECT,CREATE_NOT_FENCED_ROUTINE,IMPLICIT_SCHEMA,LOAD,CREATE_EXTERNAL_ROUTINE,QUIESCE
```

```
CONNECT,SECADM ON DATABASE TO USER $DB_USERNAME
db2 GRANT USE OF TABLESPACE MAXDATA TO USER $DB_USERNAME
db2 GRANT CREATEIN,DROPIN,ALTERIN ON SCHEMA $DB_SCHEMA TO USER $DB_USERNAME
```

f. Run the following command to break the database connection:

```
db2 connect reset
```

5. Verify that the configuration is successful.

- Go to Red Hat OpenShift console, Workload, Pods.
- In your Db2 Warehouse database instance, click the Db2u pod.
- Select the Terminal tab and run the following commands:

```
su - db2inst1
Export DB_NAME=<yourdbname>
Export DB_USERNAME=<yourdbusername> db2 connect to $DB_NAME user $DB_USERNAME using <password>
```

Tip:

- Replace <yourdbname> by the database name that you obtained in a previous step.
- Replace <yourdbusername> by the username that you obtained in a previous step.
- Replace <password> by the username password that you set when you created and configured the user in a previous step.

The database connection information details are displayed after the database is connected. The following text is an example of this information, where BLUDB is the database name and MAXIMO is the username.

```
sh-4.2$ su - db2inst1
Last login: Tue May 26 14:29:55 UTC 2020
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$ export DB_NAME=BLUDB
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$ echo $DB_NAME BLUDB
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$ export DB_USERNAME=MAXIMO
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$ db2 connect to $DB_NAME user $DB_USERNAME using MAXIMO
```

Database Connection Information

```
Database server      = DB2/LINUX8664 11.5.2.0
SQL authorization ID = MAXIMO
Local database alias = BLUDB
```

```
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$
```

d. Run the following command to list the table spaces:

```
db2 list tablespaces
```

Confirm the Db2 MAXINDEX, MAXTEMP, and MAXDATA table spaces are listed. The following text is an example of the table spaces details:

```
NAME = MAXDATA
TYPE = Database Managed Space
CONTENTS = All permanent data. Regular table space.
STATE = 0x0000
Detailed explanation = Normal
```

```
TABLESPACE ID = 5
NAME = MAXTEMP
TYPE = System Managed Space
CONTENTS = System Temporary data
STATE = 0x0000
Detailed explanation = Normal
```

```
TABLESPACE ID = 6
NAME = MAXINDEX
TYPE = Database Managed Space
CONTENTS = All permanent data. Regular table space.
STATE = 0x0000
Detailed explanation = Normal
```

```
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$
```

e. Run the following command to view the default table organization:

```
db2 get db cfg | grep DFT_TABLE_ORG
```

Confirm that the configuration db2 get db cfg | grep

DFT_TABLE_ORG is set to ROW. The following text is an example of the configuration:

```
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$ db2 get db cfg | grep DFT_TABLE_ORG
Default table organization (DFT_TABLE_ORG) = ROW
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$
```

f. Run the following command to view the default application heap:

```
db2 get db cfg | grep APPLHEAPSZ
```

Confirm that the value for APPLHEAPSZ in db2 get db cfg | grep APPLHEAPSZ is the same that you set. The following text is an example of the configuration:

```
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$ db2 get db cfg | grep APPLHEAPSZ
Default application heap (4KB) (APPLHEAPSZ) = AUTOMATIC(16384)
[db2inst1@db2wh-1589293563350-db2u-0- Db2U db2inst1]$
```

6. Disable the non-SSL Db2 database instance port for security.

- Run the following command to edit the Db2 service configuration:

```
oc edit svc -n project c-service_name-db2u-engn-svc
```

Where,

- Project is the name of the Red Hat OpenShift project where Db2 is deployed.
- **Service_name** is the identifier for the Db2 service instance.
For example, `c-db2o1tp-1605022957148004-db2u-engn-svc`.

b. Remove the following code block from the **spec.ports** section:

```
- name: legacy-server
  nodePort: 30279
  port: 50000
  protocol: TCP
  targetPort: 50000
```

c. Save the service.

Configuring Oracle Database

To configure Oracle Database for use with Maximo® Manage, you create table spaces, create a database user, and configure database settings.

Before you begin

For information about installing and deploying Oracle Database, review the Oracle Database product documentation.

For information about supported database versions, generate a [Software Product Compatibility Report](#). Search for IBM® Maximo Application Suite and select the suite version to generate the report. Check for the supported database versions in the Supported Software tab of the report.

Configure your database with the following Operating System (OS):

- Linux® or UNIX
- Microsoft Windows

Procedure

1. Log in as the Oracle software user. Typically, this user is named `oracle`.
2. To manage requests to connect to the database, create the database listener.
3. Create a database for use by Maximo Manage.
For the database initialization parameters, change the values of the following parameters:

```
nls_length_semantics
  Change this value to CHAR.
open_cursors
  Change this value to 1000.
cursor_sharing
  Set this value to FORCE.
```

Note: Ensure that the database character setting is set to **AL32UTF8** character set, which is required for Oracle Database.

4. In SQL*Plus, create a table space by running the following command. Replace the directory with the path to the database location.

```
Create tablespace maxdata datafile
'C:\oracle\product\12.1.0.1\db_1\dfs\maxdata.dbf'
size 1000M autoextend on;
```

To create table spaces for indexes, repeat the command and use a similar syntax.

5. Create a temporary table space by running the following command. Replace the directory with the path to the database location.

```
create temporary tablespace maxtemp tempfile
'C:\oracle\product\12.1.0.1\db_1\dfs\maxtemp.dbf'
size 1000M autoextend on maxsize unlimited;
```

6. To create the Maximo user and grant permissions, run the following command:

```
create user maximo identified by maximo default tablespace maxdata temporary
tablespace maxtemp;
grant connect to maximo;
grant create job to maximo;
grant create trigger to maximo;
grant create session to maximo;
grant create sequence to maximo;
grant create synonym to maximo;
grant create table to maximo;
grant create view to maximo;
grant create procedure to maximo;
grant alter session to maximo;
grant execute on ctxsys.ctx_ddl to maximo;
alter user maximo quota unlimited on maxdata;
```

If you created a separate table space for indexing, you must also grant access to that index table space to the Maximo user.

For example, if you created a separate table space for indexing that is called `TSI_MAM_OWN`, then run the following command:

```
alter user maximo quota unlimited on TSI_MAM_OWN
```

7. Create an Oracle preference arbitrary that is called MAXIMO_STORAGE and store the Oracle text indexes in dedicated table spaces.

- Store implicit indexes in MAXINDX table space.
- Store implicit tables in MAXDATA table space.
- Store implicit LOB tables in LOB table space.

For example, run the following preference definition to split the implicit objects in a text index across three table spaces; MAXDATA, MAXINDX, and MAXLOBS.

```
begin
ctx_ddl.create_preference('MAXIMO_STORAGE', 'BASIC_STORAGE');
ctx_ddl.set_attribute('MAXIMO_STORAGE', 'I_TABLE_CLAUSE',
'tablespace MAXDATA LOB(token_info) store as (tablespace MAXLOBS
enable storage in row)');
ctx_ddl.set_attribute('MAXIMO_STORAGE', 'I_INDEX_CLAUSE',
'tablespace MAXINDX compress 2');
ctx_ddl.set_attribute('MAXIMO_STORAGE', 'K_TABLE_CLAUSE',
'tablespace MAXINDX');
ctx_ddl.set_attribute('MAXIMO_STORAGE', 'R_TABLE_CLAUSE',
'tablespace MAXDATA LOB(data) store as (tablespace MAXLOBS
cache)');
ctx_ddl.set_attribute('MAXIMO_STORAGE', 'N_TABLE_CLAUSE',
'tablespace MAXINDX');
end;
```

To create an Oracle text index, the preference definition must be specified in the CREATE INDEX clause as shown here.

```
create index pm_ndx6 on pm (description) indextype is
ctxsys.context parameters ('lexer global_lexer language column
LANGCODE storage MAXIMO_STORAGE');
```

8. Set up Oracle text preferences and sub-lexer definitions.

a. Use a SQL query tool to log on to the database, as maximo, which is the schema owner and execute the following set of calls.

```
call ctx_ddl.drop_preference('global_lexer');
call ctx_ddl.drop_preference('default_lexer');
call ctx_ddl.drop_preference('english_lexer');
call ctx_ddl.drop_preference('chinese_lexer');
call ctx_ddl.drop_preference('japanese_lexer');
call ctx_ddl.drop_preference('korean_lexer');
call ctx_ddl.drop_preference('german_lexer');
call ctx_ddl.drop_preference('dutch_lexer');
call ctx_ddl.drop_preference('swedish_lexer');
call ctx_ddl.drop_preference('french_lexer');
call ctx_ddl.drop_preference('italian_lexer');
call ctx_ddl.drop_preference('spanish_lexer');
call ctx_ddl.drop_preference('portu_lexer');
call ctx_ddl.create_preference('default_lexer', 'basic_lexer');
call ctx_ddl.create_preference('english_lexer', 'basic_lexer');
call ctx_ddl.create_preference('chinese_lexer', 'chinese_lexer');
call ctx_ddl.create_preference('japanese_lexer', 'japanese_lexer');
call ctx_ddl.create_preference('korean_lexer', 'korean_morph_lexer');
call ctx_ddl.create_preference('german_lexer', 'basic_lexer');
call ctx_ddl.create_preference('dutch_lexer', 'basic_lexer');
call ctx_ddl.create_preference('swedish_lexer', 'basic_lexer');
call ctx_ddl.create_preference('french_lexer', 'basic_lexer');
call ctx_ddl.create_preference('italian_lexer', 'basic_lexer');
call ctx_ddl.create_preference('spanish_lexer', 'basic_lexer');
call ctx_ddl.create_preference('portu_lexer', 'basic_lexer');
call ctx_ddl.create_preference('global_lexer', 'multi_lexer');
call ctx_ddl.add_sub_lexer('global_lexer', 'default', 'default_lexer');
call ctx_ddl.add_sub_lexer('global_lexer', 'english', 'english_lexer', 'en');
call ctx_ddl.add_sub_lexer('global_lexer', 'simplified chinese', 'chinese_lexer', 'zh');
call ctx_ddl.add_sub_lexer('global_lexer', 'japanese', 'japanese_lexer', null);
call ctx_ddl.add_sub_lexer('global_lexer', 'korean', 'korean_lexer', null);
call ctx_ddl.add_sub_lexer('global_lexer', 'german', 'german_lexer', 'de');
call ctx_ddl.add_sub_lexer('global_lexer', 'dutch', 'dutch_lexer', null);
call ctx_ddl.add_sub_lexer('global_lexer', 'swedish', 'swedish_lexer', 'sv');
call ctx_ddl.add_sub_lexer('global_lexer', 'french', 'french_lexer', 'fr');
call ctx_ddl.add_sub_lexer('global_lexer', 'italian', 'italian_lexer', 'it');
call ctx_ddl.add_sub_lexer('global_lexer', 'spanish', 'spanish_lexer', 'es');
call ctx_ddl.add_sub_lexer('global_lexer', 'portuguese', 'portu_lexer', null);

commit;
```

What to do next

If you modified default role sets assigned to the user ID used to connect to the database, or restricted the default privileges that are granted to user IDs, then you must explicitly grant the role sets to the Maximo user. For example, if you do not grant a role such as the select_catalog_role role, you must explicitly grant that role to the Maximo user. Make the assignment by running the following SQL*Plus command:

```
grant select_catalog_role to maximo
```

Configuring Microsoft SQL Server

To configure Microsoft SQL Server for Maximo® Manage, you create table spaces, create a database user, and configure database settings.

Before you begin

For information about configuring Microsoft SQL Server, review the Microsoft SQL Server product documentation.

For information about supported database versions, you can generate a [Software Product Compatibility Report](#). Search for IBM® Maximo Application Suite and select the suite version to generate the report. Check for the supported database versions in the Supported Software tab of the report.

Procedure

1. Configure the listener port.

The default instance of the Microsoft SQL Server Database Engine listens on TCP port 1433. Named instances of the Microsoft SQL Server Database Engine and Microsoft SQL Server Compact Edition are configured for dynamic ports, which means they select any available port when the service starts. When you connect to a named instance across a firewall, configure the Database Engine to listen on a specific port to open this port in the firewall.

2. Verify that you enabled the Full-text Search setting during the installation of Microsoft SQL Server.

3. Create a Microsoft SQL Server database.

- a. From Microsoft SQL Server Management Studio, select New Database from the databases folder.

- b. Specify a unique database name.

For example, enter `maxdb80`

- c. For the maxdb80 Logical Name, change the Initial Size (MB) attribute to 500 (MB), and also set the value of the Autogrowth / Maxsize field to By 1 MB, Unlimited.

- d. Optional: Modify the log settings to accommodate your production environment.

- e. To deploy Maximo Manage in a specific language, choose the default collation for the database.

For example, to deploy the application in English, select `Latin1_General_CI_AI`.

Although Maximo Manage does not support a Microsoft SQL Server database using Unicode, it is possible to deploy Maximo Manage in multiple languages if the chosen languages support the same Microsoft SQL Server collation. For example, English and French can be installed because both support the same Microsoft SQL Server collation. However, English and Japanese cannot be installed together because they have different Microsoft SQL Server collations.

For more information, review the Microsoft SQL Server Collation and Unicode support documentation.

4. Create the Maximo user for Microsoft SQL Server.

- a. Open Microsoft SQL Server Management Studio.

- b. From the SQL Server Configuration Manager navigation, click Databases.

- c. Right-click the maxdb80 database and select New Query.

- d. Enter the following command to create the Maximo database user `MAXIMO` with a password that adheres to the password policy of the system.

```
sp_addlogin MAXIMO,password
go
```

This value is case-sensitive.

- e. Enter the following command to change the database owner to `MAXIMO`.

```
sp_changedbowner MAXIMO
go
```

Database encryption

When you deploy Maximo® Manage, the fields that require security, such as passwords and API keys, are encrypted or re-encrypted to provide security.

- [Database encryption overview](#)

When you configure Maximo Manage, specify encryption keys and encryption algorithms to determine how the fields that require security are encrypted.

- [Database encryption scenarios](#)

Your encryption and reencryption options are determined by your deployment scenario. Scenarios include deploying a new database, deploying a previously encrypted database, or changing the encryption keys for deployment.

- [Viewing database encryption history](#)

You can view the history for database encryption. Whenever you encrypt or reencrypt the database, a new entry is logged in the `syschangenetracker` table in the Maximo database.

- [Disabling automatic generation of encryption keys](#)

By default, if encryption keys are not specified when you activate Maximo Manage with a fresh database, new encryption keys are automatically generated. If you do not want to automatically generate encryption keys, you can set the `autoGenerateEncryptionKeys` property to `false`.

- [Resetting the crypto and cryptox fields in the database](#)

If you inadvertently lose your crypto and cryptox encryption keys, you can run a reset script that clears the crypto and cryptox fields in the Maximo Manage database. Then, you can then restart the server and reset your data.

Database encryption overview

When you configure Maximo® Manage, specify encryption keys and encryption algorithms to determine how the fields that require security are encrypted.

Important: You must save the encryption secret, which contains the encryption keys after Maximo Manage deployment is completed. The same keys are used for configuration when you reinstall Maximo Manage with the same database.

The following table describes the Crypto and CryptoX encryption keys for Maximo Manage:

Table 1. Encryption keys

Key	Description
MXE_SECURITY_CRYPTO_KEY	Used to encrypt Crypto fields, such as passwords. For Crypto encryption, if you specify a MXE_SECURITY_CRYPTO_KEY value that matches the MXE_SECURITY_OLD_CRYPTO_KEY value that was used in the previous deployment, no reencryption occurs. If you specify a key value during deployment that does not match the MXE_SECURITY_OLD_CRYPTO_KEY value, the database is reencrypted.
MXE_SECURITY_OLD_CRYPTO_KEY	Specifies the value for the previous Crypto encryption key that was used for the database.
MXE_SECURITY_CRYPTOX_KEY	Used to encrypt CryptoX fields, including API keys, such as the electronic signature key. For CryptoX encryption, if you specify a MXE_SECURITY_CRYPTOX_KEY value that matches the MXE_SECURITY_OLD_CRYPTOX_KEY value that was used in the previous deployment, no encryption changes occur. Because CryptoX values cannot be decrypted and the original value cannot be determined, if you specify a key value in a deployment that does not match the MXE_SECURITY_OLD_CRYPTOX_KEY value, CryptoX values are set to null when encryption is run.
MXE_SECURITY_OLD_CRYPTOX_KEY	Specifies the value for the previous CryptoX encryption key that was used for the database.

The following encryption properties are also supported:

- MXE_SECURITY_CRYPTO_ALGORITHM
- MXE_SECURITY_CRYPTO_MODE
- MXE_SECURITY_CRYPTO_MODULUS
- MXE_SECURITY_CRYPTO_PADDING
- MXE_SECURITY_CRYPTO_SPEC
- MXE_SECURITY_CRYPTOX_ALGORITHM
- MXE_SECURITY_CRYPTOX_MODE
- MXE_SECURITY_CRYPTOX_MODULUS
- MXE_SECURITY_CRYPTOX_PADDING
- MXE_SECURITY_CRYPTOX_SPEC

Note: After the database is installed, only the Crypto and CryptoX encryption keys can be changed.

You can add a value for the MXE_SECURITY_CRYPTO_KEY or MXE_SECURITY_CRYPTOX_KEY encryption keys when you configure the database settings for deployment before you activate the application. If you do not specify a value, a value is generated, and the database is encrypted. To learn how to specify the keys in the Maximo Manage configuration, see [Deploying in Maximo Application Suite](#).

If you do not specify an encryption key secret in the Maximo Manage configuration when you activate, the system automatically generates keys and names the secret in the keys by using the following naming convention:

`<workspaceId>-<appId>-encryptionsecret`

Because your database does not function without valid encryption keys, consider implementing the following best practices:

- Maintain your encryption keys in a vault or other secure management system for secrets.
- Specify your own values for encryption keys instead of using system-generated values. If you use system-generated values and do not create a backup, you cannot retrieve the keys. Without the keys, you cannot use your database.

Database encryption scenarios

Your encryption and reencryption options are determined by your deployment scenario. Scenarios include deploying a new database, deploying a previously encrypted database, or changing the encryption keys for deployment.

Deploying a new database

If you deploy a new database, you have two options for database encryption:

Table 1. Encryption for deploying a new database

Option	Action	Result
Provide your own values for the encryption keys.	Specify the values that you want for the Crypto and CryptoX encryption keys when you configure your database during deployment.	The database is then encrypted by using the key values that you provide.
Use system-generated keys.	Do not specify key values when you configure your database.	If you do not specify keys, a secret is automatically generated that contains the new MXE_SECURITY_CRYPTO_KEY and MXE_SECURITY_CRYPTOX_KEY encryption keys. Later, if you need the keys, you can view the keys in the secret.

Deploying a previously encrypted database

The following scenarios can occur if your deployment includes a database that was previously encrypted. For example, you might be upgrading from IBM® Maximo® Asset Management 7.6.0.10 or 7.6.1.2, which are not installed on Red Hat® OpenShift® but can be upgraded to Maximo Manage. You might also be upgrading from a previous Maximo Manage version. Therefore, the scenarios apply both to a database that previously implemented the default encryption for Maximo Manage or a database that was encrypted by using a different algorithm or keys.

An existing database that used the default encryption for Maximo Manage and no values were provided for the Crypto or CryptoX key

The database for Maximo Manage no longer uses a default set of keys for encryption. If you have an existing database that used the default encryption, you need to provide the MXE_SECURITY_CRYPTO_KEY and MXE_SECURITY_CRYPTOX_KEY values so that the database can be reencrypted. If your database

was previously encrypted by using keys other than the default encryption for Maximo Manage, you must provide the old MXE_SECURITY_OLD_CRYPTOX_KEY and MXE_SECURITY_OLD_CRYPTOX_KEY encryption keys so that the database can be decrypted and then reencrypted. When you configure the database, select one of the following options for reencryption:

Table 2. Encryption for existing databases where no values were provided for the encryption keys.

Option	Action	Result
Provide your own values for the encryption keys.	<ol style="list-style-type: none"> 1. Enter the MXE_SECURITY_CRYPTOX_KEY and MXE_SECURITY_CRYPTOX_KEY values. 2. Do not specify values for the MXE_SECURITY_OLD_CRYPTOX_KEY and MXE_SECURITY_OLD_CRYPTOX_KEY encryption keys. 	The database is reencrypted by using the values that you specified.
Use system-generated keys.	<ol style="list-style-type: none"> 1. Do not specify MXE_SECURITY_CRYPTOX_KEY or MXE_SECURITY_CRYPTOX_KEY values. 2. Do not specify values for the MXE_SECURITY_OLD_CRYPTOX_KEY and MXE_SECURITY_OLD_CRYPTOX_KEY encryption keys. 	The system generates new keys, and the database is reencrypted with the system-generated keys.

Note: Reencryption always occurs in this scenario.

An existing database that used values from your own Crypto or CryptoX keys

When you configure the database, select one of the following options for encryption:

Table 3. Encryption for existing databases where you provided your own values for the encryption keys.

Option	Action	Result
Do not reencrypt the database.	<ol style="list-style-type: none"> 1. Specify the Maximo Manage security properties, including the MXE_SECURITY_OLD_CRYPTOX_KEY and MXE_SECURITY_OLD_CRYPTOX_KEY encryption keys. 2. Specify the same values for the MXE_SECURITY_CRYPTOX_KEY and MXE_SECURITY_CRYPTOX_KEY encryption keys. 	Because you specified the same values for the old and new keys, the database is not reencrypted.
Reencrypt the database.	<ol style="list-style-type: none"> 1. Specify the Maximo Manage security properties, including the MXE_SECURITY_OLD_CRYPTOX_KEY and MXE_SECURITY_OLD_CRYPTOX_KEY encryption keys. 2. Select one of the following options: <ul style="list-style-type: none"> • Specify values for the new MXE_SECURITY_CRYPTOX_KEY and MXE_SECURITY_CRYPTOX_KEY encryption keys. • To use system-generated keys, do not specify encryption key values. 	The database is reencrypted.

Note: The first option is less likely to result in errors. You can change the keys later.

Changing the encryption keys for deployment

The following table describes the tasks to complete to reencrypt the database when you want to change the MXE_SECURITY_CRYPTOX_KEY and MXE_SECURITY_CRYPTOX_KEY encryption keys.

Table 4. Encryption by using new encryption keys

Option	Action	Result
Reencrypt the database by using new encryption keys.	<ol style="list-style-type: none"> 1. Set the MXE_SECURITY_OLD_CRYPTOX_KEY and MXE_SECURITY_OLD_CRYPTOX_KEY encryption keys to the values that the database currently uses for the MXE_SECURITY_CRYPTOX_KEY and MXE_SECURITY_CRYPTOX_KEY encryption keys. 2. Select one of the following options: <ul style="list-style-type: none"> • Specify values for the new MXE_SECURITY_CRYPTOX_KEY and MXE_SECURITY_CRYPTOX_KEY encryption keys. • To use system-generated keys, do not specify values for the MXE_SECURITY_CRYPTOX_KEY and MXE_SECURITY_CRYPTOX_KEY encryption keys. 	The database is reencrypted by using new encryption keys.

Viewing database encryption history

You can view the history for database encryption. Whenever you encrypt or reencrypt the database, a new entry is logged in the syschangetracker table in the Maximo® database.

The syschangetracker table contains the following columns:

- PROCESSNAME
- MESSAGE
- CHANGEBY
- CHANGEDATE
- WORKSPACEID
- APPID
- INSTANCENAME
- SYSCHANGETRACKERID
- ROWSTAMP

If you have issues with encryption keys, the record in the straightjacket table helps to identify whether reencryption occurred and when it occurred. The MESSAGE column provides the first 2 bytes and last 2 bytes of the encryption key, which can help you identify the encryption keys that are currently being used. The following

image shows an example of the syschangetracker table:

Figure 1. The syschangetracker table

PROCESSNAME	MESSAGE	CHANGEBY	CHANGEDATE	WORKSPACEID	APPID	INSTANCENAME
ReEncryptFromS... Start to re-encrypt CRYPTOX..... with key fe*****qO	maximo	2022-03-25 1...	masdev	manage	vitizumiaut1

ReEncryptFromS... Complete re-encrypt CRYPTO.....	maximo	2022-03-25 1...	masdev	manage	vri123

Disabling automatic generation of encryption keys

By default, if encryption keys are not specified when you activate Maximo® Manage with a fresh database, new encryption keys are automatically generated. If you do not want to automatically generate encryption keys, you can set the `autoGenerateEncryptionKeys` property to `false`.

About this task

The `autoGenerateEncryptionKeys` property controls whether encryption keys are automatically generated when you activate Maximo Manage with a fresh database. By default, this property is set to `true`, and encryption keys are automatically generated if no value is specified for them. You can set the property to `false` if you do not want to generate keys automatically. If you set the `autoGenerateEncryptionKeys` property to `false` and you do not provide encryption keys, deployment fails, and you receive an error message that the property is set to `false` and encryption keys are missing.

If encryption keys are automatically generated, you can easily lose track of them, especially in development and test environments where databases are reused. If you set the `autoGenerateEncryptionKeys` property to `false`, users are forced to enter the key. Users are more likely to keep track of the keys and less likely to lose them.

Note that this property takes effect when you activate the application by using an API call. If you update the property for an instance that is already activated, the property does not take effect until you make a change that is related to the encryption keys, for example, when you delete keys to trigger reencryption.

Procedure

1. In the Red Hat® OpenShift® console, in the Administration section, select Custom Resource Definitions.
2. In the CustomResourcesDefinitions window, select the ManageWorkspace custom resource definition record.
3. In the CustomResourceDefinition details window, on the Instances tab, select the instance for which you want to disable automatic generation of encryption keys.
4. On the YAML tab for the instance, in the `spec.settings.deployment.autoGenerateEncryptionKeys` section, specify `false`.
5. Save the custom resource.

Resetting the crypto and cryptox fields in the database

If you inadvertently lose your crypto and cryptox encryption keys, you can run a reset script that clears the crypto and cryptox fields in the Maximo® Manage database. Then, you can then restart the server and reset your data.

About this task

When you run the `resetcryptocryptox.sh` script, the crypto and cryptox fields are cleared. After you restart the server, you can review the data that was cleared and reset the values that were cleared, such as properties or API keys.

Procedure

1. In the Red Hat® OpenShift® Container Platform, in the Workloads section, select Pods.
2. From the Pods panel, open the `maxinst` pod.
3. On the Terminal tab, enter `resetcryptocryptox.sh`.
4. Restart the Maximo Manage server.
5. Add any variables, such as API keys or properties, that were cleared by the `resetcryptocryptox.sh` script.
6. After you reset your data, redeploy or reactivate the application.

Troubleshooting database deployment

When you deploy the Maximo® Manage application, issues that are related to database deployment might cause the deployment process to fail.

Both to prevent or solve some database configuration issues that might result in stuck or failed Maximo Manage deployment, you can follow these best practices:

- Review the database settings that you used to configure Maximo Manage. If something is wrong with the values, edit your database configuration on the Manage StatusHealth Status page and activate again.
- Ensure that the JDBC URL format and details are correct and are using the correct JDBC protocol, database URL, name, and port. Test your connection to the database by using a database tool.
- If you are using the SSL-enabled database and port, verify whether you selected the SSL option.
- To ensure that your database is ready, verify that you are using the correct username, password, schema name, tablespace name, and index tablespace name.
- Do not skip preparations steps. For example, the deployment process on Maximo Manage databases will not work if you skip the step to set its table organization to be row-based instead of column-based.
- Make sure you configured your database properly if you plan to deploy languages. Set the configuration to support Maximo Manage, SQL, or Maximo Manage for the language that is used for the databases.
- Confirm that you put the correct database certificate for the database in the Maximo Manage configuration and that is not expired.
- If you are running a Maximo Manage Maximo Manage deployment and reusing a database that had Maximo Manage previously, make sure you passed the encryption keys that are saved from the previous deployment. Otherwise, the process generates new keys, which will not match the ones that are used to encrypt the database, and the deployment process will not proceed.
 - For example, you deactivated Maximo Manage and deleted its application. Now you are redeploying the Maximo Manage application and activating it again, but you are still using the previously deployed Maximo Manage database.
- To deploy multiple Maximo Manage components at the same time, if you are using IBM® Db2® Warehouse databases or other Db2 versions, increase the *APPHEAPSZ* value to at least 16384 to avoid failures during the database deployment. Alternatively, you can deploy fewer components simultaneously, by trying to deploy first one and then another Maximo Manage component.
- For the best Maximo Manage deployment performance, the ideal location for your database is the same as the one for your Maximo Manage. If the location site of your database is different, the chances of database failures during the Maximo Manage deployment due to connection issues and latency are higher.

If the update of your database during the Maximo Manage deployment is interrupted by a situation, such as lost connection, the problem is usually automatically resolved by the Maximo Manage operator reconciliation process.

If the failure persists, make sure that your database connection is working correctly. Before you remove, re-create the database, and retry the Maximo Manage deployment, you can try the following procedures:

1. Select the Bypass upgrade version checkbox and then reactivate the Maximo Manage application. If you select this option, the deployment can run, regardless of the current version of the installed database. It skips version validations that might be preventing deployment to progress.
2. If the failure still persists, review the log files to assess the situation and note the script number for the failed deployment. To review the log files, complete the following steps:
 - a. In the Red Hat® OpenShift® console, expand Workloads and select Pods.
 - b. In the Project field, select the Manage project.
 - c. In the Pods window, select the administrative pod. The administrative pod includes `manage-maxinst` in the pod name, as shown in the following example:

```
env-managedev-manage-maxinst-7fd3c77492-kmj6z
```
 - d. To review the logs, in the Pod Details window, first select the Logs tab for the `manage-maxinst` pod to look at the messages. If you want to look at all the logs, select the Terminal tab for the `manage-maxinst` pod and look at the logs in the `/opt/IBM/SMP/maximo/tools/maximo/log` directory.
 - e. After you review the log files, manually correct the problem or problems and run the database installation again.

Demo data

When you deploy Maximo® Manage, you can add sample data to a demo database.

The sample data in the demo database is useful for development or test environments.

To set up a test or development environment with demo data, install an instance of Maximo Application Suite specifically for testing or development. Then, when you configure the database settings for your Maximo Manage deployment, select the option to install demo data.

Note: You cannot add this sample data after Maximo Manage is deployed as the database is updated without the sample data. To add the sample data after deploying Maximo Manage, recreate or clean your database, and reconfigure Maximo Manage to deploy with the sample data.

Deployment of industry solutions and add-ons

When you deploy Maximo® Manage, you can also include industry solutions and add-ons for deployment.

Before you select any Maximo Manage industry solutions or add-ons for deployment, it is important that you check the [system requirements](#). Choose the IBM® Maximo Application Suite version from the list and see the IBM Maximo Application Suite - Manage Application Compatibility Report to validate that the selected components can be deployed together.

You can deploy the following industry solutions and add-ons with Maximo Manage:

Industry solutions

- Maximo Aviation
- Maximo Civil Infrastructure
- Maximo Nuclear
- Maximo Oil & Gas
- Maximo Transportation
- Maximo Utilities

Add-ons

- Maximo Asset Configuration Manager
- Maximo Connector for Oracle Applications
- Maximo Connector for SAP Applications
- Maximo Health, Safety and Environment
- Maximo Service Provider
- Maximo Spatial
- Maximo Connector for Workday Applications
- Maximo Anywhere

Maximo Health

You can deploy Maximo Health as part of Maximo Manage to automatically connect and share data between both applications. When deployed as part of Maximo Manage, all deployment settings are shared with Maximo Health.

Note: If you deploy Maximo Health component as part of Maximo Manage, you cannot deploy the Maximo Health stand-alone application on the same Maximo Application Suite instance and vice versa.

Language support

Maximo® Manage is available in a number of languages. You can specify languages when you activate the application.

Languages that are displayed in the user interface are controlled by the following settings:

Browser language setting

If content is available for the language that users select for their browser, the application displays that language. If the language that is selected in the browser is not available, the application displays the base language.

Preferred language setting

In the IBM® Maximo Application Suite, users can select a preferred locale, language, and time zone when they set up their profile. If you change the user's preferred language setting in Maximo Manage, it is not overwritten by a future synchronization from Maximo Application Suite.

Application language settings

When Maximo Manage is deployed, you can select a base language, which is the default language for the application. By default, the base language is English. If you select a different language, the language is permanently set as the base language, and you cannot change it in subsequent deployments. However, if you do not specify a base language when you first deploy the application and use the default value instead, you can change the base language when you redeploy.

The base language can be changed only once. After it is changed, it cannot be changed back to English or any other language.

You can select other languages when you activate the application. You cannot remove languages after the application is activated.

If you use IBM Db2® and plan to install a language other than English, ensure that you select the checkbox for the Db2 Vargraphic field when you configure your database.

Although Maximo Application Suite does not support bidirectional languages, Maximo Manage provides language support for bidirectional languages.

To add a language, on the Activation page, in the Base field and the Additional field, select the language code.

The following languages are supported:

Note: If you want to use the database to deploy Maximo Manage in English only, you can choose Latin1_General_CI_AI collate for SQL Server. If you plan, for example to deploy Maximo Manage in Japanese, the choice would be Japanese_CI_AI. Refer to the [SQL Server documentation](#) to know what collate to use for each language. While SQL Server might support Unicode, Maximo Manage does not support yet for SQL Server, so you cannot set it. Therefore, you cannot deploy Maximo Manage with multiple languages in case those languages require different collates, for example: simplified Chinese and Russian.

Language	Language code
Arabic	AR
Brazilian Portuguese	PT-BR
Croatian	HR
Czech	CS
Danish	DA
Dutch	NL
English	EN
Finish	FI
French	FR
German	DE
Hebrew	HE
Hungarian	HU
Italian	IT
Japanese	JA
Korean	KO
Norwegian	NO
Polish	PL
Russian	RU
Simplified Chinese	ZH-TW
Slovak	SK

Language	Language code
Slovenian	SL
Spanish	ES
Swedish	SV
Traditional Chinese	ZH-TW
Turkish	TR

Note: Maximo Manage supports Db2, Oracle Database, and Microsoft SQL Server. However, it cannot support Microsoft SQL Server when the database collation is set to Turkish.

Because Maximo Manage does not handle Turkish *i* characters that are stored in Db2 and Oracle Database, those characters are not supported.

Server bundle overview

The application can be deployed in one or more workloads called server bundles. A server bundle isolates the workload processes so that they can be independently managed.

Server bundles can be independently scaled and managed based on your needs. For example, the user interface server bundle `ui` allows users to access the user interface by using a web browser. A cron task server bundle allows users to run background jobs. When a user interface workload and cron task workload are deployed as two separate server bundles, the CPU and memory that are consumed by these workloads do not affect each other.

A pod can be composed of one or more server bundles. The server bundles in a pod share the same database, network interface, storage volume, and resources, such as CPU and memory.

One server bundle that you deploy is designated as the default server. The server bundle that you designate as the default is used to establish the default URL, or route, that links to the app application in the workspace.

Keep in mind the following requirements and behaviors when you create your server bundles:

- You cannot have two server bundles that have the same bundle type. For example, you can specify only one server bundle of type `ui`. However, you can create a server bundle of type `all` in addition to another bundle type.
- If only one server bundle is specified, you must specify a bundle type of `all`. If you have only one bundle and do not specify type `all` for the default, the deployment might appear successful, but the application will not function properly.
- The default server bundle must have a bundle type of either `all` or `ui`. If you do not specify one of these types for the default, the deployment might appear successful, but the application will not function properly. If your default server bundle is a `ui` bundle, you must also have a server bundle of type `mea` because the `mea` server bundle is required for user synchronization.
- If you create only one server bundle and do not specify a default, that bundle is selected as the default.
- If you create multiple server bundles and do not specify a default, a server bundle that has the type `all` is randomly selected as the default server.

When you deploy the application, you specify parameters that control deployment of the server bundle pods and their associated services and routes.

You can specify the following server bundle parameters to configure the deployment:

Name

The user-defined name for the server bundle. You can also specify whether the server bundle is the default server bundle.

Pod count

The number of pods to deploy for the server bundle.

Type

The type of the server bundle. The following six bundle types are available:

- `all` - includes `ui`, `cron`, `mea`, and report bundle types.
- `ui` - includes the user interface components.
- `cron` - includes components that are required for cron tasks.
- `mea` - includes the enterprise web services API. This server bundle type is required for user synchronization.
- `report` - includes components for reports.
- `standalonejms` - for more information, see [Configuring JMS servers for Maximo Manage](#).

Additional server properties

As an option, you can add the following properties:

Route subdomain

If you specify a subdomain, it is added as a prefix to the main domain when the route is created for the server bundle. For example, if you specify `maximoui` as a subdomain, your full domain is similar to the following example: `maximoui.workspaceid.manage.domain.com`.

Additional server configurations

To configure the WebSphere® Application Server Liberty application server, you can provide custom parameters, as shown in the following example:

```
server-custom.xml: |-
<!-- Enable features -->
<featureManager>
  <feature>jsp-2.3</feature>
</featureManager>

<!-- To access this server from a remote client add a host attribute to the following element, e.g.
host="*" -->
<httpEndpoint
id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_c_mas_man_overview_de
faultHttpEndpoint"
  httpPort="9080"
```

```
httpsPort="9443" />
<!-- Automatically expand WAR files and EAR files -->
<applicationManager autoExpand="true"/>
```

Bundle-level properties

To add app system properties to specific server bundles, you can specify property names and values when you deploy the application.

Provisioning storage

Maximo® Manage supports both ephemeral storage and persistent storage.

Ephemeral storage is transient and does not persist when you redeploy or reactivate applications.

Persistent storage is used for data, such as file attachments, that you want to persist throughout multiple deployments.

- [Ephemeral storage](#)
By default, ephemeral storage is allocated for the administrative and server bundle builds when Maximo Manage is deployed. Administrators can modify the requests and also limit the amount of ephemeral storage that is provisioned.
- [Configuring ephemeral storage](#)
To configure ephemeral storage, you can add parameters to the ManageWorkspace custom resource definition by using the Red Hat® OpenShift® administrative console.
- [Persistent storage](#)
You use persistent volume storage for data, such as file attachments, that you want to persist across multiple deployments. Administrators must provision the persistent storage systems that are needed for your applications.
- [Configuring persistent volume claims](#)
You can configure a persistent volume claim (PVC) through the deployment process or by manually updating the ManageWorkspace custom resource.

Ephemeral storage

By default, ephemeral storage is allocated for the administrative and server bundle builds when Maximo® Manage is deployed. Administrators can modify the requests and also limit the amount of ephemeral storage that is provisioned.

By default, the administrative and server bundle builds request 30 GB of storage, and the builds assign a limit of 100 GB of storage, as shown in the following sample:

```
ephemeralStorage:
  requests:
    adminBuild: 30Gi
    serverBundleBuild: 30Gi
  limits:
    adminBuild: 100Gi
    serverBundleBuild: 100Gi
```

Administrators can configure different requests and limits by specifying different values in the custom resource for the application.

For more information, see [Understanding ephemeral storage](#) in the Red Hat® OpenShift® documentation.

Configuring ephemeral storage

To configure ephemeral storage, you can add parameters to the ManageWorkspace custom resource definition by using the Red Hat® OpenShift® administrative console.

About this task

By default, the administrative and server bundle builds request 30 GB of storage and assign a limit of 100 GB of storage. You can configure different requests and limits by specifying different values in the custom resource for the application.

Procedure

1. In the Red Hat OpenShift console, in the Administration section, select Custom Resource Definitions.
2. In the CustomResourcesDefinitions window, select the ManageWorkspace custom resource definition record.
3. In the CustomResourceDefinition details window, on the Instances tab, select the instance for which you want to specify ephemeral storage.
4. On the YAML tab for the instance, in the spec.settings.deployment.ephemeralStorage section, specify values for the storage request and storage limits, as shown in the following example:

```
"deployment": {
  "buildTag": "latest",
  "mode": "up",
  "persistentVolumes": [],
  "serverBundles": [
    {
```

```

        "name": "default",
        "bundleType": "all",
        "isDefault": true,
        "isUserSyncTarget": true,
        "isMobileTarget": true,
        "routeSubDomain": "all",
        "replica": 1
      },
    ],
    "ephemeralStorage": {
      "limits": {
        "adminBuild": "100Gi",
        "serverBundleBuild": "100Gi"
      },
      "requests": {
        "adminBuild": "30Gi",
        "serverBundleBuild": "30Gi"
      }
    }
  },
}

```

5. Save the custom resource.

Persistent storage

You use persistent volume storage for data, such as file attachments, that you want to persist across multiple deployments. Administrators must provision the persistent storage systems that are needed for your applications.

Creating persistent volumes gives you greater control over your storage and can make it easier to increase the amount of storage or to add existing files. Creation of external file storage systems for data and objects is outside the scope of the Maximo® Manage deployment. To provision persistent storage for Maximo Manage, you can use the Kubernetes persistent volume (PV) framework.

You can learn more about persistent storage. For more information, see [Understanding persistent storage](#).

Set up persistent volume storage before you deploy the application.

The following guidelines describe how to set up Network File System (NFS) storage. A similar process can be applied to other types of persistent storage.

1. Ensure that an NFS server is deployed and that it is enabled and started.
2. Ensure that you exported an NFS share and that it is accessible.
3. Ensure that you completed the following tasks:
 - Deployed a persistent volume provisioner.
 - Defined a storage class. Record the storage class name. When you deploy Maximo Manage, you must supply the class name for the persistent volume storage that you created.
 - Created a volume for the storage. Record the name of the volume so that you can use that name for the persistent volume claim when you deploy Maximo Manage.
 - Set the persistentVolumeReclaimPolicy for your storage volume to Retain to ensure that the data is not deleted when a persistent volume claim is released. Then, you can reclaim the content manually. For example, for test environments, you can use the Retain option to manually reclaim and reuse storage assets. For more information, see [Persistent Volumes](#) in the Kubernetes documentation.

For more information about setting up persistent storage volumes, see [Understanding persistent storage](#) in the Red Hat® OpenShift® documentation.

You can configure persistent volume claim for deployments on different platforms, such as IBM Cloud®, in Maximo Manage. For more information about Persistent Volume Claims configuration, see [Setting Persistent Volume Claims \(PVC\)](#).

You can configure a persistent volume claim through the deployment process or by manually updating the Maximo Manage Workspace custom resource (CR).

If you declare a persistent volume and do not specify a persistent volume claim in Maximo Manage, a persistent volume claim is dynamically provisioned by using the storage class that you configured for the volume.

If necessary, you can configure a persistent volume claim for a specific server bundle. The mount path that you specify for a server bundle overrides any default mount path that was specified for the deployment.

After deployment, if you want to adjust the size of a persistent volume claim, you can specify a new value for the size and redeploy the application.

If the amount of storage that you need exceeds the amount available for the storage volume and you want to add more storage capacity after deployment, you must create a new volume for the storage and move your data to the new volume. Then, you can redeploy the application and provide the persistent volume claim parameters for the new storage.

Configuring persistent volume claims

You can configure a persistent volume claim (PVC) through the deployment process or by manually updating the ManageWorkspace custom resource.

Before you configure a PVC, ensure that you prepared a persistent storage volume and can provide the volume name, class name, mount path, and size for your persistent volume claim.

If you declare a persistent volume and do not specify a persistent volume claim when you deploy Maximo® Manage, a persistent volume claim is dynamically provisioned by using the storage class that you configured for the volume.

If you configure a (PVC) when you deploy the application, the storage in the volume that you provisioned is available to all server bundles in the workspace. You can also configure persistent volume claims for specific server bundles in a deployment. If you configure a PVC for a server bundle, the mount path that you specify for the server bundle PVC overrides the path that you specify for the deployment.

- [Configuring persistent volume claims during deployment](#)
When you configure a persistent volume claim (PVC) during deployment, the storage in the volume that you provisioned is available to all server bundles in the workspace.
- [Configuring persistent volume claims for server bundles](#)
To configure a persistent volume claim for a specific server bundle, you can add parameters to the ManageWorkspace custom resource by using the Red Hat® OpenShift® administrative console. The mount path that you specify for the server bundle PVC overrides any default path that you configured for a persistent volume during deployment.

Configuring persistent volume claims during deployment

When you configure a persistent volume claim (PVC) during deployment, the storage in the volume that you provisioned is available to all server bundles in the workspace.

Before you begin

Ensure that you prepared a persistent storage volume and can provide the volume name, class name, mount path, and size for your persistent volume claim.

Configuring persistent volume claims for server bundles

To configure a persistent volume claim for a specific server bundle, you can add parameters to the ManageWorkspace custom resource by using the Red Hat® OpenShift® administrative console. The mount path that you specify for the server bundle PVC overrides any default path that you configured for a persistent volume during deployment.

Procedure

1. In the Red Hat OpenShift console, in the Administration section, select Custom Resource Definitions.
2. In the CustomResourceDefinitions window, select the ManageWorkspace custom resource definition record.
3. In the CustomResourceDefinition details window, on the Instances tab, select the instance for which you want to create persistent storage.
4. On the YAML tab for the instance, in the spec.settings.deployment.persistentVolumes section, specify values for the volume name and storage class name. You can also specify a PVC name and size for the PVC, or you can provide those parameters for specific server bundles in step 5. The following example shows how to add persistent volume parameters for the deployment:

```
spec:
  settings:
    deployment:
      persistentVolumes:
        pvcName: my_pvc_name
        volumeName: my_volume
        size: 1G
        storageClassName: my_storage_class_name
```

5. In the spec.settings.deployment.serverBundles section, specify the PVC name and mount path for a server bundle, as shown in the following example:

```
spec:
  settings:
    ...
    serverBundles:
      - name: server_bundle_name
        bundleType: bundle_type
        pvcMount:
          - pvcName: my_server_bundle_pvc_name
            mountPath: /mount_path_for_the_server_bundle_storage
```

6. Save the custom resource.

Monitoring agent for Maximo Manage

Maximo® Manage includes a monitoring agent that collects statistics about application usage and performance. Administrators can configure Prometheus service monitoring and then use visualization software, such as Grafana, to view usage information that the agent collects.

The Maximo Manage monitoring agent provides a set of REST APIs that enable HTTP-based clients to access information that is related to the current state of a deployment. Administrators can configure Prometheus to use the data that is available in Manage.

Use the following guidelines when you configure Prometheus:

- The Maximo Manage monitoring agent uses the following ports:

Port 9444

Port 9444 is used for HTTPS.

Port 9081

Port 9081 is used for HTTP.

- You must configure Prometheus user-defined projects enablement after an Red Hat® OpenShift® instance is created. You can complete the configuration either before or after Maximo Manage is deployed.
- After Maximo Manage is deployed, you must configure PodMonitor or Service Monitor.

The open source Prometheus service monitoring and alerting toolkit is available with Red Hat OpenShift version 4.3 and later.

For more information about how to configure monitoring in Red Hat OpenShift Container Platform version 4.8, see [Enabling monitoring for user-defined projects](#) in Red Hat OpenShift documentation.

For more information about monitoring in Red Hat OpenShift, see [Understanding the monitoring stack](#) in Red Hat OpenShift documentation about monitoring.

For more information about setting up Grafana dashboards, see [Configuring Grafana dashboards](#).

- [Monitoring metrics](#)
The monitoring agent for Maximo Manage provides metrics for application usage and performance.
- [Configuring Grafana dashboards](#)
Maximo Manage includes a monitoring agent that collects statistics about application usage and performance. Administrators can configure the Prometheus monitoring service and then use Grafana visualization software to view usage data that the agent collects.

Monitoring metrics

The monitoring agent for Maximo® Manage provides metrics for application usage and performance.

Monitoring Metrics for Maximo Manage 8.4.0 and earlier

Table 1. Server level monitoring metrics for Maximo Manage 8.4.0 and earlier versions

API	URL template	Description
Database	http://<host>:<port>/maximo/oslc/members/<memberid>/dbinfo	Provides information about the database that is used by the application. Some of the information that is provided includes the database version or vendor information, and driver information. The resource also provides links to the database connection pool details.
MBO count	http://<host>:<port>/maximo/oslc/members/<memberid>/mbocount	Provides MBO count information. The resource also provides links to the MBO and MboSet class. This class can be useful when you are trying to resolve out of memory (OOM) or performance issues.
Memory	http://<host>:<port>/maximo/oslc/members/<memberid>/memory	Provides information about the server heap and non-heap memory usage. All units are in Megabytes (MB).
Threads	http://<host>:<port>/maximo/oslc/members/<memberid>/threads	Provides information about the threads in the JVM, such as the current thread count, peak thread count, and if there are any deadlocks. It also provides a link to enumerate the threads in the system at that instant. The API consumer can check for thread states and lock information about each thread.
Thisserver	http://<host>:<port>/maximo/oslc/members/thisserver	Provides information about the total number of concurrent users on a particular server.
Thread pool	http://<host>:<port>/maximo/oslc/members/<memberid>/threadpoolinfo	Counts total thread pool size and total active thread pool count

Table 2. Server level monitoring metrics for Maximo Manage 8.5 and earlier versions

Metric name	URL template	Description
mas_manage_db_connectionused_total	http://<host>:<port>/maximo/oslc/members/<memberid>/dbinfo	Provides information about the database that is used by the application. Some of the information that is provided includes the database version or vendor information, and driver information. The resource also provides links to the database connection pool details.
mas_manage_db_connectionfree_total	http://<host>:<port>/maximo/oslc/members/<memberid>/dbinfo	Provides information about the database that is used by the application. Some of the information that is provided includes the database version or vendor information, and driver information. The resource also provides links to the database connection pool details.
mas_manage_uiservlet_total	http://<host>:<port>/maximo/oslc/members/thisserver/servletstats	Provides information about the total number of concurrent users on a particular server.
mas_manage_oslcservlet_total		
mas_manage_restservlet_total		
mas_manage_concurrentuser_total	http://<host>:<port>/maximo/oslc/members/thisserver/	
mas_manage_crontask_threads_total	http://<host>:<port>/maximo/oslc/memb	Provides total count of crontask threads.

Metric name	URL template	Description
mas_manage_cr onthread_peak_ total	http://<host>: <port>/maximo/oslc/memb ers/<memberid>/mbocount	Provides peak count of crontask threads within one minute.
mas_manage_m bo_total		Provides MBO count information. The resource also provides links to the MBO and MboSet class. This class can be useful when you are trying to resolve out of memory (OOM) or performance issues.
mas_manage_m boset_total		
mas_manage_h eapmemory_use d_total	http://<host>: <port>/maximo/oslc/memb ers/<memberid>/memory	Provides information about the server heap and non-heap memory usage. All units are in Megabytes (MB).
mas_manage_h eapmemory_ma x_total		
mas_manage_th read_deadlock_ total	http://<host>: <port>/maximo/oslc/memb ers/<memberid>/threads	Provides information about the threads in the JVM, such as the current thread count, peak thread count, and if there are any deadlocks. It also provides a link to enumerate the threads in the system at that instant. The API consumer can check for thread states and lock information about each thread.
mas_manage_th read_peak_total		
mas_manage_th read_total		
mas_manage_th readpool_size_t otal	http://<host>: <port>/maximo/oslc/memb ers/<memberid>/threadpoo linfo	Counts total thread pool size and total active thread pool count.
mas_manage_th readpool_active _total		
mas_manage_s essionstats_acti ve_total	http://<host>: <port>/maximo/oslc/memb ers/<memberid>/sessionst atsinfo	Provides information on total sessions, active sessions and live sessions.
mas_manage_s essionstats_live _total		
mas_manage_s essionstats_cre ate_total		

Additional monitoring metrics for Maximo Manage 8.5.0 and later

Maximo Manage 8.5.0 provides the following additional metrics.

Table 3. Additional instance level monitoring metrics for Maximo Manage 8.5.0

API	URL template	Description
Table size	http://<host>: <port>/maximo/oslc/members/ <memberid>/tablesize	Provides information about the five database tables that have the largest table size per day. The table size is measured in MB per day.
DB connection and average response time	http://<host>: <port>/maximo/oslc/members/ <memberid>/pingdb	Checks the database connection and calculates the average response time that is required to run 10 recent queries. These queries are obtained from the system tables. The queries are run on Db2® and DB2® databases.

Table 4. Additional instance level monitoring metrics for Maximo Manage 8.5

Metric name	URL template	Description
mas_manage_db_to p5tablesize_bytes	http://<host>: <port>/maximo/oslc/members/ <memberid>/tablesize	Provides information about the five database tables that have the largest table size per day. The table size is measured in MB per day.
mas_manage_pingd b_totalltime_secon ds	http://<host>: <port>/maximo/oslc/members/ <memberid>/pingdb	Checks the database connection and calculates the average response time that is required to run 10 recent queries. These queries are obtained from the system tables. The queries are run on Oracle and DB2 databases.
mas_manage_pingc os_totalltime_secon ds	http://<host>: <port>/maximo/oslc/members/ <memberid>/pingcos	Provides the response time for connecting to COS and the status for COS connectivity.
mas_manage_pingk afka_totalltime_seco nds	http://<host>: <port>/maximo/oslc/members/ <memberid>/pingkafka	Provides the response time for connecting to Kafka and the status for Kafka connectivity.
mas_manage_pingd b_availability	http://<host>: <port>/maximo/oslc/members/ <memberid>/pingdb	Checks the database connection and calculates the average response time that is required to run 10 recent queries. These queries are obtained from the system tables. The queries are run on Oracle and DB2 databases.
mas_manage_pingc os_availability	http://<host>: <port>/maximo/oslc/members/ <memberid>/pingcos	Provides the response time for connecting to COS and the status for COS connectivity.

Metric name	URL template	Description
mas_manage_pingkafka_availability	http://<host>:<port>/maximo/oslc/members/<memberid>/pingkafka	Provides the response time for connecting to Kafka and the status for Kafka connectivity.
mas_manage_report_total	http://<host>:<port>/maximo/oslc/members/<memberid>/report	Provides the total number of reports that have run for the hour before.

Table 5. Additional server level monitoring metrics for Maximo Manage 8.5

API	URL template	Description
Cron thread	http://<host>:<port>/maximo/oslc/members/<memberid>/cronthread	Counts total concurrent thread count for cron tasks and the peak count of total cron threads in each server per minute.
Integration and UI objects exchanged	http://<host>:<port>/maximo/oslc/members/<memberid>/objexchanged	Provides number of integration and UI objects that are exchanged in each server per minute.
Servlet stats	http://<host>:<port>/maximo/oslc/members/<memberid>/servletstat	Provides request and response information about the OSLCServlet, RESTServlet and UIServlet for each deployed application. The response time is measured in milliseconds.
Thread stats	http://<host>:<port>/maximo/oslc/members/<memberid>/threads	Provides runtime thread count information that includes concurrent thread count and deadlocked thread counts.

Table 6. Additional server level monitoring metrics for Maximo Manage

Metric name	URL template	Description
mas_manage_cron_thread_total	http://<host>:<port>/maximo/oslc/members/<memberid>/cronthread	Counts total concurrent thread count for cron tasks and the peak count of total cron threads in each server per minute.
mas_manage_integration_mbo_total	http://<host>:<port>/maximo/oslc/members/<memberid>/objexchanged	Provides number of integration and UI objects that are exchanged in each server per minute.
mas_manage_ui_mbo_total		
mas_manage_systemexception_total	http://<host>:<port>/maximo/oslc/members/thisserver/errcountmetrics	Provides the total count of MXSystemException created
mas_manage_applicationexception_total		Provides the total count of MXApplicationException created
mas_manage_uiservlet_responsetime_seconds	http://<host>:<port>/maximo/oslc/members/<memberid>/servletstats	Provides request and response information about the OSLCServlet, RESTServlet and UIServlet for each deployed application. The response time is measured in milliseconds.
mas_manage_oslcservlet_responsetime_seconds		
mas_manage_restservlet_responsetime_seconds		
mas_manage_thread_deadlock_total	http://<host>:<port>/maximo/oslc/members/<memberid>/threads	Provides runtime thread count information that includes concurrent thread count and deadlocked thread counts.
mas_manage_thread_total		
mas_manage_thread_peak_total	http://<host>:<port>/maximo/oslc/members/<memberid>/threads	Provides runtime thread count information that includes concurrent thread count and deadlocked thread counts.

Configuring Grafana dashboards

Maximo® Manage includes a monitoring agent that collects statistics about application usage and performance. Administrators can configure the Prometheus monitoring service and then use Grafana visualization software to view usage data that the agent collects.

To configure the monitoring dashboard, complete the following tasks:

- Configure a Red Hat® OpenShift® monitoring service.
- Configure the PodMonitor custom resource for the Maximo Manage application to monitor pods.
- Verify IBM® Maximo Monitor data.
- Configure Grafana.
- Load the Maximo Manage dashboards into Grafana.
- [Prerequisites](#)
Before you can configure the Grafana dashboards in Red Hat OpenShift, check the storage classes available in your cluster in the Red Hat OpenShift Container Platform console.
- [Configuring Red Hat OpenShift monitoring service](#)
Configure the Red Hat OpenShift monitoring service in the Red Hat OpenShift Container Platform console.
- [Configuring PodMonitor for Maximo Manage](#)
In the Red Hat OpenShift Container Platform console, configure the PodMonitor custom resource to monitor your pods for Maximo Manage.
- [Verifying the monitoring data](#)
In the Red Hat OpenShift Container Platform console, verify the monitoring data.

- [Installing and configuring Grafana](#)
Install and configure the Red Hat OpenShift Grafana operator into the openshift-user-workload-monitoring project by using the OperatorHub.
- [Loading Maximo Manage dashboard into Grafana for Maximo Manage](#)
Load the Maximo Manage dashboard in Grafana.
- [Troubleshooting monitoring issues](#)
Enable Prometheus in debug mode to troubleshoot monitoring issues. If the data source connection is not working in Grafana, you can reset the value for the authentication header.

Prerequisites

Before you can configure the Grafana dashboards in Red Hat® OpenShift®, check the storage classes available in your cluster in the Red Hat OpenShift Container Platform console.

The ocs-storagecluster-cephfs storage class that is used for Single user (RWO) and Shared Access (RWX) access modes for file system volumes is used as an example to configure Grafana dashboards.

Configuring Red Hat OpenShift monitoring service

Configure the Red Hat® OpenShift® monitoring service in the Red Hat OpenShift Container Platform console.

Procedure

1. Select your project from the Workloads > ConfigMaps and click Create ConfigMap.
2. Run the following command.

```
oc describe configmap cluster-monitoring-config -n openshift-monitoring
```

3. If the enableUserWorkload parameter is false, set the parameter to true.
When the enableUserWorkload parameter is set to true, user-defined projects in a cluster are monitored.
4. Increase the Prometheus retention policy, add storage class ocs-storagecluster-cephfs, and specify the size.
The default retention policy is 24 hours.
5. Change the Alertmanager's ocs-storagecluster-cephfs storage class and size.
To configure the core Red Hat OpenShift Container Platform monitoring components, you must create the cluster-monitoring-config ConfigMap object in the openshift-monitoring project.
The following text is an example of the cluster-monitoring-config.yml file for configuring cluster monitoring:

```
kind: ConfigMap
apiVersion: v1
metadata:
  name: cluster-monitoring-config
  namespace: openshift-monitoring
data:
  config.yaml: |
    enableUserWorkload: true
    prometheusK8s:
      retention: 90d
      volumeClaimTemplate:
        spec:
          storageClassName: ocs-storagecluster-cephfs
          resources:
            requests:
              storage: 300Gi
    alertmanagerMain:
      volumeClaimTemplate:
        spec:
          storageClassName: ocs-storagecluster-cephfs
          resources:
            requests:
              storage: 20Gi
```

6. Create or update the user-workload-monitoring-config.yml file.
To configure the components that monitor user-defined projects, you must create the user-workload-monitoring-config ConfigMap object in the openshift-user-workload-monitoring project.

```
apiVersion: v1
kind: ConfigMap
data:
  config.yaml: |
    prometheus:
      logLevel: info
      enforcedSampleLimit: 50000
      retention: 90d
      volumeClaimTemplate:
        spec:
          storageClassName: ocs-storagecluster-cephfs
          resources:
            requests:
              storage: 300Gi
```

```

alertmanagerMain:
volumeClaimTemplate:
  spec:
    storageClassName: ocs-storagecluster-cephfs
    resources:
      requests:
        storage: 20Gi
metadata:
  name: user-workload-monitoring-config
  namespace: openshift-user-workload-monitoring

```

7. To verify the status of the pods, run the following command.

```
oc get pods -n openshift-user-workload-monitoring
```

8. Check that the output matches the following sample:

NAME	READY	STATUS	RESTARTS	AGE
prometheus-operator-576bf85cc6-jdrfm	2/2	Running	0	15d
prometheus-user-workload-0	5/5	Running	1	15d
prometheus-user-workload-1	5/5	Running	1	15d
thanos-ruler-user-workload-0	3/3	Running	0	15d
thanos-ruler-user-workload-1	3/3	Running	0	15d

9. Check the PVC status to determine whether the prometheus-user-workload pods are bound or any issues exist in the bindings.

Configuring PodMonitor for Maximo Manage

In the Red Hat® OpenShift® Container Platform console, configure the PodMonitor custom resource to monitor your pods for Maximo® Manage.

Before you begin

Maximo Manage 8.x must be installed.

Procedure

1. In the Red Hat OpenShift Container Platform console, select the Maximo Manage project.
2. Create the following pod monitors to monitor the server-level serverBundle pod and instance-level monitorAgent pod.

Note:

- The port 9444 for **https** is available for your use.
- Connect to the Prometheus server without specifying certificates by using the **insecureSkipVerify** flag to disable the target certificate validation.
- Ensure that you provide a correct and valid selector because any pod in your cluster that matches the labels in the PodMonitor selector field is monitored based on the podMetricsEndpoints that are specified in the Pod Monitor custom resource.

Note: You can search for the PodMonitor using only two selectors, **appType** and **appTypeName**, or only a single selector **appType**. Other selectors are no longer required for searching.

Note: If the **appTypeName** is UI, MEA, Report, or Cron, you can skip specifying the **appTypeName: all** parameter. It is sufficient to use **appType: serverBundle** only.

```

apiVersion: monitoring.coreos.com/v1
kind: PodMonitor
metadata:
  labels:
    k8s-app: maximo-monitoragent
  name: maximo-serverlevel-monitoragent
  namespace: mas-grafana-manage
spec:
  podMetricsEndpoints:
    - interval: 30s
      scheme: https
      targetPort: 9444
      tlsConfig:
        insecureSkipVerify: true
  selector:
    matchLabels:
      mas.ibm.com/appType: serverBundle

```

```

apiVersion: monitoring.coreos.com/v1
kind: PodMonitor
metadata:
  labels:
    k8s-app: maximo-monitoragent
  name: maximo-instancelevel-monitoragent
  namespace: mas-grafana-manage
spec:
  podMetricsEndpoints:
    - interval: 30s
      scheme: https
      targetPort: 9444
      tlsConfig:
        insecureSkipVerify: true
  selector:
    matchLabels:

```

```

mas.ibm.com/appType: monitorAgent

apiVersion: monitoring.coreos.com/v1
kind: PodMonitor
metadata:
  labels:
    k8s-app: maximo-monitoragent
    name: maximo-serverlevel-monitoragent
    namespace: mas-grafana-manage
spec:
  podMetricsEndpoints:
    - interval: 30s
      scheme: https
      targetPort: 9444
      tlsConfig:
        insecureSkipVerify: true
  selector:
    matchLabels:
      mas.ibm.com/appType: serverBundle
      mas.ibm.com/appTypeName: all

```

Verifying the monitoring data

In the Red Hat® OpenShift® Container Platform console, verify the monitoring data.

Procedure

1. Log in to the Red Hat OpenShift Container Platform console and select your Maximo® Manage cluster.
2. Select **Observe > Metrics**.
3. Type `mas_manage_mbo_total`.
4. Click **Run queries** and verify that the data is displayed, which is shown in the following example.

Installing and configuring Grafana

Install and configure the Red Hat® OpenShift® Grafana operator into the openshift-user-workload-monitoring project by using the OperatorHub.

Procedure

1. In the Red Hat OpenShift Container Platform console, select Operators > OperatorHub and search for the Grafana operator that is provided by Red Hat OpenShift.
2. Install the Grafana operator for the openshift-user-workload-monitoring namespace.
3. Create an instance of Grafana.
 - a. Select Operator > OperatorHub > Grafana Operator and then select the Grafana tab.
 - b. Click Create Grafana.
 - c. On YAML tab, enter the following text:

```
apiVersion: integreatly.org/v1alpha1
kind: Grafana
metadata:
  name: mas-grafana
  namespace: openshift-user-workload-monitoring
spec:
  ingress:
    enabled: true
  dataStorage:
    accessModes:
      - ReadWriteOnce
    size: 10Gi
    class: ocs-storagecluster-cephfs
  config:
    log:
      mode: "console"
      level: "warn"
    security:
      admin_user: "root"
      admin_password: "secret"
    auth:
      disable_login_form: False
      disable_signout_menu: True
    auth.anonymous:
      enabled: True
  dashboardLabelSelector:
    - matchExpressions:
      - {key: app, operator: In, values: [grafana]}
```

A route is created, and the public URL is included in that route definition in the openshift-user-workload-monitoring namespace project.

4. Remember to update the subscription.yaml file and add the following configuration so that Grafana scans for the dashboard across the whole cluster:

```
Config:
  env:
    - name: "DASHBOARD_NAMESPACES_ALL"
      value: "true"
```

After an update, the subscription.yaml file looks like the following:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: grafana-operator
  namespace: "{{ grafana_namespace }}"
  labels:
    operators.coreos.com/grafana-operator.{{ grafana_namespace }}: ''
spec:
  channel: v4
  installPlanApproval: Automatic
  name: grafana-operator
  source: community-operators
  sourceNamespace: openshift-marketplace
  config:
    env:
      - name: "DASHBOARD_NAMESPACES_ALL"
        value: "true"
```

5. Run the following command to grant the user permission.

```
oc adm policy add-cluster-role-to-user cluster-monitoring-view -z grafana-serviceaccount
```
6. Run the following command to obtain the BEARER_TOKEN.

```
- oc serviceaccounts get-token grafana-serviceaccount -n openshift-user-workload-monitoring
```
7. Create the GrafanaDataSource, which points to the Prometheus instance that you installed earlier.
 - a. Select the Grafana Operator > Installed operators > GrafanaDataSource tab.
 - b. Enter the following text and replace the \${BEARER_TOKEN} value with the value that you obtained in a previous step.

```
apiVersion: integreatly.org/v1alpha1
kind: GrafanaDataSource
metadata:
  name: prometheus-grafanadatasource
  namespace: openshift-user-workload-monitoring
spec:
  datasources:
    - access: proxy
      editable: true
      isDefault: true
      jsonData:
        httpHeaderName1: 'Authorization'
      timeInterval: 5s
```

Note: Instead of following manual steps, you can run a playbook to install and setup Grafana. For more information, see [cluster monitoring](#)

Load the Maximo® Manage dashboard in Grafana.

1. Log on to Grafana.
2. In the Red Hat® OpenShift® Container Platform console, select Networking > Routes.
Note: Maximo operator provides the maximo-dashboard.json file during deployment without requiring to import it explicitly.
Warning: Rename and backup your dashboard before you import it to avoid overwriting the custom dashboard. After you import the dashboard, it is not necessary to import it again, except if you upgrade. If you upgrade Maximo Manage, you might have to import the dashboard and apply the changes again.
3. Load the Grafana dashboards in two ways.
 - If you install Red Hat OpenShift Container Platform monitoring before you install Maximo Manage, the dashboards are installed automatically.
 - If you install Red Hat OpenShift Container Platform monitoring after you install Maximo Manage, you must import the dashboard.
 - a. Open a terminal in the Maximo Manage workspace operator pod, which has a **-ws** in its name.
 - b. Find the dashboard at:

c. Use the **oc rsync** command to copy the file from the Maximo Manage workspace operator pod and import it through the Grafana user interface.

For example:

d. Select Import from the side menu.

Note: You can see the import option only when you log on as the admin user that you specified during Grafana instance creation.

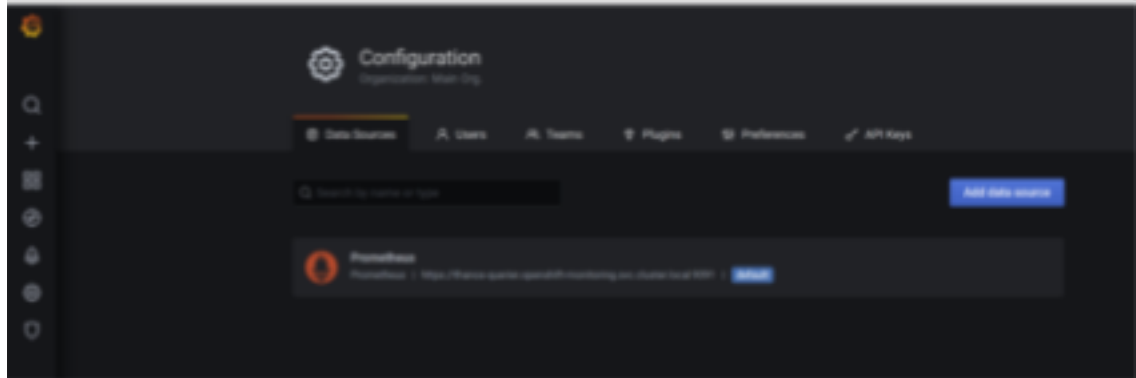

Enable Prometheus in debug mode to troubleshoot monitoring issues. If the data source connection is not working in Grafana, you can reset the value for the authentication header.

- Enable the debug mode in config.yaml file in "user-workload-monitoring-config" configmap.

```
prometheus:  
  logLevel: debug
```

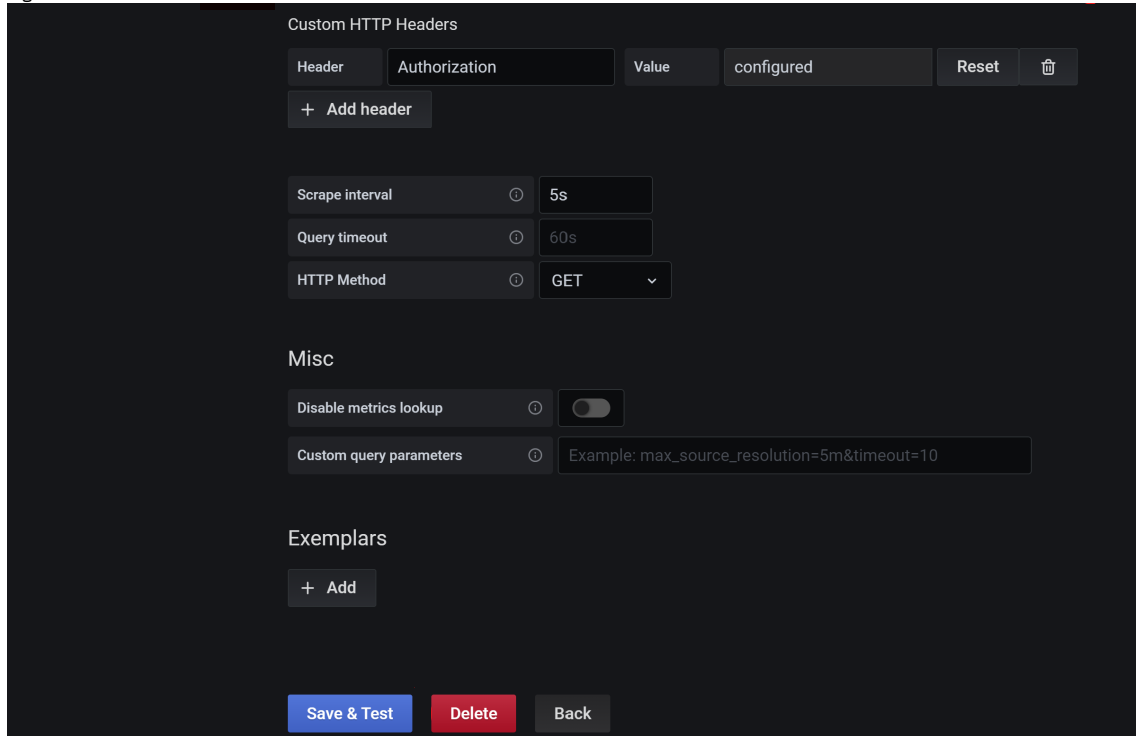

- Check the data source connection in Grafana. If you see any issue with the metrics in the Grafana chart, reset the value for the authentication header to BEARER_TOKEN.
 1. To reset the value, click Add data source from the Configuration menu.

Figure 1. Check data source - 1

2. Click Reset and provide a valid value. For more information, see [Installing and configuring Grafana](#).
3. Click Save & Test.

Figure 2. Check data source - 2

For more information, see [Troubleshooting monitoring issues](#).

Backing up and restoring Maximo Manage

To avoid disruptions to service and unplanned downtimes, create regular Maximo® Manage backups that you can restore as needed.

For more information, see [Back up and restore the Manage application in Maximo Application Suite](#).

Storing images in an external registry

When Maximo® Manage is deployed or updated, the build process generates an administrative image and a server bundle image for each bundle type. Bundle types are specified in the custom resource for the workspace. Images are stored in an internal registry. In some cases, you might want to store the build images in an external repository. For example, you might want to run security scans on images that have customizations, or you might want to test builds independently before you deploy the application in Maximo Application Suite. Administrators can configure Maximo Manage to store images in an external repository.

Creating a secret based on Docker credentials

Before you can configure Maximo Manage to store builds in an external registry, you must create a secret for the external registry repository.

Procedure

1. Log in to the Red Hat® OpenShift® console.
2. In the workspace where the Maximo Manage custom resource is located, use the command line interface or the Red Hat OpenShift dashboard to create an image pull secret.

For example, you can use the command line interface to enter the following secret:

```
kubect1 create secret docker-registry regcred
--docker-server=your_docker_registry_server
--docker-username=your_your_docker_registry_account
--docker-password=your_your_docker_registry_api_key
```

Adding images to an external registry

To add build images for Maximo Manage to an external registry, configure the custom resource for the Maximo Manage workspace.

About this task

To configure Maximo Manage to add build images to an external registry, you must add the `registryForGeneratedImages` properties to the `spec.settings` section of the custom resource and specify values for the following fields:

- `registryPath` - The path to the repository where you want to store the image.
- `secretName` - The secret that contains the credentials for accessing the repository.

Procedure

1. In the Red Hat OpenShift console, in the Administration section, select Custom Resource Definitions.
2. Select the Maximo Manage workspace and then select the instance for your external registry.
3. On the YAML tab, in the `spec.settings` section, add the following lines:

```
registryForGeneratedImages:
  registryPath:
  secretName:
```

4. Specify values for the `registryPath` and `secretName` fields, as shown in the following example:

```
spec:
  settings:
    ...
    languages:
      baseLang:
      secondaryLangs:
    registryForGeneratedImages:
      registryPath: your_docker_registry_server
      secretName: your-image-pull-secret-for-the-repository
```

5. Save the custom resource.

Results

The Maximo Manage workspace operator automatically picks up the change to the custom resource. A build is started, and the new image or images are pushed to the external registry. You can use the images to deploy Maximo Manage on a local computer.

If you no longer want to push image builds to an external repository, you must remove the lines that you added for the external registry from the custom resource for the workspace.

Configuring Java Message Service (JMS) servers

If you use Java™ Messaging Service (JMS) to integrate data, you can deploy one or more server bundles with a Liberty server that supports JMS messaging.

- [Configuring JMS servers for Maximo Manage](#)
To add a JMS server bundle, you specify `standalonejms` for the server bundle type when Maximo Manage is deployed.
- [Scaling JMS servers](#)

By default, the server bundle for JMS servers is a single pod or server bundle in Maximo Manage. You can add server bundles if you need them.

Configuring JMS servers for Maximo Manage

To add a JMS server bundle, you specify `standalonejms` for the server bundle type when Maximo® Manage is deployed.

About this task

This configuration creates a single-pod Liberty JMS server.

By default, ephemeral storage for the JMS server uses the /jmsstore directory in the container. Generally, users require persistent storage for messaging. To provide persistent storage, provision a persistent storage volume for Maximo Application Suite. Then, configure a persistent volume claim for the JMS bundle when you deploy the application. You can specify a different directory for the JMS storage while setting server configuration through the additional server configuration parameters for the bundle.

Procedure

1. Log in to Maximo Application Suite as a system administrator.
2. From Suite administration, select Workspaces from the side navigation menu and then select the Manage tile.
3. On the Manage workspace details page, click Actions, and select Update configuration.
4. In the Server bundles row, click the edit icon.
5. In the Server bundles section, if the System managed checkbox is selected, clear it. Click Add bundle.
6. In the Name column, enter a name for the bundle, such as `jmsserver`.
7. In the Type column, select `standalonejms`.
8. To configure the queues, complete the following steps:
 - a. In the Additional properties column for your JMS server bundle, click View.
 - b. Optional: Set a different route subdomain.
 - c. In the Additional server config section, use XML to specify both the default queues and the custom queues that you want to add. This step adds the default queues and two custom queues:

```
<?xml version="1.0" encoding="UTF-8"?>
<server description="new server">
  <messagingEngine>
    <fileStore path="/jmsstore"/>
    <queue
      id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_sqoutbd" maintainStrictOrder="true" maxMessageDepth="100000" failedDeliveryPolicy="KEEP_TRYING"
      maxRedeliveryCount="-1"/>
    <queue
      id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_sqinbd" maintainStrictOrder="true" maxMessageDepth="200000" failedDeliveryPolicy="KEEP_TRYING"
      maxRedeliveryCount="-1"/>
    <queue
      id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_cqinerrbd" maxMessageDepth="100000" failedDeliveryPolicy="KEEP_TRYING"/>
    <queue
      id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_cqinbd" maxMessageDepth="100000" exceptionDestination="cqinerrbd"/>
    <queue
      id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_notferrbd" maxMessageDepth="100000" failedDeliveryPolicy="KEEP_TRYING"/>
    <queue
      id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_notfbd" maxMessageDepth="100000" exceptionDestination="notferrbd"/>
    <queue
      id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_custsqoutbd" maintainStrictOrder="true" maxMessageDepth="100000" failedDeliveryPolicy="KEEP_TRYING"
      maxRedeliveryCount="-1"/>
    <queue
      id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_custsqinbd" maintainStrictOrder="true" maxMessageDepth="200000" failedDeliveryPolicy="KEEP_TRYING"
      maxRedeliveryCount="-1"/>
    </messagingEngine>
  </server>
```

Note: The fileStore path can be modified to use a different directory to store JMS messages. If you are using persistent volumes, make sure that the fileStore path is configured correctly under the persistent volume directory. For example, if your persistent volume is mounted on directory /nfs, then the fileStore path might be /nfs/jmsstore.

- d. Click Save to save the additional server bundle properties.
9. If you have a single server (all) bundle or for the mea bundle, to prepare the other Maximo Manage server bundles for the JMS queues, complete the following steps:
 - a. In the Additional properties column for the server bundle, click View.
 - b. In the Additional server config section, specify features for both the default queues and the custom queues that you want to add, as shown in the following example:

```
<?xml version='1.0' encoding='UTF-8'?>
<server description="new server">
  <featureManager>
    <feature>jndi-1.0</feature>
    <feature>wasJmsClient-2.0</feature>
    <feature>jmsMdb-3.2</feature>
    <feature>mdb-3.2</feature>
  </featureManager>
  <jmsQueueConnectionFactory jndiName="jms/maximo/int/cf/intcf" connectionManagerRef="mifjmsconfact">
    <properties.wasJms remoteServerAddress="<InstancesId>-<workspaceId>-<serverbundlename>.mas-<instanceId>-
    manage_svc:7276:BootstrapBasicMessaging"/></jmsQueueConnectionFactory>
    <connectionManager
      id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_mifjmsconfact" maxPoolSize="20"/>
    <jmsQueue jndiName="jms/maximo/int/queues/sqout"><properties.wasJms queueName="sqoutbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/sqin"><properties.wasJms queueName="sqinbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/cqin"><properties.wasJms queueName="cqinbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/cqinerr"><properties.wasJms queueName="cqinerrbd"/></jmsQueue>
```

```

    <jmsQueue jndiName="jms/maximo/int/queues/notf"><properties.wasJms queueName="notfbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/notferr"><properties.wasJms queueName="notferrbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/custsqout"><properties.wasJms queueName="custsqoutbd"/></jmsQueue>
  </jmsQueue>
  <jmsQueue jndiName="jms/maximo/int/queues/custsqin"><properties.wasJms queueName="custsqinbd"/></jmsQueue>
  <jmsActivationSpec
    id=" home markdown jenkins workspace Transform in SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
    r_maximo-all/mboejb/JMSContQueueProcessor-1" maxEndpoints="5"><properties.wasJms
    destinationLookup="jms/maximo/int/queues/cqin" maxConcurrency="5" maxBatchSize="20"
    connectionFactoryLookup="jms/maximo/int/cf/intcf"/></jmsActivationSpec>
  <jmsActivationSpec
    id=" home markdown jenkins workspace Transform in SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
    r_maximo-all/mboejb/JMSContQueueProcessor-2" maxEndpoints="1"><properties.wasJms
    destinationLookup="jms/maximo/int/queues/cqinerr" maxConcurrency="1" maxBatchSize="20"
    connectionFactoryLookup="jms/maximo/int/cf/intcf"/></jmsActivationSpec>
</server>

```

10. If you have report, cron, or UI bundles, complete the following steps for each of them:
 - a. In the Additional properties column for the server bundle, click View.
 - b. In the Additional server config section, specify features for both the default queues and the custom queues that you want to add, as shown in the following example:

```

<?xml version='1.0' encoding='UTF-8'?>
<server description="new server">
  <featureManager>
    <feature>jndi-1.0</feature>
    <feature>wasJmsClient-2.0</feature>
    <feature>jmsMdb-3.2</feature>
    <feature>mdb-3.2</feature>
  </featureManager>
  <jmsQueueConnectionFactory jndiName="jms/maximo/int/cf/intcf" connectionManagerRef="mifjmsconfact">
    <properties.wasJms remoteServerAddress="<InstancesId>-<workspaceId>-<serverbundlename>.mas-<instanceId>-
    manage.svc:7276:BootstrapBasicMessaging"/></jmsQueueConnectionFactory>
    <connectionManager
      id=" home markdown jenkins workspace Transform in SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_configure_jms_serve
      r_mifjmsconfact" maxPoolSize="20"/>
    <jmsQueue jndiName="jms/maximo/int/queues/sqout"><properties.wasJms queueName="sqoutbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/sqin"><properties.wasJms queueName="sqinbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/cqin"><properties.wasJms queueName="cqinbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/cqinerr"><properties.wasJms queueName="cqinerrbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/notf"><properties.wasJms queueName="notfbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/notferr"><properties.wasJms queueName="notferrbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/custsqout"><properties.wasJms queueName="custsqoutbd"/></jmsQueue>
    <jmsQueue jndiName="jms/maximo/int/queues/custsqin"><properties.wasJms queueName="custsqinbd"/></jmsQueue>
  </jmsQueue>
</server>

```

For steps 9 and 10:

The queueName values must match the queue names that you specified in step 8.c. Also, the difference between all bundles or mea bundle XML versus the report, cron, UI bundles XML is that the second category does not have the jmsActivationSpec lines.

When you enter the connection properties, supply the following variables:

```

<InstanceId>
  Name of your Maximo Application Suite instance.
<workspaceId>
  Name of your workspace.
<serverbundlename>
  Name of your JMS server bundle, for example, jmsserver.

```

Note: Your *remoteServerAddress* must be in the following format:

```

remoteServerAddress="<InstanceId>-<workspaceId>-<serverbundlename>.mas-<InstanceId>-
manage.svc:7276:BootstrapBasicMessaging"

```

For example:

```

remoteServerAddress="mngrel84-masdev-jmsserver.mas-mngrel84-manage.svc:7276:BootstrapBasicMessaging"

```

11. Click Save again to save the additional server bundle properties.
12. After you complete the workspace updates, activate the changes.

What to do next

After you configure the stand-alone JMS servers, you can log in to Maximo Manage and configure your JMS queues. For more information, see [JMS queue configuration](#).

Scaling JMS servers

By default, the server bundle for JMS servers is a single pod or server bundle in Maximo® Manage. You can add server bundles if you need them.

You can select one of the following options to add JMS server bundles:

- Complete the following steps to create more instances of the standalonejms server bundle and the mea server bundle:

1. Create another instance of the standalonejms server bundle.
2. Create the same set of queues that existed in your first server bundle.
3. Create another instance of the mea server bundle that uses the new standalonejms server bundle.

You can then configure an external system to use either of the mea cluster URLs to send the messages, which distributes the processing load across multiple servers.

- You can add more mea server instances for the same standalonejms server. This process effectively creates message-driven beans (MDB) that can consume messages in parallel from the JMS server.

Deployment planning worksheet

Use the planning worksheet to record the information that you need when configuring and during the deployment process, such as database parameters, server bundle files, and customization archive location.

The following table contains settings for deployment

Table 1. Settings for deployment

Setting	Default	Your value
Db2® hostname		
Db2 port		
Oracle hostname		
Oracle port		
SQL Server hostname		
SQL Server port		
Db2 Warehouse hostname		
Db2 Warehouse port		
Maximo® Manage database name		
Maximo Manage database username		
Maximo Manage password		
Database schema name	maximo	
Database table space	MAXDATA	
Database index space	MAXINDEX	
Industry solution and add-on components	See Deployment of industry solutions and add-ons	
Languages	EN See Language support	
Server bundles	All See Server bundles	
Customization archive location	See Customizing the application	
Mode	On	
Persistent volume claim (PVC) name	See Persistent storage	
PVC volume name		
PVC size		
PVC mount path		
PVC storage class name		
Build tag	Latest	
Import certificates		
Server timezone	GMT	

Deploying and activating Maximo Manage

As a system administrator, you deploy and activate Maximo® Manage in Maximo Application Suite by selecting the application version, connecting to the configured database and applying the Java™ database connectivity (JDBC) configurations.

Before you begin

- Confirm that the database is configured and you have its information available, including the correct JDBC URL specified in the correct format. It is also very important to make sure you review and understand the section about [Database encryption](#). It helps you choose the best strategy for database encryption and understand how to avoid losing the encryption keys after the database is encrypted for the first time.
- Confirm that you have your customization archive properly configured if you use it for your Maximo Manage deployment.
- Make sure that you prepare to configure persistent storage if you need it. For more information, see [Provisioning storage](#).

To record the information that you need during the deployment process, you can also use the [Deployment planning worksheet](#).

Before you select industry solutions or add-ons, review the [compatibility matrix](#) to validate that these selected components are compatible to be deployed together.

About this task

Enabling Maximo Manage in Maximo Application Suite is a two-step process. First, you deploy Maximo Manage in Maximo Application Suite by selecting the application version. This selection deploys the application controller, which includes the Maximo Manage operator and other entity managers that are essential to the deployment process and are also used to control and maintain the application after deployment. This part of the process usually takes a few minutes to complete.

Then, when you activate the application, you configure Maximo Manage for use in Maximo Application Suite. During this configuration process, you add your database settings and select the industry solutions or add-ons to co-deploy with Maximo Manage. You can also specify other configuration settings, such as language preferences, customization archive, external file storage, server bundle options, and others.

After you configure and confirm the Maximo Manage activation, the main deployment process starts. This part of the process takes longer to complete and involves building the Maximo Manage and server bundle images based on your chosen settings, configuring the data in the database by running the Maximo Manage installation scripts for a new installation or an upgrade from an existing database, and finally deploying the application in the configured server bundle. This process takes a couple of hours or more to finish. It depends on your infrastructure, database location, network, the number of industry solutions that are co-deployed with Maximo Manage, the number of included languages, and whether you are installing for the first time or upgrading.

- [Deploying the Manage application](#)
You deploy the Maximo Manage operator responsible to control the Maximo Manage deployment process and to maintain and update the application as necessary.
- [Configuring the database](#)
You must configure the database connection information for Maximo Manage.
- [Selecting Manage components](#)
You can select the version of the Maximo Manage Base component to deploy and include industry solutions or add-ons and set their respective versions to co-deploy.
- [Expanding the advanced configurations](#)
You must expand the advanced configurations to set additional required and optional settings.
- [Selecting languages](#)
You can select languages other than English.
- [Setting the server bundles](#)
You can configure server bundles for your deployment.
- [Setting customizations](#)
You can include specific customizations.
- [Setting server mode](#)
You can set the server mode.
- [Setting Persistent Volume Claims \(PVC\)](#)
You can connect to persistent volume claims (PVC).
- [Setting build data interpreter \(BDI\)](#)
You can set BDI for aviation or ACM components.
- [Setting build tag](#)
You can specify an earlier build for deployment.
- [Setting certificates for integration](#)
You can connect to external systems using certificates.
- [Setting server time zone](#)
You can specify the time zone of your database server.
- [Setting asset investment optimization](#)
You can enable asset investment optimization.
- [Monitoring Manage application deployment by using the Maximo Application Suite interface](#)
You can monitor the Maximo Manage operator deployment through the Application details page in Maximo Application Suite.
- [Activating Maximo Manage](#)
You must activate Maximo Manage before you can use it.
- [Monitoring Maximo Manage activation by using the Maximo Application Suite interface](#)
Monitor the IBM Maximo Manage activation from the Maximo Application Suite user interface.

Deploying the Manage application

You deploy the Maximo® Manage operator responsible to control the Maximo Manage deployment process and to maintain and update the application as necessary.

Procedure

1. From the Suite catalog, on the Applications tab, select the Manage tile, and review the information on the Setup page.
 - a. Optional: If you plan to co-deploy industry solutions or add-ons with Manage, select the Show all option and then click the plus icon on the respective tile of each industry solution or add-on that you want to co-deploy to reserve the necessary [AppPoints](#) for them.
 - b. Click Continue.
2. In the Administer application upgrades window, in the Upgrade strategy field, select one of the following upgrade strategies.

Option	Description
--------	-------------

Option	Description
Channel subscription	<ul style="list-style-type: none"> a. To make sure that updates are automatically offered when an updated version is added to a channel, select Channel subscription. You can choose whether this update occurs automatically with a new version or requires manual approval. If you choose an automatic upgrade strategy through Channel subscription, required downtime might occur before you have a chance to review changes in the new version or fix pack, back up the database, or take other preparatory action. Therefore, for production Maximo Manage deployments, set the approval mode to Manual. You can then be alerted about the availability of an update directly in the IBM® Maximo Application Suite application catalog, in the Maximo Manage tile. However, the update is not started until you trigger it yourself. In this case, you can be better prepared by reviewing the changes, running backups of the Maximo Manage configuration and custom resource definitions, scheduling the update, and communicating the scheduled downtime to users. b. In the Channel field, select a channel. c. In the Custom source field, specify a source. d. In the Channel details section, select whether to approve the update automatically or to require manual approval. e. Click Subscribe to channel.
Manual	<ul style="list-style-type: none"> a. To manually update the application when you are notified that an updated version is available, select Manual. b. In the Version field, select a version. c. Click Deploy version.

You can monitor the progress of the deployment of the Maximo Manage application in the Application details page. For more information, see the monitoring section in [Deploying and activating Maximo Manage](#).

What to do next

To configure Maximo Manage for use, click Activate to open the activate application page for Maximo Manage.

Configuring the database

You must configure the database connection information for Maximo® Manage.

About this task

Note: For security purposes, it is highly recommended that you use Transport Layer Security (TLS) connection protocols instead of connections that are not secure.

Procedure

1. In the "Integrations and dependencies" section, on the Database connection tile, select Configure.
2. In the Database connection page, click Configure.
3. Under JDBC connection information, specify the following fields:
 - a. If you want to use an SSL-enabled connection, you can specify this field by using one of the following JDBC URL formats. Ensure that the Port that is used contains the SSL-enabled port of the database.

Oracle Database

TCPS is the protocol to use for Oracle SSL connections. For Oracle SSL database connections in Maximo Manage, you must specify `SID=<TNS Service ID>`. You can use the following URL as an example:

```
jdbc:oracle:thin:@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCPS)(Host=mymaximodb.com)(Port=2484))(CONNECT_DATA=(SID=MAXDB)))
```

Microsoft SQL Server Database

For SQL Server SSL database connections in Maximo Manage, you must specify `encrypt=true`. Ensure that you use a semicolon to end the JDBC connection string. You can use the following URL as an example:

```
jdbc:sqlserver://mymaximodb.com:1433;databaseName=MAXDB;encrypt=false;
```

IBM® Db2® database

For Db2 SSL database connections in Maximo Manage, you must specify `sslConnection=true`. Ensure that you use a semicolon to end the JDBC connection string. You can use the following URL as an example:

```
jdbc:db2://mymaximodb.com:50001/MAXDB:sslConnection=true;
```

- i. In the User name field, specify the database username.
- ii. In the Password field, specify the database user password.
- iii. Ensure that you select the SSL Enabled option.

- b. If you want to use non-SSL enabled connection, specify the Connection string field by using one of the following JDBC URL formats, depending on the database you are using.

Oracle Database

You can use the following URL as an example:

```
jdbc:oracle:thin:@mymaximodb.com:1521:MAXDB
```

Microsoft SQL Server database

You can use the following URL as an example:

```
jdbc:sqlserver://mymaximodb.com:1433;databaseName=MAXDB;integratedSecurity=false;encrypt=false;
```

IBM Db2 database

You can use the following URL as an example:

```
jdbc:db2://mymaximodb.com:50001/MAXDB
```

- i. In the User name field, specify the database username.
 - ii. In the Password field, specify the database user password.
 - iii. Ensure that you do not select the SSL Enabled option.
4. Optional: In the "Additional driver options" section, in the Driver options field, add more driver options, which are separated by a semicolon.
- Typically, you can specify JDBC options as part of the URL for the database. However, in some cases you might want to specify JDBC options in the Driver options field.
- For example, your URL might exceed the maximum length that is allowed, or you might want to configure a JDBC option that cannot be included in the connection URL. You cannot specify the same JDBC option in both the URL and the Driver options field. If you do, JDBC driver errors might cause the connection to fail.
- If you specify an extra JDBC option for your database, the CustomProxyDriver acts as a proxy driver that routes the database requests to the actual driver for your type of database.
5. If you chose to use an SSL-enabled database connection, in the "Security > Certificates (optional)" section, click Add+ to display the fields to include in your database certificate.
- a. In the Alias field, specify an alias name to identify the certificate, for example, DB2WHcert.
 - b. In the Certificate content field, copy and paste your certificate in the format that is mentioned in the field content. You can retrieve a PEM certificate for your database. The file must be a Base-64 encoded X.509 file. You do not need to retrieve a private key. For more information, see the documentation for your database. After you copy and paste the text into the field, including the BEGIN CERTIFICATE, and END CERTIFICATE text, click Confirm.
6. Click Save. The Database connection page is closed.
7. Click in the Database connection tile to verify your database connection.
- a. Expand the Status icon that is loading in the "Configuration-scope-Workspace-application" section to display some tiles.
- Click Select once the Status icon is ready to close the page.
- Note: Click Save and Select in the previous step if you do not want to wait for the database connection verification after you complete the fields.
8. If you plan to deploy Maximo Optimizer, see [Deploying Maximo Optimizer](#).

What to do next

Now you can start to select the [Manage components](#).

Selecting Manage components

You can select the version of the Maximo® Manage Base component to deploy and include industry solutions or add-ons and set their respective versions to co-deploy.

Procedure

In the Components section, select the industry solutions or add-ons and the version that you are also activating with Maximo Manage.

- If you select latest from the New version list for the selected industry solution or add-on, the version of the component that is supported by the current Maximo Manage application version is co-deployed with Maximo Manage base component.
Note: If your configurations settings were set to the latest for the components before you upgrade the application, the components will be automatically updated after the upgrade. If you select a specific version instead, then the components are not updated until you change their versions to the current, supported version of the new application version that was now updated, both by selecting the exact version or by selecting latest.
- If you select one component that is going to be deployed by selecting the latest option, you must select latest for any other component you co-deploy. If you select one component that is going to be deployed with an exact version number, you must select the exact version number for any other extra component that you co-deploy. You cannot mix exact version numbers and the latest version in the components you want to co-deploy.
- You also can click in the New version column for a component and select Select version. In the Select unlisted version dialog, you can specify a valid version that is supported by the current application version that is deployed in the Version field and click Save.

For more information, see [Deployment of industry solutions and add-ons](#) section, including access to the compatibility matrix that shows the compatibility between application version and components versions. Some components might not be compatible with each other.

- You also can check the actual supported matrix of your current Maximo Manage application that is deployed and the matrix of compatibility between the components, through the Red Hat® OpenShift® console:
 - a. Go to the Red Hat OpenShift console, in the Workloads/Pods section, select the namespace of your Maximo Manage instance in Projects, for example, `mas-<yourmasinstancename>-manage`, and then click the `ibm-mas-manage-operator-somestring` pod.
 - b. On the Terminal tab, select to connect to webhook container.
 - c. Open the supported matrix JSON file that displays the components version that is supported by each Manage application version and look for the version that you installed. If you are not sure what the version is, click Details and click Manager in the Containers section. The version is displayed in the Image version tab or field. When you go back to the terminal, you can use this command to open the file:

```
cat
/mas-admission/metadata/supported-versions-matrix.json
```

The file has a format like this:

```
"8.3.1": [
  {
    "name": "anywhere",
    "versions": [
      "8.0.1",
      "8.0.0"
    ]
  }
]
```

```
    ]
  }
```

Note: In this example, the Manage application version is 8.3.1. The following list shows the Anywhere versions that are supported by this version. When you select latest, the page displays a section that states the current Manage application version:

```
"latest": {
  "base": "8.3.1",
  "anywhere": "8.0.1"
```

- d. Open the dependency matrix JSON file that displays the compatibility between each component by using the following command: **cat dependency-matrix.json** The file displays the components with the following attributes:

```
"aviation": {
  "description": "Maximo Aviation",
  "includesForbidden": [
    "hse",
    "serviceprovider"
  ],
  "includesCoexist": [
    "acm",
    "transportation"
  ],
  "conflict": [
    "civil",
    "health",
    "oilandgas",
    "oracleadapter",
    "nuclear",
    "sapadapter",
    "spatial",
    "utilities"
```

Note: **includesForbidden** The component cannot be co-deployed with the listed components.

includesCoexist The component can be co-deployed with the listed components.

conflict The component cannot be co-deployed with the listed components.

What to do next

Now you can configure [Optimizer](#) or [expand the advanced configuration](#) to specify at least some database configuration parameters.

Expanding the advanced configurations

You must expand the advanced configurations to set additional required and optional settings.

Procedure

1. Click Show advanced settings to view and specify the configuration settings, such as database, server bundle, language settings, and others.
2. In the Database section, clear the System managed checkbox and manually configure the database.

Schema

Enter the name of the schema that is configured in your database. For more database configuration information for Maximo® Manage, see [Setting up your database](#).

Encryption secret (optional)

This value is optional if you are deploying Maximo Manage in your database for the first time, and your database is not encrypted. You must enter your encryption keys for this parameter. For more encryption settings information, see [Database encryption](#).

In the Key/Value table, click Add property +. In the Key column, enter `MXE_SECURITY_CRYPTOX_KEY` and in the Value column, enter your encryption key value.

In the Key/Value table, click Add property +. In the Key column, enter `MXE_SECURITY_CRYPTOX_KEY` and in the Value column, enter your encryption key value.

Table space

If the default value does not match your database configuration, enter the name of the table space that was configured in your database. For more database configuration information for Maximo Manage, see [Setting up your database](#).

Index space

If the default value does not match your database configuration, enter the name of the index table space that was configured in your database. For more database configuration information for Maximo Manage, see [Setting up your database](#).

Install demo data

If you are deploying a test or demonstration environment for Maximo Manage, you can install sample data. For more information, see [Demo data](#).

Db2® Vargraphic

If you use Db2 and you plan to install a language other than English for your base language or as an additional language, select this option. If you intend to add more languages later, select this option during your initial deployment. This option does not affect the Maximo Manage deployment if it is selected and you are using a database other than Db2.

Bypass upgrade version check

Select this option to skip validation of the IBM® Maximo Asset Management version you are upgrading to Maximo Manage. Select this option to continue a failed upgrade that failed during the maxinst or updatedb process.

What to do next

Setting the other advanced configurations is optional. You can use the default configurations to activate a standard Maximo Manage deployment. For more information, see [Activating Manage](#). Alternatively, you can customize some or all the options by clearing the System managed checkbox in each configuration and start by [selecting languages](#).

Selecting languages

You can select languages other than English.

Procedure

If you want to set Maximo® Manage with a language different from English or include other languages in your Maximo Manage deployment, clear the System Managed checkbox in the Languages section. Then, in the Base field, select your preferred language to be the base language and in the Additional field, order the list of other languages. For more information, see [Language support](#).
Note: If you are selecting other languages, make sure that you do not select a language in the Additional field that was selected in the Base field. For example, if you set the base as EN, do not select EN in the Additional field.

What to do next

Now you can [activate](#) Maximo Manage or optionally [set the server bundles](#).

Setting the server bundles

You can configure server bundles for your deployment.

Procedure

1. If you want to deploy Maximo® Manage with more than one server bundle or with customized configurations for it, under the "Server Bundles" section, clear the System managed option.
A table with Name, Pod count, Type, and Additional Properties is displayed. This table has the Default, User synchronization, and Mobile optional fields available.
When you clear the System managed option, a line with the server bundle named as *all* is set with one Pod with the Type *all* and Route subdomain as *all*.
2. Click Add bundle + to add more server bundles.
3. Select which server bundle to set as respectively the Default, the server bundle to be used for user synchronization, and the server bundles for Mobile.
4. Optional: Change the name, pod count, type, route subdomain name and other customized configurations according to your preference.
5. Click the View label under Additional Properties column to view the Route subdomain value.
The Additional server bundle properties page for your selected server bundle is displayed with the Route subdomain and Additional server config fields available and a list of properties you can define by selecting Add property + option in the Bundle level properties table. For more information, see [Server bundle overview](#).
A standard four-bundle setting that you could configure for your deployment would look like:

Figure 1. Four bundle setting

Server bundles

Add the server bundles for your deployment by providing the server bundle name, pod count, and type. You can also add server bundles or increase the pod count after the initial deployment is complete. [Learn more](#)

☐ System managed ⓘ

Name	Pod count	Type	Additional properties
ui	1 - +	ui ▾	View -
mea	1 - +	mea ▾	View -
cron	1 - +	cron ▾	View -
report	1 - +	repc ▾	View -

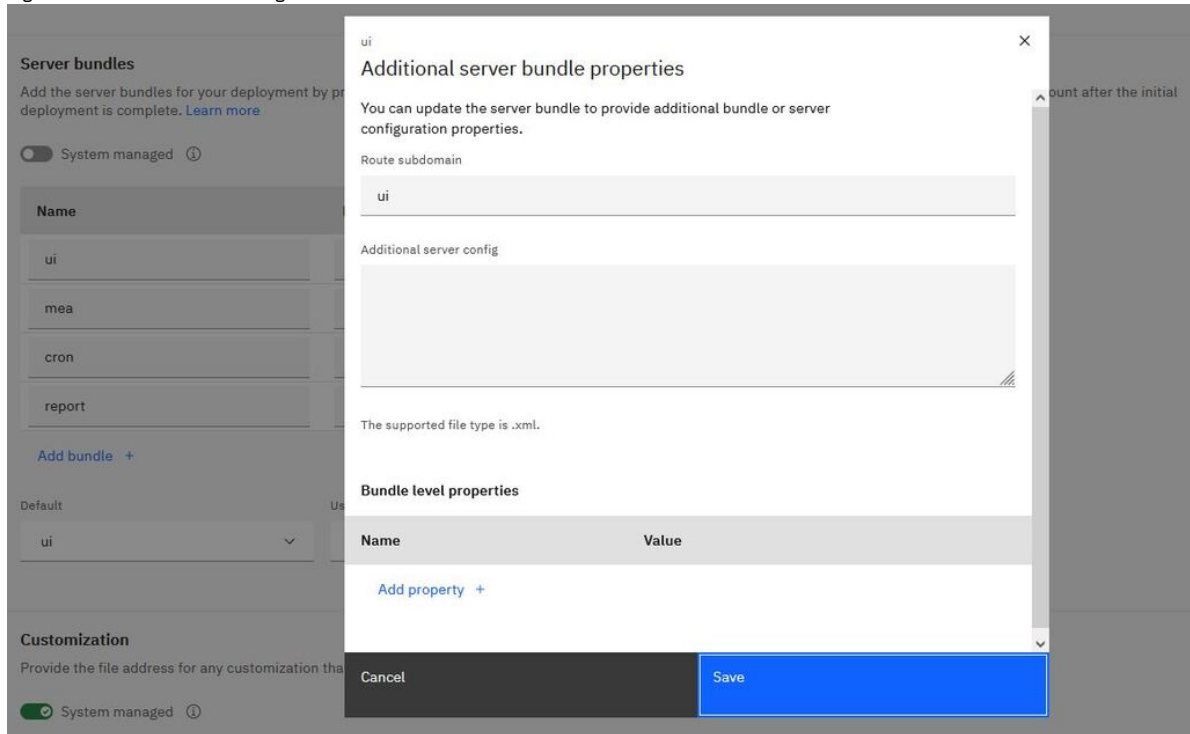

[Add bundle](#) +

Default User synchronization Mobile (optional)

ui ▾ mea ▾ ui ▾

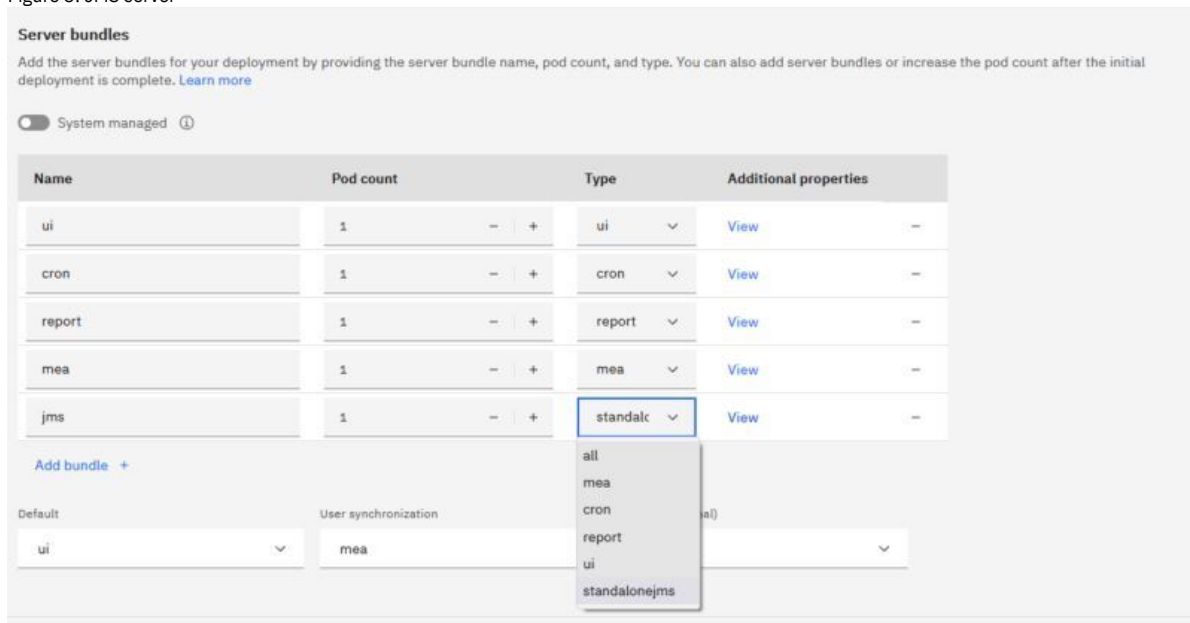

In Figure 1, for each server bundle, the route subdomain name is set with the same name as the server bundle. The route subdomain configuration can also be set like:

Figure 2. Route subdomain configuration

You can also include a stand-alone JMS server. For more information, see [Configuring a JMS server for Maximo Manage](#).

Figure 3. JMS server

What to do next

Now you can [activate](#) Maximo Manage or optionally [set customizations](#).

Setting customizations

You can include specific customizations.

Procedure

1. If you want to include specific customizations through a customization archive, clear the System managed checkbox in the Customizations section. In the File address field, specify the location of the customization archive and if you must enter credentials to access the file, specify them in the Credentials (optional) field. For more information, see the related sections in [Customizing the application](#).

2. In the Customization section of the configuration window, specify the URL for the customization archive file.

The following URL protocols are supported:

- HTTP
- HTTPS
- FTP
- FTPS

To include more customization archive files, click Add customization archive.

3. Optional: If you applied password security to the file, in the Credentials field, specify the user ID and password in the following format:

`user=your user name password=your password`

What to do next

Now you can [activate](#) Maximo Manage or optionally [set server mode](#).

Setting server mode

You can set the server mode.

Procedure

If you do not want the server bundles to start after the database operations of the Maximo® Manage deployment are completed, clear the System managed checkbox in the Server mode section.

Then, set Mode to Off to prevent access to the Maximo Manage application after deployment. You can restart the server bundle or bundles when you change the configuration to On and activate Maximo Manage again.

Setting Persistent Volume Claims (PVC)

You can connect to persistent volume claims (PVC).

Procedure

To connect to PVCs under the Persistent volume claims section, clear the System managed to Off, and click Add PVC. A table with the following columns is displayed.

Table 1. PVC details

Option	Description
PVC name	User-defined name of the persistent volume claim, maximum of 63 characters
Volume name	Leave blank as it is provisioned dynamically
Size	Amount of storage that is required for this persistent claim, for example, 60G
Mount path	Mount path for the volume within the Maximo® Manage pod

When you configure the PVCs in OCP cluster on deployments, use the default storage class name **StorageClasses ocs-storagecluster-cephfs** to create a ReadWriteMany (rwx) PVC. The storage in the volume that you provisioned are available to all server bundles in the workspace. You can also configure a PVC for specific server bundles in a deployment. If you configure a PVC for a server bundle, the mount path that you specify for the server bundle PVC overrides the path that you specify for the deployment.

Tip: To configure a PVC in OCP cluster on IBM Cloud® platform, use the default **StorageClasses ibmc-file-gold-gid** (instead of **StorageClasses ocs-storagecluster-cephfs**) to create a ReadWriteMany PVC.

What to do next

Now you can [activate](#) Maximo Manage or optionally, if you selected Asset Configuration Manager or Aviation to be co-deployed with Manage, you can set the [Build data interpreter \(BDI\)](#). If you did not select one of these components, this option is not available to you. In that case, you can [set the build tag](#).

Setting build data interpreter (BDI)

You can set BDI for aviation or ACM components.

Procedure

If you select Asset Configuration Manager or Aviation in the list of components, the "Build data interpreter" section is displayed. If you want to customize the configuration for the build data interpreter (BDI), clear the System managed checkbox. You can then specify a BDI version instead of latest. In the BDI version field, click Add instance+. You can customize each instance by selecting View in the Configuration column. The BDI Configuration page is displayed. You can change and save the configuration. Then, you can return to the BDI configuration page, select Reset to Defaults, and click Save to return to the default settings.

What to do next

Now you can [activate](#) Maximo Manage or optionally, you can [set the build tag](#).

Setting build tag

You can specify an earlier build for deployment.

Procedure

If you want to use an earlier build for deployment, in the Build section, set System managed to Off. Then, in the Build tag field, specify the build tag. Build images are tagged with a timestamp, for example **buildtag: 202011092887843**.

What to do next

Now you can [activate](#) Maximo Manage or optionally, you can [set certificates for integration](#).

Setting certificates for integration

You can connect to external systems using certificates.

Procedure

To connect to any external systems that Maximo® Manage is integrated with, import the certificate for the system.

What to do next

Now you can [activate](#) Maximo Manage or optionally, set the [database server time zone](#).

Setting server time zone

You can specify the time zone of your database server.

Procedure

You might want to specify the time zone that your database server is configured to use. In the "Server time zone" section, clear the System Managed checkbox. In the Time Zone field, select the time zone of your database server.

What to do next

Now you can [activate](#) Maximo Manage or optionally, [set asset investment optimization](#).

Setting asset investment optimization

You can enable asset investment optimization.

Procedure

If you are deploying Maximo® Health as part of Maximo Manage and plan to deploy Maximo Health and Predict - Utilities, If you plan to deploy Maximo Health and Predict - Utilities, enable asset investment optimization. In the "Asset investment optimization" section, clear the System managed checkbox. Then, select Asset investment optimization. When asset investment optimization is enabled, the Asset investment optimizer page is available in Maximo Health and Predict - Utilities. Ensure that you deploy and configure Maximo Scheduler Optimization before you enable asset investment optimization.

What to do next

Now you can [activate](#) Maximo Manage or optionally, set any other advanced configuration option that you want.

Monitoring Manage application deployment by using the Maximo Application Suite interface

You can monitor the Maximo® Manage operator deployment through the Application details page in Maximo Application Suite.

Procedure

If you did not log out, you are now in the Application details page. If you left the page, for example, logged out, access it again by following the steps:

- a. Log on to the Maximo Manage Administration page with your administration user ID and password.
Note: Find the link of the Maximo Manage Administration page by using the Red Hat® OpenShift® console from Networking/Routes. Select **mas-*<yourinstancename>-core*** in the Project list. The link is under the Location column of the listed routes.
- b. Click the gear icon in the Suite navigator page.
- c. Click Applications option from the menu in the Suite navigator page.
The Maximo Manage application is listed and if the deployment is still under progress, you can see that in the Status column.
- d. Click Manage under the Name column. You are back in the Application details page.
You can see the Application details page with tiles that show the status of each step of the Maximo Manage deployment process.
 - i. In the Operator tile, you can see the version of the Maximo Manage operator that is being deployed.
 - ii. Some messages are displayed inside the tiles while it is in progress and after some time all of them display a green icon to indicate that they are ready and display Activate.
 - iii. Click Activate and follow the steps to configure the application and confirm the activation.

Monitoring Maximo Manage application deployment by using the Red Hat OpenShift console

You can monitor the Maximo Manage operator deployment by using the Red Hat OpenShift console.

Procedure

1. Go to the Red Hat OpenShift console, under Workloads/Pods, select the **mas-*<yourinstancename>-manage*** namespace in the Project list.
2. Click in the Created column, in the pods list, to change the order of the pods that are displayed to be descending to see the most recent pods created at the beginning of the list.
When Maximo Manage deployment starts, you can see an **ibm-mas-manage-operator** pod and an **ibm-truststore-mgr-controller-manager** pod.
After some time, more pods are created like the **usersyncagent**, **groupsyncagent**, and other **entitymgr** pods.
3. Confirm the completion of the Maximo Manage operator deployment by using the Red Hat OpenShift console.
 - a. Go to Administration > Custom Resource Definitions.
 - b. In the Search field of the custom resource definitions list, specify ManageApp and click ManageApp in the Name column of listed custom resource definitions.
 - c. Go to the Instances tab and click the name of the Custom Resource of your instance.
 - d. Check the Conditions section. As soon as you see the Ready line with True in the Status column, Ready in the Reason column, and Ready to enable workspace in the Message column, it means that the Maximo Manage operator deployment is complete and you can configure Manage.
Note: If some error occurred, you can see the error message displayed in the Conditions section. You can also look for error messages in the Red Hat OpenShift console. Go to Workloads/Pods, select **mas-*<yourinstancename>-manage*** project, click the **ibm-mas-manage-operator** pod, and access the Logs tab. You can download the logs until the current point and then search for keywords like error, FAIL, or FATAL.
 - e. After you confirm that the Maximo Manage operator CR status is ready, you can configure Maximo Manage and activate it.
Note: You might be deploying using some automated deployment mode, where the Maximo Manage configuration was already passed through automation scripts at an earlier point. If that is the case, the deployment process may progress automatically from this point, depending on how your automated process was configured. If that is not the case, the process waits for the configuration to be completed and Maximo Manage to be activated.

Activating Maximo Manage

You must activate Maximo® Manage before you can use it.

About this task

Procedure

1. Review your Maximo Manage configuration and confirm that your settings meet the needs of your Maximo Manage deployment. Then, on the Maximo Manage Activation page, click Activate.
Note: You might see a warning message to confirm the activation with incomplete prerequisites. For example, a message is displayed when you do not include the database settings for database configuration. In this case, select Configure and add your [database configuration](#).
You can monitor the Maximo Manage activation progress in the Workspace details page. For more information, see the monitoring section in [Deploying and activating Maximo Manage](#).
2. In the Confirmation page, you can expand the Summary to reconfigure view and then click Activate on this screen to start the activation process.
The Maximo Manage Workspace Details page is displayed. You can now monitor the Activation process.
Note: You can reconfigure the activation process as needed. Follow these steps.
 - a. Select Actions > Workspace Details > Update configuration.
 - b. Select the specific configuration that you want to change in the Update Manage Configuration screen.
The configuration option is displayed again in the screen. You can reconfigure that option and other options as you need.
 - c. Click Activate again.
If you click Exit, you are redirected again to the Application Details page. You can continue to monitor the status through this screen, scrolling down the page to see the Workspace Activation detailed process, or under Activate in workspace, you can click Go to workspace details page link.

Results

Maximo Manage is activated, the second part of its deployment process starts, and is eventually completed. To access Maximo Manage, first you must configure at least the admin user to have permission to access Maximo Manage so that you can connect to Maximo Manage with it.

What to do next

Do the post-deployment configuration, such as giving permission to the Maximo Manage admin user to connect to Maximo Manage. After the Maximo Manage admin user is synchronized, log out and log in again to Maximo Application Suite with the admin user and access Maximo Manage.

If you deployed Maximo Health as part of Maximo Manage, after the applications are activated, you must configure some system properties. For more information, see the [Configuring the system properties](#).

When new versions are available, system administrators can update the deployed application. To update to a new version, in Maximo Application Suite, go to Suite administration, select Applications from the side navigation menu, and click Update available for ManageMaximo Health.

When updates are required, system administrators can also reconfigure and update initial implementations on the Manage workspace detailsMaximo Health page. To reconfigure and update changes, select Workspaces from the side navigation menu, and click ManageMaximo Health. On the Manage workspace detailsMaximo Health page, click Actions, and select Update configuration.

- [IBM Maximo Manage tool](#)
When Maximo Manage is deployed,some tools become available.

IBM Maximo Manage tool

When Maximo® Manage is deployed,some tools become available.

- An admin pod gets deployed when Maximo Manage is deployed.
- The command "`kubect1 exec`" can be run on the admin pod container or directly use the container console to run the tools such as integrity checker.
- Tools logged to stdout are forwarded to Elasticsearch, Fluentd, and Kibana (EFK) stack, if configured.

Monitoring Maximo Manage activation by using the Maximo Application Suite interface

Monitor the IBM® Maximo Manage activation from the Maximo Application Suite user interface.

Procedure

Monitor the Maximo Manage activation through the Manage Status page in the Maximo Application Suite.

- If you didn't log out and are following the previous step by step to deploy Maximo Manage, you are now in the Workspace details page. But if you leave the page, you can access it again by following these steps:
 - Login in the Maximo Application Suite Administration page with your administrator username and password.
Tip: You can find the link of the Administration page in the Red Hat® OpenShift® console from Networking > Routes > Projects and select `mas-<yourinstancename>-core`. The link is under the Location column of the listed routes.
You are redirected to the Maximo Application Suite navigator page.
 - In the Maximo Application Suite, click the gear icon to go to the Administration page, then click the Applications tile.
You can see the Maximo Manage application, and if the deployment is in progress, you can see that in the Status column.
 - Select the Maximo Manage application.
 - Under Active in workspaces section, click the Go to workspace details page link.
 - The status of each step of the Maximo Manage activation process is shown in the tiles view.
 - Detailed information such as the current activation status beginning with the build in progress, phase of deployment process where the Maximo Manage image is created, the ear or war files are generated to deploy the application in the Server Bundle later, and the Server Bundle images are created is shown.
 - When the build is completed, a green icon and a message with the build tag is shown on the Workspace tile.
 - After some minutes, the Deployment ready tile starts to change the message displayed and eventually shows the `maxinst/updatedb` is in progress.
 - After the `maxinst/updatedb` process is completed, the server bundles are started, deploying the Maximo Manage war or ear files. When this last deployment step is completed, you can see all tiles displaying green icons and all the Maximo Manage components in Ready status. The Maximo Manage tile also displays a green icon and Active status.

Monitoring Maximo Manage activation by using the Red Hat OpenShift console

Procedure

After the Maximo Manage activation starts, confirm if the ManageWorkspace cr of the Maximo Manage instance is created from the Red Hat OpenShift web console.

- a. Go to Red Hat OpenShift console Administration > Custom Resource Definitions.
- b. In the CRD list search field type *ManageWorkspace*, click *ManageWorkspace* under the Name column of the listed CRD's.
- c. Go to the Instances tab and click in the Name of the cr of your instance.
For Amazon Web Services customer-managed automated deployment, the name is *mas-`<uniqueid>-wsmasocp`*.
- d. Check the section conditions.
In case you see error messages wait some minutes to see if they are not solved automatically by the Maximo Manage operator. Go to Workloads > Pods view in Red Hat OpenShift console and check whether the new pod *admin-build-config* was started after some time. Otherwise, review the logs of the entity-mgr-ws pod, looking for keywords like "level": "error", FAIL, FATAL strings. These messages might clarify the reason that the process is stuck.
- e. If no errors occurred at preventing the deployment process to move, forward after activation, an *admin-build-config* pod is created where the Maximo Manage image is created based on settings that you chose.
Tip:
 - You can check the progress of the build of the image by clicking the name of the *admin-build-config* pod and going to the Logs tab. You can view the Log stream or download the full logs during the process. You can view the information about the image version being pulled and built, and messages that are related to the generation of war or ear files that are used for the deployment in the server bundle pod later.
 - If it takes too long to view the *admin-build-config* pod that is being created, you can access other pod, *entitymgr-ws* pod, and its tab Logs, and look for error messages in that log (look for "level": "error", FATAL, FAIL, or error strings).
- f. After the *admin-build-config* pod changes its status to complete, the server bundle build config pods are created. Their quantity and names might vary depending on how you configure the server bundle options before activating Maximo Manage. After some minutes the pod or pods change status to Complete, and the deployment process creates the *maxinst* pod, which installs Maximo Manage in the previously configured database.
 - i. You can monitor the status of these additional build config pods by accessing the Red Hat OpenShift console, Workloads > Pods > Project and selecting the *mas-`<yourinstance>-manage`* namespace.
Tip: Click in the Created column by sorting on descending order so you see the latest pod created in the top of the list of pods displayed.
 - ii. If your existent database is empty, the *maxinst* pod installs a new database. Otherwise, the *maxinst* pod performs validation that updates the database if updates are supported in that version.
Tip:
 - You can check the progress of the *maxinst* process, or *updatedb* process through the *maxinst* pod, by accessing the pod and going to the Logs tab. After some time, the logs should start to move fast showing several commands and output of scripts running. You also can go to the Terminal tab and type these commands that will show you the latest logs been updated along the process:
 - `cd log`
 - `ls -ltr`
 - If it is taking too much time to update the Logs tab after the *maxinst* pod is created, you can check the *entity-mgr-ws* pod, on its tab Logs, looking for keywords like "level": "error", FAIL, FATAL. You also can search for *ManageDeployment* crd through Administration/Custom Resource Definition in the Openshift console, clicking on its name, going to the Instance tab and clicking in the cr of your instance (the name should be *manage-maxinst* and the namespace column should show the namespace of your Manage instance). Then, you can go to its Conditions section and check if there is any error message.
 - If completed successfully, after some time (this may take a couple of hours or more depending of your specific configuration chosen for the deployment), you should see a message "maximo install/ update completed." as one of the latest messages shown in the tab Logs of the *maxinst* pod.
- g. After completing the *maxinst* process, its pod continues to show the status Running, but after some time, new server bundle pods are created. If you sorted the Pods view in descending order, these new pods appear listed in the top of the *maxinst* pod. Their names and number may vary depending on how you configured them before activating Maximo Manage. As soon as all the containers of each one of these server bundle pods appear as ready (usually you will see 2/2 under the Ready column of the pod view in standard server bundle configuration which uses only one pod), the Maximo Manage deployment has been completed.
Tip:
 - If you go to Administration/Custom Resource Definitions through the Openshift console, search for *ManageWorkspace*, click on its name and move to the tab Instances, then select the cr of your Maximo Manage instance, checking the Conditions, when all done you should see:
 - Line Ready with the column Status True, Reason Ready and Message: "Manage deployed in workspace `<yourworkspace>`"
 - Line Failure with the status False
 - Line BuildReady with the status Build completed.
 - DeploymentReady with the status True and Reason Ready and Message: "UpdateDB/Maxinst Completed, all - X of X pods ready..." specifying that the *updatedb* or *maxinst* done was completed and the server bundle are all started and ready.
 - You can check the logs of the server bundle pod (or pods) looking for error messages in case it does not become ready after several minutes. You can also check the logs of the *entity-mgr-ws* pod looking for error messages in case it does not become ready after several minutes.

Configuring Maximo Manage after deployment

You must give users access to the and application. Application administrators can configure the application to set up the required data structure for managing assets, including an organization, general ledger account structure, and configuring email notifications. You can also perform other post-deployment configurations.

- [Administering users](#)
Maximo Manage users are created and authenticated in Maximo Application Suite. User data is synchronized to Maximo Manage at scheduled intervals.
 - [Configuring initial data after deployment](#)
After Maximo Manage is deployed, you must complete several data configuration tasks before you use Maximo Manage.
 - [Changing database credentials](#)
If you change the username and password of your database after you deploy Maximo Manage, you must update the database connection in Maximo Application Suite to synchronize the change to the new credentials and prevent database connection errors.
-

Administering users

Maximo® Manage users are created and authenticated in Maximo Application Suite. User data is synchronized to Maximo Manage at scheduled intervals.

For more information about administering users, see the following topics:

- [Administering user access in Maximo Application Suite](#)
- [Configuring authentication in Maximo Application Suite](#)
- [Understanding application points](#)

Configuring initial data after deployment

After Maximo® Manage is deployed, you must complete several data configuration tasks before you use Maximo Manage.

Before you begin

- Create security groups and add users to the security groups.
- If you are using a directory server as part of your deployment, ensure that the user names are created in your LDAP repository.
- To ensure that you have the accounting information that you need, consult your organization's financial department.

Procedure

1. To send users email notifications of system events, first [configure the SMTP server in Maximo Application Suite](#) and then enable the mail.smtp.host and mx.e.adminEmail system properties in Maximo Manage.
 - a. From the Go To menu, select System Configuration > Platform Configuration > System Properties.
 - b. In the Global Properties section, use the filter feature to search for and expand the mail.smtp.host property.
 - c. In the Global Value field, specify the SMTP host name.
 - d. Select the mail.smtp.host check box.
 - e. From the Common Actions menu, select Live Refresh and click OK.
 - f. In the Global Properties section, use the filter feature to search for the mx.e.adminEmail property.
 - g. Expand the mx.e.adminEmail property and in the Global Value field, specify the email address for the user.
 - h. Select the mx.e.adminEmail record check box.
 - i. From the Common Actions menu, select Live Refresh and click OK.
2. Define a currency code.
 - a. From the Go To menu, select Financial > Currency Codes
 - b. Add a row and specify a currency code and a description.
For example, enter `USD` for United States of America Dollar.
3. Define item sets and company sets.
 - a. From the Go To menu, select Administration > Sets.
 - b. Add a row and specify an item set name.
For example, enter `IT Items`.
 - c. In the Type field, specify `ITEM`.
 - d. Add a row and specify a company set name.
For example, enter `IT Comps`.
 - e. In the Type field, specify `COMPANY` and save your changes.
4. Create an organization.
 - a. From the Go To menu, select Administration > Organizations.
 - b. From the toolbar, click New Organization and specify an organization name and a long description.
For example, enter `EAGLENA`.
 - c. Specify the base currency that you defined in step 3.
 - d. Specify the item set and the company set that you defined in step 4.
 - e. In the Default Item Status field, set the status to `PENDING`.
 - f. Click the Sites tab and in the Sites section, select New Row and specify a site name.
For example, enter `Factory01` and enter a long description.
5. Create a general ledger account component.
 - a. From the Go To menu, select System Configuration > Platform Configuration > Database Configuration.
 - b. From the More Actions menu, select GL Account Configuration.
 - c. Add a row and specify a component name, length for the component, and a type for the component.
For example, enter the name `MYCOMPONENT`, the length `5`, and the type `Alphanumeric`.
6. Apply changes to the database.
 - a. From the More Actions menu, select Manage Admin Mode.
 - b. Select Turn Admin Mode ON and click OK.
This task takes several minutes to complete. You can click Refresh Status to view the progress.
 - c. From the More Actions menu, select Apply Configuration Changes.
Ensure that the status `To Be Changed` does not appear in the status column of the listed objects.
 - d. From the More Actions menu, select Manage Admin Mode.
 - e. Select Turn Admin Mode OFF and click OK.
If you do not turn off Admin Mode, cron tasks fail.
7. Create a general ledger account.
 - a. From the Go To menu, select Financial > Chart of Accounts.
 - b. In the Organizations section, select your organization.
 - c. From the More Actions menu, select GL Component Maintenance.
 - d. In the Components section select the component that you entered in step 6.
 - e. Add a row and specify a GL component value and a description, and then click OK.
 - f. In the GL Accounts section, add a row and specify a general ledger account.
 - g. From the Go To menu, select Administration > Organizations.
 - h. Find your organization and select the record.
 - i. In the Clearing Account field, specify the general ledger account that you created.

- j. Select Active and save your changes.
8. Authorize a security group to modify a general ledger component type.
 - a. From the Go To menu, select Security > Security Groups.
 - b. Select the group that provides authorization.
For example, select FINANCE.
 - c. On the GL Components tab, for each GL component, select the Authorized check box.
 - d. For each GL Component that is listed, select the Authorized check box and save your changes.
You can select Authorize Group to Change All GL Component Types.
9. Update the company-related accounts.
 - a. From the Go To menu, select Financials > Chart of Accounts.
 - b. Select your organization and from the More Actions menu, select Company-Related Accounts.
 - c. Click New Row and specify the company type *Courier*.
 - d. Enter an account number in the RBNI Account, AP Suspense Account, and AP Control Account fields.
You can specify the same account number in each field.
 - e. Click OK.
 - f. From the More Actions menu, select Update Database and click OK.
10. Create a default insert site.
 - a. From the Go To menu, select Security > Users.
 - b. Find maxadmin and select the record.
 - c. In the Default Insert Site field, specify the site name that you created in step 5.
 - d. In the Storeroom Site for Self-Service Requisitions field, specify the same site name.
 - e. Click Save User.
11. Define work types, denote the importance of the work task.
 - a. From the Go To menu, select Administration > Organizations.
 - b. Find your organization and select the record.
 - c. From the More Actions menu, select Work Order Options > Work Type.
 - d. Click New Row.
 - e. In the Work Order Class field, select *WORKORDER* and specify a Work Type..
For example, enter *MAJOR*.
 - f. Set the start status to In Progress.
 - g. Set the complete status to Completed.
 - h. Click New Row and repeat steps f-i to create another work order class that has a different work type.
For example, enter *MINOR*.
 - i. Click New Row and repeat steps f-i to create a *CHANGE* work order class that has a different work type.
For example, enter *SIG* to represent a significant change.
 - j. Click OK and click Save Organization.

Changing database credentials

If you change the username and password of your database after you deploy Maximo® Manage, you must update the database connection in Maximo Application Suite to synchronize the change to the new credentials and prevent database connection errors.

Procedure

1. Log in to Maximo Application Suite as a system administrator.
2. From Suite administration, select Workspaces from the side navigation menu and then select the Manage tile.
3. On the Manage workspace details page, click Actions and select Update configuration.
4. Click the Edit icon for Database connection.
5. On the Database connection tile, in the Integrations and dependencies section, select View and click the edit configuration icon.
6. Enter the new database username and password and save your changes.
7. Click Apply changes to update the deployment with the new database credentials.

Upgrading from IBM Maximo Enterprise Asset Management to IBM Maximo Manage

Previously known as Maximo® Enterprise Asset Management, Maximo Manage is part of IBM® Maximo Application Suite and has enhanced and new features.

Maximo Asset Management 7.6.1.10 or 7.6.1.2 or later is required before you upgrade to Maximo Manage.

Maximo Mobile is a next-generation mobile application platform that allows users to securely access Maximo Manage functionality from a mobile device. For more information about Maximo Mobile, see [Managing Maximo Mobile](#).

- [Maximo Manage in Maximo Application Suite overview](#)
In Maximo Application Suite, Maximo Enterprise Asset Management is named Maximo Manage.
- [Enterprise Asset Management to IBM Maximo Manage summary](#)
Maximo Manage adds enhancements and introduces new features to support integration.
- [Architecture and deployment models](#)
Explanation of the architecture of IBM Maximo Application Suite, and deployment models for IBM Maximo Manage and Maximo Enterprise Asset Management.

- [Upgrading the Maximo environment](#)
Prerequisites, process, considerations, checking deployment status, results and how to manage users post upgrade.
- [Configuring Maximo Manage for upgrade](#)
Information on how to configure IBM Maximo Manage and connectors, customization capabilities, and how to manage users, security, and licenses.

Additional information regarding lic licensing model, docker image, how to add third-party JAR files, and debugging.

Maximo Manage in Maximo Application Suite overview

In Maximo® Application Suite, Maximo Enterprise Asset Management is named Maximo Manage.

IBM® Maximo Application Suite is an integrated suite of applications that is built on Red Hat® OpenShift® environment to provide multi-cloud portability, including support for Hybrid Cloud or On-premises deployments. For more information, see [IBM Maximo Application Suite architecture](#).

Maximo Application Suite also contains other applications such as IBM Maximo Health, IBM Maximo Predict, and IBM Maximo Monitor.

Maximo Application Suite is based on the Red Hat OpenShift deployment model. Red Hat OpenShift is a platform-as-a-service system that is built around containers and uses container orchestration that is provided by Kubernetes. It is designed to integrate well with IBM Cloud Pak® for Data components.

This document provides information about the technical consideration and the upgrade process from Maximo Asset Management to Maximo Manage in Maximo Application Suite.

After you upgrade to Maximo Manage, user licenses are managed in Maximo Application Suite.

- In IBM Maximo Application Suite, subscription term or perpetual license is managed through app points.
 - Contact IBM account team about app points and IBM Maximo Application Suite license file.
 - Buy a pool of app points.
 - The same app points can be applied to any application in IBM Maximo Application Suite.
 - For more information, see [Administering license and app points](#).

Available user entitlements:

- Limited
- Base
- Premium
- Self-Service

Enterprise Asset Management to IBM Maximo Manage summary

Maximo® Manage adds enhancements and introduces new features to support integration.

Overall changes to Enterprise Asset Management

Your current Enterprise Asset Management database is upgraded to Maximo Manage database.

In Maximo Enterprise Asset Management, authentication and user management are configured through Enterprise Asset Management or application server level. In Maximo Manage, the authentication is configured at the IBM® Maximo Application Suite level.

Deployment is now based on Red Hat® OpenShift®.

Technology changes

The Red Hat OpenShift operator does the installation, configuration, deployment, and upgrade.

For more information, see [Red Hat OpenShift deployment](#).

Authentication and user management

The authentication and user management are configured in Maximo Application Suite. All users are synchronized into Maximo Manage from Maximo Application Suite.

For more information, see [Authentication and user management](#).

Application server

WebSphere® Application Server Liberty is used as a runtime to run the code in a containerized environment in Red Hat OpenShift. WebSphere Application Server Network Deployment and WebLogic Server are not supported.

Integration

REST API replaces RMI.

For more information, see [REST API replacing RMI](#).

Message queue

If you are using SIBus, migrate to Kafka or any other supported JMS provider.

For more information, see [Migrating to Kafka](#).

For more information, see [Migrating to JMS provider](#).

Modernized user experience

Maximo Manage has a new appearance and navigation, and new mobile experience.

Serviceability

Maximo Manage has logging options like Elasticsearch, Fluentd, and Banana, and monitoring options like Prometheus and Grafana. For more information about logging and monitoring options, see the following topics.

- [Maximo Manage logging](#)
- [Monitoring](#)

Architecture and deployment models

Explanation of the architecture of IBM® Maximo® Application Suite, and deployment models for IBM Maximo Manage and Maximo Enterprise Asset Management.

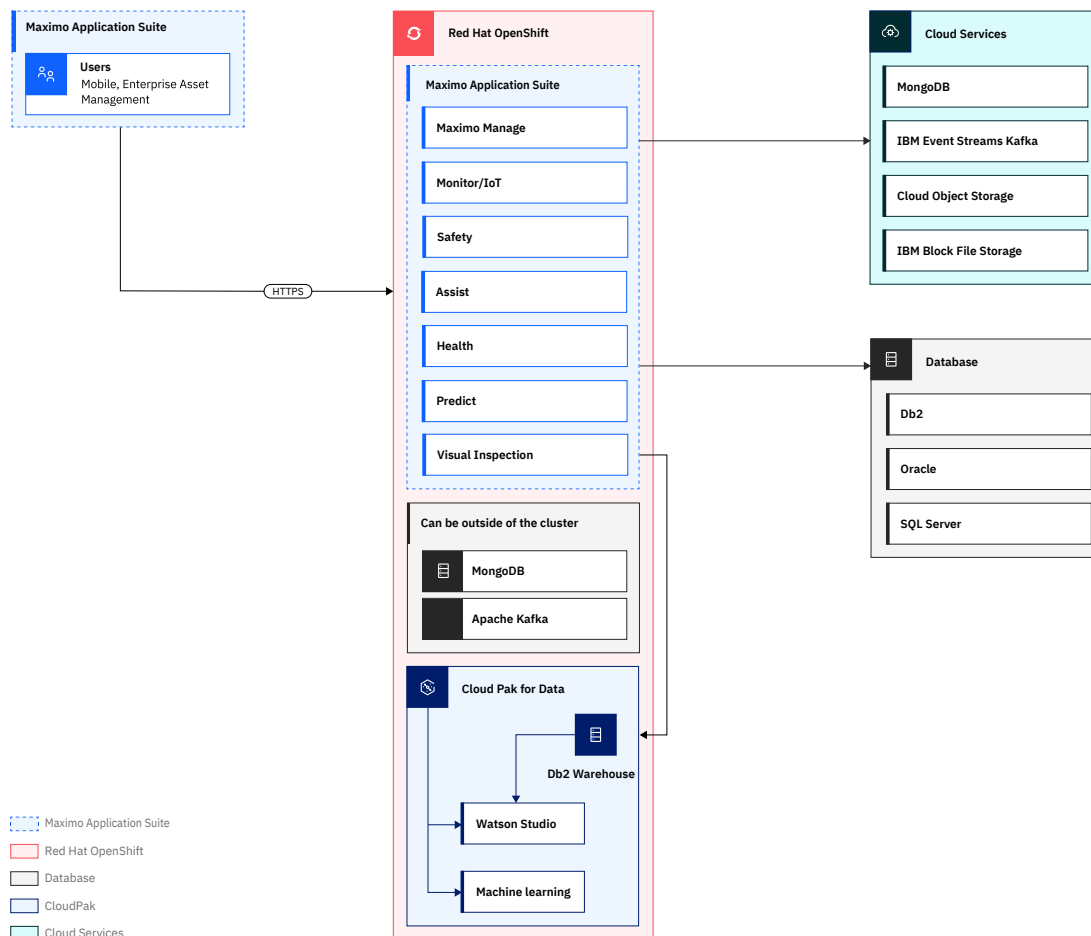

- [IBM Maximo Application Suite architecture](#)
IBM Maximo Application Suite helps drive operational resiliency and reliability. With expanded access to enterprise asset management, Maximo Manage, Maximo Health, Maximo Predict, Maximo Monitor, and Maximo Asset Performance Management On-Premises applications, your team can reach across the enterprise to unify operations and maintain business continuity.
- [Maximo Manage deployment model](#)
In Maximo Manage deployment is done in Red Hat® OpenShift® clusters.
- [Maximo Asset Management deployment](#)
Deployment and explanation of Maximo Asset Management 7.6.
- [Maximo Manage deployment in Red Hat OpenShift Container Platform](#)
When you deploy Maximo Manage in Red Hat OpenShift Container Platform, the Maximo Manage operator pulls the images from the IBM Entitled Registry and, if any customization exists, pulls the customization archive from the customer repository. The operator builds an Maximo Manage administrative image and configures images or workloads, such as UI, Cron, BIRT reporting.

IBM Maximo Application Suite architecture

IBM® Maximo® Application Suite helps drive operational resiliency and reliability. With expanded access to enterprise asset management, Maximo Manage, Maximo Health, Maximo Predict, Maximo Monitor, and Maximo Asset Performance Management On-Premises applications, your team can reach across the enterprise to unify operations and maintain business continuity.

Maximo Application Suite has the following capabilities:

- Integrated suite of applications. For example, Maximo Manage, Maximo Health, Maximo Predict, and Maximo Monitor.
- Simplified licensing model.
- Hybrid-cloud deployment.
- Comprehensive view of your assets.

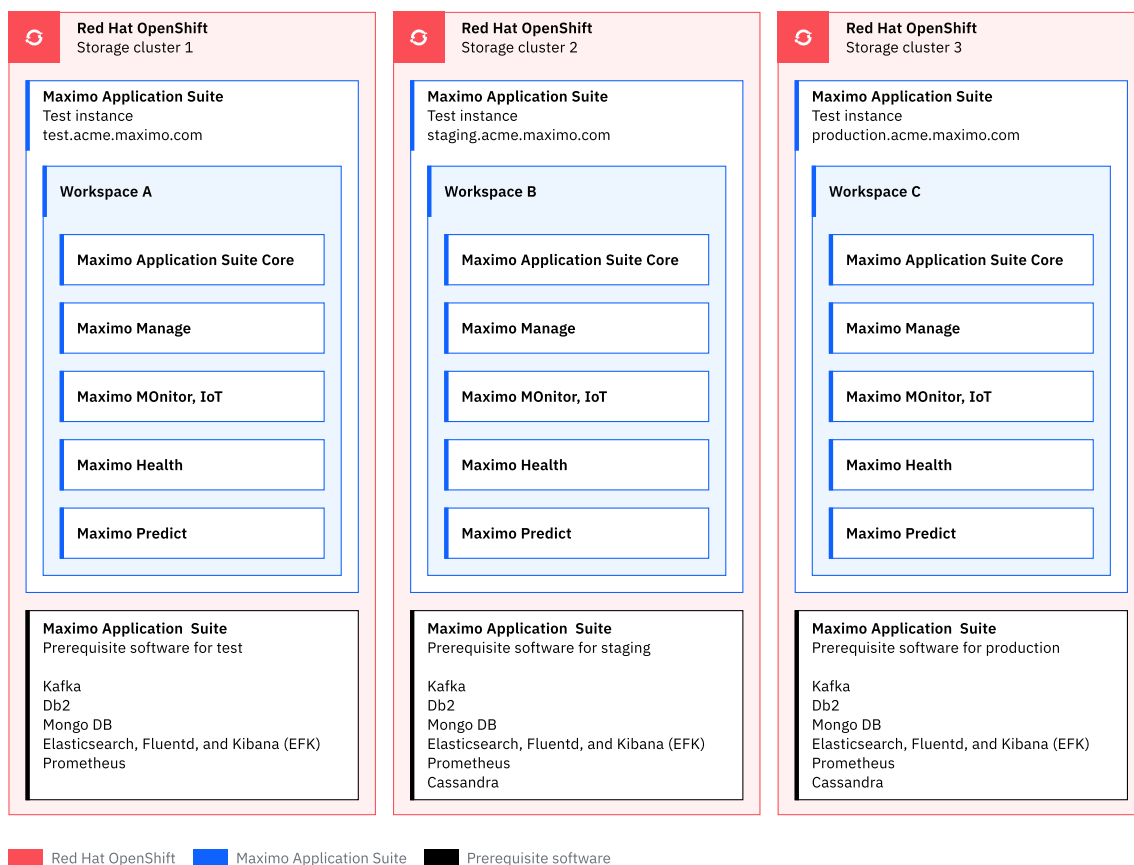

- Maximo Application Suite includes applications, such as Maximo Manage, Maximo Monitor, Maximo Health, Maximo Predict, Maximo Visual Inspection, Maximo Assist, and Maximo MRO Inventory Optimization.
- [IBM Cloud Pak® for Data](#) can run on your Red Hat® OpenShift® cluster. It offers AI-infused services for business and IT operations, development, data science, and management.
Note: If you intend to integrate Maximo Manage with other application suites, you must install [IBM Cloud Pak for Data](#). Otherwise, install only the IBM Db2® Warehouse stand-alone operator that can be one of the supported database options for Maximo Manage.
- MongoDB can exist in a cluster, cloud, or outside a cluster.
 - User, application, and entitlement metadata, such as OpenID Connect (OIDC) registration and user management is stored in MongoDB.
- IBM Event Streams is a fully managed Apache Kafka-As-A-Service Platform for Cloud. The Maximo Manage application in the suite can be configured to use Kafka service.
- Maximo Manage support for all three databases, such as IBM Db2, Oracle Database, and Microsoft SQL Server.
- Maximo Manage can be configured to use cloud services, such as Cloud Object Storage, block, or file storage.

Maximo Manage deployment model

In Maximo® Manage deployment is done in Red Hat® OpenShift® clusters.

The following diagram shows a sample Maximo Manage deployment model.

Figure 1. Maximo Manage deployment model sample

- Each cluster can run multiple Maximo Application Suite instances.
- Each instance runs its own set of pods and runtime code.
- All instances within the cluster can share a license pool.
- Each instance has its own workloads.
- Worker nodes capacity management is done per instance.
- Prerequisites stack is defined at the instance level.
- Independent storage clusters per instance.

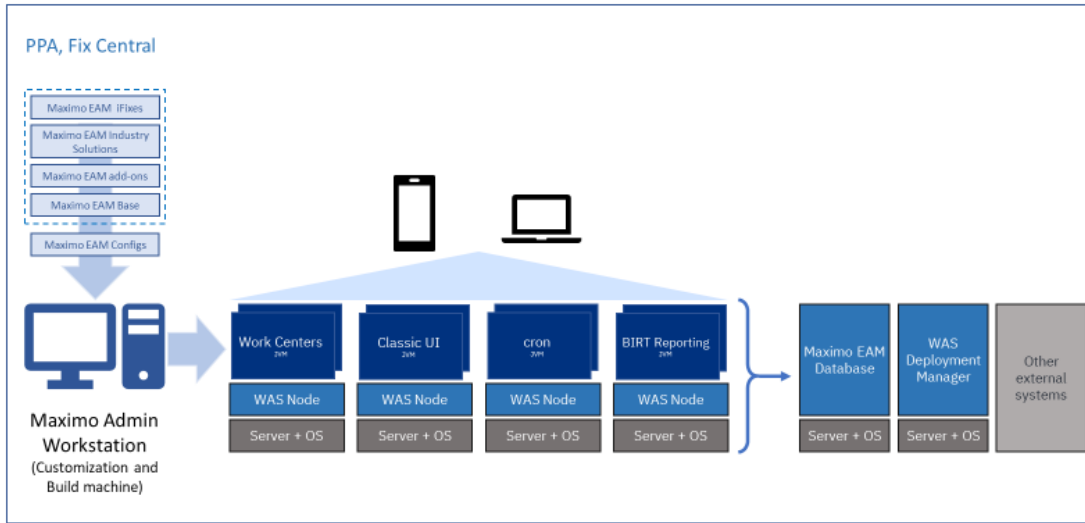

Maximo Asset Management deployment

Deployment and explanation of Maximo® Asset Management 7.6.

In Maximo Asset Management deployment, the software is downloaded on the admin workstation. The ear and war files are generated on the admin workstation and deployed on an application server. In this deployment example, the cluster is running multiple servers for Classic UI, Work Centers, Cron, and BIRT reporting to distribute the load in a WebSphere® Application Server Network Deployment. The Maximo Asset Management database and other external systems for integration are running on separate servers.

The following architectural diagram shows a typical Maximo Asset Management 7.6 deployment.

Figure 1. Maximo Asset Management 7.6 deployment architecture

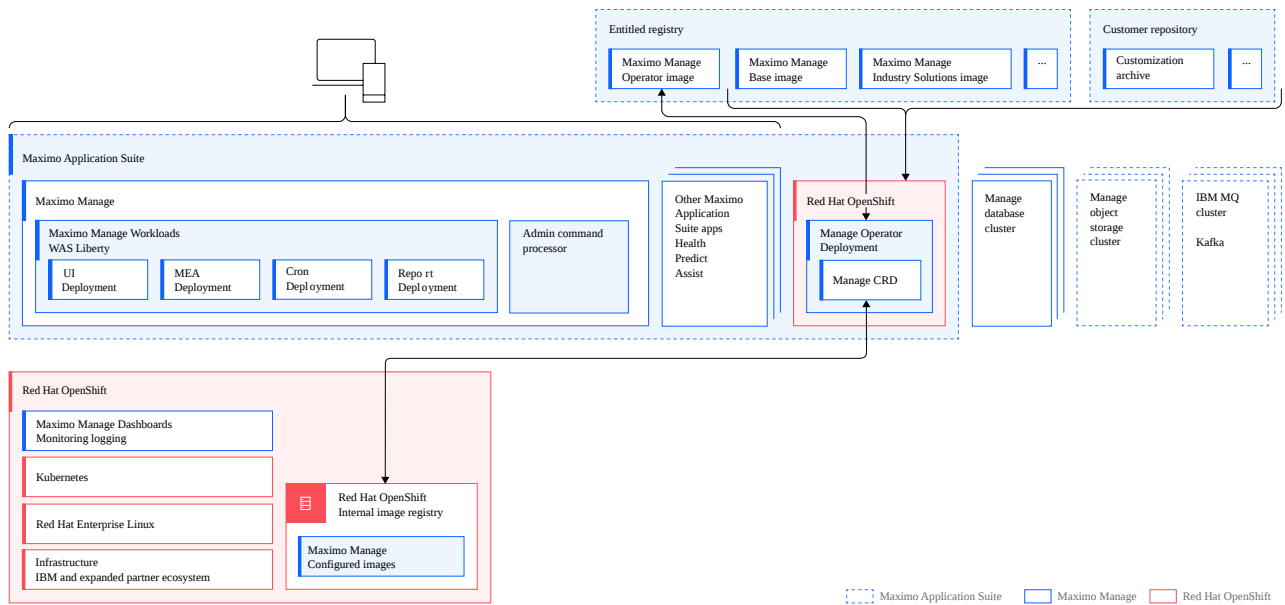

Maximo Manage deployment in Red Hat OpenShift Container Platform

When you deploy Maximo® Manage in Red Hat® OpenShift® Container Platform, the Maximo Manage operator pulls the images from the IBM Entitled Registry and, if any customization exists, pulls the customization archive from the customer repository. The operator builds an Maximo Manage administrative image and configures images or workloads, such as UI, Cron, BIRT reporting.

The configured images and workloads are deployed to the Maximo Application Suite containers.

The built images are stored in the Red Hat OpenShift internal image registry repository.

The following diagram shows an example of a Maximo Manage application deployment in Red Hat OpenShift Container Platform:

Red Hat OpenShift

Red Hat OpenShift contains the infrastructure layer, a Red Hat Enterprise Linux® operating system, Kubernetes software for deploying and managing containers, and an internal image registry to store Maximo Manage configured images and services. Maximo Manage dashboards are provided in Red Hat OpenShift. You can use the dashboards to review logs and monitor Red Hat OpenShift and other applications that are deployed in Maximo Application Suite.

Images

The images for the Maximo Manage operator, Maximo Manage base, industry solutions, and add-ons are provided by the Entitled Registry. These images contain software application classes, deployment descriptors, XML, and scripts.

Maximo Manage operator

The Maximo Manage operator is similar to an installer. The operator pulls the images from the Entitled Registry. This process is similar to downloading software from Passport Advantage® and Fix Central.

Maximo Manage workloads or server bundles

Maximo Manage supports All, UI, Cron, Report, and Maximo Enterprise Adapter workloads. You can configure the workloads during the application deployment. In the diagram, the UI, Cron, Report, and Maximo Enterprise Adapter workloads are deployed.

Customization archive

The customization archive is stored in the customer repository and can be accessed from Maximo Application Suite by using HTTPS.

Admin command processor

The admin command processor pod runs Maximo Manage tools, such as the integrity checker.

Other Maximo Application Suite applications

You can deploy other Maximo Application Suite applications, such as Maximo Assist, Maximo Health, Maximo Predict, and Maximo Monitor.

Maximo Manage database

You can deploy the Maximo Manage database, such as IBM® Db2® Warehouse, in a cluster.

Maximo Manage object storage

You can configure IBM Cloud Object Storage for document storage. For example, you can configure doc-links to use IBM Cloud Object Storage for storing documents.

Maximo Manage IBM MQ or Kafka

You can configure a messaging provider, such as JMS, IBM MQ, or Kafka, in a cluster.

Deployment from operator

The following steps describe how Maximo Manage is deployed by using the operator:

1. Create a custom resource (CR).

An administrator selects, configures, and deploys the Maximo Manage application. The deployment creates a CR. A CR contains a user-entered configuration for the application, for example, the name, version, number of pods, database type and connection, type of workloads, and location of customization archive.

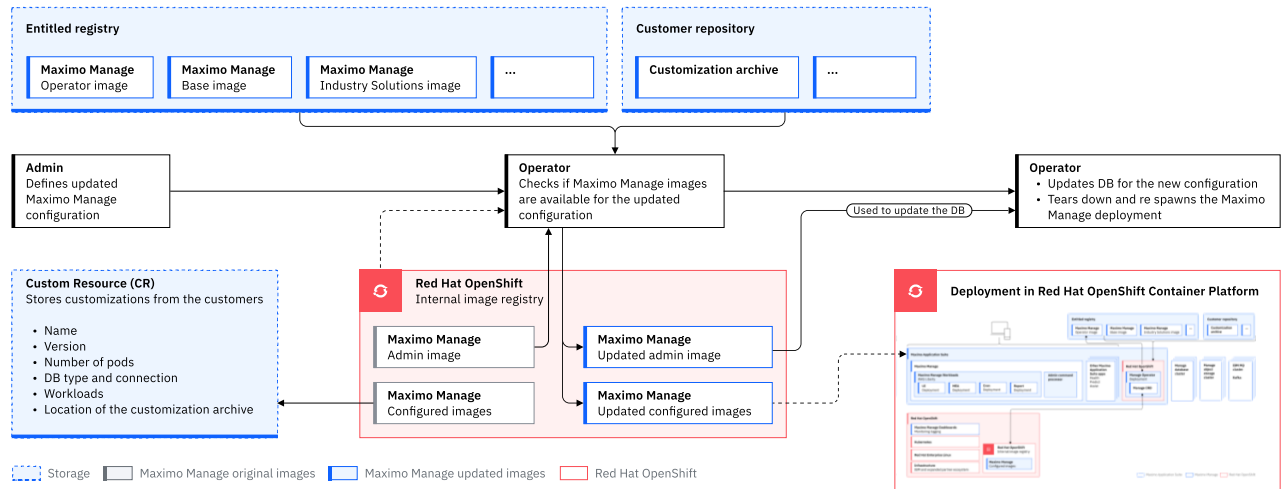

2. Create the image.

The Maximo Manage operator pulls the images from the Entitled Registry and, if any customization exists, pulls the customization archive from the customer repository. The operator deploys the industry solutions or add-on images and the customization archive over the Maximo Manage base image to create the final images. The operator also validates for the dependency matrix. The operator creates an Maximo Manage administrative image and the Maximo Manage configured images or workloads. The final images are stored in the image registry repository.

3. Update the configuration.

If the Maximo Manage database does not exist, the operator installs the Maximo Manage administrator image. If the database does exist, the operator upgrades the Maximo Manage database for a new configuration and restarts the Maximo Manage deployment. Maximo Manage configured images or workloads are deployed to containers in Maximo Application Suite.

The following diagram shows how the operator is used to deploy Maximo Manage.

Upgrading the Maximo environment

Prerequisites, process, considerations, checking deployment status, results and how to manage users post upgrade.

- **Upgrade prerequisites**
Check your Maximo Asset Management version and get your environment ready for upgrading by configuring your Red Hat® OpenShift® cluster.
- **Upgrade process overview**
The IBM Maximo Application Suite upgrade process consists of an initial test deployment, which is followed by the production deployment after successful testing. Install and configure Maximo Application Suite, create a customization archive if you find it necessary, and finally deploy and activate Maximo Manage.
- **Authentication, security, and SMTP configuration**
Before you upgrade to Maximo Manage, you must be familiar with authentication, encryption and security, and SMTP configuration.
- **Upgrading to IBM Maximo Application Suite**
You can upgrade to IBM Maximo Application Suite and then activate and deploy Maximo Manage.
- **Managing users post upgrade**
User management and consumption reports in IBM Maximo Application Suite.

Upgrade prerequisites

Check your Maximo® Asset Management version and get your environment ready for upgrading by configuring your Red Hat® OpenShift® cluster.

Product version and Red Hat OpenShift cluster

Before you upgrade to Maximo Manage, you must have Maximo Asset Management 7.6.1.10 or 7.6.1.2 or later installed.

Configure the Red Hat OpenShift cluster based on the following requirements:

1. Refer to the Maximo Application Suite and Maximo Manage documentation.
For more information, see [Maximo Application Suite](#).
2. Determine the capacity needed to upgrade the product.
For more information, see [Capacity Planning](#).
3. Secure a Red Hat OpenShift cluster for development, testing, or production.

Important things to check for before the upgrade

- Check that the mxe.int.dfltuser property is set to a user with administrative privileges. By default, this admin user is used to synchronize the Maximo Application Suite users to Maximo Manage.
- Run Integrity checker in Maximo Asset Management 7.6.1.0 or 7.6.1.2. Fix any inconsistencies in indexes, and in Maximo metadata before you upgrade to Maximo Application Suite. Object structure is used during the initial user synchronization between Maximo Application Suite and Maximo Manage. Inconsistency in indexes and metadata can result in failures.
- If you are upgrading to Maximo Application Suite 8.0, or 8.1 and Maximo Manage 8.2, you must use the database configuration to make the person ID and login ID fields the same length as the email address fields. The default length is 100. In Maximo Application Suite, the email address becomes the login ID.
- Check that each user has only one primary email address. Maximo Application Suite business logic does not allow multiple primary email addresses. However, you must double-check it, in case the data is altered by using SQL Server.
- Correct the user's login ID, if multiple users have the same login ID but differing in uppercase or lowercase letters. Two users cannot have the same login ID with only differences in case.
- Configure SMTP in Maximo Application Suite before you create the admin user. Otherwise, the email with the generated password cannot be sent.
- [Working with on-premises deployment calculator](#)
You can view environment calculation details using the Maximo Application Suite on-premise deployment calculator.

Related information

- [Plan and prepare your environment](#)

Working with on-premises deployment calculator

You can view environment calculation details using the Maximo® Application Suite on-premise deployment calculator.

About this task

Use the following steps to download and view environment calculation details.

Procedure

1. Use the Capacity Planning calculator to size your environment.
2. Download the [sizing calculator](#).
3. Update your configuration on the calculator tab.
For example, select the applications and the number of concurrent users.
4. Go to the Detailed Report tab to view the environment calculation details.

Upgrade process overview

The IBM® Maximo® Application Suite upgrade process consists of an initial test deployment, which is followed by the production deployment after successful testing. Install and configure Maximo Application Suite, create a customization archive if you find it necessary, and finally deploy and activate Maximo Manage.

The following diagram shows the upgrade process flow.

Upgrade process flow

Prepare a test database

Duplicate the existing Maximo Asset Management production database to use as a test database.

Install and configure Maximo Application Suite

Install and configure a Maximo Application Suite instance in your Red Hat® OpenShift® environment. For more information, see [Installing Maximo Application Suite](#).

Customization

Create a customization archive.

For more information, see [Customization archive guidelines](#).

Deploy

Use the Maximo Application Suite user interface to configure Maximo Manage, industry solutions, and add-ons to use the new upgraded database, and other configurations. Specify the location of the customization archive. Deploy the Maximo Manage application. For more information, see [Deploying the Manage application](#).

Activate

Activate the Maximo Manage application. Activation updates the database and deploys workloads to the containers. For more information, see [Activating Maximo Manage](#).

Authentication, security, and SMTP configuration

Before you upgrade to Maximo® Manage, you must be familiar with authentication, encryption and security, and SMTP configuration.

Authentication

- The local identity provider, which is the username or password that is registered in MongoDB, is used by default for authentication.
- LDAP or SAML can be configured for authentication before or after the installation of Maximo Manage by using the Configuration page in Maximo Application Suite.
 - Only LDAP registries that are supported by Liberty runtime can be used. For more information, see [LDAP User Registry 3.0](#)
 - If you are currently using LDAP or SAML, your existing configuration can be used in Maximo Application Suite.

For more information, see [Configuring authentication](#).

Encryption and security

If you are using custom encryption keys for CRYPTO and CRYTOX attributes, then the custom keys must be provided during the Maximo Manage application installation.

Custom encryption properties are specified in the `maximo.properties` file. After the Maximo Manage application installation, the keys are stored as a `{instance_id}-manage-encryptionsecret` secret in the Maximo Manage project in Red Hat® OpenShift®. The keys must be saved in a secured vault. If the keys are lost, the database cannot be used. For more information, see [Encryption and security](#).

For more information, see [Database encryption](#).

SMTP configuration

SMTP configuration is retained in the database during the upgrade. It is used by Maximo Manage for sending emails.

Maximo Application Suite also provides SMTP configuration. This configuration is used for sending welcome emails and user password emails.

For more information, see [Configuring SMTP](#).

Industry solutions and add-ons

All the industry solutions and add-ons that are currently installed must be manually selected to be upgraded. All the industry solutions and add-ons are preselected based on the existing environment.

Upgrading to IBM Maximo Application Suite

You can upgrade to IBM® Maximo® Application Suite and then activate and deploy Maximo Manage.

Before you begin

Plan and prepare your environment. For more information, see [Upgrade prerequisites](#).

Procedure

1. Prepare your database by duplicating or backing up the existing production database.
2. Install and configure Maximo Application Suite.
3. On the Suite administration page, click the Configurations tile to configure LDAP or SAML for authentication and SMTP.
 - LDAP authentication
 - a. In the Users and identity section, click Not configured in the Status column for LDAP authentication.
 - b. Click Configure and enter your LDAP server details.
 - c. Click Save.
 - SAML authentication
 - a. In the Users and identity section, click Not configured in the Status column for SAML authentication.
 - b. Follow the instructions on the SAML Authentication page.
 - c. Click Save.
 - SMTP configuration
 - a. In the Users and identity section, click Not configured in the Status column for SMTP.
 - b. Click Configure and enter your SMTP settings.
 - c. Click Save.
4. Create the admin user and log on to Maximo Application Suite as the admin user.
5. Optional: Create the customization archive. For more information, see [Customizing Maximo Manage](#).
6. Deploy and configure Maximo Manage.
 - a. On the Catalog page, click the Manage tile.
 - b. Select Maximo Manage Industry Solutions and Add-ons.
 - c. Click Deploy Manage.
 - d. Click Actions and then click Configure workspace.
 - e. Configure the database.
 - Click Configure.
 - f. Configure schema, table space, certificates. To configure custom certificates, see [Configuring custom certificates](#) in Maximo Application Suite online product documentation. To add customizations, see [Adding customizations to the application](#).
 - g. Optional: Add your encryption keys.
 - h. Configure languages.
 - i. Configure server bundles.
 - For more information about bundle level properties, see [Configuration](#).
 - j. Optional: Configure the customization archive.
 - k. Optional: Import the external certificate.
7. Click Activate.

Results

If you want to check the deployment status, on the Catalog page, click the Maximo Manage tile. The green circle on the Manage tile shows that Maximo Manage is ready. You can also check the deployment status by using the [Red Hat® OpenShift® console](#).

- [Checking IBM Maximo Manage deployment status](#)
 - Verify that IBM Maximo Manage is deployed successfully by checking the Custom Resource Definitions page on the Red Hat OpenShift console.

Checking IBM Maximo Manage deployment status

Verify that IBM® Maximo® Manage is deployed successfully by checking the Custom Resource Definitions page on the Red Hat® OpenShift® console.

Before you begin

Maximo Manage must be activated first.

Procedure

1. In the Red Hat OpenShift console, select Administration > Custom Resource Definition.
2. In the Name field, search for `manageworkspace` and then click the Manage Workspace custom resource definition to open it.
3. To select your project instance, select the Instances tab.
4. Check the project status on the Details tab of the Custom Resource Definitions page.
The project status can be either true or false based on various conditions.
For example, the project is build ready when the build is completed, or it is deployment ready if all the server bundles are running.

Migrating users to IBM Maximo Application Suite

Create IBM® Maximo® Application Suite users or migrate from the previous version of the application.

Migrated users

Users are migrated to Maximo Application Suite from IBM Maximo Asset Management during the upgrade.

Users are created with the **Set in Manage** access type. The user access is managed in the IBM Maximo Manage application by using security groups. For more information, see [Configuring security groups](#).

If SMTP is configured, the migrated users receive the following emails:

- Welcome to IBM Maximo Application Suite.
- Your IBM Maximo Application Suite password.

On the Users page, you can replace passwords in edit mode by using the Replace forgotten password link. A MAXADMIN user is created by default. User authorization or application access is done in the Maximo Manage application by using security groups. .

Entitlement

The following entitlements are available in Maximo Application Suite:

- Premium is set to 15 AppPoints.
- Base is set to 10 AppPoints.
- Limited is set to 5 AppPoints.
- Self-Service is set to 0 AppPoints.

For more information about entitlement calculation details, see [Maximo Application Suite licensing model](#)

Migrating users - troubleshooting

Use the database logs to fix errors after you migrate the users from IBM® Maximo® Asset Management to Maximo Application Suite during upgrade.

Before you begin

You must have administrator rights to fix the errors.

About this task

If the users are not migrated to Maximo Application Suite, check the database log and fix any errors.

Procedure

1. Create MAXADMIN user in Maximo Application Suite from the Users page.
2. Log in to Maximo Application Suite as MAXADMIN user.
3. Select the Maximo Manage application.
4. Select the user sync crontask **MASUSERSYNC** from the crontask application.
5. Create a crontask instance.
6. Run the crontask.

Accessing Manage and troubleshooting

Ways to access Manage.

Accessing IBM Maximo Manage

From IBM® Maximo® Application Suite Admin link, you can select Manage application from the App Switcher () or click the gear icon in the navigation bar.

The Red Hat® OpenShift® console also has a Manage link.

- You can use `ui` bundle or `all` bundle location link. Append `/maximo` to access Manage.
- You can go to IBM Maximo Application Suite by clicking IBM Maximo Application Suite on the header (upper left).

Troubleshooting

Link to [logging](#).

Validating customization archive

Use the Manage Assets application to validate customization archive.

About this task

A sample [Customization archive](#) has the following.

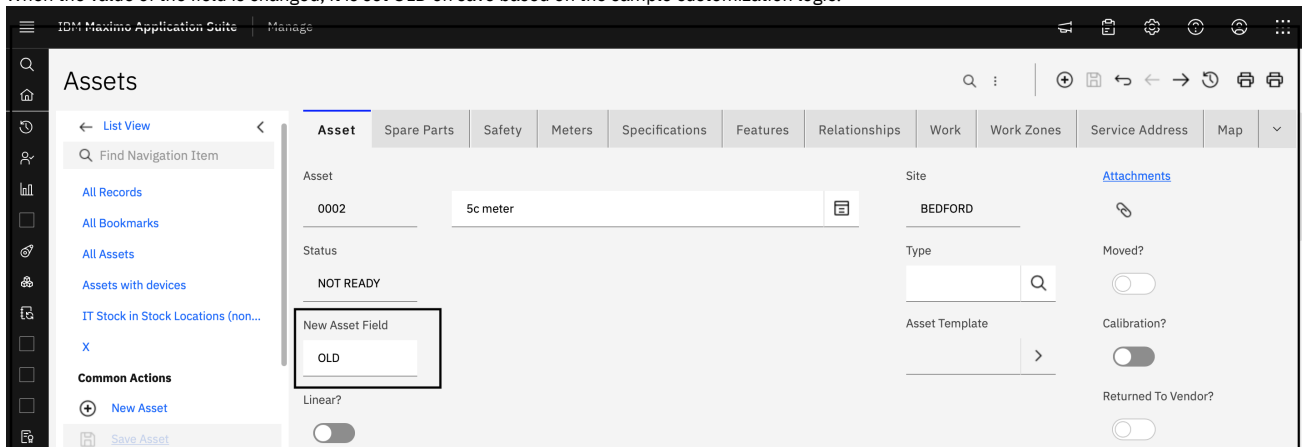

- **classes**
 - applications\maximo\businessobjects\classes\cust\app\asset\Asset.class
 - applications\maximo\businessobjects\classes\cust\app\asset\AssetSet.class
 - applications\maximo\businessobjects\classes\cust\app\asset\FldAssetNewField.class
- **product.xml**
 - applications\maximo\properties\product\customer.xml
- **script**
 - tools\maximo\en\cust\V7612_01.dbc
- **servlets**
 - applications\maximo\commonweb\classes\com\ibm\tivoli\maximo\oslc\provider\MyPingServlet.class
- **deployment descriptors (web.xml)**
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-mea\meaweb\webmodule\WEB-INF\web.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-ui\meaui\webmodule\WEB-INF\web.xml

Procedure

1. Go to Manage Assets application.

The customized "New Asset Field" is added in the Manage Assets application.

When the value of the field is changed, it is set OLD on save based on the sample customization logic.

2. Use any REST client.
For example, Postman
3. Copy the Maximo Enterprise Adapter web link from "Routes" (see Manage page) and append `\meaweb\myapi`.
4. In the response header `pingmaximo` value is set to `hello`.

KEY	VALUE
Cache-Control	no-cache
Postman-Token	<calculated when request is sent>
Host	<calculated when request is sent>
X-Content-Type-Options	nosniff
Access-Control-Allow-Credentials	true
X-XSS-Protection	1
pingmaximo	hello
Content-Language	en-US
Content-Length	0
Date	Sun, 09 May 2021 17:49:19 GMT

- On any REST client, copy the user interface web link from "Routes" (see Manage page) and append \maximo\myuiapi.
- In the response header **pingmaximo** value is set to **hello**.

KEY	VALUE
Cache-Control	no-cache
Postman-Token	<calculated when request is sent>
Host	<calculated when request is sent>
User-Agent	PostmanRuntime/7.28.0
pingmaximo	hello
Content-Language	en-US
Content-Length	0
Date	Sun, 09 May 2021 17:47:46 GMT
Set-Cookie	84849622bafd21147741b6f7bb4964c4=7432028da41b08c306dd3578c028df02; path=/; Http...

Managing users post upgrade

User management and consumption reports in IBM® Maximo® Application Suite.

About this task

User management is done in Maximo Application Suite, from the Users tile in the Suite administration dashboard, which synchronizes into IBM Maximo Manage.

Procedure

User entitlement.

- The crontask **MasUserAnalyzer** in Maximo Manage, calculates the user entitlement (Limited, Base, Premium, or Self-Service).
 - The crontask **MasUserReporting** in Maximo Manage, sends the entitlement change to Maximo Application Suite (for example: user authorization changed).
- Note: If the entitlement is higher in Maximo Manage, a message is displayed on Suite administration dashboard.

- [License type information.](#)

- [Viewing user synchronization information](#)

View information about user synchronization in IBM Maximo Manage.

Changing user password

About this task

User passwords are changed from the Users tile in the Suite administration dashboard.

Procedure

- Select the user.
- Click the pencil icon on the upper right to edit the user.

3. Click Replace forgotten password.
4. Update it manually or auto-generate.
 - a. Select Send account password in email to receive an email with the generated password.
5. Click Save.

Changing current user password

About this task

Current user password can be changed from Suite administration dashboard.

Procedure

1. Go to User profile on the upper right.
2. Click Manage profile.
3. On the menu on the left, select Change password.
4. Enter the information and click Save.

Generating user license consumption reports

Procedure

To generate License consumption reports, go to the Suite administration dashboard and click License consumption.

Viewing user synchronization information

View information about user synchronization in IBM® Maximo® Manage.

- When a user is created and is assigned the Manage role, it gets synchronized into Manage. The Manage application user sync process pulls the data from IBM Maximo Application Suite (MAS) IDP, User Registry and pushes it to Manage.
- If a user has the NO_ACCESS role or is deleted in MAS, the user becomes INACTIVE in the Manage application.
- The user synchronization process from MAS to Manage uses the Maximo Integration Framework. It uses integration's Enterprise Service to post data to Manage. If a MAS user is assigned the Manage role and has a sync status of PENDING or DELETE_PENDING, the user sync processes it and upon successful synchronization change the sync status to SYNCED.

Configuring Maximo Manage for upgrade

Information on how to configure IBM® Maximo® Manage and connectors, customization capabilities, and how to manage users, security, and licenses.

- [Overview of changes](#)
The Enterprise Asset Management data model has no significant changes.

- [Security and user management](#)
View details of security and user management.
- [Integration](#)
The API key authentication is necessary for inbound HTTP or SOAP or REST-based integration to Maximo Manage.
- [Migrating to JMS provider](#)
You must install or provision or configure JMS to migrate to it.
- [Migrating to Kafka](#)
You must install or provision or configure Kafka for migration.
- [Supported JMS provider](#)
There are certain points to consider if you use a supported JMS provider.
- [Moving from JMS to Kafka](#)
If you move from JMS queues to Kafka, there are some differences in the way the messages are processed.
- [RMI replaced by REST API](#)
Remote Method Invocation (RMI) is not supported outside of the Maximo server process.
- [Maximo properties](#)
The Maximo properties file is now redundant in Maximo Manage.
- [Changes in Maximo Application Suite](#)
Refer to the functional area details of IBM Maximo Application Suite.
- [Configuring Maximo Manage for deployment](#)
Certain configurations are required before you can deploy IBM Maximo Manage.
- [Customizing IBM Maximo Manage](#)
All customer-specific changes, such as Java™ classes, XML files, and database scripts, must be included in a customization archive. You create the customization archive in a location accessible to IBM Maximo Application Suite during deployment. The structure of the customization archive is the same as the Maximo Asset Management folder structure. Test the customization archive in a development or test environment before you apply it to the production environment.
- [Creating customization archives](#)
You can create a customization archive, which is a set of files that contain changes and customizations for the application.
- [Deployment descriptors](#)
All deployment descriptors such as web.xml, ejb-jar.xml, and webservices.xml files that are customized by users can be put into the customization archive and overlaid on the files that are supplied by IBM.
- [Using certificates](#)
You can use route or TLS certificates, SSL certificates, external certificates.
- [Configuring Oracle Connector](#)
You must configure Oracle Connector before and after the upgrade.
- [Configuring SAP Connector](#)
You must configure SAP Connector before and after the upgrade.
- [Viewing Maximo Manage Logs](#)
View the IBM Maximo Manage logs for Server, Maxinst and Update database, User sync, Workspace operator, and Build logs from the Red Hat® OpenShift® console.
- [Monitoring](#)
You can enable monitoring for applications in Red Hat OpenShift Container Platform.
- [IBM Maximo Manage tool](#)
When Maximo Manage is deployed, some tools become available.

Overview of changes

The Enterprise Asset Management data model has no significant changes.

- All three databases (IBM® Db2®, Oracle Database, and Microsoft SQL Server) are supported.
- All classic and work center UI/UX are available in Maximo® Manage.
- Only IBM WebSphere® Application Server Liberty is used within Maximo Application Suite.
- Red Hat® OpenShift® deployment.

Security and user management

View details of security and user management.

- Authentication and single sign-on (SSO) are managed by [Maximo® Application Suite Identity Provider](#). The following Identity Providers (IDP) are supported:
 - Local IDP (username and password that is registered in MongoDB)
 - LDAP
 - SAML
- All interactions other than from the user interface (Integration, REST) require API Key for authentication.
- LDAP integration is managed by IBM® Maximo Application Suite.
 - The existing Maximo EAM LDAP/VMM synchronization is not supported and is replaced by the synchronization process in Maximo Application Suite. For more information, see the [LDAP User Synchronization](#) section.
 - Maximo Application Suite uses WebSphere® Application Server Liberty to synchronize with LDAP.
 - Liberty provides a SCIM API for Maximo Application Suite to use the data from LDAP repositories into the Maximo Application Suite user registry. Maximo Application Suite pushes users and groups to Manage from the Maximo Application Suite repository.
- Existing Maximo EAM users are synchronized with Maximo Application Suite User Registry during the upgrade. The details are in the Users Synchronization section.

- Only new users can be created in Maximo Application Suite and synchronized to Manage. If you currently have integration to create or update users in Maximo , you need to integrate users to IBM Maximo Application Suite, not IBM Maximo Manage.

User synchronization

- When a user is created and is assigned the IBM Maximo Manage role, it gets synchronized into Manage. The Manage application user sync process pulls the data from IBM Maximo Application Suite IDP, User Registry and pushes it to Manage.
- If a user has the NO_ACCESS role or is deleted in Maximo Application Suite, the user becomes INACTIVE in the Manage application.
- The user synchronization process from Maximo Application Suite to Manage uses the Maximo Integration Framework. It uses integration's Enterprise Service to post data to Manage. If a Maximo Application Suite user is assigned the Manage role and has a sync status of PENDING or DELETE_PENDING, the user sync processes it and upon successful synchronization change the sync status to SYNCED.

Sample of inbound message from Maximo Application Suite

```
{ "id": "joesmith5", "username": "joesmith5", "permissions": { "systemAdmin": true, "userAdmin": true }, "issuer": "local", "displayName": "Joe Smith", "familyName": "Smith", "givenName": "Joe", "title": "Supervisor", "preferredLanguage": "EN", "locale": "en_US", "phoneNumbers": [ { "value": "555-555-5555", "type": "work" }, { "value": "555-555-4444", "type": "work" } ], "addresses": [ { "streetAddress": "100 Universal City Plaza", "locality": "Hollywood", "region": "CA", "postalCode": "91608", "country": "USA", "formatted": "100 Universal City Plaza\nHollywood, CA 91608 USA", "type": "work", "primary": true } ], "emails": [ { "value": "joesmith5@us.ibm.com", "type": "work", "primary": true }, { "value": "joesmith51@gmail.com", "type": "work" } ], "extension": { "employeeNumber": "701984", "costCenter": "4130" }, "entitlement": { "application": "PREMIUM", "admin": "ADMIN PREMIUM" }, "workspaces": { "space1": { "permissions": { "workspaceAdmin": true }, "applications": { "manage": { "role": "ADMIN" }, "iot": { "role": "ADMIN" }, "health": { "role": "USER" }, "monitor": { "role": "ADMIN" } } }, "added": { "id": "admin", "timestamp": "2020-08-10T18:01:36.694331" }, "updated": { "id": "admin", "timestamp": "2020-08-10T18:08:17.455782" }, "sync": { "status": "SUCCESS", "timestamp": "2020-08-10T18:10:16.731047" }, "applications": { "manage": { "sync": { "state": "PENDING", "reason": "", "timestamp": "2020-08-10T18:08:49.604430" } }, "monitor": { "sync": { "state": "SUCCESS", "reason": "", "timestamp": "2020-08-10T18:09:18.131171" } }, "predict": { "sync": { "state": "SUCCESS", "reason": "", "timestamp": "2020-08-10T18:08:17.471947" } } }, "token": "1000:8744077b1411c0601e4912d556d93ff859089bdfd16863f16:591949ad7b4d4f7017de846a3f3b2609ac4caef4ebe09448" }

```

LDAP synchronization

The section tagged “extension” as shown in the samples includes all extra attributes that are not part of default mapping. The default mapping can be customized by creating an Oracle Java™ user exit, automation script, or JSON Mapper.

- IBM Maximo Application Suite synchronizes users and groups from the LDAP server and there is no direct synchronization from LDAP to Manage.
- Maximo Application Suite uses Liberty to synchronize with LDAP. Liberty provides a SCIM API for Maximo Application Suite to use the data from LDAP repositories into Maximo Application Suite User Registry IDP.
 - SCIM defines the resource (Users, Groups) schema and the REST(CRUD) APIs to manage the resources.
- Maximo Application Suite to use the data from LDAP repositories into Maximo Application Suite User Registry IDP.
- SCIM defines the resource (Users, Groups) schema and the REST(CRUD) APIs to manage the resources.
- The section tagged “extension” can include all extra attributes that are not part of default mapping.
- The schema attribute mapping can be customized by using user exit, an automation script on user exit, or replacing the standard user exist with JSON Mapper user exit.

Flow

- User configures SCIM User Sync from Maximo Application Suite UI.
- Backend API creates a ScimCfg CR and secret.
- TrustManager operator adds LDAP Server certificate to the truststore.
- SCIM operator deploys Liberty server and the k8s cron job.
- Cron job gets the Users from Liberty server and stores it in Maximo Application Suite User Registry (MongoDB)

Manage group synchronization

- User Groups are synchronized into Manage from Maximo Application Suite.
- Users are added in the group only if they are valid users in Manage.
- The existing users in a group are replaced by the users in the payload same as LDAP group synchronization.

Bulk import users to Maximo Application Suite upgrade

Maximo users and their profiles, which include language, time zone, and locale, are imported to Maximo Application Suite during the upgrade.

- A one-time crontask instance is created during the upgrade to import users to Maximo Application Suite.
- Welcome emails are sent to the users with a password for their account. If the user email is not set, an email is sent to the system administrator email account.
 - The system administrator email is set up from Maximo Application Suite admin dashboard.
 - SMTP can be configured in Maximo Application Suite before upgrade, receive Welcome emails and emails with user password.
 - The user password can be reset by the System Administrator.

Welcome email Templates:

```

To: ${email}
Title: Welcome to IBM Maximo Application Suite
Body: Welcome to IBM Maximo Application Suite, a new account has been registered to ${email} in <a href="#_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_upgrade_${masHomeUrl}">IBM Maximo Application Suite (${instanceName})</a>.
  
```

```

Username: ${username}
  
```

You will receive your password in a separate e-mail (only show this if emailPassword has been set)

```

To: ${email}
Title: Your new IBM Maximo Application Suite password
Body: Welcome to <a href="#_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_upgrade_${masHomeUrl}">IBM Maximo Application Suite (${instanceName})</a>. your new password is below.
  
```

```

Password: ${password}
  
```

Integration

The API key authentication is necessary for inbound HTTP or SOAP or REST-based integration to Maximo® Manage.

The API key must be generated from the Administration Work Center. The HTTP request header must include the API key. No other authentication like native authentication is supported.

Migrating to JMS provider

You must install or provision or configure JMS to migrate to it.

Procedure

1. Install or provision or configure JMS provider. For example, IBM® MQ. You can also use Liberty messaging engine.
2. Register the JMS provider queues in Maximo Manage.
3. Associate the registered queues with the External Systems application.
4. You must register the queues and connection factories in Maximo Manage in the server. XML file for the JMS provider. Follow the [Liberty documentation](#) for setup.

Figure 1. JMS

Migrating to Kafka

You must install or provision or configure Kafka for migration.

Procedure

1. Install or provision or configure Kafka.
2. Register Kafka as a messaging provider in Manage.
3. Register Kafka topics in Manage.
4. Associate the registered topics with the External Systems application.
For more information, see [Kafka providers](#).
No text support is provided for Kafka in the initial release. Only byte messages are supported. JMS supports both text and byte.

Supported JMS provider

There are certain points to consider if you use a supported JMS provider.

If you are already using a supported JMS provider, for example IBM MQ, keep the following points in mind.

- The queues and connection factories must be registered in server.XML in Liberty server deployment that uses the same JNDI name as registered in Manage.
- The upgrade process does not move your current JMS integration messages. All messages in the queue and error table must be processed and cleared before the upgrade.
- File loading folders must be processed before the upgrade and are not moved.
 - You must configure a volume mount during deployment.
- Web Services that use SOAP 1.1 and 1.2 are supported.

Moving from JMS to Kafka

If you move from JMS queues to Kafka, there are some differences in the way the messages are processed.

For customers who are moving from JMS queues to Kafka, the message processing function is similar but slightly different. For more information, see [Migrating to Kafka](#).

- Kafka message in Manage is always bytes, no option for text.
- Kafka message is always compressed.
- Kafka message size limit is configured in Kafka server and with a Manage system property.
- Kafka messages are not deleted when processed. They are removed from the queue based on retention time.
- Continuous message consumption is done by Manage CRON tasks, not MDBs.
- Browsing messages or View Queue in a queue is done by using a REST API.

RMI replaced by REST API

Remote Method Invocation (RMI) is not supported outside of the Maximo server process.

- Security issues to the containers to open RMI ports.
- Networking issues with K8s services and routes that redirect to RMI ports.

Customers must use Maximo REST APIs instead of RMI.

- Maximo REST API follows open standards and is more secure and scalable.
- Use of REST API with standard HTTPS protocol helps make the client code language independent.
- The Maximo API Key is used for authentication in REST APIs.

Maximo properties

The Maximo® properties file is now redundant in Maximo Manage.

- The maximo.properties) file is no longer used in Maximo Manage.
- The bootstrap properties, such as database username and password and encryption keys, are set in IBM® Maximo Application Suite during deployment or in a custom resource in Red Hat® OpenShift®. These properties are applied to all workload deployments.
- The bundle-level properties for workloads are applied to the specific server and set in IBM Maximo Application Suite and stored as a configmap in Red Hat OpenShift.
For more information, see [Configuring Maximo Manage for deployment](#).
- Use the System Properties application to set the other properties. These properties are applied to all the workloads.

Changes in Maximo Application Suite

Refer to the functional area details of IBM® Maximo® Application Suite.

Functional Area	Details
Attachments	Supported. File system: <ul style="list-style-type: none">• For users that use the file system mount, same file system mount can be configured in Maximo Application Suite through volume mount in Red Hat® OpenShift®.• No change is needed for the Maximo Manage declines configuration, if the mount point is same as before. Object Storage (S3): <ul style="list-style-type: none">• No change needed to bring attached documents.• Object storage server public certificate might need to be imported.
Reporting	Business Intelligence and Reporting Tools (BIRT) supported.
Industry solutions and add-ons	All industry solutions and add-ons are supported.
IBM Maximo Anywhere	Updated mobile apps are available for download.
IBM Maximo Mobile	All connected and disconnected functions in one application. Initial version delivers Assist, followed by Technician and Inspections.
IBM Maximo Scheduler Optimization, IBM Maximo Calibration, and IBM Maximo Linear Asset Manager	Supported and are now part of Maximo Manage. IBM Maximo for Life Sciences is covered in Maximo Calibration.
Migration Manager	Supported. <ul style="list-style-type: none">• All pending migration packages must be migrated before the upgrade (prerequisite).• Configuration options are provided during deployment for persistent volume mount for file-based packages.• Maximo Anywhere APIs are available.• Supports the automation pf package creation and deployment.
Multi Languages	Available in all supported languages.
SAP and Oracle Integration	Supported.
Third party add-On	Third-party changes that exist are moved over only if the changes can be extracted completely in the customization archive.
Maximo Archiving	Not supported.

Configuring Maximo Manage for deployment

Certain configurations are required before you can deploy IBM® Maximo® Manage.

When the IBM Maximo Manage application is deployed in IBM Maximo Application Suite, a Maximo Manage deployment custom resource (CR) is created.

- The Maximo Manage deployment CR contains the configuration that you entered, which includes database URL, server bundle types, deployment size, and other information.
- The database username or password can be specified in Maximo Application Suite and persisted as a secret in the cluster.
- The Maximo Manage crypto or cryptox properties can be updated in Maximo Application Suite and persisted as a secret in the cluster.
- Both secrets, the username or password and the crypt or cryptox values can also be updated in Red Hat® OpenShift®. Any change to the values automatically redeploys the application completely or partially.

Server bundle

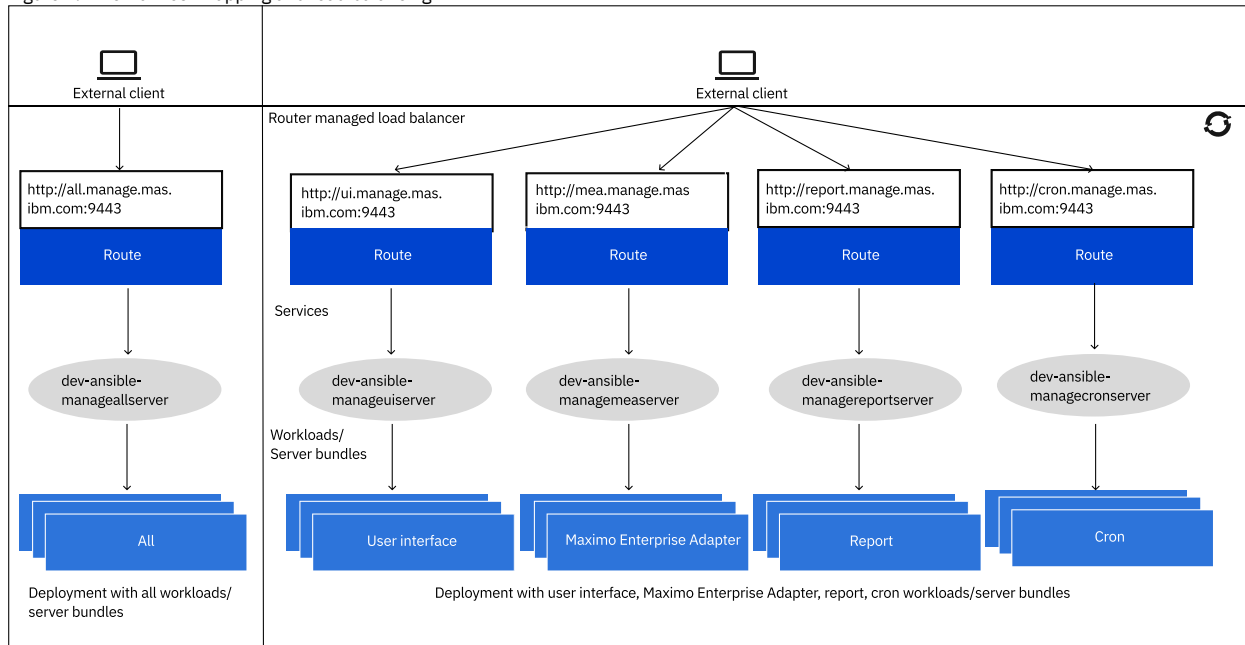

A server bundle or workload is a logical abstraction for a deployed group of point of deployment (pods) in a cluster. These server bundles do the same function and provide an access point as a service. These server bundles can be accessed as a service internally and through a route externally. A route is a way to display a service by giving it an externally reachable hostname. By using a route or service, Red Hat OpenShift balances the load to the pods that are included in a server bundle. Each server bundle defines replica size, subdomain, and other properties.

- For each server bundle, a service is created with name that is appended by **-<serverbundlename>**.

- A route is created with name that is appended by **-<serverbundlename>**.
- A default route is created to point to the service that ends with **-<serverbundlename>**.
 - Maximo Application Suite uses the default route to establish the default URL link to Maximo Manage.
- You can add or update server bundle properties. For more information, see [Adding server bundle properties](#).

The following diagram illustrates how Red Hat OpenShift Container Platform routers provide external hostname mapping and balancing of load for service end points over protocols. The router uses the hostname to determine where to send the external client request.

Figure 1. External host mapping and load balancing

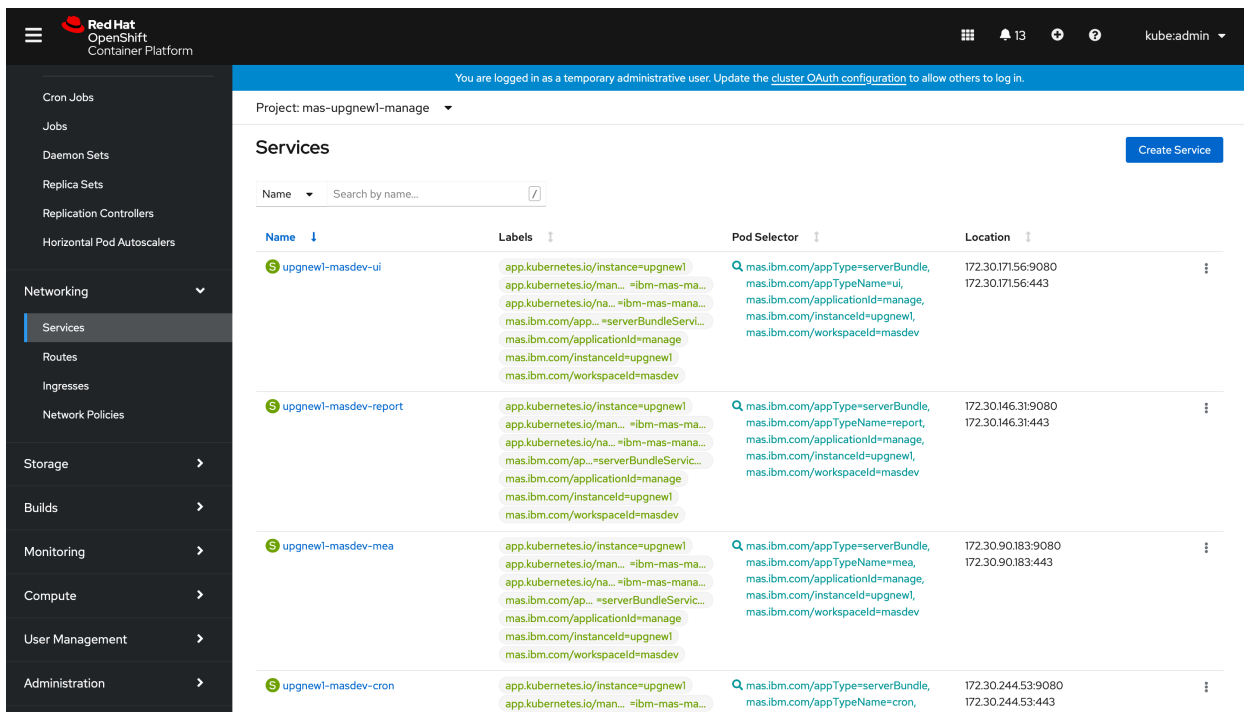

- The Maximo Manage application can be deployed with different server bundles or workloads for the processing and isolation needs.
- The deployment can be All bundle server type or a combination of the four bundle server types: UI, cron, report, and Maximo Enterprise Adapter.
 - If All bundle server type is not deployed, and you used a combination of the four bundle server types, you must use the UI bundle server type.
- Each server bundle can have its own server properties.

The following table shows the five different server bundle types.

Bundle server type	Description
All	Contains all the code.
UI	Contains UI code and supporting code. It is the interface for accessing Maximo Manage application.
Maximo Enterprise Adapter	Displays the enterprise web services API.
report	Contains the code that is needed to enable BIRT Report Only Server (BROS). It is used to separate the work load that is related to the execution of reports that are submitted in Maximo Manage.
cron	This bundle contains the code that is needed to enable BIRT Report Only Server (BROS). Used to separate out the work load that is related to execution of reports that are submitted from the Maximo Manage UI.

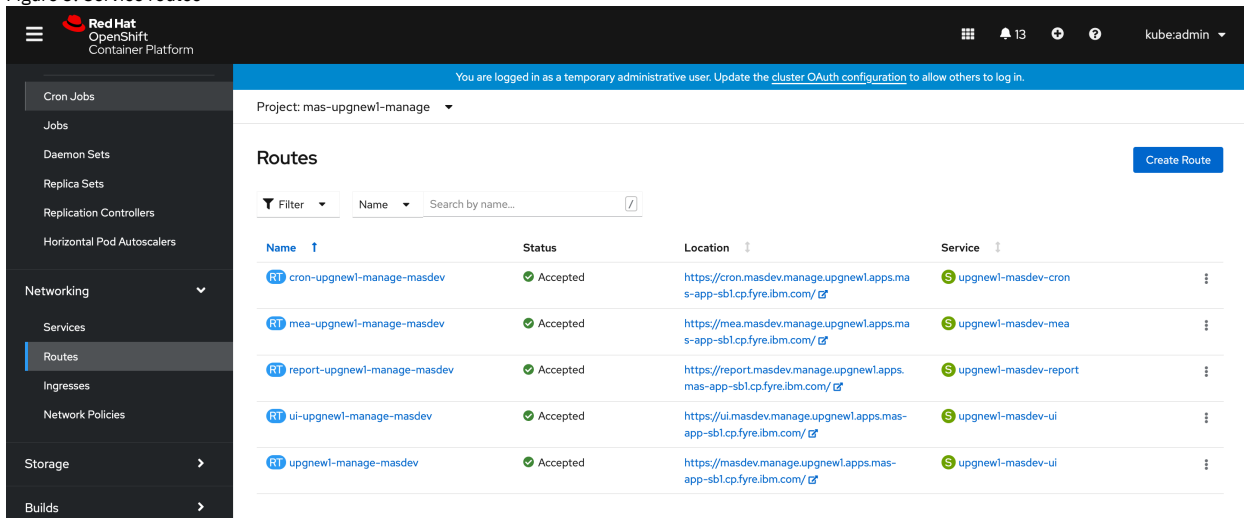

Services

Figure 2. Services

Routes

Figure 3. Service routes

Server bundle properties

The server bundles have the following properties:

- The server bundle properties can be set in Maximo Application Suite UI or in the CR.
- A configmap `<workspaceid>-<serverbundlename>-bundleproperty` is created for the server properties during deployment or operator reconciliation. It is mounted to `/config/manage/properties` on the pod. The `bundleLevelProperties` file on the pod must not be updated manually.
- Maximo Manage server process automatically detects the change and updates the Maximo Manage property cache.
- If the property value needs to be modified, update the CR directly or in Maximo Application Suite. The Maximo Manage Operator reconciles the changes. The Maximo Manage server process updates the Maximo Manage property cache with the updated value.

Liberty server XML

If you need to customize the Liberty server.xml file:

- The custom server XML can be set in Maximo Application Suite UI. For example, to create queues in JMS server.
 - If you create it in the CR directly, then you must create the secret manually. Set this secret to `additionalServerConfig.secretname` for the bundle server in the CR.
- On deployment, a secret is created for the custom server.XML file. It is mounted to `/config/manage/serverxml`. This location is included in Liberty server.xml file. The configuration is applied to the Liberty server.

Sample custom server.xml file:

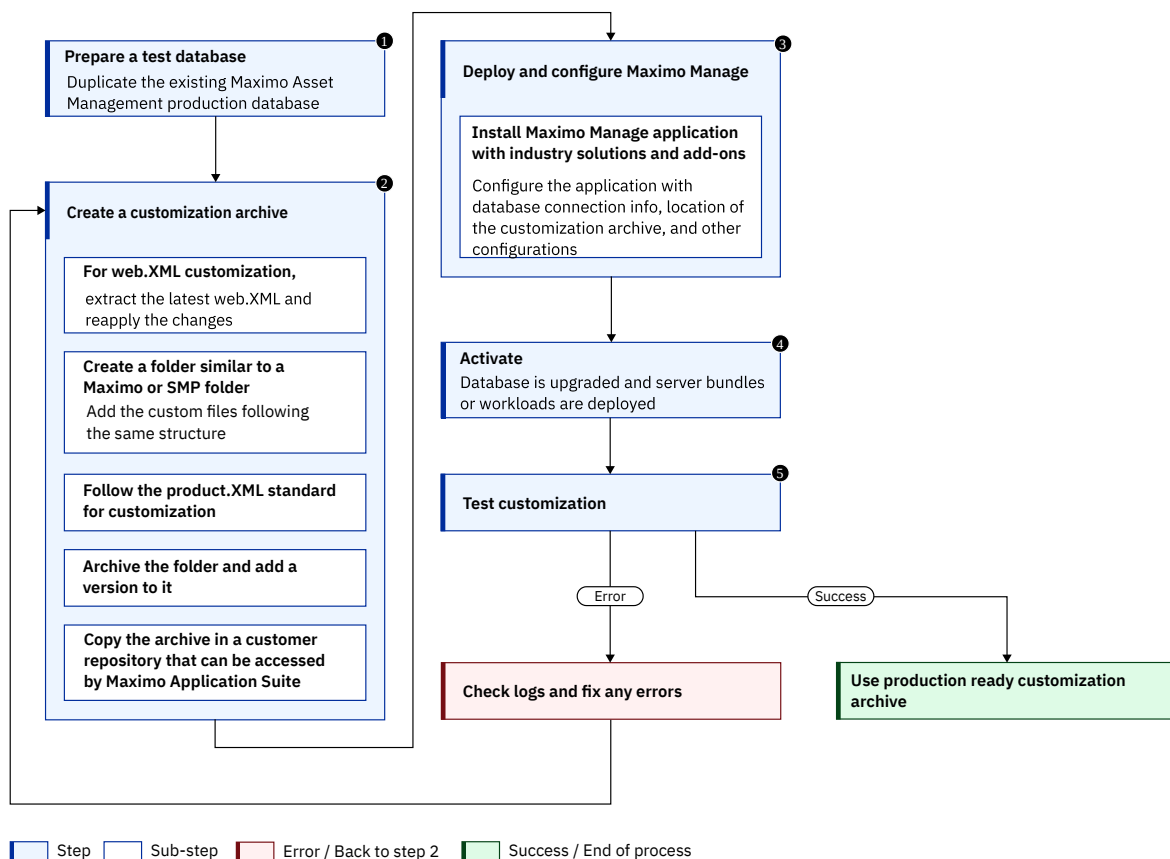

```
<?xml version="1.0" encoding="UTF-8"?>
<server description="new server">
  <featureManager>
    <feature>wmqJmsClient-2.0</feature>
    <feature>jmsMdb-3.2</feature>
  </featureManager>
  <logging traceSpecification="JMSApi=all:WAS.j2c=all"/>
  <variable name="wmqJmsClient.rar.location" value="/wmq/wmq.jmsra.rar"/>
  <jmsConnectionFactory jndiName="jms/maximo/int/cf/intcf" connectionManagerRef="MIFJMS">
    <properties.wmqJms
      transportType="CLIENT"
      hostName="mifjmsmanager-afd7.qm.us-south.mq.appdomain.cloud"
      port="31440"
      channel="CLOUD.APP.SVRCONN"
      applicationName="maxliberty"
      userName="{username}"
      password="{yourpassword}"
      queueManager="MIFJMSMANAGER"/>
  </jmsConnectionFactory>
  <connectionManager
    id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_upgrade_c_configuration_MIFJMS"
    maxPoolSize="20"/>
    <jmsQueue
      id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_upgrade_c_configuration_sqout"
      jndiName="jms/maximo/int/queues/sqout">
        <properties.wmqJms baseQueueName="sqout" baseQueueManagerName="MIFJMSMANAGER"/>
      </jmsQueue>
      <jmsQueue
        id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_upgrade_c_configuration_sqin"
        jndiName="jms/maximo/int/queues/sqin">
          <properties.wmqJms baseQueueName="sqin" baseQueueManagerName="MIFJMSMANAGER"/>
        </jmsQueue>
        <jmsQueue
          id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_upgrade_c_configuration_jms/maximo/int/queues/cqin"
          jndiName="jms/maximo/int/queues/cqin">
            <properties.wmqJms baseQueueName="cqin" baseQueueManagerName="MIFJMSMANAGER"/>
          </jmsQueue>
          <jmsQueue
            id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_upgrade_c_configuration_jms/maximo/int/queues/cqinerr"
            jndiName="jms/maximo/int/queues/cqinerr">
              <properties.wmqJms baseQueueName="cqinerr" baseQueueManagerName="MIFJMSMANAGER"/>
            </jmsQueue>
          </jmsQueue>
        </server>
```

Customizing IBM Maximo Manage

All customer-specific changes, such as Java™ classes, XML files, and database scripts, must be included in a customization archive. You create the customization archive in a location accessible to IBM® Maximo® Application Suite during deployment. The structure of the customization archive is the same as the Maximo Asset Management folder structure. Test the customization archive in a development or test environment before you apply it to the production environment.

About this task

The following diagram shows the customization process:

Procedure

1. Prepare the database.
Prepare a test database as a duplicate of the existing Maximo Asset Management production database.
2. Create a customization archive.
For more information, see [Creating customization archives](#) section. If your customization includes a web.xml file, such as customer servlet, filters, changes in the order of the servlet startup, context parameters, or session timeout:
 - a. Install Maximo Manage with industry solutions and add-ons without customization on an empty database.
 - b. Extract the web.xml file.
Use the **oc rsync** command to retrieve the web.xml file.
 - c. Apply your changes.
 - d. Copy the web.xml file to the customization archive in the appropriate directory.
3. Deploy the application.
Use Maximo Application Suite or an API to configure Maximo Manage, industry solutions and add-ons to point to the database to upgrade and other configurations. Specify the location of the customization archive. Deploy.
4. Activate the application.
Maximo Manage updates the database and deploys workloads to the liberty containers.
5. Test the application.
6. Optional: Using the admin image pod that contains maxinst, in the Red Hat® OpenShift® console, copy the entire build directory with the customization and compile. You can also pull the [Maximo Manage admin image](#) to get the code locally. You can use IDE to build the Maximo Manage project with customizations.

What to do next

After you fix any errors, create a customization archive again with the updated code. Deploy and activate the Maximo Manage application. After successful testing, use the customization archive in the production environment.

Creating customization archives

You can create a customization archive, which is a set of files that contain changes and customizations for the application.

Procedure

1. Follow the existing SMP or Maximo® folder structure to create a customization folder.
2. Copy class files (Java™ customization) in the appropriate directory and extracted with the existing Maximo binary files in the right package or module hierarchy.
The file might include the following information.
 - Mbo customization
 - Field validation
 - Maximo Integration Framework
 - Others like customer-specific code

What to do next

- Version your customization archive.
- Customization archive location is specified during Maximo Manage application configuration from IBM® Maximo Application Suite admin dashboard.
- Customization archive location must be accessible from Maximo Application Suite.
- Any database scripts can be added to customer directory and an a_customer.xml file must be used. For more information, see the [Customization archive guidelines](#). All those files need to be part of the customization archive. Update db will run after deployment to apply all customer scripts.
- The IBM Customization Detection tool allows you to detect customization on a client system for IBM Maximo Asset Management, Industry Solution, and Add-on products. For more information, see [IBM Customization Detection tool](#).

Deployment descriptors

All deployment descriptors such as web.xml, ejb-jar.xml, and webservices.xml files that are customized by users can be put into the customization archive and overlaid on the files that are supplied by IBM®.

- The following files need to be created:
 - For deployment of full Maximo® Asset Management in one deployment (Maximo -all)
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximouiweb\webmodule\WEB-INF\web.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximo-x\webmodule\WEB-INF\web.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximo-x\webmodule\WEB-INF\web-guest.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximo-x\webmodule\WEB-INF\web.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maxrestweb\webmodule\WEB-INF\web.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximo-x\webmodule\WEB-INF\web.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-all\mboweb\webmodule\WEB-INF\web.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-all\meaweb\webmodule\WEB-INF\web.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-all\mboejb\ejbmodule\META-INF\ejb-jar.xml
 - UI deployment
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-ui\webmodule\WEB-INF\web.xml
 - Maximo Enterprise Adapter
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-mea\meaweb\webmodule\WEB-INF\web.xml
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-mea\mboejb\ejbmodule\META-INF\ejb-jar.xml
 - Report deployment
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-report\webmodule\WEB-INF\web.xml
 - Cron deployment
 - deployment\was-liberty-default\config-deployment-descriptors\maximo-cron\webmodule\WEB-INF\web.xml
- IBM-specific file ibm-ejb-jar-bnd.xml is not used in Liberty deployment.

XSL customization

XSL customizations (that are part of the Maximo ear or war) that are part of customization archive and are copied to final images. Follow existing XSL customization documentation.

Using certificates

You can use route or TLS certificates, SSL certificates, external certificates.

Route or TLS certificates

Maximo® Application Suite uses cert-manager for automatic management and issuance of TLS certificates for application routes. During installation, you can provide a cluster issuer that is based on a trusted certificate authority (CA) for signing the certificates that are generated for your Maximo Application Suite domains.

By default, Maximo Application Suite provides a cluster issuer that generates Maximo Application Suite certificates that are signed by a self-signed CA. To use your own cluster issuer, include the following parameter when you run the Maximo Application Suite installer: `-c myClusterIssuerName`. For more information, see [System requirements](#).

Configuring Oracle Connector

You must configure Oracle Connector before and after the upgrade.

Configuring before upgrade

Procedure

1. Stop all transactions between Maximo and Oracle.
2. Process all transactions in the interface tables and integration queues.
3. Resolve any Oracle integration open or error transaction in Maximo .
4. Disable the External System OA12.
5. Backup PL/SQL user exits and any customization on the EBS side.
6. Stop the MX Maximo server.
7. Backup Maximo 7.6.1.2 database.

Configuring after upgrade

Procedure

1. Define the message provider and queues, which are Kafka or JMS.
2. Assign queues to External System OA12.
3. Configure Kafka crontask. If you are using Kafka, update the settings according to [MIF guide](#).
4. If you are using Kafka, disable **JMSQSEQCONSUMER** crontask .
5. Re-create interface tables and PL/SQL objects in Oracle E-Business Suite12.x MAXORA schema.
6. Reapply customizations on PL/SQL side.
7. Enable the external system.

Configuring SAP Connector

You must configure SAP Connector before and after the upgrade.

Configuring before upgrade

Procedure

1. Stop all transactions between Maximo and SAP.
2. Process all transactions in the queues.
3. Resolve any SAP integration errors in Maximo .
4. Disable the External System SAP2005.
5. Stop the MX Maximo server.
6. Backup Maximo 7.6.1.2 database.

Configuring after upgrade

Procedure

1. Define the message provider and queues as either Kafka or JMS.
2. Assign queues to the external system SAP2005.
3. Configure Kafka crontask. If you are using Kafka, update the settings according to [MIF guide](#).
4. If you are using Kafka, disable **MSQSEQCONSUMER** crontask.
5. Generate **APIKey** for integration user **sapadmin**.
6. Change connection parameters in SAP PO or Maximo HTTP channel.
7. Enable the external system SAP2005.

Viewing Maximo Manage Logs

View the IBM® Maximo® Manage logs for Server, Maxinst and Update database, User sync, Workspace operator, and Build logs from the Red Hat® OpenShift® console.

Procedure

1. Go to your Red Hat OpenShift console.
2. Go to Workload > Pods menu.
3. Select log type.
 - Maximo Manage Server logs.
Server logs are written to the standard output.
 - Select your Maximo Manage project.
 - Check your Liberty server pods.

- Select the server pod to view log.
 - cron
 - mea
 - report
 - ui
 - all
- Click Liberty server pod.
- Select the Logs tab to view the log for the selected server.
 You can also configure IBM Maximo Application Suite (MAS) supported log configuration by Red Hat OpenShift. For example, Elasticsearch, Fluentd, and Kibana dashboard (EFK) can be configured for logging. The logs automatically flow to the EFK stack.

Aggregated Maximo Manage logs can be retrieved from the EFK stack.

<https://docs.openshift.com/container-platform/4.6/logging/cluster-logging-deploying.html>

You can also push the logs to any S3 compatible object storage by following these steps.

- Set up S3 credentials.
 - Create the following four environment variables in your Maximo Manage deployment:
 - LOG_BUCKETNAME
 - LOG_S3ACCESSKEY
 - LOG_S3ENDPOINTURL
 For example, <https://s3.us.cloud.object.storage.appdomain.cloud>
 - LOG_S3SECRETKEY
 - Create a log request (POST) by using any HTTP Rest Client. For example, the Postman tool.
 Request URL: <http://manageserver:7001/maximo/oslc/service/logging?action=wsmethd:submitUploadRequest>
 - Replace the Maximo Manage server in the URL to your Maximo Manage server host or IP address.
 - A record is created in the Maximo Manage table (LOGREQUEST)
 - Use the S3 browser to view the logs by using your S3 credentials.
 - Each Maximo Manage server handles the latest log request. It compresses the log files in the liberty log directory and uploads it in Cloud Object Storage.
 - The logs can be downloaded from the Liberty server. It is saved in the directory that is set for the system property "server.output.dir".
 - For example, `/opt/was/libert/wip/usr/servers/default/`
 - A record is created in the Maximo Manage table (LOGREQUESTDET)
 - The Maximo Manage table records will be removed by crontask (LOGREQUESTCLEANUP) after the logs are posted to the object storage. The crontask needs to be activated manually. It runs one time every day.
- **Maxinst and update database logs**
 The maxinst and update database logs can be retrieved from the maxinst pod.
 - Select the maxinst pod for your project.
 - Go to the Terminal tab and `cd /log (/opt/IBM/SMP/maximo/tools/log/)` to view logs.
 You can also view the log from the Logs tab.
- **User sync logs**
 The User sync logs can be accessed from the user sync pod.
 - Click the user sync pod and select Logs tab.
- **Maximo Manage Workspace operator logs**
 The Maximo Manage Workspace operator log can be accessed from the Maximo Manage workspace pod.
 - In the Maximo Manage Workspace pod, select Logs tab.
- **Build logs**
 The Build log can be accessed from the Maximo Manage build pods.
 - In the Maximo Manage build pod, select Logs tab.

What to do next

You can install OpenShift Logging by deploying the OpenShift Elasticsearch and Red Hat OpenShift Logging Operators. For more information, see [Installing OpenShift Logging](#).

Monitoring

You can enable monitoring for applications in Red Hat® OpenShift® Container Platform.

- [Configuring monitoring and metrics](#)
 Configure monitoring and metrics using Red Hat OpenShift Container Platform.
- [Creating config map](#)
 Create a config map by using an YAML.
- [Creating service](#)
 Create a service.

- [Querying metrics](#)
You can search for metrics in Maximo Manage.
- [Setting up Grafana](#)
Follow the steps to set up Grafana.

IBM Maximo Manage tool

When Maximo® Manage is deployed, some tools become available.

- An admin pod gets deployed when Maximo Manage is deployed.
- The command `"kubectl exec"` can be run on the admin pod container or directly use the container console to run the tools such as integrity checker.
- Tools logged to stdout are forwarded to Elasticsearch, Fluentd, and Kibana (EFK) stack, if configured.

Useful information

Additional information regarding lic licensing model, docker image, how to add third-party JAR files, and debugging.

- [Maximo Application Suite licensing model](#)
The Maximo Application Suite licensing model has a user-centric view.
- [Manage Admin Docker image](#)
Information on how to install docker and get the Maximo Manage admin docker image.
- [Adding third-party JAR files](#)
You can add third-party JAR files to the Manage lib folder in the Customization Archive.
- [Debugging Maximo Manage application](#)
You can debug the Maximo Manage application.

Maximo Application Suite licensing model

The Maximo® Application Suite licensing model has a user-centric view.

User centric view

Table 1. Application concurrent user

Application concurrent user	Limited (5)	Base (10)	Premium (15)	Notes
Manage Limited	Yes	Yes	Yes	Any three Manage modules other than Planning and Scheduling, Administration, Integration, System Config, Security, and the ability to view reports, change status, and update work orders in any module. Includes Linear, Calibration, and Spatial. Spatial requires installation.
Manage Industry Solution or Add-on Limited	Yes	No	Yes	Includes Manage Industry Solutions and Add-ons. If installed and more than three Industry Solutions and Add-on modules selected, it must be a Premium user, cannot be a Base user. The three modules selected cannot be Planning and Scheduling, Administration, Integration, System Config, Security.
Mobile	Yes	Yes	Yes	Maximo Mobile, Maximo Anywhere, and third-party module. The use of requires an installation.
Maximo Monitor	Yes	Yes	Yes	
Manage	No	Yes	Yes	Includes , Linear, Calibration and Spatial. Spatial requires installation.
Maximo Health	No	Yes	Yes	
Safety	No	Yes	Yes	Base users required for Supervisor or Team Lead or Safety Officer.
Industry Solutions	No	No	Yes	Utilities, Nuclear, Aviation, Oil & Gas, Transportation, Civil Infrastructure, APM for EU. CI and APM for EU require installation.
Add-ons	No	No	Yes	Maximo Asset Configuration Manager, Service Provider, Health, Safety and Environment
Maximo Predict	No	No	Yes	
Visual Inspection	No	No	Yes	Install points are required.

Table 2. Administrative concurrent users

Administrative concurrent users	Limited (5)	Base (10)	Premium (15)	Notes
Application	No	Yes	Yes	Application administrators administrate one or more applications, adds and assigns users to these applications, and uses the application-specific user interfaces to manage further user privileges.

Administrative concurrent users	Limited (5)	Base (10)	Premium (15)	Notes
Suite	No	No	Yes	Suite administrator manages overarching system configuration settings from the Suite Administrator pane.

- Administrators are defined as users in the system.
- The app points are reserved to ensure that Administrators always have access.
- Base Administrators can set up users regardless of the application's tier level. For example, A Manage administrator is tagged as an Application Admin User and withdraws 10 app points. This administrator can set up users for Maximo Predict, which is in the Premium group.

Manage Admin Docker image

Information on how to install docker and get the Maximo® Manage admin docker image.

- [Installing Docker](#)
 - [Getting the Manage admin docker image](#)
- Use the following steps to retrieve the IBM® Maximo Manage admin image.

Installing Docker

Procedure

Use the following steps to install Docker.

1. Install Docker from <https://docs.docker.com>.
2. Make sure [docker daemon](#) is running.

Getting the Manage admin docker image

Use the following steps to retrieve the IBM® Maximo® Manage admin image.

Procedure

1. Go to oc login.

```
$ oc login --token=sha256-yLcd9N_ih1UX7tGcq9REywmoliEGvK4R-rtDu_XXXXX --server=https://api.mas-app-sb123.cp.fyre.ibm.com:6443
```

2. Expose the internal registry to external using Route.

```
$ oc patch configs.imageregistry.operator.openshift.io/cluster --patch '{"spec":{"defaultRoute":true}}' --type=merge
```

3. Verify the internal registry route hostname.

```
$ oc get route -n openshift-image-registry
```

NAME	HOST/PORT	PATH	SERVICES	PORT
TERMINATION	WILDCARD			
default-route	default-route-openshift-image-registry.apps.mas-app-sb1.cp.fyre.ibm.com		image-registry	
registry all	reencrypt	None		
image-registry	image-registry.openshift-image-registry.svc		image-registry	
registry 5000-tcp	reencrypt	None		

4. Login using the default registry route hostname.

```
docker login -u <user_name> -p $(oc whoami -t) default-route-openshift-image-registry.apps.<clustername>.<basedomain>
```

```
$ sudo docker login -u kubeadmin -p $(oc whoami -t) https://default-route-openshift-image-registry.apps.mas-app-sb123.cp.fyre.ibm.com
```

5. If you get "x509: certificate signed by unknown authority" error message, then you should place the Router trusted CA on your host.
6. Extract the CA from Red Hat® OpenShift® Container Platform cluster, where the registry is configured.

```
$ oc extract secret/router-ca --keys=tls.crt -n openshift-ingress-operator
```

7. Perform on the node, where the image pulling throws x509 error.

```
$ sudo cp tls.crt /usr/local/share/ca-certificates/.
$ sudo update-ca-certificates
```

8. Make sure that the docker daemon is running.

```
$ ps -aux | grep dockerd
```

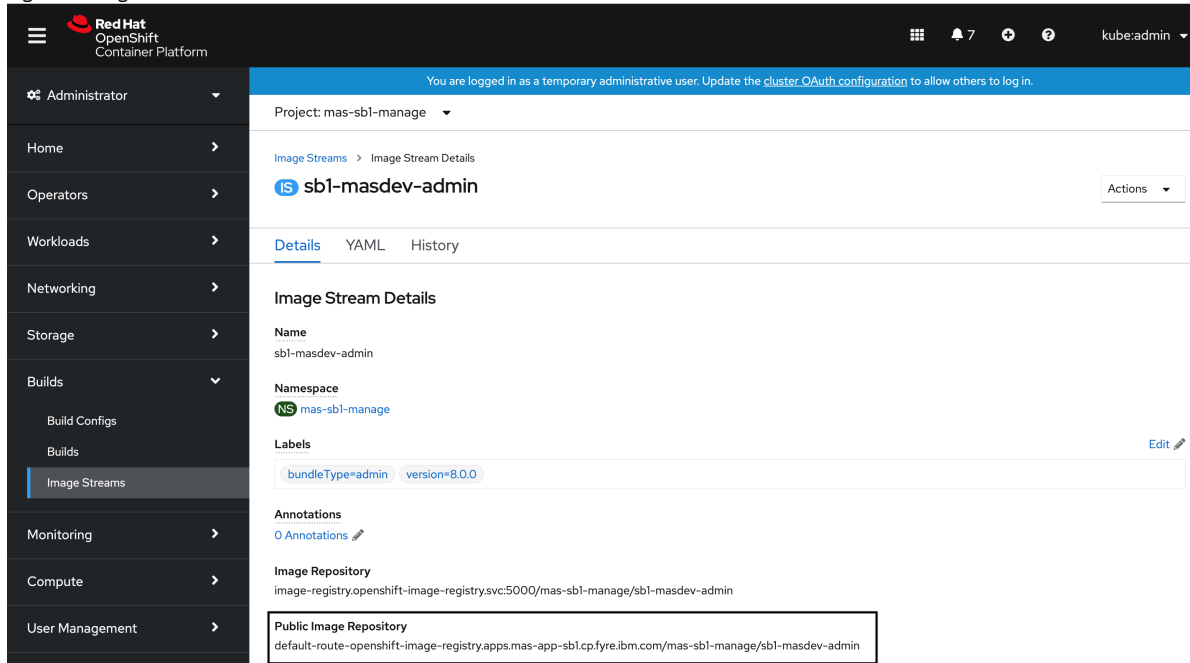

```
root      203   0.0   0.0  10508  4232 pts/0    T   01:28   0:00 sudo dockerd
```

```
root    2397    0.0    0.0    11016    4612 pts/1    S    16:49    0:00 sudo dockerd
root    2398    0.0    0.4    1538160    111260 pts/1    Sl   16:49    0:07 dockerd
sarika  3999    0.0    0.0    8160     724 pts/1    S+   23:26    0:00 grep --color=auto dockerd
```

9. Pull admin docker latest image: `docker pull <Public image`

Repository> From the Manage project in OpenShift console, get the **Public Image Repository** value from the **<instanceid>-<workspaceid>-admin** in ImageStreams under Builds.

Figure 1. Image stream

```
$ sudo docker pull `default-route-openshift-image-registry.apps.mas-app-sb1.cp.fyre.ibm.com/mas-sb1-manage/sb1-masdev-admin`
```

10. Get Image ID: `docker images`

```
$ sudo docker images
```

REPOSITORY	IMAGE ID	CREATED	SIZE	TAG
default-route-openshift-image-registry.apps.mas-app-sb1.cp.fyre.ibm.com/mas-sb1-manage/sb1-masdev-admin	c0e655398e6b	3 weeks ago	7.87GB	latest

11. Run the docker pulled admin image `docker run -d <image id>`.

```
$ sudo docker run -d c0e655398e6b
1f2dfad8d3c813792798dc1f220bf27b7935f604c4817f47346a1f96e2336a92
time="2021-06-26T16:54:46.067182200-04:00" level=info msg="starting signal loop" namespace=moby
path=/run/docker/containerd/daemon/io.containerd.runtime.v2.task/moby/1f2dfad8d3c813792798dc1f220bf27b7935f604c4817f47346a1f96e2336a92 pid=2832
```

12. Get the container ID for the pulled admin image. `docker ps -a`

```
$ sudo docker images
```

REPOSITORY	IMAGE ID	CREATED	SIZE	TAG
default-route-openshift-image-registry.apps.mas-app-sb1.cp.fyre.ibm.com/mas-sb1-manage/sb1-masdev-admin	c0e655398e6b	3 weeks ago	7.87GB	latest

13. Copy the Manage code locally.

```
$ sudo docker cp d3544a11901e:/opt/IBM/SMP/maximo/latest.zip /mnt/c/temp/.
```

14. Optional: Run tools such as integrity checker.

- a. `docker exec -it <container id> /bin/bash`
- b. Update the Maximo properties in `/opt/IBM/SMP/maxio/applications/maximo/propertiesfolder`.
- c. Execute `/opt/IBM/SMP/maxio/applications/maximo/validate_integ.sh`.

Adding third-party JAR files

You can add third-party JAR files to the Manage lib folder in the Customization Archive.

About this task

Use the following steps to add a third-party JAR file name to the Manifest file, if the deployment has an **all** or **mea** bundle server type.

Procedure

1. Follow the [Maximo® Manage admin Docker Image](#) page to pull the Manage code or go to the admin pod, which is the name of the pod that contains **maxinst**, terminal and get the file.
2. Go to `/opt/IBM/SMP/maximo/deployment/was-liberty-default` deployment folder.
 - a. Get the `maximo-all.xml` file if the deployment is **all** bundle server type. In `maximo-all.xml`, go to the `maximo.businessobjectclasspath` property name and add the JAR file name in the path. When deployed it will update the classpath in the Manifest file.
 - b. Get the `buildmaximomea-ear.xml` file if the deployment has a **mea** bundle server type and update the classpath.
3. Copy the updated file in the Customization Archive folder in the same path and archive or compress the folder.
The file path for the `maximo-all.xml` file is `<localdrive>\custasset_bin\deployment\was-liberty-default`.
4. Deploy the Customization Archive and activate the changes.
For more information, see [Customizing the application](#).

Debugging Maximo Manage application

You can debug the Maximo® Manage application.

About this task

You must follow some steps to debug the Maximo Manage application.

Procedure

1. Create a server deployment.
 - a. Create a deployment for "All" or "UI" server bundle type, replace the **spec** section with the existing "All" or "UI" server deployment.
Update the name. For example, `{instanceid}-{workspaceid}-alldebug`.
 - b. Add the port "7777" in the "Ports" section.

```
` - containerPort: 7777
  protocol: TCP`
```

```
ports:
- containerPort: 9081
  protocol: TCP
- containerPort: 9444
  protocol: TCP
- containerPort: 7777
  protocol: TCP
```

2. Update **cmd args** for the Maximo Manage server.
 - a. Replace `/tmp/startup.sh;` with `/tmp/genJDBCTruststore.sh;`
`/opt/ibm/wlp/bin/server debug defaultServer;`

```
image: >-
  image-registry.openshift-image-registry.svc:5000/mas-sb1-manage/sb1-masdev-
  all@sha256:6e6891b03d9237e64b6a3c4c41fd8dc331da74cf4cb2393a3ba70588599c600f
args:
- >-
  echo generateKeyStore...; openssl pkcs12 -export -in
  /etc/ssl/certs/internal-manage-tls/tls.crt -inkey
  /etc/ssl/certs/internal-manage-tls/tls.key -out ${java_keystore}
  -password pass:${java_keystore_password};
  /tmp/genJDBCTruststore.sh; /opt/ibm/wlp/bin/server debug
  defaultServer;
```

3. Wait for the pod to start.
4. On your local system, open PowerShell.
5. Install Red Hat® OpenShift® Container Platform interface, [OC CLI](#).
6. Log in to cluster with the OC login and switch to the correct project with the `oc project` command.
7. Run `kubectl port-forward <podname>7777:7777`.

```
kubectl port-forward sb1-masdev-alldebug-57d79d4dfc-q82vn 7777:7777
```

```
Forwarding from `127.0.0.1:7777 -> 7777`
Forwarding from `[::1]:7777 -> 7777`
```

8. Optional: You can obtain kubectl in the [Install Tools](#) page.
9. Create a Debug Configuration or Remote Java Project with **localhost** and port **7777** in your IDE or Eclipse. Start it.
 - a. Set the project with the Manage code. Use the **manageadmin** image to get the classes and libraries of the Manage code.
The pod's logs now show the server, which is starting. You can see the "Handling Connection in the PowerShell window.

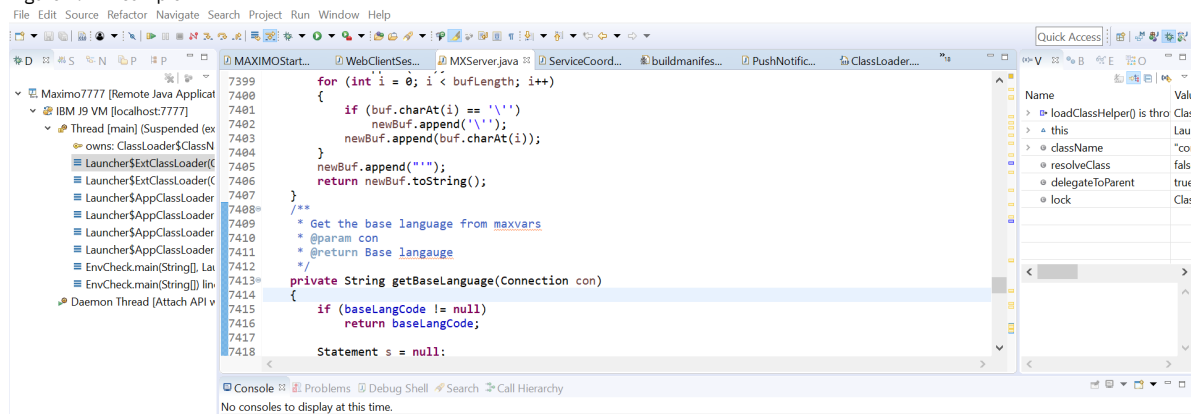

```
kubect1 port-forward sb1-masdev-alldebug-57d79d4dfc-q82vn 7777:7777
```

```
Forwarding from `127.0.0.1:7777 -> 7777`  
Forwarding from `[::1]:7777 -> 7777`  
Handling connection for 7777
```

10. Create a service and route for new deployment.

11. If you are creating a new deployment, use the new route location link to go to the Maximo Manage application. Append **/maximoto** the link.

Figure 1. IDE sample

Maximo Manage facts

- The custom resource for the Maximo® Manage workspace provides properties for activating the application. For information about the custom resource, see [Properties for workspace deployment](#).
- One default IBM® Maximo Application Suite skin is available in Maximo Manage.
- The following items are not displayed in Maximo Manage:
 - `mxe.webclient.skin`. It is set to a Maximo Application Suite skin.
 - `mxe.webclient.dynamicFontSize.iot18`. It is set to 0, “false”.
 - `mxe.webclient.verticalLabels`. It is set to 1, “vertical”.
 - “Side navigation menu” option is user’s “Default information” dialog . It is set to “Display”.
- If the electronic signature feature is used, some changes are made due to the new authentication protocol. Refer to product documentation for the updated electronic signature functions.

Connecting to Red Hat OpenShift cluster from Windows

You can connect to Red Hat® OpenShift® cluster from Windows .

Installing Linux command shell for Windows

Procedure

Install WSL.

<https://docs.microsoft.com/en-us/windows/wsl/install-win10#manual-installation-steps>

Installing Red Hat OpenShift CLI or OC

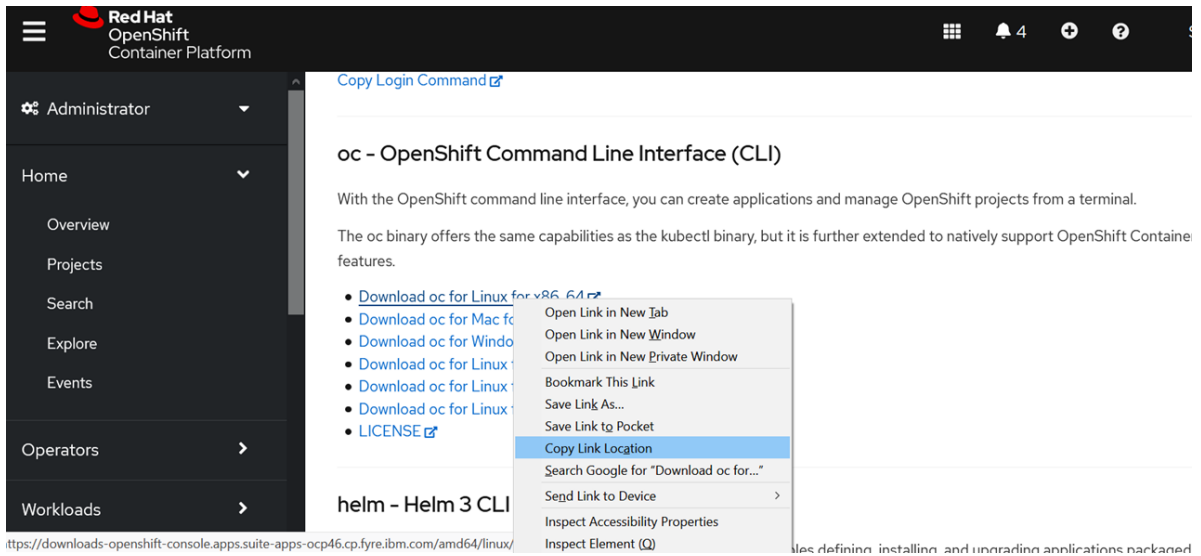

About this task

You can use the OpenShift command-line interface (CLI), and the `oc` command, to create applications and manage OpenShift Container Platform projects from a terminal. For more information, see [Getting started with the OpenShift CLI](#).

Procedure

1. From Red Hat OpenShift console, which is the Infrastructure Provider, go to Command Line Tools.
2. Copy the oc link location.

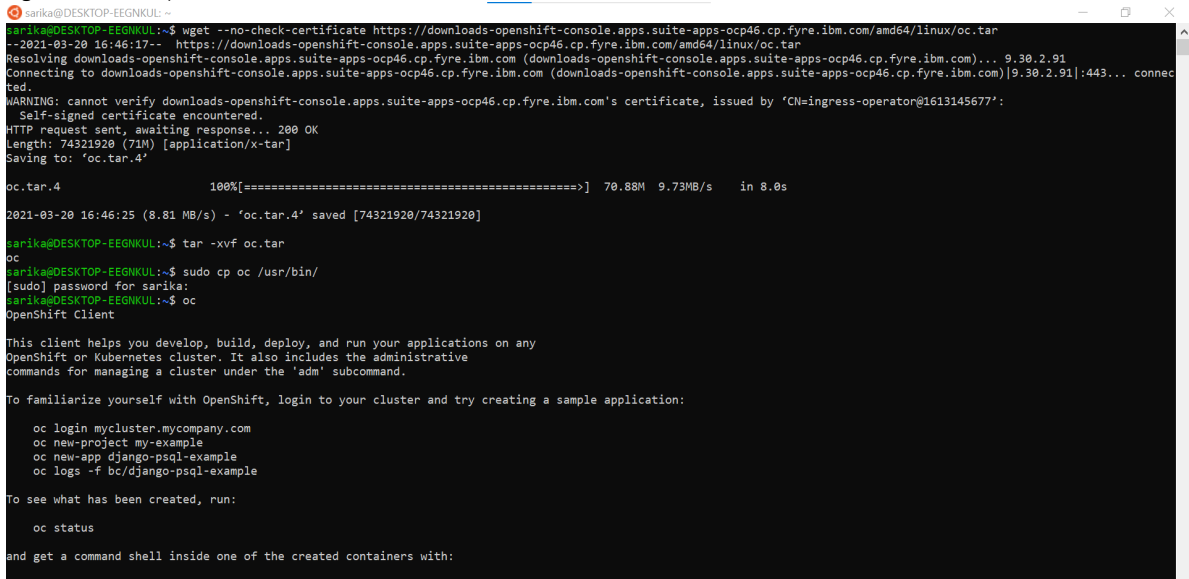

Figure 1. OC link

3. Open your Linux® command shell and install OC tool.

```
wget --no-check-certificate %link location from the previous step%
tar -xvf oc.tar
sudo cp oc /usr/bin/
oc --help
```

Figure 2. Red Hat OpenShift cmd

4. Get your token from Red Hat OpenShift console.
 - a. Use oc login command to login to your server.

Figure 3. OC login

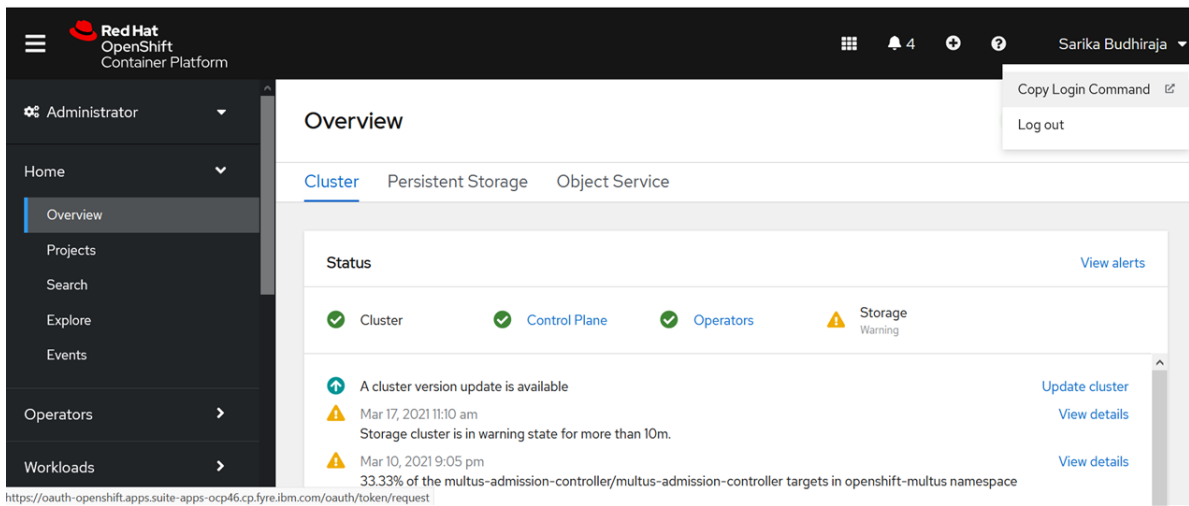

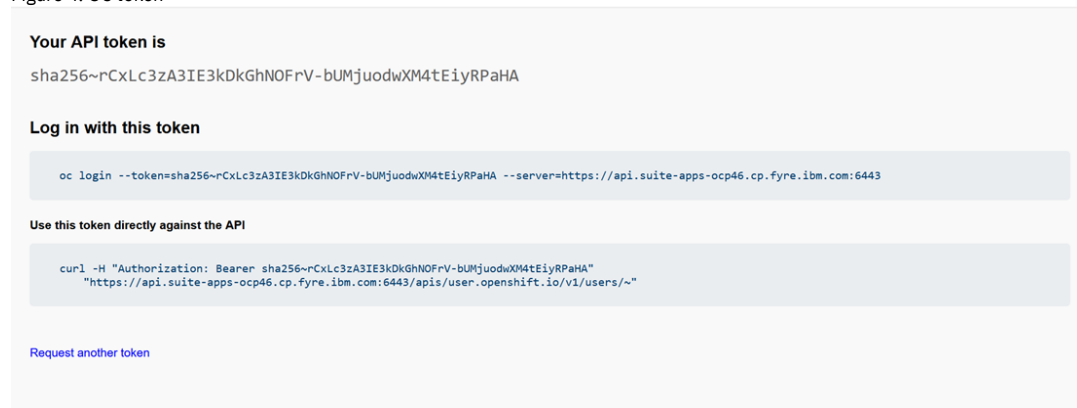

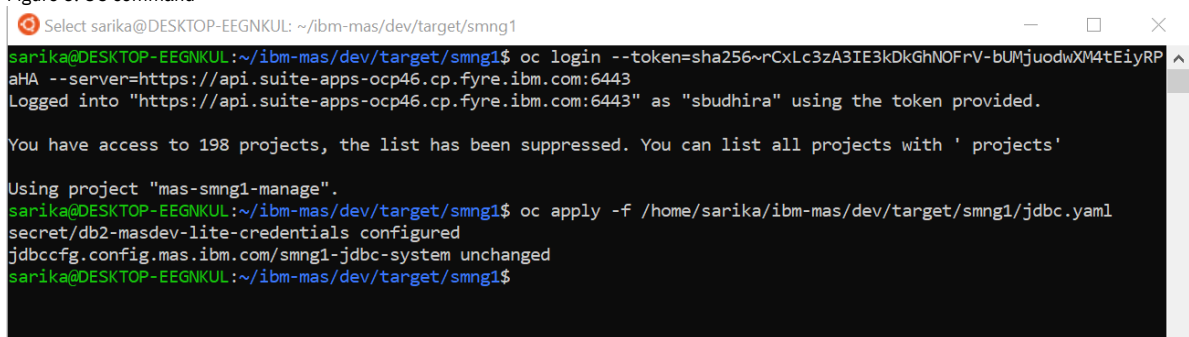

Figure 4. OC token

5. Run your Red Hat OpenShift commands from **oc – help** . It lists all the commands.

Figure 5. OC command

Useful links

Administering the product

After installation, you can configure the system and the database, and schedule backups to ensure that your database is working at optimum performance levels. You can then perform functions such as setting up organizations and specifying chart of accounts and currencies.

- **[Administrative tasks for IBM Maximo Application Suite](#)**
Maximo® Manage provides APIs and administrative features for administrators to get information or complete tasks that are related to files or processes in Maximo Application Suite.
- **[Configuring databases](#)**
When your business needs change, you can create objects to extend the scope of your database before you create additional applications. As configuration changes are based on business rational, you must understand the structure of your database and the business requirements before you begin creating objects.
- **[Migration Manager](#)**
Use Migration Manager to migrate configuration content from one product environment to another.
- **[Managing communication templates](#)**
You use communication templates to standardize frequently used email communications, which are also known as notifications. There are several ways you can use communication templates, such as with the workflow or escalation process. You can also create and send email communications from the ticket applications by using standardized information from communication templates.
- **[Managing escalations](#)**
You use escalations to ensure that critical tasks, such as those defined in service level agreements, are completed on time. You can also use escalations for events that notify you before contracts expire, or to change the status or owner of a record. You can use escalations with any application.
- **[Enabling email updates for objects and workflow assignments](#)**
With email interaction, users without access to a desktop user interface can change objects and workflow assignments. A worker assigned to an object or workflow assignment receives an email that describes the object or workflow assignment. The email recipient replies to the email to change the status of the object, accept or reject the workflow assignment, or update the attributes of the record.
- **[Managing cron tasks](#)**
Cron tasks are behind-the-scene jobs that run automatically and on a fixed schedule. Predefined cron tasks support scheduling activities such as generating preventive maintenance work orders and reordering inventory items on schedules. Predefined cron tasks are provided, and you can also create your own cron tasks.
- **[Managing domains](#)**
To help ensure consistent and valid data input, some fields in the product are associated with domains. Domains enable users to select appropriate values. Administrators can add values to existing domains or add domains.
- **[Linear assets management](#)**
A linear asset is an asset that is defined and maintained using a linear referencing method. Roads, pipelines, and railroad tracks are examples of linear assets. Using measurements along the linear asset, you can locate maintenance activities, identify where characteristics change, and plan monitoring and metering.
- **[Planning and scheduling work](#)**
You can plan and schedule upcoming work in a graphical view.
- **[Configuring default settings in the graphical view](#)**
You can specify the work and resources that appear in the data table of the Gantt view. The settings specified in the Configure Gantt Properties: Default Settings window apply to all schedules or work lists.
- **[Managing calibration assets and standards](#)**
You can manage your calibration assets and the standards that are used to calibrate them.
- **[Administering and configuring attached documents](#)**
As an administrator, you can maintain attached documents for your applications in persistent storage or in cloud object storage.
- **[Enabling edit mode](#)**
You can enable edit mode for records, such as work orders and tickets, that are used frequently by multiple users. Edit mode reduces errors that occur when two users edit a record in the same application at the same time.
- **[Log management](#)**
You can create and manage log files that contain informational, warning, or error messages about various application activities. You also can view log data about for the Maximo Manage server bundles and for processes that are handled by the administrative server.
- **[Managing bulletin boards](#)**
You use bulletin boards to post messages about critical problems and incidents, and to broadcast information throughout an organization. You can also view communication logs from service desk agents and their users, and communications that are generated by workflow processes and escalations.
- **[Working with sets](#)**
You use sets to create item sets and company sets that are shared across multiple organizations.
- **[Managing organizations](#)**
You can set up the organizations and sites that you use. You can set defaults for various options that are related to applications or groups of applications, such as Work Order Tracking, Inventory, Purchasing, Preventative Maintenance, Assets, and so on.
- **[Managing calendars](#)**
You can create and change calendars for organizations and for sites. You can create calendars to define working times as well as shifts. A calendar can also specify non-working time, such as weekends, holidays, and shutdowns.
- **[Managing classifications](#)**
You can use classifications to simplify the task of managing and of retrieving historical data from other applications. You can use classifications to align with external standards, such as vendor standards and industry standards. You can also use classifications to define the escalation path for incidents.
- **[Managing charts of accounts](#)**
You use the Chart of Accounts application to set up default general ledger accounts and resource codes for standard accounting functions.
- **[Working with cost management](#)**
You use the Cost Management application to track the financial resources required to complete the project. You can also link work orders from a project in the Cost Management application to the Work Order Tracking application.
- **[Managing currency codes](#)**
You can define and manage currencies that you can use in purchase orders, purchase requisitions, invoices, and so on.
- **[Setting system properties](#)**
You can set system properties that various components use to control how applications and other aspects of the product work.
- **[Automating routine tasks with automation scripts](#)**
You use automation scripts to implement object rules, attribute validations, workflow or escalation actions, and workflow and security condition logic for applications. Automation scripts can reduce the time that you spend on automating tasks because you do not need to recompile files or restart the server.
- **[Managing building information model data](#)**
Building Information Modeling (BIM) is a process that manages the design and build phases of building construction projects. This process is used as part of the hand-over of the construction building from the contractors to the owners. It is during this process that you can import the data into Maximo Manage so that you can manage your facility and view the data in 3D.

- [Monitoring maintenance budgets](#)
You can create budget records to monitor maintenance-related transactions in a financial period. Monitoring budget costs can help to ensure that projects or activities, such as work orders, are completed within an agreed budget and can improve estimation of the costs of future projects.
- [Removing personal information from records](#)
To remove personal information from people records, you initially specify the information that you want to remove and then delete the information. In some cases, you can also remove personal information that is stored as a transactional reference.
- [Customizing the application](#)
If you make changes to Maximo Manage, such as customized Java™ classes or database scripts, you can copy them to a customization archive. Then, you can apply the customizations to server bundles when you deploy Maximo Manage. This feature is useful for moving customizations from a test to a production environment and for upgrades.
- [Setting up a local Maximo Manage development environment](#)
You can set up a local Maximo Manage development environment to develop and test Maximo Manage Java code locally, without having to deploy development images on a remote Red Hat® OpenShift® cluster.
- [Configuring the Help menu](#)
You can add custom menu links to the Maximo Manage Help menu from Maximo Manage version 8.5 onwards.

Administrative tasks for IBM® Maximo Application Suite

Maximo® Manage provides APIs and administrative features for administrators to get information or complete tasks that are related to files or processes in Maximo Application Suite.

APIs can be used by administrators who do not have full administrative access to Maximo Application Suite to complete some of these tasks or to access certain logs.

Some tasks must be completed by accessing the administrative features in Maximo Application Suite.

- [APIs for administrative utilities](#)
You can run script commands for several key utilities by using API requests. The script commands can run the integrity checker utilities, start and stop the Maximo Manage pods, download log files or a list of log files, and upload logs to Simple Storage Service (S3) Cloud Object Storage.
- [Sending log output to S3 Cloud Object Storage](#)
You can send server bundle logs for Maximo Manage to Simple Storage Service (S3) Cloud Object Storage. You also can redirect logs from the administrative server to S3 Cloud Object Storage.
- [Adding trusted certificates](#)
To enable secure communication with an external server, administrators can add trusted certificates for external sites into the truststore in WebSphere® Application Server Liberty. The list of aliases and certificates represents a complete chain of trust for the host. The certificates are necessary only if the host presents a certificate that is signed by a certificate authority that is not already trusted by Maximo Application Suite.

APIs for administrative utilities

You can run script commands for several key utilities by using API requests. The script commands can run the integrity checker utilities, start and stop the Maximo® Manage pods, download log files or a list of log files, and upload logs to Simple Storage Service (S3) Cloud Object Storage.

Overview

Beginning with Maximo Manage 8.1, an API framework is provided for the APIs that can run script commands for certain utilities. The API framework is in the Maximo Manage administrative server that is in Maximo Application Suite. The Maximo Manage administrative server contains the `smf` folder that contains the `maximo/tools` folder for the scripts. The server also contains an instance of WebSphere® Application Server Liberty that hosts the APIs.

To work with the APIs, you use a browser or an API platform, such as Postman.

Authorization to APIs

Authorized users must have an API key and must belong to the security group that enables the signature options for the APIs for script commands. The object structure that specifies the necessary signature options is available to the default administrator group, such as MAXADMIN. The default administrator group is specified by the value of the `ADMINGROUP` varname in the MAXVARS table.

Administrators give users authorization to access the APIs for script commands by taking the following steps:

1. In the API keys application of Maximo Manage, create API keys for the users. This action registers the keys to the users. Copy the keys and provide them to your users. An API key is displayed only one time and cannot be retrieved later.
2. In the Security groups application, select the administrator group that can work with the APIs.
3. Select the Object Structures tab and grant access to the TOOLSAPI object structure.
4. For the TOOLSAPI object structure, grant access to the signature options that are associated with the APIs.

APIs for script commands

The following table describes the APIs for script commands and their actions, HTTP methods, the associated signature options, and whether the API call waits for an API response before it continues. The `toolslog` and `installexternalcert` API calls are synchronous and wait for an API response before they continue.

API	Action	HTTP method	Signature option	API request type
-----	--------	-------------	------------------	------------------

API	Action	HTTP method	Signature option	API request type
icheckerreport	Generate the integrity checker log.	POST	ICREPORT	Asynchronous
toolslog	Get a specified tools log or get a list of all tools logs.	GET	GETLOG	Synchronous
submitUploadLogRequest	Upload logs from Maximo Manage UI, Cron, Maximo Enterprise Adapter, or Report pods to S3 Cloud Object Storage.	POST	GETLOG	Asynchronous
icheckerrepair	Start integrity checker repair.	POST	ICREPAIR	Asynchronous
managestart	Start all Maximo Manage pods.	POST	MANAGESTART	Asynchronous
managestop	Stop all Maximo Manage pods.	POST	MANAGESTOP	Asynchronous
installexternalcert	Import an external certificate to a server bundle truststore.	POST	INSTALLEXTERNALCERT	Synchronous
validatedbformas	Validate the database for the migration to Maximo Manage.	POST	VALIDATEDBFORMAS	Synchronous

Note: Do not use the SetAdminMode command-line interface from Manage tools to set the admin mode. The SetAdminMode command-line interface is not available in Maximo Application Suite setup as of now. You must use the Maximo Application Suite user interface or use the REST APIs to manage the admin mode.

API request formats and actions

The following table lists the APIs for the commands and the format of the API request. In the header of any API request, supply the API key that is associated with the Manage user.

For the managestart and managestop APIs, an HTTP response code of 200 indicates a successful call.

Stop the Maximo Manage pods before you run the integrity checker utility.

Action	API request
Generate the integrity checker log.	POST <code>https://host:port/toolsapi/toolservice/icheckerreport</code>
Get an integrity checker log.	GET <code>https://host:port/toolsapi/toolservice/toolslog?logfile=name of report from icheckerreport request</code>
Get a list of all tools logs.	GET <code>https://host:port/toolsapi/toolservice/toolslog</code>
Run the integrity checker utility.	POST <code>https://host:port/toolsapi/toolservice/icheckerrepair</code>
Upload logs from Maximo Manage pods to S3 Cloud Object Storage.	POST <code>https://host:port/maximo/api/service/logging? action=wsmethod:submitUploadLogRequest</code>
Stop the Maximo Manage pods.	POST <code>http://host:port/toolsapi/toolservice/managestop</code>
Start the Maximo Manage pods.	POST <code>http://host:port/toolsapi/toolservice/managestart</code>
Import an external certificate to a server bundle truststore.	POST <code>http://host:port/toolsapi/toolservice/installexternalcert</code>
Validate the database for the migration to Maximo Manage.	POST <code>http://host:port/toolsapi/toolservice/validatedbformas</code>

Swagger interface for APIs

To use the Swagger interface for APIs, you can enter a URL into a browser.

To use the Swagger interface, complete the following steps:

1. Enter the URL for the Swagger interface into a browser, as shown in the following example:
`https://<host>:<port>/toolsapi/oas3/api.html`
2. After the Swagger interface opens, in the Manage tools api window, click Authorize.
3. In the Available authorizations window, enter the API key for the interface and click Authorize. The available APIs are displayed.
To exit the window without submitting an authorization, you can click Done.

Examples: Generate and fetch integrity checker log files

Supply the API key in the header of any API request.

To run the integrity checker tool in report mode and generate a log report, make the following request:

POST `https://host:port/toolsapi/toolservice/icheckerreport`

No request body is required. The integrity checker report process starts asynchronously. The JSON response contains the file names of the report, as shown in the following sample:

```
{
  "lisfile": "ichecker_report1622050100427.lis"
  "logfile": "ichecker_report1622050100427.log"
}
```

To fetch one of the logs, make the following request and supply one of the log file names as a parameter. The tools log process runs synchronously. The log file is returned as the response body of the request.

GET https://host:port/toolsapi/toolservice/toolslog?logfile=ichecker_report1622050100427.lis

The following related links about APIs provide detailed information about many of the APIs that work with this product and related products. The information might describe features that are not available to you.

Sending log output to S3 Cloud Object Storage

You can send server bundle logs for Maximo® Manage to Simple Storage Service (S3) Cloud Object Storage. You also can redirect logs from the administrative server to S3 Cloud Object Storage.

Before you begin

You must provision an S3 Cloud Object Storage location and note its S3 bucket name, endpoint URL, S3 access key properties, and the value of the S3 secret. If you intend to send server bundle logs to S3, you must have or obtain an API key in the Administrative Work Center.

About this task

The Maximo Manage application is deployed in one or more workloads, which are called server bundles. Server bundles include the ui, all, mea, reports, and cron types. Server bundle logs can be uploaded from your log location on WebSphere® Application Server Liberty to your S3 location.

The administrative server handles commands for the updatedb, maxinst, and the integrity checker utilities. Administrative server logs can be redirected to your S3 location.

Procedure

1. In your Red Hat® OpenShift® Container Platform deployment, go to Workloads > Secrets and add a key and value secret for your S3 configuration.
 - a. For the secret name, specify `s3secretkey`.
 - b. Set the key name to `accessSecretKey`.
 - c. Get the value from your S3 configuration.
2. In the Administration section, modify the custom resource (CR) for the ManageWorkspace custom resource definition (CRD) by taking the following steps:
 - a. Select the ManageWorkspace custom resource definition (CRD).
 - b. Select the Instance tab, then select the custom resource (CR).
 - c. On the YAML tab, add or modify the `spec.settings.deployment` section, and ensure that the custom resource (CR) for your instance contains the `loggingS3destination` property and the following child properties and values that match your S3 configuration:
 - `bucketName`: The S3 bucket name of the log destination.
 - `endpointURL`: The S3 endpoint URL. URLs for S3 can vary, depending on the S3 service that you use, such as a public, private, or regional URL service. Choose the URL that matches your deployment.
 - `accessKey`: The S3 access key.
 - `secretKey`: The name of the secret that contains the S3 access credential that you configured in Step 1.

After you modify the CR for your instance, the values are propagated to the CRs for the administrative server and the server bundle pods. If any property or value is not specified, logs are not sent to S3 Cloud Object Storage.

The following code sample for the CR shows the required properties and some fictitious values:

```
deployment:
  loggingS3Destination:
    accessKey: AQDNAWKXRTTY84LJ4G6YR
    bucketName: s3-bucket
    endpointURL: https://s3.us-area.amazonaws.com
    secretKey:
      secretName: s3secretkey
```

Logs that result from the running the maxinst, updatedb, or integrity checker utilities are now redirected to your S3 storage location. Each modified log is compressed and has a name that contains the source location and the timestamp of when the administrative command started to run.

3. To upload server bundle logs from your log location on WebSphere Application Server Liberty, make the following API request: **POST https://host:port/maximo/api/service/logging?action=wsmethod:submitUploadLogRequest**. Provide the API key in the header of the request. The body is empty.

The API request creates an entry in the LOGREQUEST table of Maximo Manage for each server bundle. A continuously running cron task uploads the compressed log files to your S3 storage location when the table is updated. The name of each file contains the source location and the timestamp of when the command started to run.

You can query the LOGREQUEST table to troubleshoot any issues. Clean up old table entries by configuring an instance of the LOGREQUESTCLEANUP cron task to run each day.

- [S3 buckets](#)

Maximo Manage 8.5 supports nested and other buckets for file backups.

Streaming WebSphere Application Server Liberty logs

You can stream WebSphere Application Server Liberty logs for server bundles by constructing a URL that you can use in a browser or other tool that you use for REST API calls.

Before you begin

Before you can stream logs, your administrator must grant you the STREAMLOG signature option for the Logging application. An API key is also required.

About this task

When you enter the URL in a browser, the browser displays the content of the WebSphere Application Server Liberty messages.log file for the server bundle that you specified.

Procedure

1. To stream the contents of the messages.log file for WebSphere Application Server Liberty, enter a URL in the following format in a browser or other API tool that you use for REST API calls:

```
https://<URL to the server bundle for which you want to stream logs>/maximo/api/service/logging?
action=wsmethod:streamLog&apikey=<your API key>
```

For example,

```
https://mas.manage.ui.mydomain.com/maximo/api/service/logging?
action=wsmethod:streamLog&apikey=n0sjvsv4m8495037r2baafag35r5qaoncps
```

2. Optional: To refresh the browser with the latest contents of the log, press Enter again.

S3 buckets

Maximo® Manage 8.5 supports nested and other buckets for file backups.

Maximo Manage supports two structures for backup and recovery folders:

- S3 bucket setup:

```
<S3bucketname>
    <S3bucketname>recovery
    <S3bucketname>backup
```

- Nested S3 bucket setup:

```
<S3bucketname>
    <S3bucketname>recovery
    <S3bucketname>backup
```

Adding trusted certificates

To enable secure communication with an external server, administrators can add trusted certificates for external sites into the truststore in WebSphere® Application Server Liberty. The list of aliases and certificates represents a complete chain of trust for the host. The certificates are necessary only if the host presents a certificate that is signed by a certificate authority that is not already trusted by Maximo® Application Suite.

Adding trusted certificates using API calls

To import trusted certificates, you can issue an API call to the maxinst server. This feature is useful if you do not have access to the IBM® Maximo Application Suite user interface.

About this task

You can use the following parameters for API calls:

Table 1. API call parameters

Parameter	Value
alias	The name to use for the imported certificate.
connect	The host and port in the format <i>hostname:port</i> .
servername	If the remote server where the certificate is located uses Server Name Indication (SNI), specify the name of the server.

Procedure

Select one of the following options for adding a trusted certificate using an API call:

- Provide a one-line string for the certificate in the body of the API.

Complete the following steps to convert the PEM-formatted certificate to a single string and add the certificate using an API call:

1. Download the certificate that you want to add.
2. Use the following command to convert the PEM-formatted string for the certificate to a single string:

```
awk 'NF {sub(/\r/, ""); printf "%s\n",$0;}' <single certificate pem file>
```

3. To add the single-string certificate, provide information for the API call that includes the alias parameter, as shown in the following example:

HTTP Method
POST

URL

```
https://maxinst.manage.myserver.com/toolsapi/toolservice/installexternalcert?alias=certainalias
```

Header

```
apikey=bfrudgf86mq874hm3hmo8859itfqsvr41rbpc8nq
```

Use the API key that is associated with the Manage user.

Request body

```
-----BEGIN CERTIFICATE-----\nMIIFljCCA36gAwIBAgINAgO8U1lrNMcy9QFQZjANBgkqhkiG9w0BAQsFADBMQsw\nnQYDVQQGEwJVUzEiMCAGA1UEChMZR29vZ2x1IFRydXN0IFN1cnZpY2VzIExmQzEU\nzMM\nDAwMDQyWhcNMjcwOT.....\n.....\ntdufThcV4q508DIrGKZTqPwJN1\n1IXNDw9bg1kWRxYtnCQ6yICmJhSFm/Y3m6xv+cXDB1Hz4n/FsRC6UfTd\n-----END\nCERTIFICATE-----
```

- Create an API call that downloads the certificate from a server.
To download a certificate from a server, provide information, as shown in the following example:

HTTP Method

POST

URL

```
https://maxinst.manage.myserver.com/toolsapi/toolservice/installexternalcert?  
alias=certalias&connect=google.com:443
```

Header

```
apikey=bfrudgf86mq874hm3hmo8859itfqsvr41rbpc8nq
```

Use the API key that is associated with the ManageMaximo Health user.

Adding trusted certificates in the user interface

You can add certificates through the user interface when you configure Maximo ManageMaximo Health for deployment. The format of the certificate must be PEM.

Procedure

- Add certificates.
 1. Log in to IBM Maximo Application Suite as a system administrator.
 2. From Suite administration, select Workspaces from the side navigation menu and then select the workspace that you want to configure.
 3. On the Overview tab for the workspace, select the Manage tile.
 4. On the Manage panel, click Actions and select Update configuration.
 5. In the Imported certificates row on the Update Manage configuration window, click the Edit icon.
 6. In the Imported certifications section, click Add to add a certificate.
You might have to disable the System managed switch before you can add a certificate.
 7. Specify the certificate alias and copy and paste the contents of the certificate.
Each alias name must be unique within the workspace.
 8. Click Confirm to save your changes.
 9. Select one of the following options:
 - If you are configuring a new deployment, click Activate.
 - If you are updating a deployment, click Apply changes.
- Add certificates.
 1. In IBM Maximo Application Suite click Administration and then click Catalog.
 2. Select the Manage tile.
 3. On the application details page, click Actions and select Update configuration.
 4. In the Imported certificates row on the Update Manage configuration window, click the Edit icon.
 5. In the Imported certifications section, click Add to add a certificate.
You might have to disable the System managed switch before you can add a certificate.
 6. Specify the certificate alias and copy and paste the contents of the certificate.
Each alias name must be unique within the workspace.
 7. Click Confirm to save your changes.
 8. Select one of the following options:
 - If you are configuring a new deployment, click Activate.
 - If you are updating a deployment, click Apply changes.

Configuring databases

When your business needs change, you can create objects to extend the scope of your database before you create additional applications. As configuration changes are based on business rational, you must understand the structure of your database and the business requirements before you begin creating objects.

- [Database design](#)
You typically extend the scope of your system because you have a use case that you want to include in the system. During the design phase you define the use case, the business objects, and the relationships between the business objects. To configure objects in the database, you must understand the structure of the database and the implications of the changes that you make to existing objects, tables, indexes, and relationships.
- [Defining objects for applications](#)
To extend the scope of your system, you must create objects. Every application is created based on the underlying objects that support the required business functions. You must understand the construction of your database before you define additional objects.
- [Configuration of general ledger accounts](#)
Default general ledger (GL) accounts are created as part of the installation process but you can create additional GL account codes at a later date. You must

configure default GL account code formats for the system level before you can create a chart of accounts. Once configured, it is not recommended that you modify the GL account formats as changing the configuration can make the existing chart of accounts unusable.

- [Configuring the database](#)

When you change the database, for example by creating or deleting objects, attributes, or indexes, changes are stored in secondary tables. The changes do not take effect until you configure the database. The product restores the backup tables as part of configuration.

- [Configuring the system for regulatory compliance](#)

Electronic signature verification and electronic audit records provide an additional level of security control and auditing capability that are often needed for regulatory compliance.

- [Controlling changes to objects](#)

Depending on your users needs, you can add functions that will help users, for example creating lookups or creating system messages.

- [Search option configuration for performance optimization](#)

You want to prevent users from performing queries that retrieve hundreds of thousands of records. You should periodically review users saved queries, you could define default queries for your users, or educate them on how to create efficient queries

Database design

You typically extend the scope of your system because you have a use case that you want to include in the system. During the design phase you define the use case, the business objects, and the relationships between the business objects. To configure objects in the database, you must understand the structure of the database and the implications of the changes that you make to existing objects, tables, indexes, and relationships.

- [Relational database structure](#)

The database and the database structure are defined in the installation process. The structure of the database depends on whether the database is Oracle Database, IBM® Db2®, or Microsoft SQL Server.

Relational database structure

The database and the database structure are defined in the installation process. The structure of the database depends on whether the database is Oracle Database, IBM® Db2®, or Microsoft SQL Server.

A database that can be perceived as a set of tables and manipulated in accordance with the relational model of data. Each database includes:

- a set of system catalog tables that describe the logical and physical structure of the data
- a configuration file containing the parameter values allocated for the database
- a recovery log with ongoing transactions and archivable transactions

Table 1. Database hierarchy

Component	Description
<i>Data dictionary</i>	A repository of information about the application programs, databases, logical data models, and authorizations for an organization. When you change the data dictionary, the change process includes edit checks that can prevent the data dictionary from being corrupted. The only way to recover a data dictionary is to restore it from a backup.
<i>Container</i>	A data storage location, for example, a file, directory, or device that is used to define a database.
<i>Storage partition</i>	A logical unit of storage in a database such as a collection of containers. Database storage partitions are called <i>table spaces</i> in Db2 and Oracle, and called <i>file groups</i> in SQL Server.
<i>Business object</i>	A tangible entity within an application that users create, access, and manipulates while performing a use case. Business objects within a system are typically stateful, persistent, and long-lived. Business objects contain business data and model the business behavior.
<i>Database object</i>	An object that exists in an installation of a database system, such as an instance, a database, a database partition group, a buffer pool, a table, or an index. A database object holds data and has no behavior.
<i>Table</i>	A database object that holds a collection of data for a specific topic. Tables consist of rows and columns.
<i>Column</i>	The vertical component of a database table. A column has a name and a particular data type for example, character, decimal, or integer.
<i>Row</i>	The horizontal component of a table, consisting of a sequence of values, one for each column of the table.
<i>View</i>	A logical table that is based on data stored in an underlying set of tables. The data returned by a view is determined by a SELECT statement that is run on the underlying tables.
<i>Index</i>	A set of pointers that is logically ordered by the values of a key. Indexes provide quick access to data and can enforce uniqueness of the key values for the rows in the table.
<i>Relationship</i>	A link between one or more objects that is created by specifying a join statement.
<i>Join</i>	An SQL relational operation in which data can be retrieved from two tables, typically based on a join condition specifying join columns.

- [Data dictionary tables](#)

The structure of a relational database is stored in the data dictionary tables of the database.

- [Integrity checker](#)

The integrity checker is a database configuration utility that you can use to assesses the health of the base layer data dictionary. The tool compares the data dictionary with the underlying physical database schema. If errors are detected, the tool produces error messages detailing how to resolve the issues.

- [Storage partitions](#)

A database storage partition is the location where a database object is stored on a disk. Database storage partitions are called *table spaces* in Db2 and Oracle, and called *file groups* in SQL Server.

- [Business objects](#)

A business object is an object that has a set of attributes and values, operations, and relationships to other business objects. Business objects contain business data and model the business behavior.

- [User-defined objects](#)

Objects can be created in two ways: you can create an object in the database or an object can be natively defined in the database. User-defined objects are

always created in the Database Configuration application.

- [Configuration levels for objects](#)

Levels describe the scope of objects and must be applied to objects. Depending on the level that you assign to objects, you must create certain attributes. For users to access an object, an attribute value must exist at the level to which they have authority. The level that you assign to an object sometimes depends on the level of the record in the database.

- [Database relationships](#)

Database relationships are associations between tables that are created using join statements to retrieve data.

- [Business object attributes](#)

Attributes of business objects contain the data that is associated with a business object. A persistent attribute represents a database table column or a database view column. A nonpersistent attribute exists in memory only, because the data that is associated with the attribute is not stored in the database.

- [Attribute data types](#)

Each database record contains multiple attributes. Every attribute has an associated data type.

- [Database views](#)

A *database view* is a subset of a database and is based on a query that runs on one or more database tables. Database views are saved in the database as named queries and can be used to save frequently used, complex queries.

- [Indexes](#)

You can use indexes to optimize performance for fetching data. Indexes provide pointers to locations of frequently accessed data. You can create an index on the columns in an object that you frequently query.

- [Primary keys](#)

When you assign a primary key to an attribute, the key uniquely identifies the object that is associated with that attribute. The value in the primary column determines which attributes are used to create the primary key.

Data dictionary tables

The structure of a relational database is stored in the data dictionary tables of the database.

The following table describes the product data dictionary tables.

Table 1. Tables in the product data dictionary

Table name	Contents
MAXOBJECT	All objects. Links an object to its table or view.
MAXTABLE	All tables.
MAXVIEW	All views.
MAXATTRIBUTE	All attributes of an object. A table or view attribute depends on the attributes of the object.
MAXVIEWCOLUMN	All view columns.
MAXRELATIONSHIP	All relationships defined on objects.
MAXSEQUENCE	All sequences used in the system. SQL Server, Oracle, and Db2® use database sequence generators.
MAXSYSINDEXES	All indexes in the system. This table contains the index name, uniqueness and storage partition that is used in the MAXSYSKEYS table.
MAXSYSKEYS	The columns in an index.

Integrity checker

The integrity checker is a database configuration utility that you can use to assesses the health of the base layer data dictionary. The tool compares the data dictionary with the underlying physical database schema. If errors are detected, the tool produces error messages detailing how to resolve the issues.

You run the integrity checker in the source environment before and after you upgrade the database. Activities that might result in errors include:

- Running the upgrade process itself
- Running the set of patch scripts included in updating a database
- Configuring the database in the Database Configuration application
- Configuring the database in the Migration Manager application

Errors reported by the integrity checker might affect migration. You run the integrity checker in both the source and the target environments when you run the Migration Manager.

You must ensure that the errors are corrected either by using the integrity checker in repair mode or by applying changes directly to the underlying database.

In Maximo® Manage you can use APIs to run integrity checker. For more information, see [APIs for administrative utilities](#).

Alternatively, run integrity checker commands by using the remote shell in the terminal of the `maxinst` pod. You must have Red Hat® OpenShift® Container Platform access to run integrity checker in the remote shell.

Storage partitions

A database storage partition is the location where a database object is stored on a disk. Database storage partitions are called *table spaces* in Db2® and Oracle, and called *file groups* in SQL Server.

When a database is created, the database administrator configures the DBSTORAGEPARTITION domain in the Domains application to include a list of available table spaces where objects are stored. When you create an object as a table, you specify the storage partition from this list of available table spaces.

In IBM® DB2®, the database or system can manage table spaces:

- If the database manages table spaces, indexes can be different from the table.
- If the system manages table spaces, indexes must be the same as the table.

The database and the system cannot manage table spaces simultaneously; you must choose one or the other.

Business objects

A business object is an object that has a set of attributes and values, operations, and relationships to other business objects. Business objects contain business data and model the business behavior.

Unlike a business object, a database object does not model behavior. A database object is a self-contained software entity that consists of both data and functions to manipulate data. A business object might consist of one or more database objects.

Every business object has a fixed set of properties that identify the business object type. The properties also specify how the database can use the business object.

Information about a business object, which is referred to as the metadata, is stored in the database in database tables. Business objects include the following metadata:

- The definition of the business object, such as its name, the database entity, whether the object is persistent or nonpersistent, and the Java™ class name
- Attributes, such as the name, data type, size, and the field validation class name
- Associated relationships

Business objects can be either persistent or nonpersistent. Persistent business objects are associated with a database view or table and store attribute values in a database. Data in a nonpersistent business object is transient and is not stored in the database.

The metadata that is associated with business objects provides information about the data in database tables and is used to manage the database objects.

User-defined objects

Objects can be created in two ways: you can create an object in the database or an object can be natively defined in the database. User-defined objects are always created in the Database Configuration application.

Existing or imported objects are first natively defined in the backend of the database. They are later redefined in Maximo® in the Database Configuration application. When an object is imported into the database, the Imported check box is automatically selected on the Objects tab.

Configuration levels for objects

Levels describe the scope of objects and must be applied to objects. Depending on the level that you assign to objects, you must create certain attributes. For users to access an object, an attribute value must exist at the level to which they have authority. The level that you assign to an object sometimes depends on the level of the record in the database.

A system-level object is the only object that does not require an attribute value as it applies to all objects. If you specify a multiple-level for an object, multiple attributes must be created. For example, if you specify the SYSTEMORGSITE level, the system attribute, the organization attribute, and the site attribute must be created.

You do not need to specify the required values for attributes when you create an object, required values can be specified at a later date.

Security is applied to configuration levels.

For certain configuration levels, you can restrict the result set by appending a condition to the WHERE clause. For example, you can specify the site level as "siteid=...".

Table 1. Configuration levels for database objects

Level	Description	Object attributes	Example
SYSTEM	A system-level object. Security restrictions are applied at the application or object level in the specific system-level business object definitions.	System attribute	
SYSTEMORG	A system-level object that can also be assigned to an organization. If the organization ID is not specified, the object operates at the system level.	System attribute and organization attribute	orgid is null or orgid = ...
SYSTEMSITE	A system-level object that can also be assigned to a site. If the site ID is not specified, the object operates at the system level.	System attribute and site attribute	siteid is null or siteid = ...

Level	Description	Object attributes	Example
SYSTEMORGSITE	A system-level object that can also be assigned to an organization, or to an organization and a site. If the site ID is not specified, the object operates at either the system level or the organization level. The level depends on whether the organization ID is assigned. If the organization ID is not specified, the object operates at the system level.	System attribute, organization attribute, and site attribute	(siteid is null or siteid = ...) and (orgid is null or orgid = ...)
SYSTEMAPPFILTER	This object is treated as a system-level object but it can ask the profile for a list of sites and organizations in the context of an application so that the application can filter data. Filtering is required for site-level administration of users and groups. Used for Users and Groups.	System attribute and application filter attribute	
ORG	An organization-level object. The framework applies security for this type.	Organization attribute	orgid = ...
ORGSITE	An organization-level object that can also be assigned to a site. If the site ID is not specified, the object operates at the organization level.	Organization attribute and site attribute	(siteid is null or siteid = ...) and orgid = ...
ORGAPPFILTER	An organization-level object with application filtering. Used for contracts so that the contract applications can filter on the special object instead of filtering by using standard security.	Organization attribute and application filter attribute	
SITE	A site level object.	Site attribute	siteid = ...
SITEAPPFILTER	A site-level object with application filtering. Reserved for future objects.	Site attribute and application filter attribute	
ITEMSET	An item set-level object. The itemsetid attribute value must exist in the insert organization for users. The framework adds the required security restriction.	Item set attribute	
COMPANYSET	A company set-level object. The compnaysetid attribute value must exist in the insert organization for users. The framework adds the required security restriction.	Company set attribute	

Database relationships

Database relationships are associations between tables that are created using join statements to retrieve data.

The following table describes the database relationships.

Table 1. Database relationships

Type of relationship	Description
One-to-one	Both tables can have only one record on each side of the relationship. Each primary key value relates to none or only one record in the related table. Most one-to-one relationships are forced by business rules and do not flow naturally from the data. Without such a rule, you can typically combine both tables without breaking any normalization rules.
One-to-many	The primary key table contains only one record that relates to none, one, or many records in the related table.
Many-to-many	Each record in both tables can relate to none or any number of records in the other table. These relationships require a third table, called an associate or linking table, because relational systems cannot directly accommodate the relationship.

In the Database Configuration application, you can define Structured Query Language (SQL) statements for joins, and create relationships between parent and child objects. You can use a join to link data from multiple objects. The parent is the existing object and the child is the object that you are create.

Example

Parent = MAXUSER, Child =SITE, and Name = DEFSITE means that maxuser exists and you want to get the site for the default site for the user.

```
siteid = :defsite
```

This configuration means `site.siteid = maxuser.defsite`. When the SQL statement is run, the value of the parent attribute replaces anything preceded by a colon.

Business object attributes

Attributes of business objects contain the data that is associated with a business object. A persistent attribute represents a database table column or a database view column. A nonpersistent attribute exists in memory only, because the data that is associated with the attribute is not stored in the database.

A persistent business object can have persistent and nonpersistent attributes. Persistent attributes of a business object relate to columns of a database table or view. All attributes of a non-persistent business object are non-persistent.

The additional metadata that is associated with business object attributes is stored apart from the basic data type information. For example, attributes can include a domain, a custom class, a default value, and to specify whether the attribute is required.

Restrictions on attributes

Before you modify an attribute, you can verify whether it was created by the system or by someone at your site. Attributes created by the system have more restrictions on modifications than user-defined attributes. You cannot delete attributes created by the system.

In integration scenarios, data for a business object might be received from external business applications. Restricting changes to attributes prevents external data from overwriting the value of an attribute.

Some restrictions depend on whether text search is enabled for the object or on the data type. The rules governing modifications vary by attribute. For example, certain data types have a set value for the length, scale, dates, or integers. The Memo field is a regular ALN data type and it does not contain restricted values.

To manage restrictions on attributes, you can perform the following actions:

- View the current object attribute restrictions
- Restrict the attributes of an object
- Remove attribute restrictions from an object

Attribute data types

Each database record contains multiple attributes. Every attribute has an associated data type.

Table 1. Attribute data types

Data type	Data type name	Description
ALN	Alphanumeric characters, mixed case	Maximum length depends on the database: <ul style="list-style-type: none">• Oracle = 4000 characters• SQL Server = 8000 characters• DB2® = 32672 characters
AMOUNT	Decimal number, used for currency	
BIGINT	Big integer	
BLOB	Binary large object	Stores JPEG, movies, or PDF files in single records inside the database instead of in external files.
CLOB	Character large object	
CRYPTO	Encrypted binary	Encrypts data on the screen and in the database. Used for password hints.
CRYPTOX	Encrypted binary (one-way)	Encrypts data in the database, but leaves it readable on the screen. Used for passwords.
DATE	Date only	
DATETIME	Date and time	
DECIMAL	Decimal number	A number that includes an integer and a fraction that consists of a fixed number of digits called the scale.
DURATION	Duration in hours	Appears as 1:30 = 1.5 hours
FLOAT	Floating number	Numbers with fractional portions with variable precision.
GL	General ledger account	An ALN data type that is used for GL Accounts.
INTEGER	Integer number	
LONGALN	Long alphanumeric.	Used only for nonpersistent Long Description attributes. The corresponding native column in the database is defined as CLOB.
LOWER	Lowercase characters	
SMALLINT	Small integer	
TIME	Time only	
UPPER	Uppercase characters	
VARCHAR	Variable length character	
YORN	Yes or No, 1 or 0 in the database	

Database views

A *database view* is a subset of a database and is based on a query that runs on one or more database tables. Database views are saved in the database as named queries and can be used to save frequently used, complex queries.

There are two types of database views: dynamic views and static views. Dynamic views can contain data from one or two tables and automatically include all of the columns from the specified table or tables. Dynamic views are automatically updated when related objects or extended objects are created or changed. Static views can contain data from multiple tables and the required columns from these tables must be specified in the SELECT and WHERE clauses of the static view. Static views must be manually updated when related objects or extended objects are created or changed.

When you create a dynamic view with data from two tables, you must ensure that both tables have the same PRIMARYKEYCOLSEQ columns or contain unique indexes with the same column name in the same order.

Database views are populated depending on the object on which they are based. For example, if you add or remove an attribute from the WORKORDER object, the attribute is either added or removed from the dynamic view that is based on the object. When you change an attribute, not all changes are applied to the associated database view. For example, if you change the data type of an attribute, the change is applied to the database view. However, if you change or add a domain to the default value of the WORKORDER object, the change is not automatically applied to the database view. Instead, you must apply this change to the database view.

Indexes

You can use indexes to optimize performance for fetching data. Indexes provide pointers to locations of frequently accessed data. You can create an index on the columns in an object that you frequently query.

You cannot redefine existing indexes. You must delete indexes and re-create their definitions.

Primary keys

When you assign a primary key to an attribute, the key uniquely identifies the object that is associated with that attribute. The value in the primary column determines which attributes are used to create the primary key.

By default, a primary key is automatically created by taking the object name, adding an ID to the object name, and assigning a primary column value of 1. If you change the value, it must be sequential, unique, and greater than 0. The sequence determines the order in which the primary index is created. Each attribute can have only one primary key. The same attribute can be used in more than one primary key. When the object is saved, the primary key can no longer be modified.

A primary index is automatically created for the primary key and ensures that the primary key is unique. You can use the primary index to retrieve and access objects from the database. The unique index is a column, or an ordered collection of columns, for which each value identifies a unique row. The sequential values that are assigned in the primary columns determine the order in which the unique index is created. A unique index can contain NULL values.

Defining objects for applications

To extend the scope of your system, you must create objects. Every application is created based on the underlying objects that support the required business functions. You must understand the construction of your database before you define additional objects.

- [Creating objects](#)
An object is a self-contained software entity that consists of both data and functions to manipulate data. You can use an abbreviation of your organization as a prefix to any new or modified object or attribute name.
- [Adding views to databases](#)
A view can contain data from more than one object in the database. You can create object views in addition to views on existing system objects. If you work with custom applications, you can add object tables in the Database Configuration application.
- [Creating applications from imported database views](#)
You can use imported database views to create applications.
- [Specifying attributes for objects](#)
Attributes contain the data that is associated with objects. When you create an object, you must specify the attributes that are assigned to the object.
- [Enabling autonumbering for attributes](#)
You can configure autonumbering at the system, set, organization, or site level. You can enable autonumbering for attributes to apply starting numbers and prefixes to items such as assets or work orders. Autonumbering can facilitate the movement of items across the organization levels.
- [Adding tax types to database tables](#)
A tax type corresponds to a kind of tax, for example, to a city sales tax. You can specify up to 27 different tax types. The requirements of your financial system determine how many tax types you can specify.
- [Adding indexes](#)
You create an index to optimize performance when searching the table using the Find function and to establish uniqueness of table columns.
- [Adding primary keys to user-defined objects](#)
Primary keys can be added to user-defined objects to uniquely identify these objects in a database. A primary index is automatically created for the primary key and ensures that the primary key is unique.
- [Creating relationships between parent and child tables](#)
To retrieve data on objects, you must define the relationships between objects. You define SQL for joins to create relationships between parent and child objects.

Creating objects

An object is a self-contained software entity that consists of both data and functions to manipulate data. You can use an abbreviation of your organization as a prefix to any new or modified object or attribute name.

Procedure

1. In the Database Configuration application, click New Object.
2. Type a name in the Object field.
The Entity field shows the value that you typed in the Object field and becomes the name of the view on the database.
3. Specify a description for the object.
4. Optional: Specify object properties:

Option	Description
Main Object	To make the object a main object for Workflow, select this check box.

Option	Description
Persistent	If the object is persistent, three attributes are created: ID, description, and rowstamp (if selected). If the object is nonpersistent, nothing is added for attributes. You cannot configure the database without creating at least one attribute for the object.
Storage Partition	If applicable to your database, click Detail and select a storage partition for the object. The values are stored in the DBSTORAGEPARTITION domain.
User Defined	If an administrator created the object, the User Defined check box is selected. If the object is a regular product object, the User Defined check box is cleared.
Unique Column	The name of the attribute that is created as a unique identifier on a persistent object. This value is used in indexing. <ul style="list-style-type: none"> If the object is flagged as imported, then a unique column is not required. If you add a unique column, it must have a new column name and cannot exist in the native database.
Language Table	To enable this object for multiple languages, specify a value. The convention is L_ <i>tablename</i> .
Text Search Enabled	Select to enable text search on the object. You can use this function with text search on attributes.

5. Click Save Object.

What to do next

After you create an object, you must add attributes before you configure the database for your changes to take effect.

Adding views to databases

A view can contain data from more than one object in the database. You can create object views in addition to views on existing system objects. If you work with custom applications, you can add object tables in the Database Configuration application.

About this task

You can add an object table or view from any tab of the Database Configuration application.

Procedure

- On the toolbar, click New Object, and specify a value and a description for the object.
- Optional: Type over the value in the Entity field to change the name of the object on the native database.
- In the Service field, specify a value or use the default value of CUSTAPP.
- In the Level field, specify the scope of the object in the Multisite scheme.
- Optional: To create a view, select an object in the Extends Object field. The View check box is selected by default.
- Optional: Provide the following additional object details:

Option	Description
Main Object	To make the object a main object for Workflow, select this check box.
Persistent	If the object is persistent, the check box is selected and three attributes are created: ID, description, and rowstamp. If the object is non-persistent, the check box is clear. Nothing is added for attributes but you cannot configure the database without creating at least one attribute for the object.
User Defined	If the object is a regular product object, the User Defined check box is clear. If the object was created by an administrator the User Defined check box is selected.
Storage Partition	If applicable to your database, specify a storage partition for the object.
Unique Column	The name of the attribute that is created as a unique identifier on a persistent object. This value is used in indexing. <ul style="list-style-type: none"> If the object is flagged as imported, then a unique column is not required. If you add a unique column, it must have a new column name and cannot exist in the native database.
Text Search Enabled	To enable text search on the object, select the check box. You can use this function with text search on attributes. (This field appears only for existing objects.)

- Optional: In the View section, define the following details for a view:

Option	Description
View Where	The WHERE clause that is used for the view.
Join to Object	The secondary object that is used in the join for this view. If the view joins two tables, you can type the name for the second table in this field.
View Select	The SELECT clause that is used for the view when the Automatically Select check box is cleared. Use the format <code>SELECT TABLE1.COL1 AS A, TABLE2.COL2 AS B</code>
View From	The FROM clause that is used for the view when the Automatically Select check box is cleared.

- Optional: In the Audit table window, create an audit table and select the Audit Enabled check box to edit the filter field for the E-audit function.
- Save the object.

What to do next

After you add an object table or view, you must configure the database for your changes to take effect.

Creating applications from imported database views

You can use imported database views to create applications.

About this task

The unique ID of the main table column cannot be renamed. All other columns can be renamed.

Procedure

1. Create a view on the database.
2. In the Database Configuration application, create an object.
The object name must be the same name as the view created on the database.
3. In the Extends Object field, ensure that you specify the object name of the unique ID of the main table column.
4. Create an application from the database view.
5. If you renamed any fields in the database view, remove these fields from the Advanced Search dialog:
 - a. Go to Application Designer and open the new application.
 - b. Click Edit Dialogs and select More Search Fields.
 - c. Remove any fields that you renamed.

Specifying attributes for objects

Attributes contain the data that is associated with objects. When you create an object, you must specify the attributes that are assigned to the object.

- **[Descriptions and long descriptions](#)**
There is a limit to the amount of data that you can store in the description fields. Each database has its own specified limit. If you know that you need to store more data than is available in the description field, you can add a long description field to an attribute.
- **[Adding attributes to objects](#)**
You can add attributes to an object when you want to provide more information about that object. You add attributes to objects using the Database Configuration application.
- **[Changing attributes](#)**
You can change attributes when necessary. Depending on how the attribute is configured, you might not be able to modify all of the fields.
- **[Creating restrictions on attributes](#)**
You can create restrictions on attributes to prevent external data from overwriting the value for the chosen attribute.
- **[Excluding user-defined attributes when duplicating objects](#)**
There might be objects that you duplicate regularly but you do not want to include all user-defined attributes in the duplicated objects. For each object, you can specify the user-defined attributes that you do not want included when you duplicate objects. By excluding attributes, you can reduce the data maintenance work required to work with duplicated objects.

Descriptions and long descriptions

There is a limit to the amount of data that you can store in the description fields. Each database has its own specified limit. If you know that you need to store more data than is available in the description field, you can add a long description field to an attribute.

The description field object is associated with the VARCHAR (variable length character) column. This column can hold a maximum number of bytes it can hold. If you associate a long description field with an attribute, a long description is added to the VARCHAR column. Long descriptions are stored in the character large object (CLOB) column of the long description (LONGDESCRIPTION) table. If you include a long description field, you can store a smaller amount of data in the main table and a larger amount in the long description table.

The long description data can contain any alphanumeric data. This data appears in the Long Description field from the user interface.

Each long description must have a long description owner. When you select the Long Description Owner check box on the Attributes tab of the Database Configuration application, you become the owner of the long description. When the Long Description Owner check box is selected for an attribute for the first time, the HASLD (has long description) column is added to the main record.

An icon exists or can be added beside the description field on the UI. The appearance of the icon changes when long description data exists. HASLD indicates that a long description exists.

The default value for HASLD is 0. When data is entered in the long description, the value of HASLD changes to 1.

Adding attributes to objects

You can add attributes to an object when you want to provide more information about that object. You add attributes to objects using the Database Configuration application.

About this task

You can use an abbreviation of your organization as a prefix to any attribute name, for example, ACME_MEMOFIELD. This practice prevents accidentally choosing a database reserved word and prevents conflicts with new standard names in an upgrade. You cannot add an attribute that is named rowstamp, tenantid, maxsetupflag, or HASLD to an object.

Procedure

1. Go to the Database Configuration application (Go To Applications, > System Configuration, > Platform Configuration, > Database Configuration).
2. On the List tab, select the object to which you want to add an attribute.
3. On the Attributes tab, click New Row.
4. In the Attribute field, specify a value.
5. Specify values in the Title field and the Description field.
6. Optional: If you want to include a long description, which can contain more data than the Description field, select the Long Description Owner check box.
7. In the Type field, specify the data type of the attribute.
The Length and Scale fields show default values that are based on the type that you select.
8. Optional: Select the Required check box if you want the attribute to represent a required field on the screen.
If the attribute is a persistent attribute, it is also required on the database.
Requirement: If data exists in the table to which the attribute belongs, and you select the Required check box, you must specify a value in the Default Value field. Specifying a value in this field ensures that you cannot enter a null value for the required attribute. The default value that you specify is only validated against the associated domain for the attribute and the data type of the attribute.
9. Optional: If you want a group of attributes to share data type and length, specify the parent attribute in the Same as attribute field.
The child attribute copies the details of the parent attribute. If you change the details of any attribute in the group, the details of all attributes in the group change.
10. Optional: Provide more information about the attribute.
11. Save the object.

What to do next

You must configure the database for your changes to take effect.

After you add attributes, you can then add the attributes to the respective application in the Application Designer application to make the attributes accessible on the user interface.

Changing attributes

You can change attributes when necessary. Depending on how the attribute is configured, you might not be able to modify all of the fields.

Before you begin

Verify whether the attribute was created by the system or by someone at your site. If it was created by someone at your site, the User Defined check box is selected. You cannot delete attributes created by the system.

About this task

Attributes created by the system have more restrictions on modifications than user-defined attributes do. Some restrictions depend on whether text search is enabled for the object or on the data type.

For example, certain data types have a set value for the length, scale, dates, or integers. The Memo field is a regular ALN. You can make it anything you want.

The rules governing modifications are complex, and vary by attribute.

Procedure

1. Locate the attribute that you want to modify.
Tip: You can use Advanced Search to search for attributes.
2. Edit the Description, Type, Length, and Required fields according to your business needs.
Some fields are read only, depending on values in other areas.
3. Click Save Object.
The status of all affected objects display To Be Changed until you configure the database.

What to do next

You must configure the database for your changes to take effect.

Creating restrictions on attributes

You can create restrictions on attributes to prevent external data from overwriting the value for the chosen attribute.

Procedure

1. In the Database Configuration application, use the List tab to search for and to locate the object whose attributes you want to restrict.
2. Click the Object tab to make the selected object the current object in the application.
3. Select the Restrict Attributes action.
4. Navigate to the attribute that you want to restrict.
Tip: You can use the Filter fields to help you locate the attribute.
5. Select the Restricted check box.
6. Click OK.

What to do next

You must configure the database for your changes to take effect.

Excluding user-defined attributes when duplicating objects

There might be objects that you duplicate regularly but you do not want to include all user-defined attributes in the duplicated objects. For each object, you can specify the user-defined attributes that you do not want included when you duplicate objects. By excluding attributes, you can reduce the data maintenance work required to work with duplicated objects.

About this task

The list of attributes available for selection in the Skip Attributes window is populated by the user-defined attributes that are available for the selected object. If user-defined attributes do not exist in the object, no attributes are available for you to select. When you select user-defined attributes to be skipped, the attributes are not listed in future selection options.

If you specify that user-defined attributes be skipped for base objects, the skip values also apply to the object views.

Procedure

1. In the Database Configuration application, select an object that you want to duplicate.
2. Select the Skip Attributes action.
3. Specify the attributes that you do not want to be copied to new objects.
4. Optional: To specify conditions when attributes are skipped, specify a value in the Condition field.
5. Click OK and save the object.

What to do next

If you specify attributes to be skipped in the duplication process, you must configure the database for the changes to take effect.

Enabling autonumbering for attributes

You can configure autonumbering at the system, set, organization, or site level. You can enable autonumbering for attributes to apply starting numbers and prefixes to items such as assets or work orders. Autonumbering can facilitate the movement of items across the organization levels.

Before you begin

You can specify an autonumber only if the Can Autonumber check box is selected on the Attributes tab of the Database Configuration application. Whether this check box is selected depends on the data type of the attribute.

Procedure

1. In the Database Configuration application, select an object.
2. On the Attributes tab, select an attribute.
3. In the Advanced section, specify an autonumber. You can create an autonumber or use an existing autonumber.
4. In the Details section, specify `&AUTOKEY&` as the default value for the attribute and save the object.
5. If you created an autonumber in step 3, use the Autonumber Setup action in the Organizations application to specify the seed value and the prefix.
6. Save the object.

What to do next

You must configure the database for your changes to take effect.

Adding tax types to database tables

A tax type corresponds to a kind of tax, for example, to a city sales tax. You can specify up to 27 different tax types. The requirements of your financial system determine how many tax types you can specify.

Before you begin

Administration mode must be turned on before you can configure the database.

About this task

When you add tax types to the database, you specify the number of tax types, you configure the database, and then you update the database tables for your organizations. If you add more than five tax types, and configure and update the database tables, all of the tax types display in the Tax Options window of the Organizations application.

Procedure

1. In the Database Configuration application, select the Tax Types, > Add/Modify Tax Types action.
2. In the Number of Tax Types field, specify the number of tax types that you want to use.
3. Click OK.
4. Select the Apply Configuration Changes action to configure the database.
5. In the Database Configuration window, provide the required information, then click OK.
6. Select the Tax Types, > Update Tax Data action to update the database tables with the changes.

Adding indexes

You create an index to optimize performance when searching the table using the Find function and to establish uniqueness of table columns.

About this task

Indexes can be defined only for persistent tables.

Procedure

1. From the List tab, select the object to which you want to add an index, and click the Indexes tab.
2. In the Indexes table, click New Row.
3. In the Index field, specify a value.
4. Optional: To make each column in the index unique, select the Enforce Uniqueness check box.
5. For IBM® DB2® and SQL Server: Select the Clustered Index check box to create a clustered index.
You can have only one clustered index per table.
6. Specify a storage partition or accept the default value.
7. In the Columns table, click New Row to add a column to the index.
 - a. In the Column field, specify an attribute from the selected object.
 - b. Optional: In the Sequence field, specify the sequence for the column.
If you do not specify a value, then the order in which you add columns determines their sequence.
 - c. Optional: Select the Ascending check box to have the index searched in ascending order.
If this field is cleared, the index is searched in descending order.
8. Click Save Object.
The index status will display Add until you configure the database.

What to do next

You must configure the database for your changes to take effect.

Adding primary keys to user-defined objects

Primary keys can be added to user-defined objects to uniquely identify these objects in a database. A primary index is automatically created for the primary key and ensures that the primary key is unique.

Before you begin

You must be logged in as an administrator.

About this task

By default, the system assigns the unique ID attribute as the primary key by assigning a value of 1 to the Primary Column field of this attribute. You can clear this value, or enter your own value in the Primary Column.

Procedure

1. In the Database Configuration application, create an object or open the object to which you want to add a primary key.
2. On the Attributes tab, assign a value to one or more attributes in the Primary Column.
3. Save the object.

Creating relationships between parent and child tables

To retrieve data on objects, you must define the relationships between objects. You define SQL for joins to create relationships between parent and child objects.

Before you begin

Before you create a relationship, review the relationships defined in the database to determine if you can reuse an existing relationship. If the definition of a relationship does not match your needs, do not modify the relationship. Instead, create an additional relationship.

About this task

You define SQL for *JOINS*. A JOIN lets you link together data from multiple tables.

Procedure

1. Use the List tab to select the table for which you want to create a relationship, and then click the Relationships tab.
2. Click New Row.
3. In the Relationship field, specify a name.
4. Create a WHERE clause.
5. Select a Child Object.
6. Optional: Type comments in the Remarks field.
7. Click Save Object.

What to do next

If the relationship that you created is for a table or attribute, the changes will not take effect until you configure the database.

Configuration of general ledger accounts

Default general ledger (GL) accounts are created as part of the installation process but you can create additional GL account codes at a later date. You must configure default GL account code formats for the system level before you can create a chart of accounts. Once configured, it is not recommended that you modify the GL account formats as changing the configuration can make the existing chart of accounts unusable.

- [General ledger account codes](#)
Each general ledger account code consists of several components (segments). In the Database Configuration application, you define the default, system-level format of the account code. In the Chart of Accounts application, you specify the valid components to be used, as well as the organization-specific format of the account code.
- [General ledger account components](#)
Some general ledger account components are required while other components are optional.
- [Sequence of components in a general ledger account code](#)
Account components display in a sequential format, with the first component in the string representing the highest level.
- [Length of components in a general ledger account code](#)
Changing the length of the component values can result in invalid general ledger accounts. If you change the length, change the values to fit the new length.

General ledger account codes

Each general ledger account code consists of several components (segments). In the Database Configuration application, you define the default, system-level format of the account code. In the Chart of Accounts application, you specify the valid components to be used, as well as the organization-specific format of the account code.

For easy identification, use delimiters to separate components when they display. For example, use hyphens to separate components: 6100-400®-SAF. Delimiters are written to the database.

For any account code, you can:

- Define 20 or fewer components.
- Restrict the number of characters in a component field.
- Include a total of 254 or fewer characters/digits.

You can use any tab of the Database Configuration application to specify the general ledger account code format.

General ledger account components

Some general ledger account components are required while other components are optional.

Table 1. Required and optional components

Type of component	On-screen display
Required	Unknown values not specific to required components contain placeholder characters.
Optional	<p>Any unknown optional components do not display.</p> <p>In the demo database, the fourth component is optional (most account codes consist of the first three components).</p> <ul style="list-style-type: none">It does not require any characters.No accounts have been assigned to it in chart of accounts, so it does not appear as part of the general ledger account.

Your general ledger system has rules regarding whether an account is acceptable when partially defined.

- Fully defined (fully specified) accounts
 - Have no unknown values (placeholders) in required components
 - Example: 6100-350-SAF is fully defined
- Partially defined (partially specified) accounts
 - Contain placeholders in some required components
 - Example: 6100-???-SAF (the required activity component is not specified and therefore contains placeholder characters)

Sequence of components in a general ledger account code

Account components display in a sequential format, with the first component in the string representing the highest level.

Example

For example, the MAXDEMO database includes the following component sequence:

- Component 1 is for cost center
- Component 2 is for activity
- Component 3 is for resource
- Component 4 is for element

Since account components are concatenated, with the highest level at the beginning, account 6100-350-SAF is represented as:

Table 1. General Ledger account component sequence

Component 1	Component 2	Component 3	Component 4
6100	350	SAF	(not used)
Cost center	Activity	Resource	Element

Length of components in a general ledger account code

Changing the length of the component values can result in invalid general ledger accounts. If you change the length, change the values to fit the new length.

Example

In maxdemo the cost center component length is 4, the resource and activity component lengths are both 3, and the element component is 10. When you add in the three delimiters, the length of the GL is 23.

If you change the cost center component length to 3 and the activity component length to 4, the total length remains 23. No configuration is required. However, the general ledger component is now invalid. The cost center component length was shortened to 3 but has a four-digit value (in this example) of 6000.

Configuring the database

When you change the database, for example by creating or deleting objects, attributes, or indexes, changes are stored in secondary tables. The changes do not take effect until you configure the database. The product restores the backup tables as part of configuration.

- [Modes of configuring the database](#)
You can choose from these modes to configure the database: command-line mode, partial live configuration with administration mode turned on or a full live configuration. The mode that you choose depends on the type of change to the Manage schema you are making. It is recommended that you back up the database for all structural changes before you configure the database.
- [Configuring the database in administration mode](#)
You can configure the database in admin mode.

- [Database changes without administration mode](#)
Some object-level and attribute-level parameters can be updated without using administration mode.

Modes of configuring the database

You can choose from these modes to configure the database: command-line mode, partial live configuration with administration mode turned on or a full live configuration. The mode that you choose depends on the type of change to the Manage schema you are making. It is recommended that you back up the database for all structural changes before you configure the database.

The following table lists the advantages and disadvantages of each configuration mode:

Table 1. Configuration modes

Configuration modes	Advantages	Disadvantages
Command-line mode	Data is backed up for certain database changes if the affected table cannot be changed with data in it. It is easier to restore data from this configuration mode as there are no updates while the database is being configured.	Must shut down the application server therefore, users have no access to the applications during the configuration. Requires an information technology administration user who has control over the application server.
Partial live with administration mode turned on	Allows an administration user to perform tasks such as adding a column to a table without shutting down the application server. Users are logged out of the system. Only administrators with Can Log in During Admin Mode permissions can access Maximo®. This permission is in the Security Groups application within the Start Center application permissions. Data is backed up for certain database changes if the affected table cannot be changed with data in it.	Blocks users from the system applications. Suspends CRON tasks. Does not allow remote connectivity Disables event listeners. Requires the user to have Administrator login security authorizations, which you must assign in the Security Groups application.
Full live	Least impact on users as active transactions are not interrupted or lost. Does not require administration mode to be turned on. If changes performed during a live update are later determined to be incorrect, you can perform another live update to reverse the changes. Changes do not disrupt the live business object definitions. If you change the field validation class for an attribute and perform a live update to apply the changes, the business objects that are already instantiated are not revalidated.	Can be used only for non-structural changes to Maximo such as adding a domain to an attribute.

Table 2. Configuration modes

Configuration modes	Advantages	Disadvantages
Partial live with administration mode turned on	Allows an administration user to perform tasks such as adding a column to a table without shutting down the application server. Users are logged out of the system. Only administrators with Can Log in During Admin Mode permissions can access Maximo. This permission is in the Security Groups application within the Start Center application permissions. Data is backed up for certain database changes if the affected table cannot be changed with data in it.	Blocks users from the system applications. Suspends CRON tasks. Does not allow remote connectivity Disables event listeners. Requires the user to have Administrator login security authorizations, which you must assign in the Security Groups application.
Full live	Least impact on users as active transactions are not interrupted or lost. Does not require administration mode to be turned on. If changes performed during a live update are later determined to be incorrect, you can perform another live update to reverse the changes. Changes do not disrupt the live business object definitions. If you change the field validation class for an attribute and perform a live update to apply the changes, the business objects that are already instantiated are not revalidated.	Can be used only for non-structural changes to Maximo such as adding a domain to an attribute.

Configuring the database in administration mode

You can configure the database in admin mode.

Before you begin

You must have administration login security authorization. You obtain this authorization from the Security Groups application.
Before you can configure and turn on administration mode, you must set the mail.smtp.host property to ensure that you can receive scheduled reports.

About this task

When you save a record the changes are stored in temporary database configuration objects. Before you configure the database, you can close and reopen the Database Configuration application without losing any saved changes. A secondary table stores pending changes, which also appear in the Status field. You cannot query on Status.

In a clustered environment, when you turn admin mode on, all other cluster members are automatically stopped. Only the cluster member that has admin mode turned on is kept running. When you turn admin mode off, the other cluster members are restarted. Use the `mxe.adminmode.stopstartclusters` system property to enable or disable this feature. The default value for the `mxe.adminmode.stopstartclusters` system property is 1.

Procedure

1. In the Database Configuration application, select Manage Admin Mode from the action menu
2. In the Turn Admin Mode ON window, modify the values in the Number of Administrative Sessions Allowed field and the Number of Minutes for User Logout field.
The default value of each field is 5. If you modify these fields, click Update Properties for the parameters to take effect.
3. Click Turn Admin Mode ON.
4. In the Electronic Signature Authentication window, enter the appropriate value in the Reason for Change field.
5. Click OK.
A window opens that indicates that the Admin Mode is starting.
6. Click OK.
7. Throughout the configuration process, click Refresh Status to view the messages that the configuration process writes in the Status window.
If you decide to cancel the configuration, click Cancel Admin Mode.
8. Select the Apply Configuration Changes action to configure the database and restore backup tables. Wait until administration mode is turned on before performing this step.
9. To turn off Admin Mode, select the Admin Mode action, and then click Turn Admin Mode OFF.

Database changes without administration mode

Some object-level and attribute-level parameters can be updated without using administration mode.

Changes to the following object-level parameters are eligible for live updates:

Table 1. Object-level parameters that are eligible for live updates

Description	Source
Description	MaxObjectCfg.Description
Esig Filter	MaxObjectCfg.EsigFilter

Changes to the attribute-level parameters that are listed in the following table are eligible for live updates.

Table 2. Attribute-level parameters that are eligible for live updates

Header	Source	Additional rules to qualify for live update
Description	MaxAttributeCfg.Remarks	None
Title	MaxAttributeCfg.Title	None
Domain	MaxAttributeCfg.DomainID	None
Default Value	MaxAttributeCfg.DefaultValue	None
Search Type	MaxAttributeCfg.SearchType	For live update, you cannot change to or from Text Search (domainid = SEARCHTYPE , maxvalue = TEXT).
Esig Enabled	MaxAttributeCfg.EsigEnabled	None
Can Autonum	MaxAttributeCfg.CanAutonum	None
Autokey Name	MaxAttributeCfg.AutokeyName	None
Is Positive	MaxAttributeCfg.IsPositive	None
Field Validation Class	MaxAttributeCfg.Classname	For live update, the specified class must be accessible to the class loader.

If any of the Cfg tables for an object or any of its attributes have changes that are not listed in the preceding tables, that object and its attributes are not eligible for live updates.

Configuring the system for regulatory compliance

Electronic signature verification and electronic audit records provide an additional level of security control and auditing capability that are often needed for regulatory compliance.

- [Electronic signatures, audit records, and login tracking](#)
Electronic signature verification, electronic audit records, and login tracking features help you comply with audit and regulatory requirements.
- [Login tracking](#)
You can use login tracking to view login attempts.
- [Electronic audit records](#)
To track changes that users make to data, administrators can enable electronic audits.
- [Electronic signature verification](#)
Electronic signatures provide an extra layer of validation to confirm that a user who changes a record is the same user who is logged in to the application. In

addition to validation, the electronic signature feature enables administrators to audit changes and to determine who made a change and why the change was made.

Electronic signatures, audit records, and login tracking

Electronic signature verification, electronic audit records, and login tracking features help you comply with audit and regulatory requirements.

You can use the following features to comply with regulatory requirements:

Login tracking

Login tracking lets administrators view the number of login attempts and displays the current login status of the user.

Electronic signature verification

Electronic signature verification requires users to provide credentials and to give a reason for changes before they can change records. It ensures that the person who saves a record, changes a record, or accesses a specific action is the person who logged in.

Electronic audit records

Electronic audit records track changes to records, keep copies of the changes, and produce an audit trail. The electronic auditing function writes audit records to the database tables. The audit tables are configured for each business object that is enabled for auditing.

You define electronic signatures and audit records at the system level, so they apply to all organizations and sites.

You must enable login tracking to use electronic signatures.

Login tracking

You can use login tracking to view login attempts.

Login tracking tracks the number of login attempts for a user and gives the login status of a user.

Login tracking must be enabled if you use electronic signatures.

Login tracking is enabled by default. Run one of the following SQL statements on the database to enable or disable login tracking and then restart the server:

- Enable tracking with the following statement: `update MAXVARS set VARVALUE = '1' where VARNAME='LOGINTRACKING'`
- Disable tracking with the following statement: `update MAXVARS set VARVALUE = '0' where VARNAME='LOGINTRACKING'`

Electronic audit records

To track changes that users make to data, administrators can enable electronic audits.

After electronic audits are enabled, an audit record is created each time that a user adds, deletes, or modifies the value of an attribute in an application and saves the change. The audit record is written to the audit table that corresponds to the regular database object.

The audit record includes the following items:

- The username of the user who changed the data.
- A copy of the changed data for each attribute for which electronic audit enabled.
- The identifier that indicates whether the change was an insertion, update, or deletion.
- The current date and time of the transaction.
- The row stamp.
- The unique electronic audit transaction ID.
- The unique e-Sig transaction ID if electronic signature is enabled.
- The key values columns for the record, even if those columns are not electronic-audit enabled. For example, the work order number is recorded even when another attribute in the WORKORDER object triggers the electronic audit.
- [Enabling electronic audits](#)
Administrators can enable electronic audits, E-audit, on any database object for any number of attributes.
- [Database updates for electronic audit](#)
Some objects and attributes can be updated for electronic audits without using administration mode.

Enabling electronic audits

Administrators can enable electronic audits, E-audit, on any database object for any number of attributes.

About this task

Procedure

1. In the Database Configuration application, select the object that you want to audit.
2. In the Audit section on the Object tab, select the Audit Enabled check box.
3. Save the record.
4. From the More Actions menu, select Manage Admin Mode and refresh the database.

Results

An audit table is created for the object. For example, an A_ASSET audit table is created for the ASSET object.

What to do next

After you enable electronic audits for an object, you can select specific attributes and enable electronic audits for the attributes.

Database updates for electronic audit

Some objects and attributes can be updated for electronic audits without using administration mode.

An audit table is an object that the MAXTABLECFG.EAUDITBNAME column references.

Example

If the Person table is audited and the audit table is named A_Person, two rows exist in the MAXTABLECFG table, as shown in the following example:

Table 1. Electronic Audit Tables

Table name	Table name for electronic audit table
PERSON	A_PERSON
A_PERSON	(null)

For the base table, changes to the audit-related, object-level parameters in the following tables can be updated without using administration mode. For an audit table, if the object you add (that is, MAXOBJECTCFG.CHANGED = 1) and its base table can be changed without using administration mode, then the audit table is also eligible.

The following table lists the object-level parameters that can be changed without using administration mode:

Table 2. Object-level parameters that are eligible for live updates

Description	Table and object	Additional rules to qualify for live update
Electronic Audit Filter	MAXOBJECTCFG.EAUDIT FILTER	None
Electronic Audit Enabled	MAXOBJECTCFG.EAUDIT ENABLED	No additional rules. Field validation in the Database Configuration application ensures that when electronic auditing is enabled, there is a non-null value for EAUDITBNAME.
Electronic Audit Table Name	MAXTABLECFG.EAUDIT BNAME	If either of the following conditions is true, live updates for changes of EAUDITBNAME are supported: <ul style="list-style-type: none">• EAUDITBNAME is non-null and the object that is referenced by EAUDITBNAME is a new object (that is, MAXOBJECTCFG.CHANGED = 1).• EAUDITBNAME is being set to null (that is, EAUDITENABLED is being turned on).

The following table lists changes to the audit-related, attribute-level parameters on the base table that are eligible for live updates:

Table 3. Attribute-level parameters that are eligible for live update

Description	Attribute	Additional rules to qualify for live update
Electronic Audit Attribute Enabled	MAXATTRIBUTECFG.EAUDITENABLED	No additional rules. An attribute that is eligible for live update is turned on or off.

Electronic signature verification

Electronic signatures provide an extra layer of validation to confirm that a user who changes a record is the same user who is logged in to the application. In addition to validation, the electronic signature feature enables administrators to audit changes and to determine who made a change and why the change was made.

When an application or feature is configured to require an electronic signature, users can complete an action or change the application only if they supply the required password or key in the Electronic Signature Authentication window that opens. Users must also specify the reason for the change.

Users create an electronic signature key in the Set or Modify E-Signature Key dialog box that is available from their profile. Electronic signature keys must conform to the same rules as product passwords. Any key that is manually created or automatically generated from a reset action is validated using the rules for user passwords, such as password length or excluded words.

Requirements for passwords and electronic signature keys are configured in the Security Controls dialog box for a selected user.

Electronic signature records the user name and full user name of users who change database records or who perform actions in an application. The modification to the record such as change, insert, update, or delete, known as the identifier, is also recorded.

The full user name corresponds to the DISPLAYNAME attribute in the PERSON object.

All verification attempts are saved in the LOGINTRACKING object. The LOGINTRACKING object records the following items:

- User name or login ID
- Full user name, which is the person's display name
- Date and time of the attempt
- Whether the authentication was successful
- Application name where the electronic signature was invoked
- Reason for the change, as typed on the Electronic Signature Authentication window
- Unique transaction identifier
- Key values columns for the record
- [Configuring electronic signature verification](#)
To configure electronic signature verification, administrators must configure email messaging to notify users when their signature key is reset. Then the administrator can enable electronic signature requirements for specific objects and attributes.
- [Resetting the electronic signature key](#)
If users forget their electronic signature key or if the key is compromised, users can request a new electronic signature key from their administrator. Administrators can reset the key.

Configuring electronic signature verification

To configure electronic signature verification, administrators must configure email messaging to notify users when their signature key is reset. Then the administrator can enable electronic signature requirements for specific objects and attributes.

To implement electronic signature verification, complete the following configuration tasks:

1. Configure the mx.e.esigresetemailfrom system property that specifies an email address for communicating with users about signature key resets.
 2. Create the subject line and body text for email messages to users about signature key resets.
 3. Enable electronic signature verification for specific objects or attributes.
- [Configuring the email address property for signature key resets](#)
Administrators must configure the mx.e.esigresetemailfrom system property to specify an email address that sends a message to inform users when their electronic signature key is reset.
 - [Configuring email subject lines and body text](#)
In addition to specifying an email address for sending messages about electronic signature resets, administrators can also configure the subject line and body text of the email message that they send.
 - [Creating a drop-down list for the Reason for Change field](#)
When electronic signatures are required, users must enter a reason for changing a record. Administrators can configure the Reason For Change field to provide a list of options to choose from.
 - [Adding electronic signature requirements to objects and attributes](#)
After administrators configure email messages, they can enable electronic signature requirements for specific objects and attributes.

Configuring the email address property for signature key resets

Administrators must configure the mx.e.esigresetemailfrom system property to specify an email address that sends a message to inform users when their electronic signature key is reset.

About this task

If users forget their electronic signature key or if the key is compromised, users can request a new electronic signature key from their administrator.

Administrators can reset the electronic signature key in the Users application. Resetting the key triggers an email to the user to notify them that their key is reset and to provide them with a new key.

The key is randomly generated and has no expiration time limit.

Administrators specify the email address that sends the notification in the mx.e.esigresetemailfrom system property.

Procedure

1. In the Global Properties table in the System Properties application, select Filter to search for the mx.e.esigresetemailfrom property.
2. Expand the row for the property.
3. In the Global Value field, enter a valid email address.
4. In the Common Actions menu, click Save Property.
5. In the Global Properties table, select the check box for the mx.e.esigresetemailfrom property.
6. In the Common Actions menu, click Live Refresh.
7. In the Live Refresh window, verify that the current value for the property is the correct email address and click OK.

What to do next

After you configure the system property for the email address, in the Database Configuration application, you can specify the subject line and the body of the text that you want in your email. As a best practice, you can suggest to your users that they change the key after their initial login to make it more meaningful and easier to remember.

Configuring email subject lines and body text

In addition to specifying an email address for sending messages about electronic signature resets, administrators can also configure the subject line and body text of the email message that they send.

About this task

Two messages are added to the signature message group in the Database Configuration application for email messages:

- `esigresetbody`: Use this message to provide the text for the body of your email message.
- `esigresetsubj`: Use this message to provide a subject line for your email message.

Adding text for the body of the electronic signature email message

Procedure

1. In the Database Configuration application, from the More Actions menu, select Messages.
2. Click Filter.
3. In the Message Key column in Messages table, search for `esigresetbody` and expand the row.
4. In the Value field for the message, enter text for the body of the email message, as shown in the following example.

```
Enclosed is your new Maximo Esig key {0}. To log in and change your key, follow this link:  
http://{1}/maximo/ui.
```

Note: When entering text, ensure that you do not change or delete the variables or brackets. The electronic signature key will be supplied for variable `{0}`. The host name of your environment will be supplied for variable `{1}`.

5. Click OK.
6. From the More Actions menu, click Apply Configuration Changes.

Adding text for the subject of the electronic signature email message

Procedure

1. In the Database Configuration application, from the More Actions menu, select Messages.
2. Click Filter.
3. In the Message Key column in Messages table, search for `esigresetsubj` and expand the row.
4. In the Value field for the message, enter text for the subject line of the email message.
5. Click OK.
6. From the More Actions menu, click Apply Configuration Changes.

What to do next

After you complete the messages for the subject and body text, from the More Actions menu, select Manage Admin Mode and refresh the database.

Creating a drop-down list for the Reason for Change field

When electronic signatures are required, users must enter a reason for changing a record. Administrators can configure the Reason For Change field to provide a list of options to choose from.

About this task

By default, the Reason For Change field in the Electronic Signature Authentication window is a free-form text field where users can enter up to 50 characters to describe the reason for a change. Administrators can configure the field to require users to choose from a defined value list by adding values to the `CHANGEREASON` domain.

Note: You do not assign this value list to a database object and attribute. The connection to the database for this value list is already present.

Procedure

1. In the Domains application, open the `CHANGEREASON` domain.
2. Click Edit Detail.
3. In the ALN Domain window, click New Row.
4. In the Value field and Description field, specify values for the `CHANGEREASON` domain.
The following conditions apply to this value list:

- These values are not written to the database.
- The value in the Description field is what users see when they use the list.

For example, you want users to see a value list that contains only `Changed the record` and `Deleted the record`. In the Value field and Description field, enter the following information:

Value field	Description field
CHANGE	Changed the record
DELETE	Deleted the record

5. Click OK.

Adding electronic signature requirements to objects and attributes

After administrators configure email messages, they can enable electronic signature requirements for specific objects and attributes.

Before you begin

Before enabling electronic signature verification for specific objects and attributes, ensure that you have completed all configurations that are required for your implementation.

Note: The addition of electronic signature is supported only for Work Order Tracking, Purchase Order, and Purchase Requisition.

About this task

When you enable electronic signature verification for an object or attribute, users must create an electronic signature key on the Set or Modify E-Signature Key window in their user profile. Then, whenever they attempt to change any record that has an electronic signature requirement, users must enter the electronic signature key.

Procedure

1. In the Database Configuration application, select the object for which you want to require electronic signature verification.
2. On the Attributes tab, expand the row for the attribute for which you want to require an electronic signature.
3. In the Advanced section for the attribute, select the E-signature Enabled check box.
4. Save the record.
5. In the More Actions menu, click Manage eSig Actions.
6. In the Applications table in the Manage eSig Actions window, select the application for which you want electronic signature verification.
7. In the Options table for the application that you selected, select the E-signature Enabled check box for each action for which you want to require an electronic signature.
8. Click OK.

Resetting the electronic signature key

If users forget their electronic signature key or if the key is compromised, users can request a new electronic signature key from their administrator. Administrators can reset the key.

Before you begin

Before you reset a user's electronic signature key, ensure that you have completed all configurations that are required to designate the email address that sends the message and to configure the subject line and body text of the message.

About this task

Resetting the key sends an email to the user to notify them that their key is reset and to provide them with a new key. The key is randomly generated and has no expiration time limit. Users are not required to change the key after their first login. However, as a best practice, you can suggest to your users that they change the key after their initial login to make it more meaningful and easier to remember.

Procedure

1. In the Users application, locate the user whose key you want to reset.
 2. From the More Actions menu, select Reset Esig Key.
 3. In the confirmation window, click OK.
- An email is sent to the user with a new electronic signature key.

Controlling changes to objects

Depending on your users needs, you can add functions that will help users, for example creating lookups or creating system messages.

- [Defining lookup maps](#)

You define a lookup map to associate a source object and a source field with a target object and related fields. The product is delivered with pre-defined lookup maps, but you can define your own lookup maps for objects that you create.

- [Adding system messages](#)

You can add, change, and delete system messages that display when required to assist users as they use the application.

- [Query definitions](#)

Users typically have a well-defined set of columns that they want to query in each application. You can identify these columns by asking users or by examining reports of slow-running SELECT statements. Indexing these columns can improve system performance.

Defining lookup maps

You define a lookup map to associate a source object and a source field with a target object and related fields. The product is delivered with pre-defined lookup maps, but you can define your own lookup maps for objects that you create.

Procedure

1. On the Attributes tab, select the attribute for which you want to specify details.
2. Click Edit Lookup Map.
3. Click New Row.
4. Specify the following details for the target attribute:
 - In the Target Attribute field, select the attribute to which you want to return values.
 - In the Source Object field, specify the source from which values are returned.
 - In the Source Key field, specify the key of the source object from which you want to return values.
 - In the Sequence field, specify a numeric value to determine the attributes that are to be set before other attributes. A lower numeric value has priority over a higher numeric value.
5. Optional: Select the Allow Null check box if you want the target attribute to accept null values.
6. Click OK.

Adding system messages

You can add, change, and delete system messages that display when required to assist users as they use the application.

About this task

Single quotation marks (') do not appear in the displayed message. To include quotation marks in the displayed message, you must use double quotation marks (") when you write the text of the message.

Procedure

1. In the Database Configuration application, select the Messages action.
2. Click New Row and specify the message group to which you want the new message to belong.
3. In the Message Key field, type a unique string that you want to be associated with the message.
4. Specify the display method for the message.
5. In the Message ID field, specify the prefix and product to be associated with the message.
Customer-generated messages typically use the BMXZZ prefix. The complete identifier is generated when you click the prefix.
6. Select the Display ID check box to display the message identifier whenever the message is displayed.
7. In the Value field, enter the message text.
8. In the buttons, icons, and explanation and responses sections, specify additional details.
9. Click New Row to add more messages, or save your changes.

Query definitions

Users typically have a well-defined set of columns that they want to query in each application. You can identify these columns by asking users or by examining reports of slow-running SELECT statements. Indexing these columns can improve system performance.

Users can create and save their own queries and share queries with other users. Saved queries are stored in a table named QUERY. You must periodically review these saved queries for inefficient conditions and use of unindexed columns.

With SQL statements, you can create special-purpose queries for example, return all Preventive Maintenance work orders created since Monday of this week. When you create these queries, you can save users the effort of querying larger sets and sorting and scrolling through the sets.

You also can provide users with an efficient default query for frequently used applications so that they can see a preferred record set when they access the application. For example, in the Work Order Tracking application, you can specify a default query for supervisor Smith. With this default query in place, initially the user can see only work orders with **SMITH** in the Supervisor field.

Search option configuration for performance optimization

You want to prevent users from performing queries that retrieve hundreds of thousands of records. You should periodically review users saved queries, you could define default queries for your users, or educate them on how to create efficient queries

- [Text search function](#)
The text search function uses SQL to index, search, and analyze text and documents that are stored in system databases. You can search for information based on text, content metadata, or attributes.
- [Search type configuration](#)
By setting search types for database columns, you can improve the results that are returned by user queries. Setting the search type can also reduce the load on the database.

Text search function

The text search function uses SQL to index, search, and analyze text and documents that are stored in system databases. You can search for information based on text, content metadata, or attributes.

A default search method is associated with each attribute. If text search is enabled for an object, you can change the Search Type of an attribute from the Database Configuration application on the Attribute tab.

A text search is allowed only for fields of the ALN data type. A text search is designed to search long descriptions, or fields that are long data types.

A full text search is a language-specific text search. Parts of words, not words, are indexed. For example, if you search for *par*, results do not include *part*.

A text search is flagged on the object and on the attributes.

Search type configuration

By setting search types for database columns, you can improve the results that are returned by user queries. Setting the search type can also reduce the load on the database.

Tables with fewer than 2000 or 3000 records are typically scanned regardless of indexes. The input output (I/O) cost to read an entire table is less than the average I/O cost of the index lookup plus the table lookup. The SEARCHTYPE value does not affect database behavior when such scans are performed. Tables with relatively few rows have no noticeable degradation in performance.

The following search types are available for user queries.

Table 1. Search types for user queries

Search type	Description	Benefit	Entry required
Exact	Filters data based on the keywords that you specify. You specify an exact search type when you require accurate and targeted results. Exact searches use wild cards only if a user explicitly enters wildcard characters on the List tab or in the WHERE clause.	Key fields, such as Work Order and Purchase Order, and value list fields, such as Work Order Status, can benefit from the indexing that is used in exact searches.	=
Wildcard	The default search type is wildcard search. You can apply a wildcard search on description fields of tables that have a relatively small number of rows for example, 2000 or fewer rows. When a user enters a value in a field on the List tab, the wildcard search type condition looks like this: <code>column like '%value%'</code> In wildcard searching, the database engine cannot use indexes. Searching without indexes can result in slower search times, especially on tables with many rows.	Wildcard searching provides flexibility for the users.	%

Search type	Description	Benefit	Entry required
Full text	<p>You can specify a text search type on description fields of tables with large numbers of rows, for example, tens of thousands of rows. The text search engine takes time to refresh the indexes, so new records might not be found until the text search index refreshes itself.</p> <p>Stem search is also performed. For example, a search for service returns servicing and serviced.</p> <p>Most system tables have one or more ALN data type columns for descriptions, memos, or remarks. You can define text search types and a corresponding IBM® DB2® text search index, Oracle text index, or SQL Server full text catalog for columns that have excessive text.</p> <ul style="list-style-type: none"> On IBMDB2, you can update the text search index by using the UPDATE INDEX FOR TEXT command or the SYSPROC.SYSTS_UPDATE procedure. On Oracle, you can modify the maximo_ts_job_call procedure to change the schedule of the synchronization process to any interval. On SQL Server, you can set and modify the population schedule for the full text catalog. <p>Text indexing increases the load on the database because of the constant background processing to keep the indexes synchronized. However, text indexing produces efficient word searching of description fields.</p>	<p>Text searches produce faster search responses than wildcard searches. Fields that are text-search enabled have text search indexes and, therefore, result in a faster search response.</p> <p>If an object is enabled for text search, the full text searches on the attributes provided.</p>	Any combination of the words in the text search
None	The none search type is used for columns that cannot be searched. If you do not specify a search type, the value defaults to none or no search.	You use this search type to specify that a column should not be searched.	

You can use a combination of methods to refine searches.

Application Designer application

You can use the Application Designer application to customize an application by adding or removing columns from the List tab. You can then ensure that the columns to be queried are all indexed.

Application cloning feature

You can clone an application and then use the Application Designer application to create an alternate version with a restricted number of columns that can be queried.

Security groups feature

After you clone applications, you can use security groups to assign users to specific application clones. You can also use security groups to prohibit access to the More Search fields and WHERE clause advanced query options. When you prohibit access to those options, you limit users to query on the List tab of the application.

Migration Manager

Use Migration Manager to migrate configuration content from one product environment to another.

You typically migrate configuration content from a development environment to a test environment and then to a production environment.

- [Getting started with Migration Manager](#)
Migration Manager migrates configuration content from one product environment to another. You typically migrate configuration content from a development environment to a test environment and then to a production environment.
- [Planning for migration](#)
Before you migrate your configuration content, devote sufficient time to develop a migration plan.
- [Migrating your configuration content](#)
The migration process includes a series of preparatory and implementation steps that include setting up your migration collections and package definitions, and then creating, distributing, and deploying packages.
- [Migration troubleshooting](#)
You can identify and correct most errors by responding to the error messages that are displayed in the user interface and by reviewing the messages on the Messages tab of the Migration Manager application. For further troubleshooting, use the log files.

Getting started with Migration Manager

Migration Manager migrates configuration content from one product environment to another. You typically migrate configuration content from a development environment to a test environment and then to a production environment.

After you develop and configure your applications, you can migrate the configurations to a test environment. After testing the configurations, you can migrate them to a production environment. By using Migration Manager, you can migrate iterative configuration changes in a planned and controlled manner.

To migrate the configuration content, you organize it into *packages*. The packages go through a series of steps that make up the migration process. Some steps occur in the originating environment, called the source environment, and some steps occur in the destination environment, called the target environment.

Figure 1. Package movement

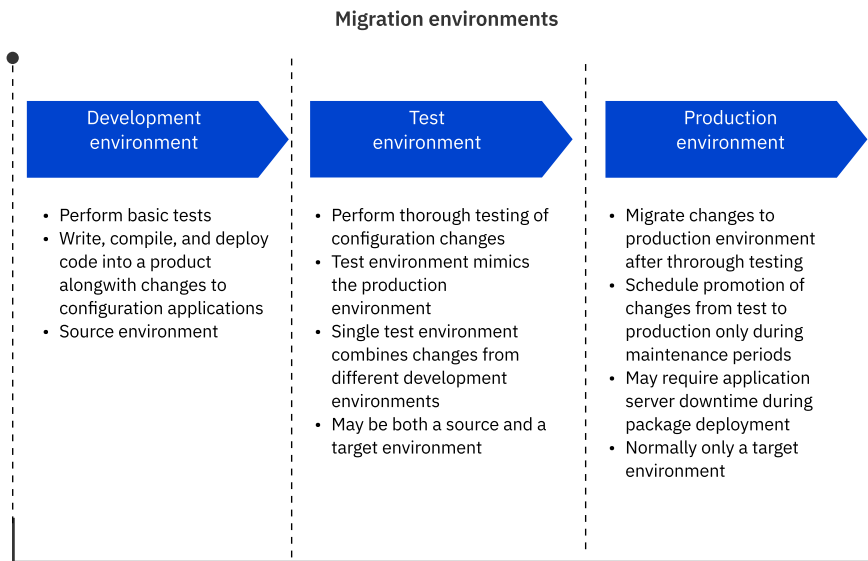

- [Migration environments](#)
You migrate configuration content from one environment to another.
- [Migration process](#)
The migration process involves several tasks in both the source and target environments.
- [Applications used in the migration process](#)
As you migrate configuration content, you use several applications to perform migration tasks.
- [What content you can migrate](#)
The configuration content that you can migrate comes from tables that are in the database or from files that are outside the database.
- [Package definitions and packages](#)
A package definition is a template that specifies the configuration content that goes into a package. A package is an instance of a package definition and contains the configuration content that is migrated.
- [Migration collections](#)
A migration collection is a group of configuration records that can be used to create package definitions. Migration collections simplify the creation of package definitions.

Migration environments

You migrate configuration content from one environment to another.

Development and testing typically occurs in a preproduction environment. You typically migrate configuration content between the following environments:

Figure 1. Migration environments

Development environment

After you identify the configuration changes that you want to make to your product, you can implement them in a development environment. In the development environment, you can perform basic tests to the changes. A development environment is useful if code must be written, compiled, and deployed into a product to accompany changes to configuration applications. In the migration process, in most situations, the development environment is only a source environment.

Test environment

You perform thorough testing of the configuration changes in the test environment. Complete end to end testing and check the logs. You can use a single test environment to mimic the production environment. For the most accurate testing, the test environment must contain all the business applications and configuration changes that you intend to use in the production environment. A single test environment is best suited to aggregating changes that you create in separate development environments. In the migration process, the test environment can be both a source and target environment.

Production environment

After thorough testing, when the software is ready for release, you are ready to migrate your changes to the production environment. When moving configuration content to production, schedule the promotion to occur during maintenance periods. The deployment of Migration Manager packages must be treated in the same manner as product installations and fix packs. In some situations, the deployment of packages might require your application server to remain unavailable to your users for some time. In the migration process, in most situations, the production environment is only a target environment.

When you migrate content, you perform the following steps:

1. Identify the configuration changes and implement them in your product in a development environment.
2. Do basic tests to the changes in the development environment.
3. Test the configuration changes in the test environment.
4. Migrate the changes from test to production environment after thorough testing. Schedule the migration to occur during maintenance periods.

You identify source and target environments by using unique identifiers. The identifier is the combination of the database host name, the database identifier, and the database schema name.

You can set inbound restrictions in a target environment to prevent the distribution and deployment of packages to that environment from restricted sources.

Migration process

The migration process involves several tasks in both the source and target environments.

The process migrates configuration content from a source environment to a target environment. You perform the first set of steps in the source environment and the second set of steps in the target environment.

Steps in the source environment

Step	Description
Optional: Collect	Create migration collections to efficiently collect the configuration records that you want to migrate.
Define	You create, validate, approve, and activate the package definitions. The package definitions specify but do not contain the configuration data. You also define references for the target environments to which you intend to migrate content.
Create	You create packages from the package definitions. The packages contain the configuration data.
Distribute	You specify a target to which you want to distribute the package, and you distribute the package.

Steps in the target environment

Step	Description
Optional: Preview	If the package is in a file, you upload the file to the server. You preview the deployment to ensure that the package deploys without errors.
Deploy	Deploy the package. When the deployment completes, the configuration content is migrated and the migration process ends. You might need to do some post-deployment steps.

Applications used in the migration process

As you migrate configuration content, you use several applications to perform migration tasks.

You use the following applications in the migration process:

Application	Usage
Object Structures	Optional. You can use the Object Structures application to view, create, and modify an object structure. One or more related business objects comprise an object structure. A business object is an object-relational representation that corresponds to a database table of the product. The predefined object structures support many product configuration applications, and you can perform many migrations by using the provided structures.
Automation Scripts	Optional. You can create scripts for integration in the Automation Scripts application to apply custom logic during the processing of object structures when you perform migrations.
Migration Groups	Optional. You use the Migration Groups application to organize and group configuration content that you want to migrate. In many situations, you can work with the predefined (internal) migration groups instead of creating your own (user-defined) migration groups.
Migration Collections	You use the Migration Collections application to define migration collections. A migration collection is a group of configuration records that can be migrated to another environment. Migration collections simplify the creation of package definitions.
Migration Manager	You use the Migration Manager application to migrate your configuration content between product environments. You use this application in both your source and target environments. In a source environment, you define, create, and distribute the packages. In a target environment, you preview and deploy the packages.

What content you can migrate

The configuration content that you can migrate comes from tables that are in the database or from files that are outside the database.

Content that is in the underlying database is usually in tables. The data that is related to the configuration applications is aggregated into groups that can be migrated.

Content that is outside the database is typically in the form of files on the application server file system. When you extend or customize an application you might have files that the application depends on to run. Therefore, you might have to migrate the content that is outside the database together with the configuration content that is in the database. Content that is outside the database is referred to as a compiled source.

For example, suppose that you extend the Purchase Order application in a development environment by making the following changes:

- You add a table and columns to the database by using the Database Configuration application.
- You add a tab to the Purchase Order application by using the Application Designer application.
- You add a domain that contains look-up values by using the Domains application.
- You create a business workflow to automate the approval of the data that is managed by the new table.

The configuration content that you must migrate to your test and production environments includes the table, the tab, the domain and its look-up values, and the workflow. The configuration content includes database content and might include compiled sources.

- **Database configuration content**
Database configuration content is organized into migration objects and migration groups.
- **Compiled sources**
Compiled sources is a term for nondatabase content that is migrated. You can include compiled sources in a package definition, or you can upload compiled sources just before you create a package.

Database configuration content

Database configuration content is organized into migration objects and migration groups.

Business objects, migration objects, and migration groups have the following relationship:

- A business object is a representation of a product database table. Business objects are Java™ objects that help to manage the data in the tables.
- One or more related business objects make up a migration object. The set of business objects is used by an application to perform various tasks.
- One or more related migration objects are organized into a migration group.

Migration objects

A migration object is a group of one or more related business objects that represent database tables. One or more migration objects make up a migration group.

Your database might contain hundreds or thousands of business objects. Many of the business objects are related and are organized into object structures. An object structure therefore facilitates the migration of related data and is called a migration object.

Migration objects exist for many types of records, such as cron tasks, integration channels, security groups, and user interface presentations.

For example, the Workflow Process (DMWFPROCESS) migration object contains 16 business objects that enable the migration of workflow processes, nodes, and notification records that the Workflow Designer application manages.

You can use the predefined migration objects in the migration process or you can use the Object Structures application to create custom migration objects. You define migration objects in a development instance and then move them into test and production environments.

Migration groups

A migration group is a set of related migration objects. When you include a migration group in a package definition, all migration objects in the migration group are migrated. All other migration groups that the migration group depends on are also migrated.

Many applications provide complex features that must be represented by multiple migration objects. The migration groups organize the migration objects and their dependencies to simplify the migration process.

For example, a workflow process defines the process flow, the roles that act on the process, the actions that are run during the process flow, and the notifications (communication templates) that are generated as a result of the process flow. These roles, actions, and communication templates also have their own separate configuration applications. Depending on the nature of your configurations, the DMWFPROCESS migration object might depend on the DMACTION, DMROLE, and DMCOMMTTEMPLATE migration objects. To organize these complex relationships, the Business Process Management (BPM) migration group is provided to order all of the migration objects that are used to migrate workflow and related data.

The ordering of the migration objects within a migration group is critical because of data dependencies. For example, the configuration data for a communication template (represented by the DMCOMMTTEMPLATE) must be processed before the workflow process (DMWFPROCESS) that refers to the communication template. The migration group specifies an order to ensure that migration of the configuration content succeeds.

A migration group can be internal or user-defined. The predefined migration groups are internal. They are linked to other logically related migration groups by dependencies. A dependency ensures that all dependent configuration content is included in a migration. You cannot modify an internal migration group, but you can copy one and modify the copy.

User-defined migration groups are migration groups that you create, including copies of internal migration groups. When you create or modify migration groups, you must include all the necessary migration objects so that you maintain the referential integrity of the database.

Compiled sources

Compiled sources is a term for nondatabase content that is migrated. You can include compiled sources in a package definition, or you can upload compiled sources just before you create a package.

A compiled source is any file that is outside the product database, but is part of the enterprise archive (EAR) file. Compiled sources can be any type of file, such as class files, archive files, image files, property files, and other file types. Compiled sources can also be aggregations of files from the server file system that must be migrated with configuration content from the database. These files are placed into the EAR and deployed into the application server.

To migrate multiple compiled source files, you aggregate them into a single compressed file. To include many files in a package, such as a set of Java™ class files, you create a compressed file of the customizations that preserves the folder structure.

When a package is deployed to a target environment, you can download the compressed compiled source file, extract the contents into the build location, and build the EAR file. To migrate compiled sources, you must ensure that the target environment has a build environment in which you can run the scripts that rebuild the product EAR file.

Package definitions and packages

A package definition is a template that specifies the configuration content that goes into a package. A package is an instance of a package definition and contains the configuration content that is migrated.

Package definitions

A package definition specifies, but does not contain, configuration content. You use package definitions to create packages. By using the same package definition, you can create distinct packages that contain different sets of configuration content.

A package definition specifies the following information:

Header

The name of the package definition, the environment where it is created, and the type (Change, Snapshot, or Collection).

Set of migration groups

The configuration content that is contained in every package that is created from the package definition.

Compiled sources

Optional content from outside the database that is contained in every package that is created from the package definition.

Throughout the migration process, you must manage your package definitions. You must ensure that the correct types of package definitions are created. You must implement an approval process to ensure collaboration among all the migration participants. You must also ensure that package definition statuses are changed at the appropriate time.

If a package definition is incomplete or incorrect, steps of the migration process can fail. For example, if you define a package definition to migrate workflow definitions but do not include the associated communication templates, a package that is based on that package definition might fail to deploy in the target environment.

You can delete a package definition only if it is not activated, its status is not Locked, and no packages are based on it.

Packages

When a package is created, it is instantiated from a package definition and contains the following data:

Type of data	Description
Package manifest	Information about the content of the package, including the following details: <ul style="list-style-type: none">The migration objects that are included in the package.The number of records for each migration object.The readme information that was entered in the source environment by a deployment administrator.Version information about the source environment.Types of content that are in the package.
Package metadata	Information about the definition of the package.
Structural configuration content	Content that is stored in the underlying relational database schema as tables, views, columns, and indexes. For example, objects, attributes, and index definitions are structural content.
Nonstructural configuration content	Content that is typically stored as records in a table. For example, workflow process definitions are nonstructural content.
Compiled sources	Files that include source code customizations, libraries, configuration files, and report executable files. For example, Java™ class files are compiled sources.
History	Life cycle information about the package.

You can create, distribute, and deploy packages. The package is the item that you migrate from one environment to another.

- [Snapshot packages](#)
If you create a Snapshot package definition, its corresponding package contains the configuration content that exists at the moment the package is created.
- [Change packages](#)
A Change package contains configuration content that is captured over a defined period.
- [Collection packages](#)
A Collection package contains records that are based on the information in a migration collection.
- [Package definition status](#)
The status of a package definition determines the actions that you can apply to the package definition and its packages.
- [Package status](#)
The status of a package indicates that it is being created, deployed, or is in an interim state. You can use the status to track the steps of a package or to identify and resolve errors.
- [Deletion of package definitions](#)
When you delete a package definition, all the data that is related to the package definition is also deleted.
- [Deletion of packages](#)
If a package is no longer required or contains errors, you can delete it if it meets certain conditions.

Snapshot packages

If you create a Snapshot package definition, its corresponding package contains the configuration content that exists at the moment the package is created.

Use a Snapshot package definition when you want to migrate the following configuration content:

- Many changes at the same time
- Data that you cannot capture in Change packages because the data loading is performed by scripts
- The initial data load when you are setting up an environment
- Complex changes that require frequent revisions

Typically, you use a Snapshot package during the initial configuration of an environment.

By default, all records in a package definition are contained in a Snapshot package. However, you can filter the data to be included by defining SQL WHERE clauses on the migration objects that are in the package definition. For example, if you create two workflow processes, you can construct an SQL WHERE clause that ensures that only the records that are related to those two processes are included in the package. The criteria are applied to the root object of each object structure that is part of the package definition.

For Snapshot package definitions, you must specify a processing action. The default processing action, Replace, is used at deployment time to replace existing records in the target and to delete related records that are not in the Snapshot package. The AddChange processing action is used at deployment time only to add changed records to the target. Use the AddChange processing action only when configuration records have already been migrated to a target environment and changes have been made in the target environment that you do not want to lose when migrating further changes.

You can override the processing action in the Upload Compiled Sources window when you create a package.

An escalation for service requests is created in a development environment and migrated to a production environment by using a Snapshot package. The escalation has two escalation points. In the production environment, a third escalation point is added to support a business requirement. At the same time, in the development environment, minor changes are made to one of the previous escalation points.

The package that contains the changed escalation point is migrated again to the production environment by using the Replace processing action. In this situation, the production change to the escalation is lost because the escalation in the production environment is replaced by the updated development escalation.

Change packages

A Change package contains configuration content that is captured over a defined period.

You typically use a Change package if you must migrate a limited number of records that change after the initial configuration of an environment. The changes can include database inserts, updates, and deletions.

Use a Change package to migrate the following configuration content:

- Few or selective changes
- Changes that are made by specific users
- Changes that are made to a single application
- Deletions to records in tables

Change packages cannot contain business objects that have unique ID primary keys. You cannot migrate Change packages that contain business objects with unique ID primary keys. A unique ID column has the same name as the corresponding table, followed by the letters ID (for example, column DMMESSAGEID in the DMMESSAGE table). Values for unique ID columns are unique to a database. Migration of such data fails in a target environment because unique ID values might point to different records in the target and source databases. If a Change package definition contains business objects with unique ID primary keys, you cannot activate the package definition.

Insert changes might cause deployment errors if the record exists in the target. Before you migrate Change packages that contain database insert changes, ensure that the target environment does not contain the corresponding record. The record might exist from a previous migration or because it was created in the target environment. If the record exists, the Change package might fail to deploy. An error message indicates that the record exists and cannot be inserted.

Activation

The data in a Change package is based on the database changes that occur between the time that you activate the package definition and the time that you create the package or deactivate the package definition. After you activate a package definition, event listeners monitor the business objects in each object structure of the migration groups that are included in the package definition and start to capture the change information. When you deactivate a Change package definition, the event listeners stop capturing changes.

You use the menu actions in the Migration Manager application to activate and deactivate package definitions. You can activate a package definition only if its status is approved (Appr). An activated package definition cannot be modified.

Event tracking

After a Change package definition is activated, you can view and delete the records that are captured in the package in the View Event Tracking Records window. Typically, you delete Change records only in rare situations, such as if a change is made inadvertently or if a change is made only as a test.

When you use Change packages, you must occasionally reset event tracking to prevent system performance degradation. When you activate a Change package definition, the Migration Manager application captures and writes database changes to a change event tracking table in the database. Over time, the event tracking table might become large and slow down the tracking of changes, and you might need to reset event tracking. When you reset event tracking, the change

information is copied to a history table and removed from the change event tracking table. Do not reset event tracking immediately after you create a package from a package definition because you must first ensure that the deployment occurs without error.

If you migrate ticket templates by using Change packages, you must activate the package definition before any ticket templates are created or updated. After the Change package is deployed, you must reset the event tracking records for the package definition in the source environment.

Time considerations

The length of time that you capture events in a Change package is not restricted. However, Change packages are intended to capture a relatively small number of changes. If you use Change packages, take into account the following considerations:

- Change packages capture events only for the objects that are specified in the package definition. If an object is inadvertently omitted and a long time passes, all the changes to the object are lost.
- If a Change package contains many records captured over a long time, and if changes occur in the target environment simultaneously, the chances of deployment errors increase.
- If test changes are made while a Change package is active, the test changes are captured and are migrated to the target environment.

Administration mode

To make structural changes to the database using the Database Configuration application, administration mode must be turned on. When administration mode is on, event tracking stops. Do not make any other changes while administration mode is on. Wait until the database configuration is complete and administration mode is turned off.

Collection packages

A Collection package contains records that are based on the information in a migration collection.

You cannot create a package definition of type Collection in the Migration Manager application. Instead, you create Collection package definitions from the Migration Collections application after you have defined a migration collection.

Package definition status

The status of a package definition determines the actions that you can apply to the package definition and its packages.

You change the status of a package definition by using the Migration Manager application. The status might also change when you do some steps in the migration process. A package definition can have one of the following statuses:

Wappr (Waiting for approval)

Wappr is the default status when you create or duplicate a package definition. You can modify a package definition only when its status is Wappr. You can change this status to Appr only.

Appr (Approved)

You cannot modify a package definition whose status is Appr. You can toggle the status of a package definition between Appr and Locked. You can change this status to Locked or Wappr. You can activate a Change package definition only when its status is Appr.

Locked

The following restrictions apply to a package definition whose status is Locked:

- You cannot change the content of the package definition.
- You cannot create or distribute packages based on the package definition.
- You cannot create distributions from the package definition.
- For Change package definitions, you cannot reset tracking records.
- In a target environment, you cannot deploy a package that is based on a locked package definition.

You can toggle the status of a package definition between Locked and Appr. You can change this status to Appr only.

You can override the default status of Wappr for a package definition by setting the `mxe.dm.autoapprovepkgdef` property in the System Properties application. If you specify a value of 1 for the system property, the default status is Appr. Specify a value of 0 to use the default status.

Package status

The status of a package indicates that it is being created, deployed, or is in an interim state. You can use the status to track the steps of a package or to identify and resolve errors.

You do not set or change the status of a package. The status is created by the Migration Manager application during the creation or the deployment of a package. You can see the status and the history of status changes on the Package tab in the Migration Manager application.

In a source environment, a package can have one of the following statuses:

Status	Description
CREATE_NEW	The package is marked for creation, but compiled sources are not yet uploaded.

Status	Description
CREATE_INPROGRESS	The package is being created and compiled sources are uploaded.
CREATED	The package is created and can be deployed.
CREATE_ERROR	An error prevented the creation of the package.
CLOSED	The package is closed. Closing a package copies the file to an archive folder and deletes the staging table records. You cannot view or deploy a closed package. If your package is in the form of records in the staging table (distribution is type DATABASE), closing the package deletes the staging table records.

In a target environment, a package can have one of the following statuses:

Status	Description
DEPLOY_NEW	The package is marked for deployment and does not contain compiled sources.
DEPLOY_NEW_CMPSRC	The package is marked for deployment and contains compiled sources.
DEPLOY_INPROGRESS	The package is being deployed.
DEPLOYED	The package is deployed.
DEPLOY_ERROR	An error prevented the deployment of the package.
REDISTRIBUTE	The package is being redistributed.
REDISTRIBUTED	The package is redistributed.
REDISTRIBUTE_ERROR	An error prevented redistribution of the package.
CLOSED	The package is closed.

Deletion of package definitions

When you delete a package definition, all the data that is related to the package definition is also deleted.

You can delete a package definition at any time except when a corresponding package has a status of Create_Inprogress or Deploy_Inprogress.

When you delete a package definition, its related data is deleted. The related data includes the following items:

- The packages that have been created from the package definition.
- The targets and distributions that have been associated with the package definition.
- For a Change package definition, the changes that have been tracked.

You delete a package definition by selecting the Delete Package Definition action.

Deletion of packages

If a package is no longer required or contains errors, you can delete it if it meets certain conditions.

You can delete a package if any of the following conditions is true:

- In the source environment, the status of the package is CREATED, but you have not distributed the package to any target environment.
- In the source environment, the status of the package is CREATE_ERROR.
- In the target environment, the status of the package is DEPLOY_ERROR.

If the package type is FILE and you want to archive the file to refer to later, close the package instead of deleting it.

Migration collections

A migration collection is a group of configuration records that can be used to create package definitions. Migration collections simplify the creation of package definitions.

You can create migration collections to help you organize and create your package definitions, particularly if your product environment is shared by multiple developers.

You can configure migration collections to capture configuration events as they occur, similar to a Change package. Furthermore, you can configure applications so that users can add records to a migration collection from the application.

Each migration collection has an owner. The owner can add and remove configuration records from the migration collection or delete the migration collection. A migration collection is also either private or public. If a migration collection is public, other users with sufficient rights can also do these tasks.

The configuration records that are in a migration collection can be exported to an XML file, which can help you to track configurations externally. For example, you can export the configuration records and then add them to a version control system.

Planning for migration

Before you migrate your configuration content, devote sufficient time to develop a migration plan.

Planning a successful migration of configuration content requires you to do at least the following types of planning:

- Form a qualified migration team to do the migration steps and tasks.
- Identify the configuration changes and content that you must migrate.
- Identify the source and target environments for your migration.
- Devise a schedule for migrations.

You must also consider whether you must track the configuration content that you migrate in an external system, and how you handle the migration limitations that might apply to your content.

- **[Migration participants and roles](#)**
Planning and implementing the migration of configuration content involves several participants and roles.
- **[Validation of database integrity](#)**
Migration errors can be minimized by maintaining the integrity of the database in the source and target environments. Use the Integrity Checker utility to analyze the database.
- **[Migration and database backups](#)**
The Migration Manager application does not provide the capability to roll back a package that fails to deploy in a target environment. Before you migrate configuration content, you must back up your target database.
- **[Migration scheduling](#)**
Schedule migrations to take place during maintenance periods when users are not using the product.
- **[Determining the configuration content to migrate](#)**
As part of migration planning, you must determine whether the predefined migration objects and migration groups meet your needs. You can also compare source and target databases to determine what must be migrated.
- **[Migration limitations](#)**
Although most configuration content can be migrated in most environments, some configuration cannot be migrated. Extra steps are required in some circumstances.
- **[Migration reports](#)**
Several reports are provided to help you plan and manage the migration process.

Migration participants and roles

Planning and implementing the migration of configuration content involves several participants and roles.

The following roles are typical migration roles:

Role	Tasks
Database administrator	Database administrators monitor the integrity of the product databases, and back up and restore the databases.
Product administrator	The product administrators ensure that the product environment is available to the users. Product administrator might need to restart the application servers during the migration process.
Deployment manager	A deployment manager, also called a change manager, controls and coordinates the migration staff, ensures the timely execution of migration tasks, and resolves issues or conflicts. The deployment manager also ensures that all tasks are completed according to your change management plan.
Deployment specialist	Deployment specialists coordinate migration with the component developers and consultants. These specialists must identify and have access to both the development and test environments. They might also require access to production environments. They must be familiar with your IT policies so that they can manage the migration within your software maintenance periods. These specialists must be thoroughly familiar with the Migration Manager applications.
Component developer or consultant	Depending on the configuration changes in your organization, developers and consultants might be required to develop components such as workflows and escalations. Software developers might be required to write Java™ code.

Ensure that deployment specialists and administrators have sufficient user rights to deploy packages. For example, to deploy packages that contain inactive sites, the user must have rights to access inactive sites.

Validation of database integrity

Migration errors can be minimized by maintaining the integrity of the database in the source and target environments. Use the Integrity Checker utility to analyze the database.

Run the Integrity Checker on the databases that are in your source and target environments before and after you migrate configuration content. Examine and correct the warnings or errors in the report. The structure of the database and the data dictionary, which reflects the structure, must not show any discrepancies.

Run the Integrity Checker consistently in both source and target environments.

For more information about the Integrity Checker utility, see the *Upgrade Guide: IBM® Maximo® 6 to Version 7 Products* at [Maximo Upgrade Resources](#).

Migration and database backups

The Migration Manager application does not provide the capability to roll back a package that fails to deploy in a target environment. Before you migrate configuration content, you must back up your target database.

Before migrating changes from a source environment to a target environment, back up your target database. You can use the backup utility from your database vendor. If a migration fails, you can use your backup to restore the database.

Migration scheduling

Schedule migrations to take place during maintenance periods when users are not using the product.

You must plan and control migrations to production environments. Production environments might have users who need the production environment to be available at all times. Consider migrating your configuration content during a maintenance period. System downtime is not required for some migrations. However, using maintenance periods for migration ensures that you can handle any errors that occur and that you can restore the production system if necessary.

Determining the configuration content to migrate

As part of migration planning, you must determine whether the predefined migration objects and migration groups meet your needs. You can also compare source and target databases to determine what must be migrated.

The predefined migration objects and migration groups cover the migration of most typical configuration content. Review them to determine whether you must create migration objects and groups for your business requirements.

If you must customize the provided configuration content or create configuration content, you define the object structures in the Object Structures application. You can then add the object structures to migration groups in the Migration Groups application.

- [Predefined migration objects and migration groups](#)
Several migration objects and migration groups are included with the product to enable the migration of configuration content.
- [Creating migration objects](#)
You can create a migration object, or object structure, if no predefined object structure exists for one or more tables that you want to migrate. As an alternative to creating an object structure, you can add one or more objects to a predefined object structure.
- [Migration object processing sequences](#)
The order of the migration objects within a migration group determines the sequence in which the objects are processed. The order must be correct to ensure that the deployment of packages succeeds.
- [Creating migration groups](#)
You create a migration group to specify the configuration content that is to be migrated in a package. If you create your own object structures or reorganize the predefined object structures, you might need to create a migration group to contain those structures.
- [Deletion of migration groups](#)
You can delete a migration group if it meets certain conditions.
- [Comparing source and target databases](#)
For each package definition, you can identify the differences between a source database and a target database before you deploy the package. The results of a database comparison can help you determine the configuration content that must be migrated.
- [Setting inbound restrictions](#)
In a target environment, you can prevent the distribution and deployment of packages that come from restricted source environments. To accept packages that come only from an authorized source environment, set restrictions on all other environments.

Predefined migration objects and migration groups

Several migration objects and migration groups are included with the product to enable the migration of configuration content.

Each migration group contains one or more migration objects.

- [Data Dictionary migration group](#)
The Data Dictionary migration group manages objects, such as tables, attributes, relationships, and indexes.
- [Document Library migration group](#)
The Document Library migration group manages document library types and links to various product applications.
- [Application migration group](#)
The Application migration group manages the application user interface.
- [Resources migration group](#)
The Resources migration group is used to manage people and groups of people.
- [Functional migration group](#)
The Functional migration group is used to manage shifts, shift patterns, work periods, and calendars.
- [Application Security migration group](#)
The Application Security migration group is used to manage application security.
- [Reporting migration group](#)
The Reporting migration group is used to manage reports.
- [System migration group](#)
The System migration group performs various server-side tasks in the product. Object structures in this group are used, for example, to run cron tasks, create log file entries, and manage system properties.
- [Integration migration group](#)
The Integration migration group is used to manage integration interfaces, external systems, and other integration components.

- [Business Process Management migration group](#)
The Business Process Management migration group is used in the management of workflow processes, roles, communication templates, email listeners, actions, and escalations.
- [Migration migration group](#)
The Migration migration group is used to manage migration groups, dependencies, and migration packages.
- [Ticket Template Data migration group](#)
The Ticket Template Data migration group manages ticket templates.
- [Classification Data migration group](#)
The Classification data migration group manages classifications.
- [Interaction System Objects migration group](#)
The Interaction System Objects migration group is used to manage business objects that are related to web service interactions.
- [Interaction Artifacts migration group](#)
The Interaction Artifacts migration group is used to manage web service interactions.
- [Scripting System Objects migration group](#)
The Scripting System Objects migration group is used to manage automation scripts.
- [OSLC migration group](#)
The OSLC migration group is used to manage OSLC interactions, providers, and resource types.

Data Dictionary migration group

The Data Dictionary migration group manages objects, such as tables, attributes, relationships, and indexes.

DMCONDITION object structure

Managing application	Condition Expression Manager
Supported objects	Conditions
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMCURRENCY object structure

Managing application	Currency Codes
Supported objects	Currency codes
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the CURRENCY business object.
Carries records in multiple languages	No

DMDEFGLCONFIGURE object structure

Managing application	Database Configuration
Supported objects	General ledger (GL) definition configuration and components
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra processing logic to ensure that GL components can be loaded without error.
Carries long description	No
Carries records in multiple languages	No

DMGLCONFIGURE object structure

Managing application	Database Configuration
Supported objects	General ledger (GL) configuration and components
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra processing logic to ensure that GL components can be loaded without error.
Carries long description	No
Carries records in multiple languages	No

DMLANGUAGE object structure

Managing application	Not applicable
Supported objects	Languages
Outbound content processing	None
Inbound content processing	When a package is deployed, this object structure ensures that the enabled language is not disabled.
Carries long description	No
Carries records in multiple languages	No

DMMAXDOMAIN object structure

Managing application	Domains
Supported objects	Domains
Outbound content processing	During package creation in a source environment, this object structure skips internal domains that are not synonyms. This object structure does not extract the DBSTORAGEPARTITION domain, because this extraction must be managed separately in individual environments.
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that CROSSOVERDOMAIN records can be loaded without error.
Carries long description	No
Carries records in multiple languages	Yes, for the MAXDOMAIN, ALNDOMAIN, and SYNONYMDOMAIN business objects.

DMMAXINTOBJECT object structure

Managing application	Object Structures
Supported objects	Object structures
Outbound content processing	During package creation in a source environment, this object structure extracts only the structures that are configurable.
Inbound content processing	When a package is deployed, this object structure ensures that new objects that are associated with the object structure are loaded without error.
Carries long description	Yes, for the MAXINTOBJECT business object.
Carries records in multiple languages	No

DMMAXLOOKUPMAP object structure

Managing application	Database Configuration
Supported objects	Related keys
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMMAXMESSAGES object structure

Managing application	Database Configuration
Supported objects	Messages
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	Yes, for the MAXMESSAGES business object.

DMMAXOBJECTCFG object structure

Managing application	Database Configuration
Supported objects	Objects, attributes, indexes, views, tables, columns, autokeys, audit table settings
Outbound content processing	During package creation in a source environment, this object structure does not extract MXIN_INTER_TRANS and MXOUT_INTER_TRANS business objects. It also does not extract TEXTSEARCH indexes.
Inbound content processing	During package deployment in a target environment, this object structure checks whether the underlying target database is a Db2® database. If it is, the index that serves as a native primary key for the underlying database is not migrated.
Carries long description	No
Carries records in multiple languages	Yes, for the MAXOBJECTCFG and MAXATTRIBUTECFG business objects.

DMMAXRELATIONSHIP object structure

Managing application	Database Configuration
Supported objects	Relationships
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	None

DMMAXSEQUENCE object structure

Managing application	Database Configuration
Supported objects	Sequences
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMMAXSERVICE object structure

Managing application	Database Configuration
Supported objects	Services
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	Yes, for the MAXSERVICE business objects.
Additional information	A service is associated with a Java™ class. When you migrate this object structure, you must migrate the class file as a compiled source. Restart the application server to start new services.

DMMAXVARS object structure

Managing application	Multiple applications
Supported objects	Maxvars
Outbound content processing	None
Inbound content processing	When a package is deployed, this object structure skips new MAXVAR records.
Carries long description	No
Carries records in multiple languages	No

DMORGANIZATION object structure

Managing application	Organizations
Supported objects	Organizations and sites
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra processing logic to ensure that address references for a site can be resolved. If you created an organization in the target, the new organization is inactive.
Carries long description	Yes, for the ORGANIZATION, ADDRESS, and SITE business objects.
Carries records in multiple languages	No

DMSETS object structure

Managing application	Sets
Supported objects	Sets
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the SETS business object.
Carries records in multiple languages	No

Document Library migration group

The Document Library migration group manages document library types and links to various product applications.

DMDOCTYPES object structure

Managing application	Multiple applications
Supported objects	Document library
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that DOCINFO records can be loaded without error.
Carries long description	Yes, for the DOCINFO business object.
Carries records in multiple languages	No

Application migration group

The Application migration group manages the application user interface.

DMKPIMAIN object structure

Managing application	KPI Manager
Supported objects	KPI (key performance indicator)
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the KPIMAIN business object.
Carries records in multiple languages	No

DMMAXAPPS object structure

Managing application	Application Designer
Supported objects	Applications
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that APPDOCTYPE records can be loaded without error.
Carries long description	Yes, for the SIGOPTION business object.
Carries records in multiple languages	Yes, for the MAXAPPS, MAXLABELS, and SIGOPTION business objects.
Additional information	If you insert or update an application presentation, you might need to restart the application server.

DMMAXLAUNCHENTRY object structure

Managing application	Launch in Context
Supported objects	Launch entries
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the MAXLAUNCHENTRY business object.
Carries records in multiple languages	No

DMMAXMENU object structure

Managing application	Application Designer
Supported objects	Menus
Outbound content processing	None
Inbound content processing	When a package is deployed, this object structure ensures that MAXMENU records are loaded without errors. The position column for the MAXMENU might be changed if the position is in use in the target environment.
Carries long description	No
Carries records in multiple languages	Yes, for the MAXMENU business object.

DMMAXMODULES object structure

Managing application	Not applicable
-----------------------------	----------------

Supported objects	Modules
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	Yes, for the MAXMODULES business object.

DMSCTEMPLATE object structure

Managing application	Start Center
Supported objects	Start center templates
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No
Additional information	Only the start center templates are supported for migration. After you migrate a start center template, you can apply the template to an appropriate Start Center.

Resources migration group

The Resources migration group is used to manage people and groups of people.

DMPERSON object structure

Managing application	People
Supported objects	People
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that PERSON records are loaded without error.
Carries long description	Yes, for the PERSON business object.
Carries records in multiple languages	No

DMPERSONGROUP object structure

Managing application	Person Groups
Supported objects	Person groups
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that PERSONGROUPTEAM records are migrated without error.
Carries long description	Yes, for the PERSONGROUP business object.
Carries records in multiple languages	No

Functional migration group

The Functional migration group is used to manage shifts, shift patterns, work periods, and calendars.

DMCALENDAR object structure

Managing application	Calendars
Supported objects	Calendars
Outbound content processing	None
Inbound content processing	When a package is deployed, this object structure ensures that WORKPERIOD records are loaded without error.
Carries long description	Yes, for the CALENDAR business object.
Carries records in multiple languages	No

DMSHIFT object structure

Managing application	Calendars
Supported objects	Shifts

Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that SHIFTPATTERNDAY records are loaded without error.
Carries long description	Yes, for the SHIFT business object.
Carries records in multiple languages	No

Application Security migration group

The Application Security migration group is used to manage application security.

DMCTRLGROUP object structure

Managing application	Application Designer
Supported objects	Control security
Outbound content processing	None
Inbound content processing	When a package is deployed, the object structure ensures that CTRLCONDITION records and CTRLCONDPROP records are loaded without errors.
Carries long description	No
Carries records in multiple languages	Yes, for the CTRLCONDPROP business object.

DMMAXGROUP object structure

Managing application	Security Groups
Supported objects	Security groups
Outbound content processing	When a package is created, this object structure adds the SCTEMPLATE information.
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic. This logic ensures that security signature options records for change password and start center functions can be loaded securely.
Carries long description	Yes, for the MAXGROUP business object.
Carries records in multiple languages	No

DMMAXSERVSECURITY object structure

Managing application	Security Groups
Supported objects	Service security
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMMAXUSER object structure

Managing application	Users
Supported objects	Users
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, if a new user must be created, a new password is generated for the user. An email message with the password is sent to the email address that is specified in the person record of the user. If no email address is specified, the user cannot receive the password and cannot log in.
Carries long description	No
Carries records in multiple languages	No
Additional information	In the Users and Security Groups applications, an administrator can control the generation of an email notification to a new user. The PWRESET communication template is used to create this notification. If you want the email notification to go to new users, ensure that the PERSON records for these users are migrated with appropriate email IDs. If you want to alter the content of the email notification, duplicate the PWRESET communication template and use the new communication template to send notifications.

DMSIGOPTFLAG object structure

Managing application	Application Designer
Supported objects	Signature options flags
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMSIGOPTION object structure

Managing application	Security Groups
Supported objects	Signature Options
Outbound content processing	None
Inbound content processing	When a package is deployed, this object structure ensures that SIGOPTION records are loaded without errors, and skips SIGOPTION records that are carried by MAXAPPS records.
Carries long description	Yes, for the SIGOPTION business object.
Carries records in multiple languages	Yes, for the SIGOPTION business object.

Reporting migration group

The Reporting migration group is used to manage reports.

DMKPIMAIN object structure

Managing application	KPI Manager
Supported objects	KPI (key performance indicator)
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the KPIMAIN business object.
Carries records in multiple languages	No

DMREPORT object structure

Managing application	Report Administration
Supported objects	Reports
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that REPORTAUTH and REPORTLOOKUP records are loaded without error.
Carries long description	No
Carries records in multiple languages	Yes, for the REPORT and REPORTLABEL business objects.

DMREPORTDESIGN object structure

Managing application	Report Administration
Supported objects	Report design
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

System migration group

The System migration group performs various server-side tasks in the product. Object structures in this group are used, for example, to run cron tasks, create log file entries, and manage system properties.

DMCRONTASKDEF object structure

Managing application	Cron Task Setup
Supported objects	Cron tasks
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, any added cron task receives parameters from the CRONTASKINSTANCE business object in the target environment.
Carries long description	Yes, for the CRONTASKDEF and CRONTASKINSTANCE business objects.
Carries records in multiple languages	No

DMMAXLOGAPPENDER object structure

Managing application	Logging
Supported objects	Log appenders
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMMAXLOGGER object structure

Managing application	Logging
Supported objects	Loggers
Outbound content processing	None
Inbound content processing	When a package is deployed, this object structure ensures that child logger records are loaded without error.
Carries long description	No
Carries records in multiple languages	No

DMMAXPROP object structure

Managing application	System Properties
Supported objects	System properties
Outbound content processing	During package creation in a source environment, the only system properties that are extracted are those that are user-defined, that do not have file overrides configured, and that are common to all instances of the application server.
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

Integration migration group

The Integration migration group is used to manage integration interfaces, external systems, and other integration components.

DMMAXENDPOINT object structure

Managing application	End Points
Supported objects	Endpoints
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the MAXENDPOINT business object.
Carries records in multiple languages	No

DMMAXEXTSYSTEM object structure

Managing application	External Systems
Supported objects	External systems
Outbound content processing	None
Inbound content processing	When a package is deployed, this object structure ensures that MAXEXTOVER records are loaded without error.
Carries long description	Yes, for the MAXEXTSYSTEM business object.
Carries records in multiple languages	No

DMMAXIFACECONTROL object structure

Managing application	External Systems, Publish Channels, Enterprise Services
Supported objects	Interface controls
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the MAXIFACECONTROL business object.
Carries records in multiple languages	No

DMMAXIFACEIN object structure

Managing application	Enterprise Services
Supported objects	Enterprise services
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the MAXIFACEIN and MAXIFACEPROC business objects.
Carries records in multiple languages	No

DMMAXIFACEINVOKE object structure

Managing application	Invocation Channels
Supported objects	Invocation channels
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the MAXIFACEINVOKE business object.
Carries records in multiple languages	No

DMMAXIFACEOUT object structure

Managing application	Publish Channels
Supported objects	Publish channels
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the MAXIFACEOUT and MAXIFACEPROC business objects.
Carries records in multiple languages	No

DMMAXQUEUE object structure

Managing application	External Systems
Supported objects	Queues
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMWSREGISTRY object structure

Managing application	Web Service Library
Supported objects	Library of all the registered web services
Outbound content processing	None
Inbound content processing	All the web services are registered, the WSDL is generated, and the deployment descriptor is updated.
Carries long description	Yes
Carries records in multiple languages	No, except for the Description column.

Business Process Management migration group

The Business Process Management migration group is used in the management of workflow processes, roles, communication templates, email listeners, actions, and escalations.

DMACTION object structure

Managing application	Actions
Supported objects	Actions
Outbound content	None

processing	
Inbound content processing	During package deployment in a target environment, checks whether an action is linked to an escalation. If an action is linked to an escalation, the object structure does not delete the action and instead places a message in the product log file.
Carries long description	Yes, for the ACTION business object.
Carries records in multiple languages	No

DMACTIONGROUP object structure

Managing application	Actions
Supported objects	Action groups
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No
Additional information	The Migration Manager application migrates actions before it migrates action groups.

DMCOMMTEMPLATE object structure

Managing application	Communication Templates
Supported objects	Communication templates
Outbound content processing	When a package is created, the class adds the SCTEMPLATE information to the package.
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that DOCLINKS records for a communication template can be loaded without error.
Carries long description	No
Carries records in multiple languages	No

DMESCALATION object structure

Managing application	Escalations
Supported objects	Escalations
Outbound content processing	None
Inbound content processing	When a package is created, this object structure ensures that escalation records for new communication templates are loaded without error.
Carries long description	Yes, for the ESCALATION business object.
Carries records in multiple languages	No
Additional information	An escalation can include a reference to an action group, which in turn can contain one or more actions. Therefore, migrate action groups and actions before escalations. Similarly, an escalation can include a reference to one or more communication templates. Therefore, migrate communication templates before actions.

DMINBOUNDCOMMCFG object structure

Managing application	Email listeners
Supported objects	Email listeners
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that email listener references to a workflow process are resolved correctly. Also ensures that email listener configuration records are loaded without error.
Carries long description	No
Carries records in multiple languages	No

DMROLE object structure

Managing application	Roles
-----------------------------	-------

Supported objects	Roles
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the MAXROLE business object.
Carries records in multiple languages	No

DMWFPROCESS object structure

Managing application	Workflow Designer
Supported objects	Workflow process
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure creates a revision of a workflow process whenever workflow data is imported. This object structure performs extra processing to ensure that other workflow-related records can be loaded without error. Before you import a workflow process, deploy into the target environment any subprocesses and communication templates that the workflow process depends on.
Carries long description	Yes, for the WFPROCESS, WFNODE, WFASSIGNMENT, and WFINTERACTION business objects.
Carries records in multiple languages	No

Migration migration group

The Migration migration group is used to manage migration groups, dependencies, and migration packages.

DMCFGGROUP object structure

Managing application	Migration Groups
Supported objects	Migration groups
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that migration group records with references to object structures can be loaded without error.
Carries long description	No
Carries records in multiple languages	No

DMDEPENDENCY object structure

Managing application	Migration Groups
Supported objects	Dependencies
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMMAPDEF object structure

Managing application	Migration Manager
Supported objects	Attributes selected for replacement
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMMAPRULES object structure

Managing application	Migration Manager
Supported objects	Replacement rules
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure applies the attribute replacement rules.

Carries long description	No
Carries records in multiple languages	No

DMPACKAGE object structure

Managing application	Migration Manager
Supported objects	Packages
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No
Additional information	All the object structures that comprise the Migration Manager and Migration Groups applications are nonconfigurable, to prevent errors when packages are processed. You cannot add business objects to the respective object structures. You cannot include or exclude attributes of individual business objects in the respective object structures.

DMPACKAGEDEF object structure

Managing application	Migration Manager
Supported objects	Package definitions
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the DMPACKAGEDEF business object.
Carries records in multiple languages	No

DMPKGDSTTRGT object structure

Managing application	Migration Manager
Supported objects	Package targets
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

Ticket Template Data migration group

The Ticket Template Data migration group manages ticket templates.

DMTKTEMPLATE object structure

Managing application	Migration Manager
Supported objects	Ticket templates, ticket template specifications, ticket template activity records
Outbound content processing	During package creation in a source environment, this object structure sets the values for the HIERARCHYPATH and EXTERNALREFID attributes.
Inbound content processing	During package deployment in a target environment, this object structure finds the CLASSSTRUCTUREID value based on the HIERARCHYPATH attribute and sets the value. It also sets the TKTEMPLATESPEC, TKTEMPLACTIVITY, and TKTEMPLACTYSPEC objects so that the correct records are found for Change or Replace actions.
Carries long description	Yes
Carries records in multiple languages	No
Additional information	To enable the update of ticket templates, the object structure uses the EXTERNALREFID persistent attribute as an alternate key. Do not change this attribute. Also, do not remove the HIERARCHYPATH non-persistent attribute from the TKTEMPLATE, TKTEMPLACTIVITY, and TKTEMPLACTYSPEC objects, or deployment errors occur.

Ticket template dependencies

Ticket templates can have many dependencies. A ticket template record might depend on a person group, person, service group, service, company, classification, or organization. A ticket template activity record might depend on a job plan, organization, site, person, person group, company, or classification. A ticket template specification record or a ticket template activity specification record might depend on an asset attribute or unit of measure. None of this related data is part of the ticket template object structure. Therefore, the following related data must be migrated separately or created in the target environment before or after you migrate a ticket template:

Related data	Migration
Classifications, organizations, and sites	Migrate the related data separately or create it in the target environment.
Person groups and person records	Migrate the related data separately or create it in the target environment, and then link the related data to the migrated ticket template.
Asset attributes, companies, job plans, services and service groups, and units of measure	After the ticket template is migrated, create the related data in the target environment and then link the related data to the migrated ticket template.

Autokey values

If you do not want to use autokey values for the TEMPLATEID attribute, and want the users to always specify a value that is migrated, you must make the following customizations in the source and target environments:

- Remove the attribute restriction from the TEMPLATEID attribute and disable the autokey for the TKTEMPLATE object by using the Database Configuration application.
- Remove the alternate key that is defined on the TKTEMPLATE object of the DMTKTEMPLATE object structure by using the Object Structures application.

If you leave the autokey enabled, do not remove the restriction from the TEMPLATEID attribute. If you remove the restriction, but users do not override the generated autokey value, records could be updated in error.

Classification Data migration group

The Classification data migration group manages classifications.

DMCLASSIFICATION object structure

Managing application	Classifications
Supported objects	Classifications
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure processes the class structure from the hierarchy path.
Carries long description	Only the CLASSSTRUCTURE long description
Carries records in multiple languages	No
Additional information	Do not remove the HIERARCHYPATH or DATATYPE non-persistent attributes, or deployment errors occur. Do not change the autokey attribute CLASSSTRUCTUREID, or records cannot be migrated.

Classification dependencies

Classifications can have many dependencies. A class structure record might depend on an organization or site. A classification Use With record might depend on a business object. A class specification might depend on a domain, unit of measure, organization, or site. A classification specification Use With record might depend on an organization, site, or other business object. None of this related data is part of the classification object structure. Therefore, the following related data must be migrated separately or created in the target environment before or after you migrate a classification:

Related data	Migration
Organizations, sites, and domains	Migrate the related data separately or create it in the target environment.
Units of measure	Create the data in the target environment.
Other business object	Migrate the related data separately, or create it in the target environment and apply the configuration changes by using the configdb utility.

Interaction System Objects migration group

The Interaction System Objects migration group is used to manage business objects that are related to web service interactions.

DMMAXDOMAIN object structure

Managing	Domains
-----------------	---------

application	
Supported objects	Domains
Outbound content processing	During package creation in a source environment, this object structure extracts only the domains that are not internal. This object structure does not extract the DBSTORAGEPARTITION domain, because this extraction must be managed separately in individual environments.
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that CROSSOVERDOMAIN records can be loaded without error.
Carries long description	No
Carries records in multiple languages	Yes, for the MAXDOMAIN, ALNDOMAIN, and SYNONYMDOMAIN business objects.

DMMAXINTOBJECT object structure

Managing application	Object Structures
Supported objects	Object structures
Outbound content processing	During package creation in a source environment, this object structure extracts only the structures that are configurable.
Inbound content processing	None
Carries long description	Yes, for the MAXINTOBJECT business object.
Carries records in multiple languages	No

DMMAXOBJECTCFG object structure

Managing application	Database Configuration
Supported objects	Objects, attributes, indexes, views, tables, columns, autokeys
Outbound content processing	During package creation in a source environment, this object structure does not extract business objects that are marked as INTERNAL. This object structure does not extract business objects that are audit tables.
Inbound content processing	During package deployment in a target environment, this object structure checks whether the underlying target database is a Db2® database. If it is, the index that serves as a native primary key for the underlying database is not migrated.
Carries long description	No
Carries records in multiple languages	Yes, for the MAXOBJECTCFG and MAXATTRIBUTECFG business objects.

DMMAXRELATIONSHIP object structure

Managing application	Database Configuration
Supported objects	Relationships
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	None

Interaction Artifacts migration group

The Interaction Artifacts migration group is used to manage web service interactions.

DMINTERACTION object structure

Managing application	Create Interaction, Interactions
Supported objects	All interactions with external applications.
Outbound content processing	During package creation in a source environment, this object structure exports the interactions.
Inbound content processing	During package deployment in a target environment, this object structure imports the interactions..
Carries long description	Yes
Carries records in multiple languages	No, except for the Description column.

DMMAXAPPS object structure

Managing application	Application Designer
Supported objects	Applications
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic to ensure that DOCINFO records can be loaded without error.
Carries long description	Yes, for the SIGOPTION business object.

Carries records in multiple languages	Yes, for the MAXAPPS, MAXLABELS, and SIGOPTION business objects.
Additional information	If you insert or update an application presentation, you might need to restart the application server.

DMMAXENDPOINT object structure

Managing application	End Points
Supported objects	Endpoints
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the MAXENDPOINT business object.
Carries records in multiple languages	No

DMMAXGROUP object structure

Managing application	Security Groups
Supported objects	Security groups
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure implements extra logic. This logic ensures that security signature options records for change password and start center functions can be loaded securely.
Carries long description	Yes, for the MAXGROUP business object.
Carries records in multiple languages	No

DMMAXIFACEINVOKE object structure

Managing application	Invocation Channels
Supported objects	Invocation channels
Outbound content processing	None
Inbound content processing	None
Carries long description	Yes, for the MAXIFACEINVOKE business object.
Carries records in multiple languages	No

DMMAXMENU object structure

Managing application	Application Designer
Supported objects	Menus
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	Yes, for the MAXMENU business object.

Scripting System Objects migration group

The Scripting System Objects migration group is used to manage automation scripts.

DMLAUNCHPOINT object structure

Managing application	Automation Scripts
Supported objects	Automation script launch points and launch point variables
Outbound content processing	None
Inbound content processing	During package deployment in a target environment, this object structure creates, updates, or deletes the script launch points and their variables.
Carries long description	No
Carries records in multiple languages	No

DMSCRIPT object structure

Managing application	Automation Scripts
Supported objects	Automation scripts and automation script variables
Outbound content processing	During package creation in a source environment, this object structure extract the scripts and the script variables that are

	defined in the application.
Inbound content processing	During package deployment in a target environment, this object structure creates, updates, or deletes the scripts and their variables.
Carries long description	No
Carries records in multiple languages	No

OSLC migration group

The OSLC migration group is used to manage OSLC interactions, providers, and resource types.

DMOSLCINTERACTION object structure

Managing application	OSLC Providers
Supported objects	OSLCINTERACTION, OSLCPREFILLMAP
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMOSLCPROVIDER object structure

Managing application	OSLC Providers
Supported objects	OSLCPROVIDER
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

DMOSLCRESTYPE object structure

Managing application	OSLC Providers
Supported objects	OSLCRESOURCETYPES
Outbound content processing	None
Inbound content processing	None
Carries long description	No
Carries records in multiple languages	No

Creating migration objects

You can create a migration object, or object structure, if no predefined object structure exists for one or more tables that you want to migrate. As an alternative to creating an object structure, you can add one or more objects to a predefined object structure.

About this task

You can include or exclude attributes of any business object that is part of a migration object. For example, it might be necessary to exclude attributes that are set by some configuration applications. Do not modify included or excluded attributes of business objects that are part of the included object structures that are used by the Migration Manager application. If you modify these attributes, the corresponding migration objects might not work correctly.

If you create your own object structures, you must test them by including them in a migration group and migrating the corresponding data. Sometimes, application business rules can prevent the processing of data that is migrated by using your own object structure. In this situation, you can author Java™-based object structure processing classes that can help control the migration.

Procedure

1. In the Object Structures application, on the toolbar, click New Object Structure
2. In the Object Structure field, specify a name.
The name must begin with an alphabetic character.
3. In the Consumed By field, specify MIGRATIONMGR.
4. Define the source objects for this object structure:
 - a. In the Source Objects table window, click New Row.
 - b. To add the primary (top-level) object to an object structure, specify a value in the Object field.
 - c. To add a child object to an object structure, specify values in the Object, Parent Object, Relationship, and Object Order fields.

- In a child object entry, the Relationship field can contain only a reference to a parent object or a reference to itself. If you establish a self-referencing relationship, the Self Reference check box is selected.
5. Click Save Object Structure.

Migration object processing sequences

The order of the migration objects within a migration group determines the sequence in which the objects are processed. The order must be correct to ensure that the deployment of packages succeeds.

Each migration object within a migration group must have a unique sequence number. Objects are processed in sequential order during the creation and deployment of the package. You can view the processing order of migration objects for all the predefined migration groups in the Migration Groups application.

If you use the predefined migration objects, the correct processing order is already established. If you create new migration groups, you must determine the order of the migration objects within the migration group.

You can use the Business Process Management migration group to migrate workflow processes. The migration group contains the following migration objects, which must be processed in the order shown:

1. DMACTION
2. DMACTIONGROUP
3. DMROLE
4. DMCOMMTEMPLATE
5. DMESCALATION
6. DMWFPROCESS

This order must be followed because a workflow process might refer to one or more actions, roles, communication templates, or escalations. Similarly, an escalation might refer to one or more actions or communication templates, and a template might refer to a role.

Configuration content for a communication template (DMCOMMTEMPLATE migration object) must be processed before the workflow process (DMWFPROCESS migration object) that refers to the communication template. Therefore, in the BPM migration group, the DMCOMMTEMPLATE migration object has a processing order of 4 and the DMWFPROCESS migration object has a processing order of 6.

Creating migration groups

You create a migration group to specify the configuration content that is to be migrated in a package. If you create your own object structures or reorganize the predefined object structures, you might need to create a migration group to contain those structures.

About this task

Be sure to identify all the relationships between the business objects, including dependencies. If you omit required migration objects or dependencies, packages that use the migration group might fail to deploy.

Include all the necessary migration objects so that you maintain the referential integrity of the database to which you are migrating the configuration content. Assign the correct process order numbers, to ensure that the migration objects are processed in the correct order. Use the predefined migration groups as a reference when you are adding dependencies to your own migration groups.

Procedure

1. In the Migration Groups application, click New Migration Group.
2. In the Migration Group field, specify the name of the migration group.
3. Optional: To change the default process order, specify a new value in the Migration Group Order field.
4. Specify one or more migration objects to be added to the migration group:
 - a. In the Migration Objects table window, click New Row.
 - b. In the Migration Object field, specify the name of a migration object.
If you click Detail Menu and go to the Object Structures application to create a migration object, specify `MIGRATIONMGR` in the Consumed By field in that application.
 - c. Optional: To change the default process order, enter a new value in the Migration Object Order field.
5. Specify any dependent migration groups:
 - a. In the Dependency table window, click New Row.
 - b. In the Dependent Migration Group field, specify a migration group.
6. Save the migration group.

Deletion of migration groups

You can delete a migration group if it meets certain conditions.

You can delete a migration group if all the following conditions are true:

- The group is not an internal migration group.
- The group is not included in any active or inactive migration package.

- No other migration group depends on the migration group.

Comparing source and target databases

For each package definition, you can identify the differences between a source database and a target database before you deploy the package. The results of a database comparison can help you determine the configuration content that must be migrated.

The results of a database comparison can be added to a migration collection, which you can then use to create the packages that must be migrated.

Before you begin

Before you can run a database comparison, the package definition must exist in the source environment and the target must be defined in the Migration Manager application.

About this task

You can run a database comparison at different times to help determine what content must be migrated and tested. You can specify any type of package definition for the database comparison.

The results of the database comparison indicate whether the records match or whether the records are in only the source database or the target database.

Procedure

1. In the Migration Manager application, select a package definition.
2. On the Comparison tab, click Start Comparison Job.
3. Select a target database and click Start Job.
4. Click Refresh Job Status and review the status messages.
5. Optional: When the job finishes, add the results to a migration collection.

Setting inbound restrictions

In a target environment, you can prevent the distribution and deployment of packages that come from restricted source environments. To accept packages that come only from an authorized source environment, set restrictions on all other environments.

Before you begin

Obtain the host names, database names, and database schema names of the restricted source environments from a system administrator.

About this task

For a database distribution, the application checks the target for any restrictions before distribution. If a restriction is found, the database is not distributed to the target. For a file distribution, restrictions are checked when a package file is selected for deployment.

Procedure

1. In a target environment, start the Migration Manager application and click Select Action > Set Inbound Restrictions.
2. In the Set Inbound Restrictions window, click New Row.
3. In the Database Host field, specify the host name of the computer where the database is running. For example, if the fully qualified host name is xyz.usa.example.com, type xyz in the field.
4. In the Database Name field, specify the database instance or the database identifier on the server where the database is running.
For databases that use names longer than eight characters, such as Oracle databases, the first eight characters of the name must be unique so that inbound restrictions for different source environments are applied correctly.
5. In the Database Schema field, specify the database schema in the database instance on the computer where the database is running.
6. Click OK.

Migration limitations

Although most configuration content can be migrated in most environments, some configuration cannot be migrated. Extra steps are required in some circumstances.

Actions

To migrate a WFINITIAE action, which initiates a workflow process, the workflow process must be active. Therefore, two deployments are required. Migrate the workflow process and activate it in the target environment first, and then migrate the action.

Action groups

To migrate action groups that are created in the Actions application, you must also migrate all the actions that are in each action group. If you do not migrate the actions, the action groups cannot be used in the target environment.

Base language

A target environment must have the same base language as the source environment. If the target base language is different from the source base language, packages cannot be deployed.

Charts of accounts

Migration Manager does not migrate charts of accounts (GLs).

Classifications

The following limitations affect the migration of classifications:

- Data that is related to the CLASSIFICATION table is not migrated.
- You cannot migrate a classification hierarchy in which a parent classification was changed to alter the parent-child classification relationship.
- In Snapshot packages, regardless of the selected processing action, a database update is performed for classification records.
- You cannot migrate two or more different classifications that have the same hierarchy path.

Collection restrictions

Data restrictions for objects and attributes are migrated, but collection restrictions are only partially migrated. Data in the SECURITYRESTRICT table is migrated. Data in the COLLECTIONAUTH table is not migrated.

Conditions on security groups

In some situations you might need to create and deploy two separate Change packages. For example, consider the following scenario:

You have a security group that has a data restriction, and the data restriction references a condition. You create a package for application security and deploy the package to the target environment. You then remove the condition from the security group in the source environment, and delete the condition. You create a new package for application security and deploy the package to the target environment, but an error occurs.

The error occurs because during deployment, the Migration Manager attempts to delete the condition first.

To avoid this error, you must perform the migration in two steps. First, create a Change package that removes the condition from the security group, and deploy the package to the target environment. Then, create a second change package that deletes the condition, and deploy the second package to the target environment.

Crossover domains

To migrate a crossover domain to which an attribute has been added, you must create and deploy two packages. The first package to deploy must contain the attribute but not the domain. The second package to deploy must contain the domain.

Database configuration

In Oracle databases, setting up a system to run with a login user name that is different from the schema owner is a complex manual task and might cause migration errors. To avoid errors, ensure that the system properties `mxs.db.user` and `mxs.db.schemaowner` have the same value.

Also for Oracle databases, ensure that the semantics are set to CHAR in all source and target environments. Migrations between environments that have different semantics (CHAR and BYTE) might cause database errors.

Database indexes

For Db2® databases, indexes might not be migrated.

If a package is deployed and an index exists in the target environment, the index in the package is not deployed. If an index does not exist in the target environment, the index is created. If the index in the package is marked to be deleted, the index in the target with the same table and attribute combination is marked to be deleted.

Discarded configuration changes

A Change package can listen for database configuration events that occur in the Database Configuration application. Event information (inserts, updates, deletes) are persisted in the event tracking table. If a user discards all the database configuration changes by using the Discard Configuration Changes action, the events that are already captured remain in the tracking table. A migration user might not be aware that the events remain in the tracking table and might proceed to create, distribute, and deploy a package. During deployment, the Database Configuration application can determine that the data provided by the package does not contain changes and does not configure the database. The deployment of such a package does not harm the target environment, but the event tracking entries might be confusing to a user.

Electronic auditing

If you use the Database Configuration application to enable electronic auditing, the settings that control electronic auditing are migrated. If any electronic auditing tables are created, the tables are only useful for the specific environment. Therefore, any auditing tables and the data they contain are not migrated.

Exchange rates

You can migrate exchange rates only if the application servers in the source and target environments are configured to use the same time zone. If the time zones are different, a package might not deploy because of overlapping exchange rate validity periods. You cannot use exchange rates that have overlapping validity periods.

Integration tables

Changes to the Integration module interface tables, default queue tables MXIN_INTER_TRANS and MXOUT_INTER_TRANS, and any customized queue tables are not migrated. If you make any configuration changes in the source database to these tables, you must make the same changes in the target database.

Lookup maps

When you migrate lookup maps for new business objects, the migration of a single package that contains both the lookup map records and the business object records fail. The migration fails because the lookup map is processed first and depends upon the business object, which is not processed yet.

To work around this limitation, define two Change packages: one to capture the new business object and another to capture the lookup map. Migrate the business object Change package first.

MAXVARS table

The source and target environments must define the same MAXVARS. Migration Manager supports the update of existing MAXVARS only.

Organizations

After deployment of a package, a newly created organization in a target environment is inactive. It is inactive because a newly created organization cannot be activated without a clearing account (GL). The association of a GL account with an organization is a manual post-deployment step.

Person and site records

When a site is created, a default location of type HOLDING is generated. However, a location of type HOLDING cannot be associated with a person record. In order to associate a location with a new person record, you need to change the location type to another status, such as OPERATING.

If you try to migrate the site and person records in a single package, the location with type HOLDING causes a deployment error to occur. If this deployment error occurs, navigate to the Locations application and change the location type to OPERATING. Then return to Migration Manager and continue the deployment of the same package. Migration Manager now creates the person record and links it to the location record.

Restricted attributes

If an attribute is restricted by the Database Configuration application in a target environment, and an override of the restriction is not set up at the object structure level, the value of the attribute is not deployed.

Security settings

The following limitations apply to the migration of security settings:

- If you use LDAP, do not use the Migration Manager application to migrate user IDs. Use the LDAP server and tools to manage user IDs.
- When user IDs are migrated to a target environment, the passwords are reset and sent to the users in an email message. To receive the email message, the email server must be set up in the target environment. Additionally, the users must have configured email addresses in the target environment. The password sent in the email is a temporary password. The temporary password expires when the user logs in for the first time, at which time the user must reset the password. Use the mail.smtp.host system property in the System Properties application to set up the email server. The value for the property is the name of the host running the SMTP mail server.
- Password hint questions and answers are not migrated.
- Data in the MAXUSERSTATUS and LOGINTRACKING tables is not migrated.
- The product user data that is stored in the MAXUSER table is migrated. However, the corresponding native database user data that is stored in the data dictionary of the database is not migrated. If you want to maintain the product users as database users in the target environment, you must create the database users corresponding to the product users. You must also grant database access to these users. You can create the database users and grant them database access by selecting Database Access from the Select Action menu in the Users application.
- The following information in security groups is not migrated:
 - Labor authorizations
 - Limits and tolerances
 - Purchase general ledger
 - Status history
 - Storeroom authorizations
- User storerooms are not migrated. You must ensure that the storerooms are the same in the source and target environments.

Start centers

Only the start center templates can be migrated. After you migrate a start center template, you can apply the template to an appropriate start center.

System properties

When you use the DMMAXPROP migration object, only system properties that meet specific conditions are migrated.

To be migrated, a system property must meet the following conditions:

- The property is user-defined. Migration Manager does not migrate system-defined system properties.
- The property is not configured for a file override with a value in the maximo.properties file.
- The property value is a global property and does not have an instance-specific value. Instance-specific properties are system properties that are unique to a particular server.

When you configure the system-defined properties, always use the Systems Properties application within the target environment.

System XML files

Migration Manager does not support migration of user interface system XML files between product environments. System XML files include lookups.xml, menus.xml and library.xml. These XML files are not application-specific. They store common user interface components or resources. Use the Application Designer application to manage the export and import of these system XML files.

Ticket templates

The following limitations affect the migration of ticket templates:

- When you deploy a ticket template that references a job plan, the job plan must exist in the target and have a status of ACTIVE. If the status of the job plan is not ACTIVE, the deployment of the ticket template will fail.
- When you deploy a ticket template, a new autokey value is generated for the record by default. If this behavior is unsuitable, you must customize the DMTKTEMPLATE object structure.
- If you migrate ticket templates by using Change packages, you must activate the package definition before any ticket templates are created or updated. After the Change package is deployed, you must reset the event tracking records for the package definition in the source environment.
- To migrate ticket templates that have activities and activity specifications, a classification must be associated with the template.
- The status of ticket templates is preserved. For example, if a template is active in the source environment, the template is also active in the target environment after migration.

User and person records

If a person record is inactive and its related user record is also inactive, a deployment error occurs. The person record must be active for it to be added to a user record. To work around this limitation, migrate the person records, activate them in the target environment, and then migrate the user records.

Migration reports

Several reports are provided to help you plan and manage the migration process.

Before you can use the reports, they must be enabled. To enable reports, an administrator must import the reports into the database, create request pages for the reports, and authorize access to the reports.

Package Definition report

The Package Definition report shows the contents of a package definition. A change or deployment manager can use this report to review and approve a package definition.

If you generate the report before a package definition is approved, the report can be shared or sent by email to the appropriate manager. If you generate the report after a package definition is approved, the report shows any packages that were created in the source environment from the package definition.

Package Life Cycle report

The Package Life Cycle report shows the status changes of a package, the user who changed the status, and the date and time of each status change. You can use this report to audit packages.

In a source environment, this report also shows the targets to which a package was distributed. In a target environment, the report shows only the status changes of a package.

Migrating your configuration content

The migration process includes a series of preparatory and implementation steps that include setting up your migration collections and package definitions, and then creating, distributing, and deploying packages.

- [Setting up migration collections](#)
Use migration collections to simplify the creation of package definitions.
- [Setting up package definitions](#)
Package definitions must have a target to specify where the configuration content is migrated, and at least one or more configuration records to specify the content. Package definitions can also be set up to replace attributes at deployment time. Some package definitions can be created from migration collections.
- [Creating packages](#)
When you create a package, the actual configuration data is collected and added to the package and the package manifest is created. The package is in the form of records in a staging table.
- [Distributing packages](#)
After you create a package, you can distribute it to one or more target environments.
- [Deploying packages](#)
Deployment applies the configuration records that are in a package to a target environment.

Setting up migration collections

Use migration collections to simplify the creation of package definitions.

- [Exporting and importing configuration records to and from external systems](#)
To help plan and manage your migrations, you can export and import migration collections and store them in an external system, such as a version control system.
- [Creating migration collections](#)
The groups of configuration records that you migrate to another environment are migration collections. A migration collection can contain one or more configuration records of many types.
- [Capturing events in migration collections](#)
Instead of adding configurations one at a time to a migration collection, you can configure a migration collection to capture events as they occur, similar to a Change package.
- [Defining the related configuration records in migration collections](#)
You can enable and define the rules that determine the related configuration records that are added to migration collections by the validation process.
- [Validating migration collections](#)
A validation determines whether a migration collection is complete and whether it contains any orphan records or duplicate records that must be deleted. Validations run as background jobs, similar to cron tasks.
- [Enabling users to add records to migration collections](#)
You can configure some applications so that users can add records to a migration collection from the application, without using the Migration Collections application. An application that is configured in this way has a migration collections button in the menu bar.

Exporting and importing configuration records to and from external systems

To help plan and manage your migrations, you can export and import migration collections and store them in an external system, such as a version control system.

- [Exporting migration collection records](#)
You can export XML representations of the records in a migration collection to help you track or manage the configurations in external systems.
- [Downloading exported migration collection records](#)
You can download from the application server the XML representations of the records in a migration collection that were exported.
- [Importing migration collection records](#)
If configuration records were exported from the Migration Collections application, you can import the records into the database or a migration collection.

Exporting migration collection records

You can export XML representations of the records in a migration collection to help you track or manage the configurations in external systems.

For example, you can track configurations in an external version control system so that you can compare changes over time.

Before you begin

Exported configurations are saved to the `maximo/migration/collectionexport` folder on the application server. In a clustered environment, all application servers in the cluster must be able to access the folder. You can specify a different folder in the `mxe.dm.dmroot` system property.

About this task

Exported configurations are saved to a file whose name is `collection_objectstructure_datetime.xml`.

Procedure

1. In the Migration Collections application, select a migration collection.
2. Click Export Configuration on the row of a single record, or select multiple records and click Export Configurations.
3. If you exported a single record, specify the destination for the XML file and save the file.

What to do next

Store the exported records in your external system.

Downloading exported migration collection records

You can download from the application server the XML representations of the records in a migration collection that were exported.

Procedure

1. In the Migration Collections application, select a migration collection from which you have exported configuration records.
2. Select the configurations that were exported and click Download Exported Configurations
3. In the list of selected configurations, select a record that has exported files and then click Download File for the exported file.
4. Specify the destination for the XML file and save the file.
The name of the file is in the form *collection_objectstructure_datetime.xml*. A copy of the XML file with the same name is also saved to the *maximo/migration/collectionexport* folder on the application server.

Importing migration collection records

If configuration records were exported from the Migration Collections application, you can import the records into the database or a migration collection.

For example, you can export configuration content from a development environment, add the content to an external version control system, and then import the content into another development environment.

About this task

Only the primary business objects of each record in the XML file are added to a migration collection.

Procedure

1. In the Migration Collections application, select a migration collection.
2. Select the Import Configurations action.
3. Specify the name and location of the file that you want to import, specify whether you want to add the configuration records to a migration collection, and click OK.

Creating migration collections

The groups of configuration records that you migrate to another environment are migration collections. A migration collection can contain one or more configuration records of many types.

About this task

You can add a configuration record to a migration collection only if the record is supported by a migration object that can migrate the data that is contained in the record. Each configuration record in a migration collection is identified by its keys. Related configuration records can also be added to migration collections.

Procedure

1. In the Migration Collections application, click New Migration Collection.
2. On the Migration Collection tab, specify a name for the collection.
3. Optional: To enable other users to modify or delete the collection, select Is Public.
4. In the Configurations section, click New Row.
5. In the Application field, select the application from which you want to select configuration records and then click Go To Application.
6. In the List tab of the application that you selected, select a configuration record and then click Return With Value.
7. Add additional records to the migration collection.
8. Save the migration collection.

What to do next

After you create or modify a migration collection, validate it to ensure that it is complete.

Capturing events in migration collections

Instead of adding configurations one at a time to a migration collection, you can configure a migration collection to capture events as they occur, similar to a Change package.

About this task

You can capture add, update, and delete events, and you can restrict the events that are captured by role and by the type of event. You can add records manually while event tracking is enabled.

Procedure

1. In the Migration Collections application, select a migration collection and select the Configure Event Tracking action.
2. In the Configure Event Tracking window, click New Row.
3. Optional: Select a role.
4. Specify an application, or both an application and an object structure, and specify the types of events that you want to capture.
5. Add rows for each application or object structure, and click OK.

Results

The collection starts capturing the specified events immediately.

Defining the related configuration records in migration collections

You can enable and define the rules that determine the related configuration records that are added to migration collections by the validation process.

About this task

To ensure that the package definitions you create from your migration collections are complete, related configuration records are identified and can be added to the collections by the validation process. The system-defined rules are enabled by default but you can customize or disable them if necessary. The lookup rules identify data such as MAXVARS and system messages.

Procedure

1. In the Migration Collections application, select the Define Related Data and Lookup Rules action.
2. Optional: To disable any of the system defined related data rules, clear the Enabled check box.
3. To define a related data rule, click the Related Data Rules tab, click New Row, and specify the primary object and the related object.
4. To define a lookup rule, click the Lookup Rules tab, click New Row, and specify the primary object and an SQL WHERE clause.

Validating migration collections

A validation determines whether a migration collection is complete and whether it contains any orphan records or duplicate records that must be deleted. Validations run as background jobs, similar to cron tasks.

About this task

To ensure that a migration collection is complete and that any package definitions that are created from the collection are valid, validate the migration collection. The results of the validation include any orphan records or duplicate records, and any related configurations that you might need to add to the collection.

Orphan records are configurations that were deleted after the migration collection was created.

Duplicate records are configurations that were added to a migration collection, deleted and recreated in the originating application, and then added again to the migration collection. This sequence results in two records that refer to the same configuration.

You can inspect the related configurations to determine whether they can be deleted or need to be added to the collection.

Validations cannot be canceled and must run until they finish. You can perform other tasks during that time.

Procedure

1. In the Migration Collections application, select the migration collection that you want to validate.
2. Select the Validate Migration Collection action.
3. In the Validate Migration Collection window, click Start.
4. When the validation job finishes, view the orphan records, duplicate records, and related configurations on the Validation Results tab.
5. Inspect the orphan records and duplicate records and delete them if you do not want them in the collection.
6. Inspect the related configurations and either delete them or add them to the migration collection.
7. Save the migration collection.

Enabling users to add records to migration collections

You can configure some applications so that users can add records to a migration collection from the application, without using the Migration Collections application. An application that is configured in this way has a migration collections button in the menu bar.

About this task

Only applications that are enabled for migration by a migration object can be configured in this way.

Procedure

1. In the Migration Collections application, select the Add Migration Collections to Applications action.
2. In the list of applications, click Add Support and click OK.

Results

Users of the application can add configuration records to a migration collection by clicking the Add to Migration Collections button in the application menu bar. Users might need to log out and then log in before they can use the button.

Setting up package definitions

Package definitions must have a target to specify where the configuration content is migrated, and at least one or more configuration records to specify the content. Package definitions can also be set up to replace attributes at deployment time. Some package definitions can be created from migration collections.

- [Defining target environments and their distribution types](#)
For each source environment, you must define all the target environments to which you might distribute a package.
- [Creating package definitions](#)
Package definitions specify the configuration content that you want to migrate to another environment.
- [Attribute replacements](#)
The attributes of configuration records can be replaced as part of the migration process. Attribute replacement might be required when the data in configuration records in the target environment does not match the data in the source environment.
- [Selecting attributes to replace during deployment](#)
When you create a package definition, you can specify the attributes that must be replaced with appropriate values at deployment time. Attributes must be replaced, for example, when the data constraints in the target environment do not match the data constraints in the source environment.
- [Creating package definitions from a migration collection](#)
You can create package definitions based on the information in your migration collections.

Defining target environments and their distribution types

For each source environment, you must define all the target environments to which you might distribute a package.

About this task

You can define a target as a database or as a file.

When you distribute a package to a database target, the content of the package is placed into a staging table in the remote database. You can then deploy the package. Use a database target and distribution to migrate configuration content from a development environment to a test environment.

When you distribute a package to a file target, the content of the package is placed into a file in a folder on the application server in the source environment, and is then copied to the specified folder. Use a file target and distribution to migrate configuration content to a production environment where direct access to the production database is strictly controlled.

Procedure

1. In the Migration Manager application, select the Manage Targets action.
2. Define one or more targets:
 - a. In the Manage Targets window, click New Row.
 - b. In the Target Name field, specify a name for the target environment.
 - c. In the Type field, specify `DATABASE` or `FILE`.
 - d. In the Database URL or File Path field, specify a value:
 - For a Database target, specify the URL in standard JDBC format, for example, `jdbc:db2://localhost:50000/mxdb2`.
 - For a File target, specify the path to an existing folder that is on or accessible to the file system of the application server, for example, `C:\temp`.
 - e. For a Database target, specify a user name, password, and schema name.
3. Click OK.

What to do next

After you have created your targets, you can associate one or more of them with each package definition.

Creating package definitions

Package definitions specify the configuration content that you want to migrate to another environment.

About this task

Use this procedure only to define Snapshot and Change packages. To define Collection packages, you must use the Migration Collections application.

For Snapshot package definitions, you can filter the data by specifying an SQL WHERE clause so that a package contains a smaller set of configuration content. For example, to create a package that migrates only a specific workflow process, you can filter the workflow process migration object in the package definition to select only that one workflow process.

To include GL records, enter an SQL WHERE clause for the DMDEFGLCONFIGURE and DMGLCONFIGURE object structures.

- For the DMDEFGLCONFIGURE object structure, enter the SQL WHERE clause: `orgid is null order by glorder`.
- For the DMGLCONFIGURE object structure enter, the SQL WHERE clause: `orgid is not null order by orgid,glorder`.

Procedure

1. In the Migration Manager application, click New Package Definition.
2. Specify a name for the package definition.
3. In the Type field, specify `SNAPSHOT` or `CHANGE`.
4. For a Snapshot package definition, in the Processing Action field, specify `AddChange` or `Replace`.
5. Optional: To track only the changes in a Change package that are made by users that are in a specific role, specify the role in the Change Role field.
6. Add one or more migration groups to the package definition:
 - a. In the Migration Groups table window, click New Row.
 - b. Specify a migration group.
Any dependencies are shown in the Dependencies table window.
 - c. Optional: To filter the migration objects for a Snapshot package definition, click Set Where Clause and enter an SQL WHERE clause.
7. Optional: Add compiled sources to the package definition by adding rows to the Compiled Sources table window and specifying the file location.
8. On the Distribution tab, associate one or more of the defined target environments with the package definition.
9. Save the package definition.
10. When the package definition is ready to be used, change its status to Appr
11. Optional: To start capturing events in a Change package, activate the package definition.

Attribute replacements

The attributes of configuration records can be replaced as part of the migration process. Attribute replacement might be required when the data in configuration records in the target environment does not match the data in the source environment.

Attribute replacement can be used when the creator of the package definitions does not know the data constraints in the target environments to which packages might be deployed.

You select the attributes for replacement when you create a package definition in the source environment. The specified attributes to be replaced are stored in the metadata of a package. The replaced values are determined by the attribute replacement rules that you define in the target environment.

Selecting attributes to replace during deployment

When you create a package definition, you can specify the attributes that must be replaced with appropriate values at deployment time. Attributes must be replaced, for example, when the data constraints in the target environment do not match the data constraints in the source environment.

About this task

The attributes to be replaced are stored in the metadata of a package. The replacement values are determined by the replacement rules that are defined in the target environment.

Procedure

1. In the Migration Manager application in a source environment, select a package definition.
2. Select the Select Attributes for Replacement action.
3. For each object, select the attributes that must be replaced:
 - a. In the tree, select a migration object.
 - b. In the Attributes section, select Replacement Required for each attribute that you want to replace during deployment.
 - c. In the Remarks field, provide an explanation of why the replacement is required.

4. Click OK.

What to do next

Define the attribute replacement rules in the target environment.

Creating package definitions from a migration collection

You can create package definitions based on the information in your migration collections.

Before you begin

Validate a migration collection before you create package definitions from it.

About this task

Usually, a single package definition is created. However, depending on the ordering of the migration groups and object structures, in some cases two package definitions are created. If two are created, the first is used to migrate the object definitions without the domain references, and the second is used to migrate the table domains and the object configurations. The cases in which two package definitions are created are defined by the exceptions in the Define Package Definition Exceptions window.

Procedure

1. In the Migration Collections application, select a migration collection.
2. Select the Create Package Definition action.

Results

The package definition is shown on the Package Definitions tab.

Creating packages

When you create a package, the actual configuration data is collected and added to the package and the package manifest is created. The package is in the form of records in a staging table.

Before you begin

1. Create and approve the package definition.
2. Identify targets to which the package will be distributed.
3. For CHANGE package definitions, activate the package definition.

Procedure

1. In the Migration Manager application, select the package definition.
2. On the Package tab, click Create.
3. In the Upload Compiled Sources window, in the Read-Me Information field, type information about the package that you are creating. This information is to help the administrator to deploy the package in the target environment.
4. Optional: For a Snapshot package, specify a different processing action from what was specified when the package was defined.
5. If the Compiled Sources table window contains files, click Upload File next to each file.
The listed files were specified in the package definition.
6. Optional: Upload any compiled sources that were not specified in the package definition:
 - a. Click New Row.
 - b. In the File Name field, click Upload File.
 - c. In the Upload a File window, click Browse to specify a file to upload, and then click OK.
7. Click Continue, and then click OK after the package is created.

What to do next

After the package is created, you can distribute it.

Distributing packages

After you create a package, you can distribute it to one or more target environments.

Before you begin

Define the targets to which you will distribute the package.

You can prevent the distribution and deployment of packages that come from restricted sources by setting inbound restrictions in the target environment.

About this task

Packages are distributed one at a time. If you select multiple packages for distribution, the packages are distributed in sequence. If an error prevents the application from distributing a package to a target, the application can continue to distribute packages to other targets.

In a source environment, when you create a package, the Migration Manager application stores the data that makes up the package in the staging table. When you distribute the package, the staging table is accessed and the records extracted and copied into the physical package file. The staging table is also used in a target environment to start the deployment of a package. If you distribute a package as a file, the contents of the file are extracted and placed as records into the staging table. The deployment of the package applies the data in these records into the target database.

After you distribute a file type package to a target environment, a copy of the package is retained on the application server in the source environment. You can optionally download the copy to a client computer so that you can move it into source control or move it to other environments.

Procedure

1. In the Migration Manager application, select the package definition.
2. On the Package tab, select the package.
3. Click Distribute.
4. In the Distribute Package window, select the targets to which you want to distribute the package and click OK.
5. After the package is distributed, click OK.
A message indicates that the distribution was successful.
6. Optional: For a file type package, on the Package tab, click Download Package File next to the package that you want to download. Then, specify the location on the client computer to which you want to download the package and click Save.

What to do next

Preview and deploy the package in the target environment.

Deploying packages

Deployment applies the configuration records that are in a package to a target environment.

Important: Before you deploy a package, ensure that you have a backup of your database. Run the Integrity Checker utility to monitor the integrity of your database. Preview a deployment to identify potential data validation errors before you deploy the package.

The migration activities that precede deployment occur in a source environment, whereas you preview and deploy a package in a target environment. The deployment steps depend on the type of content in the package.

You can deploy only one package at a time. The time that it takes to deploy a package depends on the size of the package and the type of processing applied by the package.

- [Deployment overview](#)
A deployment is typically preceded by a deployment preview. The steps of the deployment depend on the type of configuration content in the package and on some aspects of the target environment.
- [Attribute replacement rules](#)
Attribute replacement rules are used to specify the conditions for replacing the values of fields in a configuration object at deployment time. The replacement rules apply to every package that is deployed in the target environment.
- [Uploading packages to a target environment](#)
If a package that you want to deploy is a file that was downloaded to a client computer, you must upload the package from the client computer to the target application server.
- [Deploying a package](#)
The deployment of a package applies the configuration records to the target environment. To analyze the effect of the changes without applying them, you can preview the deployment.
- [Downloading compiled sources](#)
If a package contains compiled sources, you can download them to a client computer or to a build environment to rebuild the EAR file before you deploy the EAR file to the application server.
- [Deployment data errors](#)
When a migration package is deployed, application data validations are applied to the configuration data that is imported from the package. If a data validation fails for data in the package, a deployment data error occurs and processing of the package stops.
- [Post-deployment activities](#)
After you deploy a package, you might need to activate some types of records, update database statistics, update user IDs, edit user queries, and deactivate administration mode.

Deployment overview

A deployment is typically preceded by a deployment preview. The steps of the deployment depend on the type of configuration content in the package and on some aspects of the target environment.

- [Deployment previews](#)
You can preview a deployment before you deploy a package to the target environment. By previewing a deployment, you identify potential data validation errors so that you can correct them in the source environment.
- [Deployment steps and package content](#)
The deployment steps depend on the type of content that is in a package. For some content, manual steps are required.
- [Deployment to an environment that has different products or versions](#)
If the target environment has products and version levels that differ from the source environment, the deployment might stop. You might be able to continue the deployment by excluding some products from the compatibility checks.
- [Deployment of a package to its source environment](#)
You can create a package that includes a set of configuration records for a defined environment and then deploy that package to the same environment.

Deployment previews

You can preview a deployment before you deploy a package to the target environment. By previewing a deployment, you identify potential data validation errors so that you can correct them in the source environment.

You preview a deployment by selecting the Preview check box and a rollback point in the Deploy Package window. You can then review the messages and potential errors, which are either displayed in the status window or saved to a preview log file. After you correct any errors, re-create the package and then preview the deployment again or deploy it.

You do not need to enable administration mode to preview a deployment. However, you cannot preview a deployment if structural changes are pending in the target environment or if a package has inbound restrictions.

Rollback points

When you preview a deployment, the preview data is stored temporarily in the target database tables so that the data validations can be run. The rollback point determines how long the preview data is stored in the tables.

For packages that have few dependencies, use a rollback point that stores the data in the target tables for a short time. For packages that have many dependencies, use a rollback point that stores the data in the target tables for a long time.

Rollback point	Description	When to use
Roll back every record	The data that is inserted or updated in the table is rolled back before the next record of the table is loaded. This rollback point stores the data in the target tables for the shortest time.	Use this rollback point when the content does not have dependencies. For example, use this rollback point for currency data.
Roll back every XML document	The data remains in the target tables until all the records of an XML document in a package are loaded. The data that is inserted or updated in the table is rolled back before the next XML document is processed.	Use this rollback point when one row of a table depends on another row of the same table, such as in a hierarchy of classifications.
Roll back every object structure	The data remains in the target tables until all the records of all the XML documents for an object structure are loaded. Depending on the volume of data, the data for a table might span multiple XML documents. The data that is inserted or updated in the table is rolled back before the next object structure is processed.	Use this rollback point for a set of domains where the domain content spans multiple XML documents.
Roll back every migration group	The data for all the object structures of a migration group type is stored in the target tables until the data for the entire migration group is loaded. The data that is inserted or updated in the table is rolled back before the next migration group type is processed. This rollback point stores the data in the target tables for the longest time.	Use this rollback point when the content has dependencies, such as for the data dictionary object structures. Do not use this rollback point for large packages.

Memory constraints

A deployment preview can use a large amount of memory in the application server. The amount that is used depends on the size of the package and the rollback point.

Before and during a deployment preview, Migration Manager checks the memory and stops the preview if a threshold is reached. The `mxe.dm.previewfreememorythreshold` system property defines the threshold as a percentage of the total available memory. Its default value is 20, which means that the preview stops, or cannot start, if less than 20% of the available memory is available.

Large packages, such as those that contain multiple migration groups and thousands of records, cannot be previewed. However, you can create several smaller packages by collecting subsets of the data in snapshot packages and by specifying SQL criteria. You can also reduce the number of migration groups in a package.

The preview log file indicates the available memory at each rollback point. Therefore, by rolling back at every record, you can study the preview log file to determine how much memory is used by a deployment preview.

Preview log files

The preview log file provides details on what occurs if the package is deployed. For example, the preview log file lists the processing of the XML documents that comprise the package and the data validations that check the configuration data in the XML documents. If data validation errors occur, the error messages are included in the preview log file. One validation error is captured for each record that is previewed, even if multiple errors occur for a record.

If you preview a deployment of a package again, the previous preview log file is deleted and a new log file is created. If you deploy a package that was previously previewed, the preview log file is deleted.

When a deployment preview completes, you can download the preview log file from the Package tab of the Migration Manager application.

The name of the preview log file matches the package name and has the suffix `_preview` and the extension `.log`.

Configuration commands and script log files

If the package includes structural changes that require the database to be configured, you can include the configuration commands in the preview log file and the script log file. However, the configuration changes do not occur.

The configuration commands are SQL-based Data Definition Language (DDL) statements. The commands are written to a script log file that is in the same folder as the preview log file. You can use the script log file to assess the structural changes, but you cannot run the script file on the target database.

The name of the script log file name matches the package name and has the suffix `_script` and the extension `.log`.

Deployment steps and package content

The deployment steps depend on the type of content that is in a package. For some content, manual steps are required.

The database content is classified as structural content or nonstructural content. Structural content is content that must be reflected in the database schema as tables, views, columns, keys, and indexes. Nonstructural content is all other database content, which is typically stored in records in a table.

The content that is outside the database consists of files that are on the application server file system, such as Java™ class files and properties files. These files are the compiled sources.

When you deploy a package, compiled sources must be downloaded first. Next, structural changes are processed. Finally, nonstructural changes are processed. However, the specific steps that must occur depend on the contents of the package. Deployment might involve manual steps, such as switching the system to administration mode to restrict user access, downloading compiled sources, deploying EAR files, and restarting the system. When manual steps are required, the deployment pauses and prompts you to do the steps.

The steps that occur depend on the following combinations of content that are in a package:

Type of content in the package	Steps required during deployment
Nonstructural content	No manual steps are required in the deployment of packages that contain only nonstructural content, such as workflow process definitions.
Structural content	If a package contains only structural content, such as object, attribute, or index definitions, the deployment pauses after data loading is complete. You must enable administration mode to apply the structural changes to the database.
Nonstructural and structural content	If a package contains both nonstructural and structural content, such as object, attribute, or index definitions and workflow process definitions, the deployment pauses after data loading is complete. You must enable administration mode to apply the structural changes to the database. After the structural changes are applied, the nonstructural content is loaded.
Compiled sources	If a package contains only compiled sources, such as custom Java packages and Java class files, the deployment pauses to enable the download of the compiled sources to a client computer. If the compiled sources include Java classes, you must rebuild the product EAR file and deploy the new EAR file. You then continue the deployment to confirm that the compiled sources have been deployed to the application server.
Compiled sources and nonstructural content	If a package contains compiled sources, such as custom Java packages and Java class files and workflow process definitions, the deployment pauses to enable the download of the compiled sources to a client computer. If the compiled sources include Java classes, you must rebuild the product EAR file and deploy the new EAR file. You then continue the deployment to confirm that the compiled sources have been deployed to the application server, and then nonstructural content is loaded.
Compiled sources, structural content, and nonstructural content	If a package contains compiled sources, such as custom Java packages and Java class files, structural content, such as object, attribute, or index definitions, and nonstructural content, such as workflow process definitions, the deployment pauses to enable the download of the compiled sources to a client computer. If the compiled sources include Java classes, you must rebuild the product EAR file and deploy the new EAR file. You then continue the deployment to confirm that the compiled sources have been deployed to the application server. The deployment pauses a second time after data loading is complete. You must enable administration mode to apply the structural changes to the database. After the structural changes are applied, the nonstructural content is loaded.

Deployment to an environment that has different products or versions

If the target environment has products and version levels that differ from the source environment, the deployment might stop. You might be able to continue the deployment by excluding some products from the compatibility checks.

When you deploy a package, Migration Manager checks for compatibility and shows the differences in the Version Compatibility window. You cannot deploy packages that are incompatible because the package content might cause errors or invalid product configurations. However, if the differences between the products and version levels are minor, you can exclude some products from the compatibility checks and continue the deployment.

The following product compatibility rules determine whether the deployment stops or can continue:

- If the version or release numbers do not match, the deployment stops.
- If the modification or fix pack numbers do not match, an information message is shown but the deployment can continue.
- If the interim fix numbers do not match, an information message is shown but the deployment can continue.
- If the target has products that are not in the source, an information message is shown but the deployment can continue.
- If the source has products that are not in the target, you must exclude the products from the compatibility checks to continue.

Products are numbered in the following format: *version.release.modification.fix_pack-interim_fix*. For example, 7.5.1.3-LX20110928 means version 7, release 5, modification 1, fix pack 3, interim fix LX20110928.

Deployment of a package to its source environment

You can create a package that includes a set of configuration records for a defined environment and then deploy that package to the same environment.

If you distribute the package as a compressed file, you can then deploy it to its source environment if either of the following conditions is met:

- The package definition has been deleted.
- All the packages that are based on the original package definition no longer exist in the source environment.

Attribute replacement rules

Attribute replacement rules are used to specify the conditions for replacing the values of fields in a configuration object at deployment time. The replacement rules apply to every package that is deployed in the target environment.

You select the attributes for replacement when you create a package definition in the source environment.

If the records and fields in a package meet the replacement rule conditions, the values are replaced when the package is deployed. For example, values of a configuration object can be replaced with a property value or MAXVAR value. The replacement rules affect every package that is deployed if the package contains migration objects that are referenced by the rules.

If you specify multiple conditions for a replacement rule, at least one condition must return a value of True for the replacement to occur.

If you specify multiple field evaluations for a condition, all the evaluations must return a value of True for the replacement to occur.

If a deployed package has attributes that are selected for replacement but there are no corresponding replacement rules, the deployment stops unless Skip prompts to create attribute rules is selected. You can then create the replacement rules.

- [Defining attribute replacement rules in a target environment](#)
Attribute replacement rules specify the conditions under which an attribute value is replaced at deployment time.

Defining attribute replacement rules in a target environment

Attribute replacement rules specify the conditions under which an attribute value is replaced at deployment time.

Procedure

1. In a target environment, open the Migration Manager application and select the Add/Modify Replacement Rules action.
2. In the Select Migration Object window, select a migration object in the tree and click Add/Modify Rules.
3. In the Replacement Rules section of the Add/Modify Replacement Rules window, click New Row.
4. Specify a name and sequence number for the rule.
5. To enable the rule for immediate use, select Enabled.
6. To apply the rule to database insertions, updates, or deletions, select the Apply on Primary Object check boxes.
7. On the Attributes tab, for each attribute, click New Row and define the attribute replacement rule:
 - a. Specify the field to replace.
 - b. To replace the value only when the value is null, select Replace When Null.
 - c. Select the type of replacement and specify the value. You can specify a property name, value, MAXVAR value, or field.
8. On the Conditions tab, for each condition, click New Row and define the condition:
 - a. To change the order in which the condition is applied, change the value in the Condition field.
 - b. In the Field Evaluation for Conditions section, click New Row
 - c. Specify an XML field.
 - d. In the Evaluation Type field, specify an operator.
 - e. Specify the value to evaluate. You can specify a value, MAXVAR value, or comparison field.
9. Click OK.

Uploading packages to a target environment

If a package that you want to deploy is a file that was downloaded to a client computer, you must upload the package from the client computer to the target application server.

Procedure

1. In the Migration Manager application, select the Upload Package action.
 2. Specify the name of the file and click OK.
- [Increasing the package size upload limit](#)
The default size limit for uploading a package to the application server is 20 MB. You can change the limit by editing the Migration Manager presentation XML file.

Increasing the package size upload limit

The default size limit for uploading a package to the application server is 20 MB. You can change the limit by editing the Migration Manager presentation XML file.

Before you begin

To edit the presentation XML file, you must be an administrator and you must know how to use the Application Designer application.

About this task

If you set a limit that is too high, the application server might run out of memory.

Procedure

1. Log in as an administrator and start the Application Designer application.
2. Export the dm.xml presentation XML file to a client workstation.
3. In a text or XML editor, find the section of the file that contains the following XML:

```
<dialog
id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_gp_migmgr_t_increase_package_size_limit_UPLOADPKG" label="Upload Package" beanclass="psdi.webclient.beans.dm.DMUploadBean">
<uploadfile
id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_gp_migmgr_t_increase_package_size_limit_UPLOADPKG_sec" label="Specify a File" oklabel="OK" cancellabel="Cancel" />
</dialog>
```

4. Add a maxfilesize parameter to the <uploadfile> tag and specify a package size upload limit.
For example, the following maxfilesize parameter specifies a 50 MB limit:

```
<uploadfile
id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mbs.doc_gp_migmgr_t_increase_package_size_limit_UPLOADPKG_sec" label="Specify a File" oklabel="OK" cancellabel="Cancel" maxfilesize="50" />
```

5. Save the presentation XML file.
6. In the Application Designer application, import the edited dm.xml presentation XML file.

Deploying a package

The deployment of a package applies the configuration records to the target environment. To analyze the effect of the changes without applying them, you can preview the deployment.

Before you begin

Distribute the package to the environment where you will deploy it. If the package was downloaded to a client computer, upload it to the target application server.

Back up the target database.

Procedure

1. In the Migration Manager application, select the package definition that corresponds to the package that you want to deploy or preview.
2. Select the Deploy Package action.
3. Optional: To inspect and verify the contents of the package, click View Manifest.
4. Optional: Preview the deployment:
 - a. Select Preview.
 - b. Optional: To output SQL commands that correspond to structural changes in the package, select Include Database Configuration Commands.
 - c. Select a rollback point.
5. Confirm that you have a current backup of the database on the target environment.
6. If a package definition has attributes selected for replacement, but no attribute replacement rules are defined and you do not want to define the rules, select Skip prompts to create attribute rules.
7. Select a package and then click Deploy.
8. If the package contains compiled sources, download them to a client system.
If the compiled sources include Java™ class files, deploy the compiled sources:
 - a. Stop the application server.
 - b. Rebuild and deploy the EAR file.
 - c. Restart the application server.
 - d. In the Migration Manager application, on the Package tab, click Continue Deployment.
 - e. Confirm that the compiled sources are deployed to the application server.
9. If the package contains structural content, enable administration mode so that the structural changes are applied:
 - a. Select the Manage Admin Mode action, click Turn Admin Mode On, and click Close.
 - b. On the Package tab, click Continue Deployment.
10. Review the deployment messages in the status window and click OK.

11. Optional: If you previewed the deployment, download the preview log file to your client computer from the Package tab.

What to do next

- Before you deploy another package to the same environment, you must activate any organizations, sites, workflow processes, and communication templates that were migrated.
- If you enabled administration mode to apply structural changes, turn administration mode off.

Downloading compiled sources

If a package contains compiled sources, you can download them to a client computer or to a build environment to rebuild the EAR file before you deploy the EAR file to the application server.

Procedure

1. In the Migration Manager application, on the Package tab, click Download Compiled Sources next to the package.
2. In the Download Compiled Sources window, click Download File.
3. In the Save As window, select a folder on the client computer in which to save the compiled source file and click OK.
4. Select Downloaded and click Close.

Deployment data errors

When a migration package is deployed, application data validations are applied to the configuration data that is imported from the package. If a data validation fails for data in the package, a deployment data error occurs and processing of the package stops.

Depending on the type of error, you may be able to correct the data that caused an error and continue the deployment of a package. The deployment continues from the start of the configuration data file that caused the error.

Some deployment data errors are caused by data validation failure that results from loading data contained in the package XML. In these cases, the error is displayed on the Package tab of the Migration Manager application. The tab shows details about the error, including the configuration data that caused the error.

If multiple errors occur for the same package, the tab shows a history of all the errors. The history of the errors can be useful for audits. You can delete old deployment data error records, but you then lose the history of the errors for the package.

- [Correcting deployment data errors](#)
If a deployment of a package fails because of a data error, you can continue the deployment by correcting the error.

Correcting deployment data errors

If a deployment of a package fails because of a data error, you can continue the deployment by correcting the error.

Procedure

1. On the Packages tab of the Migration Manager application, select a package that has a status of DEPLOY_ERROR.
2. On the Deployment Data Errors tab, expand the record for the migration group that contains the error.
3. Review the details of the error message and the corresponding XML error data, and click Edit Error Data.
4. In the Error Data field of the Edit Error Data window, edit the XML data to correct the error, and click OK.
As you edit the data, you can refer to the original error data in the Original Error Data field.
5. In the Packages section, click Continue Deployment.

What to do next

If the deployment fails again, you can repeat the steps to correct the next error.

Post-deployment activities

After you deploy a package, you might need to activate some types of records, update database statistics, update user IDs, edit user queries, and deactivate administration mode.

Activating records

After you deploy a package that contains organizations, sites, workflow processes, or communication templates that were active in the source environment, you must activate them in the target environment before you deploy any other packages to the same environment.

Use the related application to activate the specific records. For example, use the Organizations application to activate organizations and sites.

Updating database statistics

After you deploy a package that applies table or index changes to a target environment with administration mode turned on, you must update the database statistics so that the query optimizer can determine the most efficient way to run SQL statements.

The update is required because when you use the Migration Manager application to change database objects, the statistics typically become incorrect. For example, when a migration adds an index, no statistics exist for the index. Therefore, statistics must be generated for the index to be used effectively. Similarly, when a migration modifies a table so that it is renamed and rebuilt, the indexes for the table are also rebuilt. Therefore, the statistics must be regenerated.

Use the Database Configuration application to update the statistics.

Updating user IDs

When you migrate product user IDs, the user data for associated database user IDs is not migrated. Therefore, if some users require their database user IDs, you must re-create the properties for those database user IDs in the target environment.

Editing user queries

When you migrate the Start Center template, the associated queries that are configured for each user are not migrated. After you migrate the Start Center template, you must open the template and edit the queries so that they correctly match the target environment.

Deactivating administration mode

If administration mode is enabled during package deployment, only users with administrative privileges can access the product. All escalations and cron tasks stop, except for Bulletin Board cron tasks.

When the deployment finishes, you must turn off administration mode. You perform this step so that the cron tasks and escalations restart and users without administrative privileges can access the product.

Migration troubleshooting

You can identify and correct most errors by responding to the error messages that are displayed in the user interface and by reviewing the messages on the Messages tab of the Migration Manager application. For further troubleshooting, use the log files.

Package creation and deployment tasks run in the background and have no corresponding user interface, except for a progress dialog. Therefore, errors, warnings, and informational messages for these tasks are displayed on the Messages tab of the Migration Manager application. The messages are deleted when the package definition or the package is deleted.

- [Migration logger](#)
The most detailed migration messages, including low-level errors, exceptions, and stack traces, are available in the log file.
- [Package creation errors](#)
In a source environment, if an error occurs when a package is created, the package has a status of CREATE_ERROR.
- [Package distribution errors](#)
If a distribution error occurs, you can review the error message, fix the problem, and try to distribute the package again.
- [Package deployment errors](#)
Deployment errors occur primarily when the configuration data in the package cannot be validated. If you cannot correct the errors that are displayed in the Deployment Data Errors tab, you can take further action.
- [Migration error messages](#)
You can take corrective actions in response to error messages that occur while you use the Migration Manager application.

Migration logger

The most detailed migration messages, including low-level errors, exceptions, and stack traces, are available in the log file.

You can configure the migration logger, which is named dm, in the Logging application. The sql and integration loggers provide further information to support migration.

Table 1. Migration logger and supporting loggers

Group / Area	Logger	Description	Log level
Migration	dm	Logs information about the migration manager.	Typically, loggers are activated and set at the ERROR level, which produces log statements only when errors are encountered. If you need more information to identify a migration error, change the level of the dm logger to INFO or DEBUG. If you must contact support about migration, send the dm logger with the level set to DEBUG.

Group / Area	Logger	Description	Log level
Integration	integration	Logs information about the integration framework configuration, creation, management, and runtime processing. Migration Manager uses the integration framework object structure.	To identify whether a migration error is caused by the integration framework object structure or XML processing, set the integration logger to DEBUG.
SQL	sql	Generates log statements of SQL statements run in the escalation server. The integration framework uses business objects, which typically work on the SQL database.	To identify whether a migration error is caused by executing a SQL operation, set the sql logger to INFO.

Package creation errors

In a source environment, if an error occurs when a package is created, the package has a status of CREATE_ERROR.

A package with a status of CREATE_ERROR cannot be migrated. You must delete the package, correct the cause of the error, and re-create the package.

You can sometimes correct package creation errors by reviewing the Messages tab and by analyzing the package manifest. To review more detailed information, open the log file.

Package distribution errors

If a distribution error occurs, you can review the error message, fix the problem, and try to distribute the package again.

If an error occurs when you distribute a package to a database, all the records of the package that were placed in the staging table in the target database are rolled back or deleted.

Although you can select multiple packages to be distributed, the application distributes only one package at a time in sequence. If an error prevents the application from distributing a package to a target, the application can continue to distribute packages to other targets.

Package deployment errors

Deployment errors occur primarily when the configuration data in the package cannot be validated. If you cannot correct the errors that are displayed in the Deployment Data Errors tab, you can take further action.

Error determination

During a deployment, the Migration Manager application creates progress messages that show the steps that succeeded. This information can help you to determine the cause of the error. The messages are stored in the product log file, if it is configured, and persist in the messages table.

To discover where an error is occurring, you can create package definitions with smaller sets of data. This step helps to determine which set of data deployed correctly and which set of data created an error.

Types of errors

An incomplete configuration might occur if the related configuration data is not in the package and if the data is not in the target environment. An incorrect configuration might occur if the configuration is created by using SQL scripts without validations.

If an error is caused by bad configuration data in a package, restore the target database from the database backup. Then, correct the configuration data in the source environment and re-create the package. For example, an incorrectly defined database index must be recreated in the source environment.

If an error occurs because the data in the target database must change, you can modify the data in the target database and redeploy the package. You do not have to re-create the package in the source environment. For example, if a workflow process revision is active and enabled in the target environment, the package that contains updates to this revision fails to deploy. You can deactivate and disable the workflow process in the target environment and deploy the package again.

If the application server stops running while a package is being deployed, the package remains in the DEPLOY_INPROGRESS status. You might be able to restart the deployment by clicking Continue Deployment. Depending on the stage of deployment, the structural integrity of the database might be compromised and a database restore operation might be necessary.

Integration framework errors

By default, a validation mechanism listens for data dictionary changes, identifies the changes to the integration framework integration components, and requests that the configurations be updated.

To ensure the deployment of packages that contain database updates that affect integration framework configurations, you can set the system property mxe.int.validatemmpackage to 1.

If this property is enabled, during a deployment the validation process identifies whether any business object changes affect the configuration of the components and which migration groups must be updated.

Migration error messages

You can take corrective actions in response to error messages that occur while you use the Migration Manager application.

The following list of messages is not comprehensive but it contains the messages that you are most likely to encounter.

Error code	Error message	Details in the Messages table	Explanation and response
BMXAA5198E	Could not create package <i>package_name</i>	Exception stack trace is written to the Message Details field	A package cannot be created. Check the associated stack trace to determine the cause of the error.
BMXAA5199E	Package distribution to target <i>target_name</i> failed	Exception stack trace is written to the Message Details field	A package cannot be distributed. The stack trace provides more details. Depending on the cause of the error, you can try to distribute the package again.
BMXAA5201E	Error checking distribution status in target environment for package <i>package_name</i>	Exception stack trace is written to the Message Details field	The database operations that determine the prior distribution status of the selected package failed. Check the associated stack trace to determine the cause of the error.
BMXAA5205E	Could not delete staging table records in target environment for incompletely dis-tributed package <i>package_name</i>		A package is not completely distributed to a target environment database and the Migration Manager application attempts to clean up committed records from the target database staging table. Depending on the cause of the error, you might have to remove records manually.
BMXAA5206E	Could not read staging table records in source environment for package <i>package_name</i>		The Migration Manager application cannot extract the staging table records in the source environment of a package that is being distributed. Check the associated stack trace to determine the cause of the error.
BMXAA5207E	Could not write staging table records in target environment for package <i>package_name</i>		The Migration Manager application cannot insert records into the staging table on the target environment database. Check the associated stack trace to determine the cause of the error.
BMXAA5209E	Migration Manager root directory has not been configured using System Property <i>system_property</i> . The directory will default to <i>default_directory</i> .		No root folder has been configured for the mx.e.dm.dmroot system property. If no root folder is configured, the Migration Manager application file operations are performed on the home folder of the application server. Use the System Properties application to specify the appropriate value for the mx.e.dm.dmroot property.
BMXAA5212E	Error creating XML document in manifest for package <i>package_name</i>		The XML document that represents the manifest of a package cannot be generated. Check the associated stack trace to determine the cause of the error and try the action again.
BMXAA5214E	Could not create version header in manifest for package <i>package_name</i>		The application cannot retrieve and construct the version information of the package manifest that is being created or distributed. Check the associated stack trace to determine the cause of the error.
BMXAA5220E	Could not get database name in source environment		The name of the source database cannot be retrieved from the database to generate the source information for a package definition. Check the associated stack trace to determine the cause of the error. You might have to work with a database administrator to correct the error.
BMXAA5221E	Could not get database schema name in source environment		The schema name of the source database cannot be retrieved from the database to generate the source information for a package definition. Check the associated stack trace to determine the cause of the error. You might have to work with a database administrator to correct the error.
BMXAA5227E	Could not register event listeners for package <i>definitionpackage_definition_name</i> and source <i>source_string</i>		The application cannot register the event listeners for the active change packages. The error is recorded in the log file if the logger is configured. The associated stack trace indicates the cause of the error.
BMXAA5228E	Could not register event listeners for all active Migration Manager change packages		The application cannot register the event listeners for the active change packages. The error might occur when the application server starts. The error is recorded in the log file if the logger is configured. The associated stack trace indicates the cause of the error.
BMXAA5234E	Error in tracking events for package definition <i>package_definition_name</i> and source <i>source_string</i>		The application cannot capture event information and write it to the event tracking table. The error is recorded in the log file if the logger is configured. The associated stack trace indicates the cause of the error.

Error code	Error message	Details in the Messages table	Explanation and response
BMXAA5244E	Cannot read manifest information from file <i>file_name</i>	Exception stack trace is written to the Message Details field	The manifest of a package cannot be read during deployment. The package file contents might be corrupted. You can test the file by copying it and extracting the manifest from the copy. If you cannot extract the manifest, re-create or redistribute the package. If the package file is not corrupted or if the manifest can be extracted, review the associated stack trace to identify the cause of the error.
BMXAA5252E	Error in checking entry in dmrestriction table		The application cannot check the restriction entries in the target database environment when distributing a package. The error is recorded in the log file if the logger is configured. The associated stack trace indicates the cause of the error.
BMXAA5257E	Package redistribution to target <i>target_name</i> failed	Exception stack trace is written to the Message Details field	The stack trace provides details of the error. Depending on the cause of the error, you can try the redistribution again.
BMXAA5290E	Could not locate or create the folder <i>folder_name</i>		The application cannot locate the processed folder under DMROOT or cannot create the folder. Check if you have write permissions in the parent folder and if there is enough disk space.
BMXAA5291E	Could not close package <i>package_name</i> to file <i>file_name</i>		The package file cannot be copied to the processed folder. Check if you have write permissions and if there is enough disk space
BMXAA5309E	Could not export package configuration records to the staging table for package <i>package_name</i>	Exception stack trace is written to the Message Details field	The package metadata records cannot be exported from the source database. Check the associated stack trace to determine the cause of the error.
BMXAA5310E	Could not export configuration records to the staging table for package <i>package_name</i>	Exception stack trace is written to the Message Details field	Configuration data records cannot be exported from the source database. Check the associated stack trace to determine the cause of the error.
BMXAA5311E	Could not export data dictionary configuration records to the staging table for package <i>package_name</i>	Exception stack trace is written to the Message Details field	The data dictionary records cannot be exported from the source database. Check the associated stack trace to determine the cause of the error.
BMXAA5313E	Could not connect to the target database specified by URL <i>database_URL</i>	Exception stack trace is written to the Message Details field	The target database is not running at the time of distribution. Check with the target environment database administrator for database availability and the required connection parameters and update the target definition.
BMXAA5314E	Could not create staging table records in the target database specified by URL <i>database_URL</i>	Exception stack trace is written to the Message Details field	Database operations to insert package records fail. Check the associated stack trace to determine the cause of the error. The cause of the error might be a database issue related to table spaces or permissions.
BMXAA5315E	Could not create consolidated package file <i>package_file_name</i> into the folder <i>target_folder_path</i>	Exception stack trace is written to the Message Details field	The application cannot write the file to the outbound folder under the DMROOT folder on the application server or cannot copy the file from the DMROOT folder to the user-specified target folder. Check the write permissions on the folder and check for enough disk space.
BMXAA5316E	Could not stage selected package file <i>package_name</i>	Exception stack trace is written to the Message Details field	The contents of the package file cannot be extracted and written to the staging table. Check the associated stack trace to determine the cause of the error. Alternatively, obtain a new package from the source and deploy the new package.
BMXAA5317E	Could not import package metadata records for package <i>package_name</i>	Exception stack trace is written to the Message Details field	Package metadata records cannot be imported into the target database. Check the associated stack trace to determine the cause of the error. Alternatively, obtain a new package from the source and deploy the new package.
BMXAA5318E	Could not import data dictionary records for package <i>package_name</i>	Exception stack trace is written to the Message Details field	Data dictionary records cannot be imported into the target database. Check the associated stack trace to determine the cause of the error. Alternatively, obtain a new package from the source and deploy the new package.
BMXAA5319E	Could not import configuration records for package <i>package_name</i>	Exception stack trace is written to the Message Details field	Package configuration records cannot be imported into the target database. Check the associated stack trace to determine the cause of the error.
BMXAA5320E	Could not apply data dictionary changes into database using Database Configuration for package <i>package_name</i> . Please check configdb log file for more detail.	Exception stack trace is written to the Message Details field	The target database cannot be configured after the data dictionary records are imported from the package. Do not try to redeploy the package. Instead, check with the administrator of the source environment to determine whether the same data dictionary changes were successfully applied in the source. If necessary, obtain a new package.
BMXAA5324E	Could not extract or write XML document to staging table record for migration object <i>migration_object_name</i> for package <i>package_name</i>		The application cannot create the XML document that represents the migration object record or cannot write the XML document to the staging table in the source environment. Check the associated stack trace to determine the cause of the error.

Error code	Error message	Details in the Messages table	Explanation and response
BMXAA5367E	Could not redistribute package metadata records for package <i>package_name</i>	Exception stack trace is written to the Message Details field	Metadata records that are regenerated for redistribution cannot be written to the staging table. Check the associated stack trace to determine the cause of the error.
BMXAA5648E	Could not distribute package <i>package_name</i> to target <i>target_name</i> . Source database is different than target database.		An attempt is made to distribute a package to a target database that is a different database management system than the source database. The Migration Manager application works only between databases of the same type. Distribute the package as a file instead.
BMXAA5651E	Target environment base language <i>language_name</i> is different from source base language <i>language_name</i> . You must change target base language to match that for source base language before you can deploy the package.		The application requires that packages are deployed in the base language. The target environment base language also must match the source environment. When a new package is available for deployment, check its manifest and determine the base language of the package. If the base language of the target environment, change it to match the source environment.
BMXAA6001E	Could not generate manifest for package <i>package_name</i> during redistribution	Exception stack trace is written to the Message Details field	The manifest of the package cannot be generated when a package is redistributed. Check the associated stack trace to determine the cause of the error.

Managing communication templates

You use communication templates to standardize frequently used email communications, which are also known as notifications. There are several ways you can use communication templates, such as with the workflow or escalation process. You can also create and send email communications from the ticket applications by using standardized information from communication templates.

- [Communications template overview](#)
You can create and manage communication templates that can be used to standardize frequently used e-mail communications (which are also known as notifications).
- [Working with communication templates](#)
You can create and manage communication templates that can be used to standardize frequently used e-mail communications also known as notifications.

Communications template overview

You can create and manage communication templates that can be used to standardize frequently used e-mail communications (which are also known as notifications).

- [Communication templates and escalations](#)
You can use escalations to monitor time-sensitive records and key performance indicators (KPIs). When you create escalation records, you can specify that email notifications are generated when a record reaches the defined escalation point.
- [Substitution variables for communication templates](#)
In the Communication Templates application, you use substitution variables in the Subject field and in the Message field. When you use substitution variables in a communication template that is used to create a notification, the substitution variables are replaced with the corresponding values in the record that generates the notification.
- [Predefined communication templates](#)
In the Communication Templates application, there are predefined communication templates that you can use to create notifications. You can use the predefined templates with the Workflow application, the Service Requests application, and the Incidents application. You can also use the predefined templates with the system database or with the demo database (MAXDEMO).
- [Recipients of communication templates](#)
In the Communication Templates application, you can add recipients to communication templates. You can choose from four types of recipients: roles, persons, person groups, and email addresses. You can add one or more recipients from each category, and you can add more than one type of recipient.
- [Attachments for communication templates](#)
In the Communication Templates application, you can attach many types of document files to communication templates. These document files include text files, images, spreadsheets, videos, web pages, and document folders. When you create a communication based on a template, the attachments are always sent with the communication.
- [Communication logs](#)
In the Communication Templates application, a communication log lists the inbound and outbound communications for a record, such as a ticket or work order. For outbound communications that are generated with the Create Communication action, the communication log entry contains the details from the email message and any attachments.

Communication templates and escalations

You can use escalations to monitor time-sensitive records and key performance indicators (KPIs). When you create escalation records, you can specify that email notifications are generated when a record reaches the defined escalation point.

You can create each notification in the Escalations application, or you can create communication templates for frequently generated notifications. Notifications are sent when records are found that meet the conditions that an escalation point defines.

In the Escalations application, you can create a template-based communication. A template-based communication uses all the features that are available in a communication template, including attachments. The default values for role or recipient, subject, and message are derived from the template. You cannot change these values in the Escalations application.

For example, a service desk agent does not complete assignments within the specified time span of six hours. The assignment is escalated to the supervisor and the supervisor receives an email communication.

- [Communication templates and the service desk](#)
You can use communication templates to create and send email messages from the service desk applications. These applications include the Service Requests application, the Incidents application, and the Problems application.
- [Communication templates and workflow](#)
You can design a workflow process to generate notifications about the progress of a specific record. Notifications can be made through email or through pager, providing that your paging system supports email.

Communication templates and the service desk

You can use communication templates to create and send email messages from the service desk applications. These applications include the Service Requests application, the Incidents application, and the Problems application.

When you create communication templates for the service desk applications, you ensure that communications with service desk customers contain standardized information.

Communication templates and workflow

You can design a workflow process to generate notifications about the progress of a specific record. Notifications can be made through email or through pager, providing that your paging system supports email.

When you design a workflow process that includes email notifications, you can create the notification, and apply a communication template and change or complete the notification.

For workflow processes, you create templates that use roles as a recipient. You can add one or more roles. You can add more than one category of recipient, such as persons, person groups, or email addresses. In the Workflow Designer application, you can create a template-based communication. A template-based communication uses all the features available in a communication template, including attachments. The default values for role or recipient, subject, and message are derived from the template. You cannot change these values in the Workflow Designer application.

You can create a template for purchase requisition approvals or rejections, which can be sent as the request flows through the workflow process. You create a workflow process for purchase requests. A user submits a request for a notebook. The request enters the workflow process and is approved by the immediate supervisor. After the purchase requisition is approved by finance, the status is set to approved and the user is notified of the approval.

Substitution variables for communication templates

In the Communication Templates application, you use substitution variables in the Subject field and in the Message field. When you use substitution variables in a communication template that is used to create a notification, the substitution variables are replaced with the corresponding values in the record that generates the notification.

When you use substitution variables in the Message field, you type the text in the Subject field or in the Message field. You then add a space and a colon before the substitution variable to format the output correctly. If more text or other variables follow, you must insert a space after any variables in the Subject field or the Message field.

You can also use dot notation with relationships in substitution variables. For example, `rel1. rel2. fieldname`.

Your Incident #:TICKETID was opened on :REPORTDATE . The person assigned to work on your issue is :OWNER . You will be contacted on or before :TARGETSTART .

Predefined communication templates

In the Communication Templates application, there are predefined communication templates that you can use to create notifications. You can use the predefined templates with the Workflow application, the Service Requests application, and the Incidents application. You can also use the predefined templates with the system database or with the demo database (MAXDEMO).

Templates for the system database

You can customize templates for the system database for your business needs. Because there is an associated escalation or workflow process that refers to these templates, you cannot delete them.

Templates for the demo database

You can change or delete templates for the demo database (MAXDEMO). You can use the demo database communication templates in your test environment to gain experience adding and managing templates.

The email Listeners application uses default templates for error notifications. If an error is encountered while staging inbound records, an error notification is sent to the email administrator. The type of error determines the error notification that is sent to the email administrator.

Recipients of communication templates

In the Communication Templates application, you can add recipients to communication templates. You can choose from four types of recipients: roles, persons, person groups, and email addresses. You can add one or more recipients from each category, and you can add more than one type of recipient.

If you are creating a communication template for use with a workflow process or escalation process, you must add at least one recipient. If you are creating a template for use with the Ticket application or the Work Order application, you do not have to add a recipient. If you do not add a recipient, users who apply the template to a record are notified that an email is not sent, because there are no recipients.

Attachments for communication templates

In the Communication Templates application, you can attach many types of document files to communication templates. These document files include text files, images, spreadsheets, videos, web pages, and document folders. When you create a communication based on a template, the attachments are always sent with the communication.

Communication logs

In the Communication Templates application, a communication log lists the inbound and outbound communications for a record, such as a ticket or work order. For outbound communications that are generated with the Create Communication action, the communication log entry contains the details from the email message and any attachments.

Working with communication templates

You can create and manage communication templates that can be used to standardize frequently used e-mail communications also known as notifications.

- [Creating communication templates](#)
You can create communication templates to standardize frequently used email communications. You can also use communication templates to create email notifications to use with the automated workflow and escalation processes.
- [Attaching documents to communication templates](#)
You can send additional information in an email communication using a communication template. You can attach document folders, files, and web pages to email communications.
- [Copying communication templates](#)
You can create a template that is based on an existing template.
- [Changing communication templates](#)
Once you create a communication template, you can change it to reflect any changes in your business needs.
- [Deleting communication templates](#)
You can delete a communication template that is no longer being used.
- [Changing the status of communication templates](#)
You can manage the use of communication templates by changing the status to either active or inactive. An active status indicates that the template is ready for approval or use. An inactive status indicates that you no longer want to use the template.

Creating communication templates

You can create communication templates to standardize frequently used email communications. You can also use communication templates to create email notifications to use with the automated workflow and escalation processes.

Procedure

1. In the Communication Templates application, click New Communication Template.
A new communication template opens with an inactive status.
2. Optional: If the Template field is blank, provide a name or identifier.
3. In the Applies To field, specify a value.
4. In the Accessible From field, specify from where users can access the template:

Option	Description
ALL	For the template to be available: <ul style="list-style-type: none">• From the Create Communication action in other applications• For use with workflow and escalation processes

Option	Description
APPS	For the template to be available from the Create Communication action in other applications, except for the Escalations application and the Workflow application
ESCALATION	For the template to be available only with the escalation function
WORKFLOW	For the template to be available only with the workflow function

5. Optional: Create an entry in the communication log and attach files to the communication template.
6. Complete the following details for the communication template:
 - a. Specify the email address from which the communication template is sent.
 - b. Optional: If the recipient must reply to an email address other than the address of the sender, provide an email address in the Reply to field.
 - c. In the Subject field and Message field, specify substitution variables.
 - d. Optional: Add a recipient on the Recipients tab. If you are creating a communication template for a workflow or escalation process, you must add at least one recipient.
 - e. Optional: If you are creating a communication template for a workflow process and you want the last memo to display first in the list of memos, type `:wfassignment.lastmemo` as part of the description for the template.
 - f. Optional: If you are creating a communication template for a workflow process and you need memos to be available immediately, type `:wfassignment.currentmemo` as part of the description for the template.
7. Save your changes.

- [Adding email addresses as communication template recipients](#)

When you create a communication template, you can use email addresses as a recipient. You can add one or more email addresses, and you can add more than one category of recipient such as persons, person groups, or roles.

- [Adding person groups as communication template recipients](#)

When you create a communication template, you can use person groups as a recipient. You can add one or more person groups. You can also add more than one category of recipient such as email addresses, persons, or roles.

- [Adding persons as communication template recipients](#)

When you create a communication template, you can use persons as a recipient. You can add one or more persons. You can also add more than one category of recipient such as person groups, email addresses, or roles.

- [Adding roles as communication template recipients](#)

When you create a communication template, you can use roles as a recipient. You can add one or more roles. You can also add more than one category of recipient such as persons, person groups, or email addresses.

Adding email addresses as communication template recipients

When you create a communication template, you can use email addresses as a recipient. You can add one or more email addresses, and you can add more than one category of recipient such as persons, person groups, or roles.

Procedure

1. In the Communication Templates application, open or create a communication template.
2. Click the Recipient tab.
3. Click Show Table to expand the email table window.
4. Click New Row to add a recipient.
5. Select whether the recipient receives the communication directly, is copied, or is blind copied.
6. Save your changes.

Adding person groups as communication template recipients

When you create a communication template, you can use person groups as a recipient. You can add one or more person groups. You can also add more than one category of recipient such as email addresses, persons, or roles.

About this task

The email communication is sent to the first available person according to the calendar and shift. If no one is available, the email communication is sent to the default person in the person group.

Procedure

1. In the Communication Templates application, open or create a communication template.
2. On the Recipient tab, click Show Table to expand the Person table window.
3. Click Select Groups to add multiple recipients. In the Select Person Groups window, choose the groups that you want to add and click OK. For each person in the person group, you can select any of the following options:
 - To - the person receives the email communication directly.
 - cc - the person is copied on the email communication.
 - bcc - the person is blind copied on the email communication.
4. Optional: If you do not want the communication sent to every person in the group, clear the Broadcast check box.
5. Save your changes.

Adding persons as communication template recipients

When you create a communication template, you can use persons as a recipient. You can add one or more persons. You can also add more than one category of recipient such as person groups, email addresses, or roles.

Procedure

1. In the Communication Templates application, open or create a communication template.
2. Click the Recipient tab.
3. Click Show Table to expand the Person table window.
4. Select one of the following options:

Option	Description
New Row	To add a single recipient, in the Person field, specify a value.
Select People	To add multiple recipients, in the Select People window, select the people that you want to add and click OK.

5. Select whether the recipient receives the communication directly, is copied, or is blind copied.
6. Save your changes.

What to do next

On the Communication Template tab, you can view the recipient that you added.

Adding roles as communication template recipients

When you create a communication template, you can use roles as a recipient. You can add one or more roles. You can also add more than one category of recipient such as persons, person groups, or email addresses.

Procedure

1. In the Communication Templates application, open or create a communication template.
2. Click the Recipient tab.
3. Click Show Table to expand the Role table window.
4. Choose one of the following options:

Option	Description
New Row	To add a single recipient. In the Role field, specify a role.
Select Roles	To add multiple recipients. In the Select Roles window, select the roles that you want to add and click OK.

5. Choose whether the recipient receives the communication directly, is copied, or is blind copied.
6. Save your changes.

What to do next

On the Communication Template tab, you can view the roles that you added.

Attaching documents to communication templates

You can send additional information in an email communication using a communication template. You can attach document folders, files, and web pages to email communications.

- [Attaching document folders to communication templates](#)
To send additional information with a communication template, you can attach document folders. When you create a communication based on a template, the document folders are always sent with the communication.
- [Attaching files to communication templates](#)
To send additional information with a communication template, you can attach many types of files, including text files, images, spreadsheets, and videos. When you create a communication based on a template that has attachments, the attachments are always sent with the communication.
- [Attaching web pages to communication templates](#)
To send additional information with a communication template, you can attach web pages. When you create a communication based on this template, the attachments are always sent with the communication.
- [Linking records to communication templates](#)
You can insert a hyperlink to a record within the body of your communication template message that includes the application name and record ID.

Attaching document folders to communication templates

To send additional information with a communication template, you can attach document folders. When you create a communication based on a template, the document folders are always sent with the communication.

About this task

The business object to which the template applies determines which document folders you can view in the Folders table window. These folders are defined in the originating application. For example, if you create a communication template for incidents, the system lists any document folders that have been defined in the Incidents application. The system also links any folders linked in the database to the Incidents application.

Procedure

1. In the Communication Templates application, open or create a communication template.
2. Click the Attachment Folders tab.
3. Select the Send with Communication check box for the document folders that you want to attach to the template.
4. Save your changes.

Attaching files to communication templates

To send additional information with a communication template, you can attach many types of files, including text files, images, spreadsheets, and videos. When you create a communication based on a template that has attachments, the attachments are always sent with the communication.

Procedure

1. In the Communication Templates application, open or create a communication template.
2. On the Communication Template tab, click Attachments and select whether to attach files or attach files from the library.
3. Save your changes.

Attaching web pages to communication templates

To send additional information with a communication template, you can attach web pages. When you create a communication based on this template, the attachments are always sent with the communication.

Procedure

1. In the Communication Templates application, open or create a communication template.
2. On the Communication Template tab, click Attachments.
3. To attach a Web page, select Add New Attachments, > Add New Web Page.
4. Save your changes.

Linking records to communication templates

You can insert a hyperlink to a record within the body of your communication template message that includes the application name and record ID.

Procedure

Insert the following link into the body of your message:

```
http://:HOSTNAME/maximo/ui/maximo.jsp?event=loadapp&value=:APP&uniqueid=:OWNERID
```

where *HOSTNAME* is the name or IP address of the MXServer

where *OWNERID* is the name of the owner

Results

When a notification is generated, the application name and record ID appear in the message as a hyperlink that leads directly to the record.

To access the record, the email recipient must be a registered user with a security permission in the specified application.

Copying communication templates

You can create a template that is based on an existing template.

About this task

When you copy a communication template, the copy has the same information as the existing template, except for a new template ID and an inactive status.

Procedure

1. In the Communication Templates application, display the template that you want to copy.
2. Select the Duplicate Template action.
3. Optional: If the Template field is blank, specify a value.
4. Save your changes.

Changing communication templates

Once you create a communication template, you can change it to reflect any changes in your business needs.

Before you begin

You do not need to deactivate the template before you change it.

Procedure

1. In the Communication Template application, open the template that you want to change.
2. Change the information in the appropriate fields.
3. Save your changes.

Deleting communication templates

You can delete a communication template that is no longer being used.

Before you begin

You can delete a communication template only if it is not referenced by a workflow process or escalation process.

Procedure

1. In the Communication Templates application, open the template that you want to delete.
2. Select the Delete Template action.
3. Click Yes.

Changing the status of communication templates

You can manage the use of communication templates by changing the status to either active or inactive. An active status indicates that the template is ready for approval or use. An inactive status indicates that you no longer want to use the template.

Before you begin

If the template is used for an active escalation or workflow process, you cannot change the status of a template to inactive. Only templates that you set to active can be applied by other users to a ticket record.

About this task

The default status of a template is inactive.

Procedure

1. In the Communication Templates application, open a communication template.
2. Click Change Status.
3. In the Status field, select a status.
You can view the date and time of the status change in the Status Date field.
4. Click OK.

Managing escalations

You use escalations to ensure that critical tasks, such as those defined in service level agreements, are completed on time. You can also use escalations for events that notify you before contracts expire, or to change the status or owner of a record. You can use escalations with any application.

- [Escalations overview](#)
An escalation is a mechanism for monitoring time-sensitive records. Escalations can take actions or send notifications when a record reaches a defined escalation point. Your workflow administrator can specify that a task assignment has a time limit. If the assignment is not completed within the specified time limit, an escalation can be triggered for the record.
- [Working with escalations](#)
You use escalations to automatically monitor the critical processes in your enterprise. You can also use escalations for events, such as contract expiration, a change in the status of a records, or a change in the ownership of a record.

Escalations overview

An escalation is a mechanism for monitoring time-sensitive records. Escalations can take actions or send notifications when a record reaches a defined escalation point. Your workflow administrator can specify that a task assignment has a time limit. If the assignment is not completed within the specified time limit, an escalation can be triggered for the record.

- [Escalation engine](#)
The product contains an escalation engine that runs the escalations. Escalations help you ensure that critical tasks, such as those defined in service level agreements, are completed on time.
- [Predefined escalations](#)
To help simplify escalation management, the Escalation application has two categories of predefined escalations: those escalations for the Maximo® database and those escalations for the demonstration (Maxdemo) database.
- [Escalations and service level agreements](#)
Escalations help businesses comply with service level agreement commitments by proactively avoiding service level agreement violations.
- [Communication templates and notifications](#)
An escalation can initiate notifications when records are not acted upon in a timely manner. You can ensure that notifications are uniform in structure by basing them on communication templates. Notifications are sent out in the form of emails through your email service.
- [Escalation record fields](#)
An escalation is a mechanism to monitor records that can be acted upon or to send notifications when a record reaches a defined escalation point. In the Escalations application, you can create an escalation for any business object. Because all applications are associated with business objects, you can create escalations for any application.
- [Deletion rules for escalations](#)
In the Escalations application, you can manage escalations by deleting them.

Escalation engine

The product contains an escalation engine that runs the escalations. Escalations help you ensure that critical tasks, such as those defined in service level agreements, are completed on time.

The escalation engine performs the following tasks:

- Drives the escalation process
- Uses the cron task function
- Tests all active escalation definitions at a set schedule
- Retrieves escalation definitions from the database and constructs appropriate SQL statements
- Runs SQL statements against target objects for the escalation
- Retrieves records, and performs actions and notifications associated with the escalation definitions
- [Escalation logs](#)
You can monitor the execution of escalations by the escalation engine. To do so, you can configure logging and examine the log files for log statements related to the escalation engine.
- [Structured Query Language Expression Builder](#)
Use the Structured Query Language (SQL) Expression Builder to easily specify conditions to which an escalation applies. You also can build SQL expressions manually.
- [Escalation points](#)
In an escalation, you define the conditions to be met for an associated record, such as a work order, an asset, or a purchase order. When the conditions are met, the escalation is triggered. An escalation point represents the condition that must be met. You can use one or more of escalation points to define an escalation.

Escalation logs

You can monitor the execution of escalations by the escalation engine. To do so, you can configure logging and examine the log files for log statements related to the escalation engine.

To enable escalation engine logging, you use the Logging application. For each of the loggers set the wanted log level. If the logger does not exist, create your own logger. Verify that the loggers are all active. Associate an appender with a logger to ensure that log statements send to a product log file. When you save your changes, run the Apply Settings action in the Logging application for the settings to take effect immediately.

The following table lists the escalation loggers, a description of the logger, and the log level to set each logger to.

Logger	Description	Log level
crontask	Root logger that generates log statements for all cron tasks	DEBUG
ESCALATION	Child logger that inherits from cron task root logger and generates log statements specifically for the escalation engine	DEBUG
sql	Root logger that generates log statements of SQL statements run in the application server	INFO
COMMTEMPLATE	Child logger that inherits from service root logger and generates log statements specifically for communication templates and notifications events	INFO
mail	Root logger that generates log statements for communication with the mail server when sending notifications.	DEBUG

Structured Query Language Expression Builder

Use the Structured Query Language (SQL) Expression Builder to easily specify conditions to which an escalation applies. You also can build SQL expressions manually.

The SQL Expression Builder is a tool for building SQL expressions. This tool requires a basic understanding of SQL structure and syntax. The SQL statement evaluates to a true or to a false result at run time.

The SQL Expression Builder includes the following functions:

- Common SQL conditions
- Operators
- Mathematical functions
- Calendar lookup
- Classification lookup
- Keywords

The SQL Expression Builder also contains a relationship tree. This relationship tree allows you to drill down through the fields and related tables for the specified object or application and select a value.

Escalation points

In an escalation, you define the conditions to be met for an associated record, such as a work order, an asset, or a purchase order. When the conditions are met, the escalation is triggered. An escalation point represents the condition that must be met. You can use one or more of escalation points to define an escalation.

Activating an escalation does not trigger an escalation process. An escalation is triggered only when the escalation engine finds records that meet the criteria defined by the escalation points.

You can create the following categories of escalation points:

Elapsed time since a past event

Compares the current date and time to the specified field that represents an event in the past. You can select from a list of DATETIME fields on the record. For example, a Start Date on a workflow assignment, an Actual Start date on a work order, or a Status Date on a record that includes status.

Time until a future event

Compares the current date and time to the specified field that represents an event in the future. For example, a Renewal Date on a contract, a Due Date on an invoice, or a Target Finish date on a work order.

Condition

Condition without a time measurement. If you want to trigger the actions and notifications of an escalation based on a condition that does not have a time measurement, you can specify the condition in the Escalation Point Condition field. You also can use the Condition field to specify that the escalation point is applied only to the subset of records specified by the condition.

- [Actions associated with escalation points](#)

When records meet the conditions in an escalation point, an action can be triggered. An action is an event, such as a changing status. Escalation points are the components of an escalation that represent a monitored condition or threshold, such as measuring elapsed time. To activate an escalation, you must associate at least one action with an escalation point.

Actions associated with escalation points

When records meet the conditions in an escalation point, an action can be triggered. An action is an event, such as a changing status. Escalation points are the components of an escalation that represent a monitored condition or threshold, such as measuring elapsed time. To activate an escalation, you must associate at least one action with an escalation point.

Action types define categories of actions. You can use a predefined action type, such as set owner, status change, and create ticket, or you can create an action type.

Action groups are predefined sets of actions that are grouped in a specific sequence. Escalation points are associated with actions through the action group. If you associate a predefined action, an action group is created for that action, and the predefined action becomes a member of that action group. Only the action group with the escalation point is associated, not the action itself.

When you add multiple actions, you can assign a preexisting action a sequence number. The values for the description and the action type are defaulted based on the object and action that you chose.

Action groups can be created automatically when you add actions in the Escalations application, or you can add action groups in the Actions application. In the Actions application, you create actions and specify that an action is used with an escalation.

Predefined escalations

To help simplify escalation management, the Escalation application has two categories of predefined escalations: those escalations for the Maximo® database and those escalations for the demonstration (Maxdemo) database.

To use the predefined escalations, you must activate them.

Predefined escalations for the database

You can change predefined escalations for the database to suit your business needs. You must not delete these predefined escalations because they are required for the escalations functionality to work.

The following table describes the predefined escalations for the database.

Table 1. Predefined escalations for the database

Escalation name	Application	Description
INVDUE	Invoice application	Changes the invoice status to the target invoice status when the due date is reached on invoices that were generated from a payment schedule
MSTRCTREFF	Master Contracts application	Changes the status of a contract to approved when the contract start date is reached
LEACTREFF	Lease Contracts application	Lease contract start date has been reached and the status should be changed to approved.
LABCTREFF	Labor Contracts application	Labor contract start date has been reached and the status should be changed to approved.
PURCTREFF	Purchasing Contracts application	Purchase contract start date has been reached and the status should be changed to approved.
REPORTLONG	Report Administration application	The report is taking longer than the specified amount of time to complete.
WARCTREFF	Warranty Contracts application	Warranty contract start date has been reached and the status should be changed to approved.

Predefined escalations for Maxdemo database

The following table describes examples of the predefined escalations for the Maxdemo database.

Table 2. Examples of the predefined escalations for the Maxdemo database

Escalation name	Application	Description
Warranty expiring	<ul style="list-style-type: none">Master Contracts applicationLease Contracts applicationWarranty Contracts applicationPurchasing Contracts applicationLabor Contracts application	Notifies the current owner of the warranty 90 days, 60 days, and 30 days before the expiration of the warranty of the asset
Contract renewal	<ul style="list-style-type: none">Master Contracts applicationLease Contracts applicationWarranty Contracts applicationPurchasing Contracts applicationLabor Contracts application	Notifies the buyer of the contract 90 days, 60 days, and 30 days before the contract renewal date
SLA review date	<ul style="list-style-type: none">Service Level Agreements application	Notifies the service level agreement (SLA) administrator 30 days, 60 days, and 90 days before the SLA review date for all active SLA
Autoclose resolved tickets	<ul style="list-style-type: none">Service Requests applicationIncidents applicationProblems application	Automatically closes all non-historical tickets (all classes) that have been in a resolved status for more than 10 days

Escalations and service level agreements

Escalations help businesses comply with service level agreement commitments by proactively avoiding service level agreement violations.

- Each service level agreement has a one-to-one relationship with an escalation.
- Each commitment in a service level agreement maps to an escalation point in the corresponding escalation.
- After defining a service level agreement, you can define the corresponding escalation, and the service level agreement application populates escalation points (you can modify them).
- The service level agreement application contains an Escalation tab, providing a view into the corresponding escalation.

Communication templates and notifications

An escalation can initiate notifications when records are not acted upon in a timely manner. You can ensure that notifications are uniform in structure by basing them on communication templates. Notifications are sent out in the form of emails through your email service.

A notification includes a template ID, the role or recipient name, the subject of the notification, and the message. If you have information that is sent out repeatedly, you can create a communication template for it and attach it as a notification on an escalation.

You can create two types of notifications in the Escalations application:

- A free-form notification that uses only a few features of a communication template
- A template-based notification that can use all the features of a communication template, including attached documents

If you create a free-form notification the system generates a template ID for it. However, the system does not save the notification for reuse in the Communication Templates application. If you select an existing communication template, the system defaults the values in the Role/Recipient, Subject, and Message fields from the communication template you chose. You cannot change these read-only values from within the Escalations application.

Escalation record fields

An escalation is a mechanism to monitor records that can be acted upon or to send notifications when a record reaches a defined escalation point. In the Escalations application, you can create an escalation for any business object. Because all applications are associated with business objects, you can create escalations for any application.

An escalation record consists of the following fields

Object (Applies To field)

You create escalation records for a specific business object. The escalation engine retrieves records, from the business object, that meet the escalation point criteria.

SQL statement — (Condition field)

An escalation record can apply to all application records, or to a specific set of records. You can create an SQL statement that specifies records to which the escalation is applied. The conditions can apply to one or more tables associated with the object.

Organization and Site

Escalations are stored at the system level. You can create escalations for use with a specific organization or site.

Schedule

A schedule that defines how often the system checks for records that meet the criteria for the escalation. The polling interval can be seconds, minutes, hours, days, weeks, or months. You also can specify whether the interval is calendar or date based.

Calendar Organization

The organization that is associated with the escalation calendar.

Calendar

The calendar that specifies the days and times for which the escalation is valid.

Shift

The shift that specifies the days and times for which the escalation is valid.

Escalation Point

Date-and time-based, or other condition criteria for when the actions or notifications specified on the escalation record are triggered. An escalation record can have one or more escalation points.

Actions

Any actions that must be taken when a record reaches the conditions of an escalation point. You define actions separately for each escalation point. You can associate multiple actions for each escalation point. You use the Actions application to define actions.

Notifications

Any notifications that the system must generate when a record reaches the conditions of an escalation point. You define notifications separately for each escalation point.

Deletion rules for escalations

In the Escalations application, you can manage escalations by deleting them.

The following rules apply when you delete escalations:

- When you delete an escalation, the actions and notifications are not deleted. Instead, the associations between the escalation points and the actions and notifications are removed. You delete actions in the Actions application and notifications in the Communication Templates application.
- In the Escalations application, you cannot delete escalations that are associated with service level agreements (SLA).
- If a service level agreement that is associated with an escalation is deleted, then the escalation is also deleted.

Working with escalations

You use escalations to automatically monitor the critical processes in your enterprise. You can also use escalations for events, such as contract expiration, a change in the status of a records, or a change in the ownership of a record.

- [Creating escalations](#)
You create an escalation to monitor time-sensitive records that could require action. You can create an escalation for any business object and for any application. You can create escalations at the organization or site level.
- [Validating escalations](#)
You must validate an escalation record before you can activate it. Validation checks the Structured Query Language (SQL) statements to ensure that the SQL is valid and that the escalation engine can run it.
- [Activating escalations](#)
You can activate an escalation record that has at least one escalation point and one action or notification defined for each escalation point. The product polls for records meeting the criteria set by the escalation. If a match is found, the appropriate action is triggered.
- [Modifying escalations](#)
You can change existing escalations.
- [Deactivating escalations](#)
You deactivate an escalation record to modify the record or to delete it.

Creating escalations

You create an escalation to monitor time-sensitive records that could require action. You can create an escalation for any business object and for any application. You can create escalations at the organization or site level.

Before you begin

Before you can activate and use an escalation record, you must define at least one escalation point and at least one action or notification for the escalation point. An *escalation point* defines the threshold at which an escalation is triggered. An *action* is the event that is triggered when an escalation point is reached.

Procedure

1. On the toolbar, click New Escalation. If the Escalation field is empty, specify a value.
 2. In the Description field, type a description.
 3. In the Applies To field, specify the object to which to apply the escalation.
 4. Optional: Specify values in the Organization and Site fields. If you specify a value for either organization or site, you restrict the use of the escalation to either that organization or site. If you specify values for both organization and site, the escalation can be used only at that site.
 5. Optional: Type an expression in the Condition field to indicate to which records the escalation applies. For example, if you want to escalate only task assignments that have a value specified in the Time Limit field, include the following text in your SQL statement: **TIMELIMIT is not null**. You can type the SQL condition manually. You can also use the Expression Builder to create the SQL statement.
 6. In the Schedule field, click the Set Schedule icon to set how frequently to poll the database for records.
 7. Optional: In the Calendar Organization, Calendar, and Shift fields, specify values to limit when the escalation is run.
 8. Click Save Escalation.
- [Defining escalation points](#)
You can define one or more escalation points for an escalation. For each escalation point, you can specify one or more actions or notifications.

Defining escalation points

You can define one or more escalation points for an escalation. For each escalation point, you can specify one or more actions or notifications.

Procedure

1. In the Escalations application, create, or display an escalation record.
2. In the Escalation Points table window, click New Row.
3. In the Row Details window, specify the condition that triggers the escalation point by selecting one of the following options:
 - If you are creating a time-based escalation point, specify values in the Elapsed Time Attribute field, in the Elapsed Time Interval field, and in the Interval Unit of Measure field. Type a positive number in the Elapsed Time Interval field to indicate a time period in the past. Type a negative number to indicate a time in the future.
 - If you are creating a condition-based escalation point, type an SQL statement in the Escalation Point Condition field to specify the condition that triggers the escalation. You can specify a value manually or click the SQL Expression Builder icon.

4. If you want the actions and notifications of the escalation point triggered more than once, select the Repeat check box.
5. Click Save Escalation.

What to do next

Now you define an action to take for each escalation point that you created.

- **Defining actions for escalation points**
You define at least one action or notification for each escalation point on an escalation record. You define actions separately for each escalation point. You use the Actions application to create action records.
- **Defining notifications for escalation points**
You must define at least one action or notification for each escalation point on an escalation record. You can use a communication template to create a notification. You can also type the subject, message, and recipients manually. You define notifications separately for each escalation point.

Defining actions for escalation points

You define at least one action or notification for each escalation point on an escalation record. You define actions separately for each escalation point. You use the Actions application to create action records.

About this task

To define actions for an escalation point, complete the following steps:

Procedure

1. In the Escalations application, create or display an escalation record.
2. In the Escalation Points table window, select the escalation point for which you want to define actions.
3. Click the Actions sub tab.
4. In the Actions window, click New Row.
5. In the Action field, specify a value.
6. Optional: Modify the Sequence field to indicate the order in which the action is performed.
7. Click Save Escalation.

What to do next

You must validate the escalation before activating it.

Defining notifications for escalation points

You must define at least one action or notification for each escalation point on an escalation record. You can use a communication template to create a notification. You can also type the subject, message, and recipients manually. You define notifications separately for each escalation point.

Procedure

1. In the Escalations application, create, or display an escalation record.
2. In the Escalation Points table window, select the escalation point for which you want to define notifications.
3. On the Notifications sub tab, click New Row.
4. Perform one of the following steps:
 - In the Template field, specify a value.
 - Type entries in the Role/Recipient field, in the Subject field, and in the Message field.
5. Click Save Escalation.

Validating escalations

You must validate an escalation record before you can activate it. Validation checks the Structured Query Language (SQL) statements to ensure that the SQL is valid and that the escalation engine can run it.

About this task

The validation process checks for syntax errors and ensures that escalation conditions have been defined in the table for the specified object. The product does not validate actions or notifications.

If an error is discovered in one or more SQL statements, the errors are written to the Validation Results section of the escalation record.

Procedure

1. In the Escalations application, display the record that you want to validate.
2. Select the Validate action.
3. If the validation fails, click the Maximize button to expand the Validation Results section and to view the error log. The SQL error might be in the Condition field or in the Escalation Point Condition fields. Correct the SQL statements and validate the record again.
4. Click Save Escalation.

What to do next

Activate the escalation.

Activating escalations

You can activate an escalation record that has at least one escalation point and one action or notification defined for each escalation point. The product polls for records meeting the criteria set by the escalation. If a match is found, the appropriate action is triggered.

Before you begin

An escalation record must be validated before it can be activated.

About this task

The product checks for records that meet the frequency criteria defined in the Schedule field of the escalation record. If records are found that match, and any of those records meet the conditions defined by the escalation points, then the escalation mechanism triggers the appropriate actions, notifications, or both.

Activating an escalation does not trigger an escalation process. The escalation process triggers only when the escalation engine finds records meeting the criteria defined by the escalation points.

When you activate an escalation, all fields on the record become read-only. You cannot edit an escalation record while it is active.

Procedure

1. In the Escalations application, display the record that you want to activate.
2. Select the Activate/Deactivate Escalation action. The product selects the Active check box in the record heading and creates an instance of the ESCALATION cron task.
3. Click Save Escalation.

Modifying escalations

You can change existing escalations.

Before you begin

All fields on an activated escalation are read-only. You must deactivate the escalation before you can edit it.

About this task

You can modify the following elements of a deactivated escalation:

- You can delete one or more escalation points.
To activate an escalation, it must have at least one escalation point. When you delete an escalation point, the links to the associated actions and notifications. are deleted.
- You can delete one or more actions or notifications associated with an escalation point.
To activate an escalation, it must have at least one action or notification defined for each escalation point.

Procedure

1. From the Escalations application, display the escalation that you want to edit.
2. If you have not deactivated the escalation, select the Activate/Deactivate Escalation action.
3. On the Escalations tab, edit the information as needed. If a field has a Detail Menu, click it and select an option to retrieve a different value.
4. Click Save Escalation.
5. If you are ready to active the escalation, select Activate/Deactivate Escalation.

Deactivating escalations

You deactivate an escalation record to modify the record or to delete it.

Procedure

1. In the Escalations application, display the record that you want to deactivate.
2. Select the Activate/Deactivate Escalation action.
3. Click Save Escalation.

What to do next

After you deactivate an escalation, you can perform the following actions:

- You can delete one or more escalation points. When you delete an escalation point, the links to the associated actions and notifications are deleted.
- You can delete one or more actions or notifications associated with an escalation point. To activate an escalation, it must have at least one action or notification defined for each escalation point.

Enabling email updates for objects and workflow assignments

With email interaction, users without access to a desktop user interface can change objects and workflow assignments. A worker assigned to an object or workflow assignment receives an email that describes the object or workflow assignment. The email recipient replies to the email to change the status of the object, accept or reject the workflow assignment, or update the attributes of the record.

- [Email interaction overview](#)
You use email interaction to send work order and purchasing information to remote users who do not have access to the desktop. The email recipient can change the status of an object or update a workflow assignment. The email recipient changes the status of an object or updates a workflow assignment by specifying a value in an email from a portable device.
- [Examples of email interaction](#)
You use email interaction to send work order and purchasing information to remote users who do not have access to the desktop. The email recipient can change the status of an object or update a workflow assignment. The email recipient changes the status of an object or updates a workflow assignment by specifying a value in an email from a portable device.
- [Configuring updates by using email interaction](#)
You configure email interaction to ensure that users who do not have access to a desktop computer can change the status of objects or workflow assignments.

Email interaction overview

You use email interaction to send work order and purchasing information to remote users who do not have access to the desktop. The email recipient can change the status of an object or update a workflow assignment. The email recipient changes the status of an object or updates a workflow assignment by specifying a value in an email from a portable device.

Email interaction supports two configurations. Email recipients can reply to an email to change the status of an object or to complete a workflow assignment. For example, an off-site technician can update the status of an assigned work order from Approved to In Progress. For both configurations, email interaction has two email format types. In the simple format, the email recipient can change the status of an object or accept or reject a workflow assignment. In the advanced format, the email recipient can modify attributes that are associated with an object status change or workflow assignment. For example, the user can change the start date, completion date, priority level, or description.

- [Simple and advanced email formats](#)
Email interaction can process email notifications in both simple and advanced formats. The email format determines whether the user can change the attributes of the target object in the body of the email. You choose either the simple or advanced format in the People application.

Simple and advanced email formats

Email interaction can process email notifications in both simple and advanced formats. The email format determines whether the user can change the attributes of the target object in the body of the email. You choose either the simple or advanced format in the People application.

Simple format

In simple format, the email recipient can update a record only. The first email that is sent to the user contains a list of values that is associated with record update options. The value in the first line of the reply email corresponds to the value that is associated with the update to the record.

For example, in an object status change configuration, the status options for a work order might be 1 = Approved, 2 = In progress and 3 = Complete. If the work order is approved, the value 1 is listed in the first line of the reply email.

Advanced format

In advanced format, the email recipient can update a record and change the attributes of the target object that is specified in the configuration. The attributes can also be changed with or without changing the status of the record in the object status change configuration.

For example, in a workflow assignment the start date and completion date of a workflow task changes. The new start date is 10/01/12 and the new completion date is 12/30/12. The email recipient updates the record by changing the attributes of start date to 10/01/12, and completion date to 12/30/12 in the body of the email.

- **Email variables in email interaction**

You use existing communication templates for email interaction. If you choose to create your own communication templates, you must specify variables. All the communication templates except for confirmation and error notification must contain the variables.

Email variables in email interaction

You use existing communication templates for email interaction. If you choose to create your own communication templates, you must specify variables. All the communication templates except for confirmation and error notification must contain the variables.

The Subject field of the communication templates must contain the @@MAILKEY@@ variable. The following table shows the variables that you must include in the body of the communication templates for email interaction. You can also include some optional variables to instruct users how to reply to an email or to list the tasks in a work order.

Variable	Purpose	Optional or required	Email format
SELECTIONLIST	Adds a list of number prompts or name-value pairs	Required	Simple and advanced
OBJID	Adds the ID of the object	Required	Simple
GUIDANCE	Adds instructions for how to reply	Optional	Simple and advanced
TASKLIST	Adds the list of tasks on a work order	Optional	Simple and advanced

Examples of email interaction

You use email interaction to send work order and purchasing information to remote users who do not have access to the desktop. The email recipient can change the status of an object or update a workflow assignment. The email recipient changes the status of an object or updates a workflow assignment by specifying a value in an email from a portable device.

Email interaction supports two configurations. Email recipients can reply to an email to change the status of an object or to complete a workflow assignment. For example, an off-site technician can update the status of an assigned work order from Approved to In Progress. For both configurations, email interaction has two email format types. In the simple format, the email recipient can change the status of an object or accept or reject a workflow assignment. In the advanced format, the email recipient can modify attributes that are associated with an object status change or workflow assignment. For example, the user can change the start date, completion date, priority level, or description.

- **Example: Enabling email updates to purchase orders**

A system administrator wants to enable an assessor, who works in the field and does not have access to a desktop, to update the status of a purchase order.

- **Example: Enabling email updates to workflow assignments**

A system administrator wants to ensure that a supervisor, who does not have access to a desktop, can approve or reject workflow assignments. The system administrator also wants the supervisor to be able to change the start date and completion date of the workflow assignment.

Example: Enabling email updates to purchase orders

A system administrator wants to enable an assessor, who works in the field and does not have access to a desktop, to update the status of a purchase order.

Before you begin

To configure email interaction, you must have an email client, SMTP mail server, a user ID, and a password for email authentication. Because you are only updating purchase orders, you must set the Email format field of the People application to simple. Existing communication templates and escalations are provided for email interaction. For example, you can use the template for the email that notifies the assessor that the purchase order is complete.

About this task

A system administrator works in the head office of a large public insurance company. Some of the company's employees travel long distances, from the company headquarters to remote sites around the country. Maria, an assessor, who travels to remote sites to assess the progress of purchase orders, does not have access to a desktop. Maria does have email access from a mobile device. Email interaction setup allows Maria to communicate back, to the system administrator, the status of the purchase order. The customer service department can then pass information about the job to the customer.

Procedure

1. In the Systems Properties application, specify the address of the mail server as `mail.smtp.` host your user ID as `mxe.smtp.password`, and password as `mxe.smtp.password` for email authentication.

2. In the E-mail Listener application, enter your E-mail Address, E-mail Password, and Mail server. The protocol is a standard pop3 account.
 - a. In the Select Security Settings window, create a row and specify the SR object.
 - b. In the Select Security Settings window, select the PURCHASEORDER object that is associated with the status update.
 - c. Activate the email listener and MFMAILCLEAN cron task.
3. To find existing templates, in the Communications Template application, search for MFMAIL in the Template field.
 - a. The MFMAILSENDWO template is an existing template, for the first email that is sent to Maria when the purchase order is approved.
 - b. In the MFMAILRESCOMPWO, MFMAILRESNOSTWO, MFMAILRESWO, MFMAILSMPREJ templates, specify the address of the email listener in the Send from field.
 - c. Do not specify a recipient in the communication templates. The role is specified in the Send to field in the configuration.
4. In the Escalations application, open the MFMAILSENDWOM escalation.
 - a. For object status change configurations, you must include status as one criteria of the condition query.
The status in the escalation, must be the same status that is specified in the first email.
 - b. Specify the custom class for object status change as `com.ibm.tivoli.maximo.mfmail.MfMailSTSendAction`.
5. In the Email Interaction Setup application, choose status for the configuration type and complete the fields.
 - a. In the Task Completion Notification Template field of the object status change configurations window, specify MFMAILRESCOMPWO in the row where you assign the selection value.
 - b. In the Status Change Response Template field of the Selection Values window, specify MFMAILRESWO in the row where you assign the selection value for accepting the status update.
 - c. In the Status Change Response Template field of the Selection Values window, specify MFMAILRESNOSTWO in the row where you assign the selection value for reminding Maria to change the status of the purchase order.
 - d. In the Status Change Response Template field of the Selection Values window, specify MFMAILSMPREJ in the row where you assign the selection value for rejecting the status update.
 - e. Validate and activate the configuration.

Results

When a purchase order is approved, Maria receives an email with a request to update the status of the purchase order. When Maria arrives at the remote site, the purchase order is already started. Maria sends a reply email that updates the status of the purchase order to, in progress. Maria then receives another email that requests the status of the purchase order to be updated. When the purchase request is complete, Maria sends back a reply email that updates the status of the purchase order to 'complete'. Maria receives a final email to confirm that the status of the purchase order is complete.

Example: Enabling email updates to workflow assignments

A system administrator wants to ensure that a supervisor, who does not have access to a desktop, can approve or reject workflow assignments. The system administrator also wants the supervisor to be able to change the start date and completion date of the workflow assignment.

Before you begin

Configuring email interaction requires an SMTP mail server with an administrator account for authentication. To allow a supervisor to change the attributes of the workflow assignment, in the record for the user in the People application, in the Email Format field must be set to Advanced. The default value for the field is advanced, so in this example, the system administrator does not change this field. Existing communication templates are provided for email interaction. For example, a template for the email that notifies the supervisor that the workflow assignment was approved is provided.

About this task

In a large textiles company, every work order in a workflow must be approved by Marco, the head supervisor. The company has a large factory floor and Marco is often on the floor without access to a desktop. The system administrator wants to configure email interaction so that when a work order is created, Marco receives an email on the portable device that he carries. The system administrator wants Marco to be able to reply to the email to approve or reject the work order. Also, due to a busy schedule, Marco must frequently delay the start date of work orders. The system administrator wants Marco to be able to edit the email to change the start date and completion date of the workflow assignment.

Procedure

1. In the Systems Properties application, specify the address of the mail server as `mail.smtp.host`, your user ID as `mxe.smtp.password`, and the password as `mxe.smtp.password` for email authentication.
2. To find existing templates, in the Communications Templates application, search for MFMAIL in the Template field.
 - a. In the MFMAILSENDWFA1, MFMAILRESCOMPWF, and MFMAILRESREJWF1 templates, in the Send from field, specify the address of the E-mail Listener.
 - b. Do not specify a recipient in the communication templates. The role is specified in the Send to field in the configuration.
3. In the E-mail Listener application, enter `MFMAILRCV` for the workflow process.
 - a. In the Select Security Settings window, create a row and specify the SR object.
 - b. In the Select Security Settings window, create a row and specify the target object that is associated with the email notification.
 - c. Activate the email listener and MFMAILCLEAN cron task.
4. In the Workflow Designer application, open the task node properties and in the Communication template field, specify `MFMAILSENDWFA1`.
The MFMAILSENDWFA1 template is an existing template for the first email that is sent to Marco when a work order is created.
5. In the Escalations application, open and modify the MFMAILSENDWFM escalation.
This escalation has an escalation point and an action that starts email interaction.
 - a. Modify the SQL query in the escalation to specify the workflow process that sends the first email.
 - b. Specify the custom class as `com.ibm.tivoli.maximo.mfmail.MfMailWFSEnder`.
6. In the Email Interaction Setup application, specify `Workflow` for the configuration type and complete the fields.
 - a. In the Workflow Assignment configurations window, in the Task Completion Notification Template field, specify `MFMAILRESCOMPWF`.

- b. In the Selection Values window, in the Workflow Change Response Template field, specify MFMAILRESCOMPWF in the row where you assign the selection value for accepting the work order.
- c. In the Workflow Change Response Template field, specify MFMAILRESREJWF1 in the row where you assign the selection value for rejecting the work order.
- d. Select the Validate and activate action.

Results

When a work order is created in a workflow, Marco receives an email with a request to approve or reject the work order. Marco can reply to the email to change the start date and completion date. Marco receives a second email with a request to approve or reject the work order. Marco replies to approve the work order and receives one final email that confirms that the choice was processed.

Configuring updates by using email interaction

You configure email interaction to ensure that users who do not have access to a desktop computer can change the status of objects or workflow assignments.

Before you begin

The configuration tasks require a mail server, a user ID, and password for email authentication. Set up an email client or use an existing client to communicate with the specified mail server.

Procedure

1. In the People application, in the Email format field, select the email format for email interaction.
2. In the Systems Properties application, specify the mail server and the user ID and password for email authentication.
3. In the Communications Template application, create communication templates for email interaction.
Search for MFMAIL in the Template field to find existing templates.
 - a. In each template that you identified for email interaction, in the Send from field, specify the address of the email listener.
Do not specify a recipient in the communication templates. The role is specified in the Send from in the Email Interaction Setup application.
4. In the Email Listener application, in the Workflow Process field, enter MFMAILRCV.
 - a. In the Select Security Settings window, create a row and specify the SR object.
 - b. In the Select Security Settings window, create a row and specify the target object that is associated with the email notification.
 - c. Activate the email listener and the MFMAILCLEAN cron task.
5. Optional: If you are using email interaction for a workflow assignment, open the Workflow Designer application. Open the Task node properties window and in the Communication template field, specify the communication template for the first email that is sent to the user.
6. In the Escalations application, create an escalation for email interaction.
Search for MFMAIL in the Escalation field to find existing escalations.
 - a. Optional: For object status change configurations, specify **status** as one of the criteria for the condition query.
 - b. Modify the SQL query in the escalation to specify the status or workflow process that sends the first email.
 - c. Specify a custom class depending on the type of configuration:

Option	Description
Object status change	com.ibm.tivoli.maximo.mfmail.MfMailSTSendAction
Workflow assignment	com.ibm.tivoli.maximo.mfmail.MfMailWFSEnder

7. In the Email Interaction Setup application, complete the fields to identify the type of configuration, specify the communication templates, and assign number prompts.
8. Select the validate and activate action.

Managing cron tasks

Cron tasks are behind-the-scene jobs that run automatically and on a fixed schedule. Predefined cron tasks support scheduling activities such as generating preventive maintenance work orders and reordering inventory items on schedules. Predefined cron tasks are provided, and you can also create your own cron tasks.

- [Cron task setup overview](#)
You can reschedule cron tasks and change parameter values without stopping and restarting the server. You can create cron tasks and cron task instances, remove cron tasks or cron task instances, and change cron task parameters.
- [Working with cron tasks](#)
Cron tasks are behind-the-scene jobs that run automatically and on a fixed schedule. You can create or change cron tasks.

Cron task setup overview

You can reschedule cron tasks and change parameter values without stopping and restarting the server. You can create cron tasks and cron task instances, remove cron tasks or cron task instances, and change cron task parameters.

- [Preexisting cron tasks](#)
There are cron tasks that are supplied by the product and are set up to run scheduled jobs on the system server. Cron tasks are behind-the-scene jobs that

run automatically and on a fixed schedule.

- [Access levels for cron tasks](#)
Access levels determine what users can do when they are using the Cron Task Setup application.
- [Cron task parameters](#)
The cron task class file lists parameters. Parameter tables store parameter values for cron task instances.
- [Instances of cron tasks](#)
An instance is a copy of a cron task that you can change to meet your business needs. You can create multiple instances for each cron task.
- [Owner and Issuer for cron task instance](#)
You might want to set different owner and issuer for different cron task instances. For example, some user wants to have issuer as <varname>saml</varname> and owner as <varname>scim</varname> and others want to have issuer as <varname>saml</varname> and owner as <varname>local </varname> to be able to manage users in <keyword conref="..../shared/conrefs.dita#conrefs/prodname_imas_short"/>.

Preexisting cron tasks

There are cron tasks that are supplied by the product and are set up to run scheduled jobs on the system server. Cron tasks are behind-the-scene jobs that run automatically and on a fixed schedule.

The following table describes the cron tasks that are supplied by the product. All these cron tasks are set to full access level, except for ESCALATIONS and LSNRCRON (READONLY).

Table 1. Cron tasks that are supplied by the product

Cron task	Description
ReorderCronTask	The reorder cron task determines the rules or parameters for scheduled reordering, direct issue, and inventory items.
PMWoGenCronTask	The preventive maintenance work order generation cron task runs and generates scheduled work orders for planned maintenance.
KPICronTask	This cron task generates key performance indicators.
ESCALATION	The escalation cron task processes escalations to ensure that critical tasks are completed on time.
LSNRCRON	The e-mail listener cron task runs continuously on the application server, and processes inbound e-mail messages through a staging table.
JMSQSEQCONSUMER	This cron task is used by the integration framework to poll the queue.
IFACETABLECONSUMER	This cron task is used by the integration framework to poll the interface tables.
SwSuiteCronTask	This cron task determines whether the software titles in the Deployed Asset application are present.
ReconciliationCronTask	This cron task runs reconciliation tasks that consist of link and comparison rules. These rules are used to determine how assets are performing relative to the discovered data in the Deployed Asset application. Outputs from this task include a RECONLINK table. This table links assets to their counterpart assets and a reconciliation results table that lists the differences between compared assets and deployed assets.
MeasurePointWorkOrderCronTask	This cron task generates work orders when meter readings or measurements reach a condition that is defined in the Condition Monitoring application.
FLATFILECONS	This cron task processes inbound flat files.
XMFILECON	This cron task processes inbound XML files.
BBCron	This cron task periodically updates the count for the number of bulletin board messages.

Access levels for cron tasks

Access levels determine what users can do when they are using the Cron Task Setup application.

You can set the access level to one of these options:

- FULL enables users to change or delete the cron task definitions and instances.
- MODIFYONLY enables users only to change the cron task.
- READONLY enables users only to view the cron task.

Cron task parameters

The cron task class file lists parameters. Parameter tables store parameter values for cron task instances.

When you create a cron task instance, the parameter names are retrieved from the cron task class file. For each parameter, a row is added to the parameter table for this instance. When instances are initialized and associated parameters are changed, the instances dynamically obtain the changes from the database.

Example

Table 1. Example of CRONTASKPARAMETER table with data for the ReorderCron cron task

CRONTASKNAME	INSTANCENAME	PARAMETER	VALUE
ReorderCronTask	NA	directisse	

CRONTASKNAME	INSTANCENAME	PARAMETER	VALUE
ReorderCronTask	NA	emailto	
ReorderCronTask	NA	ignoreorderpoint	0
ReorderCronTask	NA	leadtime	0
ReorderCronTask	NA	logfile	
ReorderCronTask	NA	storeroom	Nashua
ReorderCronTask	NA	useagreement	1
ReorderCronTask	NA	directisue	
ReorderCronTask	NA	emailto	
ReorderCronTask	NA	ignoreorderpoint	0
ReorderCronTask	NA	leadtime	0
ReorderCronTask	NA	logfile	
ReorderCronTask	NA	storeroom	Central,Bedford
ReorderCronTask	NA	useagreement	1

Instances of cron tasks

An instance is a copy of a cron task that you can change to meet your business needs. You can create multiple instances for each cron task.

You can change the attributes or parameters of a cron task instance. Using this method, the same cron task can perform different functions.

Each instance has an entry in the CRONTASKINSTANCE table. The instance includes the following attributes:

- Set schedule string (defines the schedule for this instance)
- Description
- Flag indicating whether the instance is active
- Datetime field indicating the date and time that the load or reload of the cron task is requested (not displayed to users)
- Run as user ID

If you have a cron task that performs backups, you can create instances to perform backups at different frequencies, such as daily, weekly, or monthly.

Owner and Issuer for cron task instance

You might want to set different owner and issuer for different cron task instances. For example, some user wants to have issuer as `<varname>saml</varname>` and owner as `<varname>scim</varname>` and others want to have issuer as `<varname>saml</varname>` and owner as `<varname>local </varname>` to be able to manage users in `<keyword conref="../shared/conrefs.dita#conrefs/prodname_imas_short"/>`.

Symptoms

During upgrade to Manage, all Maximo® users are synchronized to Maximo Application Suite. You can specify the authentication method, which was used before the upgrade. To specify the authentication method, you must configure MXE_OLDAUTHINTICATION in Manage custom resource. A valid list of values is *local*, which is default, *saml*, and *ldap*. Based on this setting, two user properties are set in Maximo Application Suite:

- Authentication method, which is set to MXE_OLDAUTHINTICATION.
- Owner, which is set to *local* for type *local* and *scim* for values *ldap* and *saml*. If Owner is set to *scim*, the user cannot be changed in Maximo Application Suite because it controls an external repository.

Causes

One setting controls two properties. You might want users to be managed in Maximo Application Suite even if the authentication method is set to *saml* or *ldap*. Also, you might have internal and external users even if all authentication is done in *saml*. In this case, you want to maintain some users in Maximo Application Suite and other users to be external and managed by *ldap*.

Resolving the problem

You can configure Owner and Issuer (authentication type) during user synchronization from Manage to Maximo Application Suite.

To do this, two new cron task parameters are added to the user synchronization MASUSERSYNC cron task:

- Owner
- Issuer

By default, the Owner and Issuer are set to *null* so that the default logic remains the same. It is relayed to MXE_OLDAUTHINTICATION to set authentication method and owner in Maximo Application Suite.

If you want to fix users, which were already sent to Maximo Application Suite, you can fix these users after the initial synchronization. You must reset the MASISSUER column in the MAXUSER table to *null*, setting Owner and Issuer as cron task parameters and starting MASUSERSYNC cron task.

If you create users that use Maximo Integration Framework in Manage and want to synchronize it to Maximo Application Suite, then you can set cron task parameters in the way you want and synchronize new users.

For example, if you want to have the authentication method as *saml* but the user to be managed in Maximo Application Suite, you can set:

Issuer - *saml*

Owner - *local*

Working with cron tasks

Cron tasks are behind-the-scene jobs that run automatically and on a fixed schedule. You can create or change cron tasks.

- [Creating cron task definitions](#)
A cron task definition consists of a name, class name, access level, and description. You can create cron task definitions to meet the specific needs of your organization.
- [Deleting cron task definitions](#)
Cron tasks have a definition that includes name, class name, access level, and description. In the Cron Task Setup application, you can delete cron task definitions that you are no longer using.
- [Working with instances of cron tasks](#)
You can create multiple instances for each cron task. You can also reload instances of cron tasks, and you can delete instances of cron tasks.
- [Disabling cron tasks for a server bundle](#)
Active cron tasks run on all servers in a sequence. In you have multiple server bundles, you can disable a cron task instance on one or more of the bundles to reduce the workload on the bundles.
- [Viewing hidden cron tasks](#)
READONLY cron tasks are hidden. If necessary, you can view these hidden cron tasks.

Creating cron task definitions

A cron task definition consists of a name, class name, access level, and description. You can create cron task definitions to meet the specific needs of your organization.

Before you begin

Create a class file for your custom cron task and package the class file into an Enterprise Application Archive (EAR) file. Then, deploy the EAR file in the application server.

Procedure

1. In the Cron Task Setup application, click New Cron Task Definition.
2. Provide a name for the cron task.
3. In the Class field, enter the name of the cron task class file.
The name is case-sensitive.
4. Specify a value to indicate the level of access that a user has to the cron task.
5. Save the cron task definition.

Deleting cron task definitions

Cron tasks have a definition that includes name, class name, access level, and description. In the Cron Task Setup application, you can delete cron task definitions that you are no longer using.

About this task

The deletion of cron task definitions is based on these rules:

- Cron task definitions with instances or with access levels of READONLY or MODIFYONLY cannot be deleted.
- Cron task definitions must be inactive to be deleted.

Procedure

1. Display the cron task definition that you are deleting.
2. Ensure that the cron task definition has no instances.
3. Select the Delete Cron Task action.

Working with instances of cron tasks

You can create multiple instances for each cron task. You can also reload instances of cron tasks, and you can delete instances of cron tasks.

- **[Creating cron task instances](#)**
Before you can run custom cron tasks, you must create a cron task instance. You can create numerous instances for a single cron task, which allows you to fine-tune these tasks to your business needs.
- **[Copying cron task instances](#)**
After you create a cron task instance, you can copy it and change it. When you copy a cron task instance, the active status, schedule, run as user ID, and parameter values are also copied.
- **[Changing cron task instances](#)**
You can change the attributes or parameter values for a cron task instance to suit your specific needs. You can change the attributes or parameter values without restarting the application server.
- **[Reloading cron task instances](#)**
You use the Cron Task Setup application to reload instances of cron tasks.
- **[Deleting cron task instances](#)**
In the Cron Task Setup application, you can delete cron task instances that you are no longer using. An instance is a copy of a cron task that you can change to suit your business needs.

Creating cron task instances

Before you can run custom cron tasks, you must create a cron task instance. You can create numerous instances for a single cron task, which allows you to fine-tune these tasks to your business needs.

Before you begin

You must have FULL access to the cron task you are creating an instance for. You cannot add new instances to cron task definitions that you have READONLY access or MODIFYONLY access to.

About this task

When you create an instance, the cron task automatically imports a group of associated parameters from the cron task definition. You cannot add new parameters, but you can set parameter values and schedules for each instance.

Procedure

1. In the Cron Task Setup application, select the cron task definition for which you want to create an instance.
2. On the Cron Task tab, click New Row.
3. Specify a name and a schedule for the cron task instance.
The date is shown as a string in the Schedule field. Do not change the string in the Schedule field. Click Set Schedule to change the schedule.
4. Specify a user with the necessary privileges. The user must have access for the actions that the cron task performs.
5. Optional: Select the Active check box.
6. Save your changes.
7. Select the Reload Request action.
8. Select the instance, and click OK.

Copying cron task instances

After you create a cron task instance, you can copy it and change it. When you copy a cron task instance, the active status, schedule, run as user ID, and parameter values are also copied.

Procedure

1. In the Cron Task Setup application, select the relevant cron task instance.
2. Click Duplicate.
3. Provide a name for the cron task instance.
4. Optional: Change additional information.
5. Save your changes.

Changing cron task instances

You can change the attributes or parameter values for a cron task instance to suit your specific needs. You can change the attributes or parameter values without restarting the application server.

Before you begin

Before you change a cron task instance, the instance must have an access level of FULL or MODIFYONLY.

Procedure

1. In the Cron Task Setup application, select the cron task with the instance that you want to change.
2. Click View Details for the instance that you want to change.
3. Change applicable information.
4. Save your changes.
5. Determine if the changes that you made require a reload.
6. Optional: If a reload is required, select the Reload Request action.

Example

You change the schedule on which a cron task runs, suspend a task by making it inactive, or change the run as user ID.

Reloading cron task instances

You use the Cron Task Setup application to reload instances of cron tasks.

Procedure

1. You must reload an instance only in certain situations. These are the possible situations under which you might need to reload an instance.

Option	Description
Reload Request Not Required	<ul style="list-style-type: none">• When switching cron task from Active to Inactive.• Generally, do not submit a reload request after changing parameter values.
Reload Request Required	<ul style="list-style-type: none">• When you change any other attributes on the crontask instance, such as schedule and runasuser.• If the parameter value is cached when crontask instance starts or reloads. Check the parameter field to see if this instance occurs.

2. If a reload is required, select the Reload Request action.
3. In the Reload Request window, select the instances that you want to reload.
4. Click OK.

Deleting cron task instances

In the Cron Task Setup application, you can delete cron task instances that you are no longer using. An instance is a copy of a cron task that you can change to suit your business needs.

About this task

The deletion of cron task instances is based on these rules:

- Cron task instances with access levels of READONLY or MODIFYONLY cannot be deleted.
- Cron task instances must be inactive to be deleted.

Procedure

1. Display the instance that you want to delete.
2. Clear the Active check box to make the instance inactive.
3. Click Mark Row for Delete.

Disabling cron tasks for a server bundle

Active cron tasks run on all servers in a sequence. In you have multiple server bundles, you can disable a cron task instance on one or more of the bundles to reduce the workload on the bundles.

About this task

You can prohibit all or a selected set of instances from running by modifying the bundleLevelProperties property when you deploy the application. You can use a combination of system properties to run a cron task on a server bundle, and exclude a particular instance of that cron task.

For example, the ReorderCronTask and the PMWoGenCronTask are process-intensive. To reduce the workload on a server bundle, you can disable these two cron tasks on that bundle.

If the mxe.crontask.dorun property is left empty, all cron tasks run except for those specified on the mxe.crontask.donotrun property.

If the same cron task is specified on both the mxe.crontask.dorun property and on the mxe.crontask.donotrun property, the mxe.crontask.donotrun property takes priority, and the cron task will not run.

Procedure

1. In the Server bundles section of the deployment panel, select View in the Additional properties column.
2. In the Bundle level properties section of the Additional server bundle properties window, click Add property.
3. Specify the appropriate property name, for example `mxe.crontask.donotrun`.
4. Specify a value for the bundle-level property in the format `crontaskname . instanceName`, where *crontaskname* is the name of the cron task and *instanceName* is the name of the cron task instance.
For example, if you want to disable a cron task instance on a server bundle, specify `mxe.crontask.donotrun` for the property name and specify a property value such as `ReorderCronTask.ReorderCronTask01`.
5. To implement your changes, redeploy the server bundle.

Viewing hidden cron tasks

READONLY cron tasks are hidden. If necessary, you can view these hidden cron tasks.

Procedure

1. In the Cron Task Setup application, delete FULL from the Access field.
2. Press Enter to view the hidden cron tasks.

Managing domains

To help ensure consistent and valid data input, some fields in the product are associated with domains. Domains enable users to select appropriate values. Administrators can add values to existing domains or add domains.

- [Domains overview](#)
You can add domains or modify existing ones to ensure consistent and valid data input. Domains can standardize data and reduce input errors.
- [Working with domains](#)
You use domains to select or enter valid values for certain fields. The defined values are specified by domains. Many domains are used in the product's applications.
- [Applications associated with domains](#)
After you create a domain, you need to apply the domain to an attribute. You use the Classifications, the Database Configuration, and the Application Designer applications to apply and to modify domains.

Domains overview

You can add domains or modify existing ones to ensure consistent and valid data input. Domains can standardize data and reduce input errors.

Domains are used throughout the product. They validate entered field values, provide lookup lists from which users can select field values, and can copy data sets or values to fields. Table domains allow you to choose values from another table in the product. Crossover domains allow data from a source table to be copied into the application that you are working in.

If invalid data is entered into a field, an error message is displayed. For crossover and table domains, by using the Database Configuration application, you can customize messages to provide more assistance about selecting valid values.

You can add ALN, Numeric, Numeric Range, Table, and Crossover domains. You can add synonym values to Synonym domains. After adding or modifying domains, additional tasks are typically required. For example, you associate a new domain with an extra attribute in the Database Configuration application and apply the configuration changes. Then, in Application Designer, you can add a control for the attribute and associate it with a lookup list.

If you add a pick list to an attribute in the Classifications application, the changes do not need to be configured further.

- [Types of domains](#)
There are several types of domains that are used in the product. Domains define the values that are allowed in fields. They can be available in lookup list dialog boxes that are also referred to as *Select Value* lists. Domains also define the values that can be typed directly in a field. Domains helps ensure that valid and consistent data is entered and reported on. Domains are used throughout the product.
- [Domains and organizations or sites](#)
Applying domains to the organization or site level (by typing appropriate values in the organization field and site field) might create unintentional access restrictions. Leaving these fields blank is the default, and stores domains at the system level.

Types of domains

There are several types of domains that are used in the product. Domains define the values that are allowed in fields. They can be available in lookup list dialog boxes that are also referred to as *Select Value* lists. Domains also define the values that can be typed directly in a field. Domains helps ensure that valid and consistent data is entered and reported on. Domains are used throughout the product.

You can add or edit all types of domains except synonym domains, which can only be edited. You can work with the following types of domains:

ALN

A static list of alphanumeric values.

Numeric

A static list of numeric values.

Numeric range

A list of numeric values that you define by specifying a range.

Synonym

These are special, reserved domains that list internal values used by the product's business logic. You cannot add or delete synonym domains or internal values but you can add synonym values that are presented to the user.

Table

A list of values that are chosen from another table. The data in the other table can change frequently.

Crossover

A special table domain in which the values from another table are copied (or crossed over) and brought into the application where the user is working.

Internal domains

Some domains are used by the business logic of the product. These domains are called *internal* domains. You can modify only the description of the internal domain and internal domain values.

- [ALN domains](#)
Alphanumeric, or ALN, domains are simple lists of values that use one of the alphanumeric data types: ALN, UPPER, and LOWER. They are typically used for static lists of values that rarely change.
- [Numeric domains](#)
Numeric domains are static lists of numeric values that rarely change.
- [Numeric range domains](#)
A numeric range domain is a domain that uses any of the numeric data types, but does not contain individual values. Instead, they specify valid ranges of values.
- [Crossover domains](#)
Crossover domains are similar to table domains because they validate a field value against another table in the product. However, crossover domains allow data from the other table to be copied into fields in the current application. For example, you can return the serial number of an asset from the ASSET table to a field in the Item Master application.
- [Synonym domains](#)
Synonym domains are special domains that are reserved by the system. Their internal values are used by the business logic of the product. You cannot add internal values to synonym domains, but you can add synonyms to an internal value and display the synonym to the user.
- [TABLE domains](#)
TABLE domains are dynamic sets of values based on the values in a column of a table. This means that they allow fields in one application to be validated against other fields in the product.
- [Foreign keys and TABLE domains](#)
Using domains, you can create a foreign key from a system level for site-level or for organization-level objects.

ALN domains

Alphanumeric, or ALN, domains are simple lists of values that use one of the alphanumeric data types: ALN, UPPER, and LOWER. They are typically used for static lists of values that rarely change.

ALN domains can only be edited in the Domains application.

Example

Your company requires that calendar information is consistent because the data is used in reports and audits. You create a list of valid values for days of the week or months of the year.

Numeric domains

Numeric domains are static lists of numeric values that rarely change.

A length and scale are always specified for these domains and should match the attribute you link them to. They can only be edited in the Domains application.

Examples of numeric domain lists include amounts in currency, decimal values, durations in hours, integer values, small integer values, and floating values.

Numeric range domains

A numeric range domain is a domain that uses any of the numeric data types, but does not contain individual values. Instead, they specify valid ranges of values.

You can specify the following kinds of ranges:

Discrete

A range with a defined interval between values, for example, a range from 0 to 10, with valid values 0, 2, 4, 6, 8, and 10. The interval in this example is 2.

Continuous

A range within which any value that satisfies the data type is valid. For example, in a range of 1 to 6 with a decimal data type and scale of 2, values such as 1, 1.03, 2.14, 3, 4.73, 5.2, and 6 are all valid. The interval in this example is null (no value in the Interval field).

A length and scale are always specified for these domains and should match the attribute you link them to.

You cannot create lookups for numeric range domains. Add meaningful help in the attribute's Description field to help users choose valid values. Also, consider the types of values a user or automated process normally enter into a field with their type of domain. An invalid value results in an error message.

Numeric ranges with more than one segment

You might use multiple segments in your numeric range domain for various reasons. Here are two examples:

- You want to define a measurement range for meter readings that is more precise at low measurements than at high measurements. You define three segments:
Segment 1: minimum 0, maximum 0.8, interval 0.2, resulting valid values 0, 0.2, 0.4, 0.6, 0.8
Segment 2: minimum 1, maximum 9, interval 1, resulting valid values 1, 2, 3, 4, 5, 6, 7, 8, 9
Segment 3: minimum 10, maximum 30, interval 5, resulting valid values 10, 15, 20, 25, 30

A user or automated process would always enter one of those values.

- You want values inserted into a field only if the reported values are beyond the accepted normal range. For example, meter readings could be above or below the accepted tolerances. You can define two segments:
Segment 1: minimum 0, maximum 9.9, interval null. Any reading between 0 and 9.9 could be entered.
Segment 2: minimum 20.1, maximum null, interval null. Any reading of 20.1 or higher could be entered.

Meter readings from 10 and 20 would not be recorded.

Crossover domains

Crossover domains are similar to table domains because they validate a field value against another table in the product. However, crossover domains allow data from the other table to be copied into fields in the current application. For example, you can return the serial number of an asset from the ASSET table to a field in the Item Master application.

When you create a crossover domain, you can specify one or more conditions that must be met before values are returned from a source object. You can define conditions for the source object and the destination object, and if the conditions are met, values are returned to the destination field. You use the Conditional Expression Manager to define conditions for crossover domains.

To learn more about data structures and relationships, you can view information in the Object Structures application.

Be aware of the level at which data is used. For example, an asset is added at the site level, so it is possible that identical asset identifiers are used in more than one site. If you add a clause to select an assetnum, you also specify a site identifier.

Order of fields and conditions on crossover domains

If you define conditions on crossover domains in custom applications, carefully consider the order that users scan through the fields. When you define a condition, the condition is evaluated at the moment the value for the attribute is set. If a condition relates to another field with a value that has not been set, values are not returned as expected. For example, this situation might occur due to the order of the layout of the application interface.

Example: Serial number crossover

You want to add a serial number (the destination) to a work order. You want the serial number to cross over from the serial number of the related asset, the source, when the work type is emergency maintenance, the condition. Select the work type before you select the asset number for the crossover to occur as expected.

Synonym domains

Synonym domains are special domains that are reserved by the system. Their internal values are used by the business logic of the product. You cannot add internal values to synonym domains, but you can add synonyms to an internal value and display the synonym to the user.

Synonym domains are common and are often found on status and type fields. An example of a synonym domain is work order status. The internal values of the domain include APPR (Approved), CAN (Canceled), CLOSE (Closed), COMP (Completed), WAPPR (Waiting on Approval), and others. You can add synonyms of the internal values that fit your business needs.

Example: Synonym values for WAPPR (Waiting on Approval)

Your company requires two people to approve a work order with costs over \$300.00. You add synonym values for the internal WAPPR value to indicate the next role to approve the work, such as WAPPRMAN and WAPPRVP. The work manager puts the work order in WAPPRMAN status and the approving manager puts the work order in WAPPRVP status. The vice president has final approval and puts the work order into APPR status.

TABLE domains

TABLE domains are dynamic sets of values based on the values in a column of a table. This means that they allow fields in one application to be validated against other fields in the product.

The domain specifies the object that you want to validate against. It also specifies a Validation WHERE clause that defines the 1:1 relationship to a record in the child table object.

To learn more about data structures and relationships, you can view information in the Object Structures application.

Be aware of the level at which data is used. For example, an asset is added at the site level, so it is possible that identical asset identifiers are used in more than one site. For that reason, when you add the clause to select the assetnum, you also specify a site identifier.

Example

You can use a TABLE domain to present a valid list of records from the PERSON table to be typed in the OWNER field on a service request.

Foreign keys and TABLE domains

Using domains, you can create a foreign key from a system level for site-level or for organization-level objects.

Example

If you want to add a new attribute for assets on the TKTEMPLATE object, perform the following steps:

1. Create a TABLE domain.
2. Add the assetnum attribute to the TKTEMPLATE.
3. Add a relationship to the asset table.
4. Add the attribute siteid to TKTEMPLATE.

Domains and organizations or sites

Applying domains to the organization or site level (by typing appropriate values in the organization field and site field) might create unintentional access restrictions. Leaving these fields blank is the default, and stores domains at the system level.

Example one

When you specify an organization or site for domain values, note where the domain is being used.

In the Labor application, you use the SKILLLEVEL domain on the CRAFTSKILL object. You specify both the organization and site values for domain values. When you access the Labor application and lookup the skill level, you do not see your values. This issue occurs because you specified a site, and the object that is using the domain is at the organization level. To fix this problem, remove the site from the domain value.

Example two

You might want to leave the organization field and site field empty for all values (users in all organizations and sites can access them). If you specify an organization or site for one value, you must specify an organization or site for all values (users in the specified organizations or sites can access them).

Otherwise, complicated outcomes can result. For example, you can set an organization with the following domain values:

Table 1. Sample domain setup with specific organizations

Value	Organization
GREEN	A
BLUE	B
RED	(No organization specified)

With this domain configuration, you get the following results:

- Records in Organization A can access GREEN only.
- Records in Organization B can access BLUE only.
- Records in other organizations (other than Organization A and Organization B) can access RED only.

Working with domains

You use domains to select or enter valid values for certain fields. The defined values are specified by domains. Many domains are used in the product's applications.

In some cases, you can specify error messages that users see when an invalid value is entered.

Work with the application in your nonproduction environment, and then import the changes to your production environment.

If you add or modify a domain, existing records are not validated or changed unless a user edits the value in a field. Your users are helped to enter valid values by the information that you specify in the Attribute Description field.

A new domain can be linked to an attribute in the Database Configuration application. Domains can also be specified on classification attributes to provide pick lists for users. Domains that are added to classification attributes do not require further configuration.

When a field is linked to a domain, you can show a lookup indicator on the field. Configure that control to specify a lookup list in Application Designer. The lookup definition and format are defined in the Lookups.xml file. In Lookups.xml, you can add lookups to select the displayed columns, and can add sorting and filtering as you require. You can export the Lookups.xml file from Application Designer, modify it, and import and test the changes.

Work with these applications in your nonproduction environment, and import the changed files to your production environment.

- [Adding alphanumeric domains](#)
You add an alphanumeric (ALN) domain when you want to add a domain that uses one of the alphanumeric data types.
- [Adding numeric domains](#)
You add a numeric domain when you want to add a domain that uses one of the numeric data types.
- [Adding numeric range domains](#)
You add a numeric range domain when you want to add a domain that uses one of the numeric data types. However, you specify a range rather than specific values.
- [Adding table domains](#)
You add a table domain when you want to draw a single, dynamic value directly from a column in the database. This process creates a dynamic value list because the values it draws from the database might change. For example, you want to associate a lookup list with an extra field that the product provides.
- [Adding crossover domains](#)
You add a crossover domain when you want to return a value from a field in one application to a field in another application.
- [Associating domain values with conditions](#)
You can associate ALN, synonym, and numeric domain values with a condition to limit the number of values available to users for conditions such as status, priority, and asset. This association ensures that only users determined by you can set certain statuses, change the priority of work orders, and so on.
- [Creating synonyms of internal values](#)
You can create synonyms of internal values so that you can present different values to users based on your business needs.
- [Deleting synonyms of internal domain values](#)
You can delete a synonym of an internal value when it is no longer useful.
- [Deleting domains](#)
You can delete most domains when they are no longer useful.

Adding alphanumeric domains

You add an alphanumeric (ALN) domain when you want to add a domain that uses one of the alphanumeric data types.

About this task

Work with the application in your nonproduction environment, and then import the changes to your production environment.

Because you can use a domain with multiple fields, the length you specify must be less than or equal to the length of the shortest field with which you intend to use the domain. For example, if you want to use the domain with three fields of lengths 8, 10, and 12, specify a length of 8 or less. If you specify a length greater than the field the domain is used in, you cannot assign the domain to the attribute in the Database Configuration application. Alternatively, you can specify a greater length in the Domains application and use the Database Configuration application to change the length of the field that uses the domain.

Procedure

1. Open the Domains application.
2. At the bottom of the Domains table window, click Add New Domain and select Add New ALN Domain.
3. In the Domain field, specify a name for the domain.
4. In the Description field, type a short description for the domain.
5. In the Data Type field, specify a data type for the domain.
6. In the Length field, specify a length that is equal to or less than the length of the field that uses the domain.
For example, if you are adding a domain for a field in the Assets application that has a length of 12, then specify a length of 12.
7. Click New Row.
8. Fill the Value and Description fields.
9. Optional: Apply a domain value to a specific organization or site by entering the relevant values in the Organization and Site fields.
Domains are applied at the system level by default.
You can leave the Organization and/or Site fields empty for all values so that users in all organizations and sites can access them. Or you could specify an organization and/or site for all values so that only the users in the specified organizations and/or sites can access them. Otherwise, complicated outcomes can result.

For example, if you enter a value RED with no organization specified, a value GREEN with Organization A specified, and a value BLUE with Organization B specified, then records in Organization A has access to GREEN only. Records that are in Organization B has access to BLUE only. Records that are in other organizations has access to RED only. When you specify an organization and/or site for one value, records in that organization and/or site no longer have access to values that have no organization or site specified.

10. Optional: Click New Row again to add more values.
11. Click OK.

What to do next

After you add a domain, you might still have several tasks to perform, depending on the domain and how you want to display it. In the Classifications application, you can associate an ALN domain with an attribute in the Attributes table window. No further configuration is needed.

If you use a domain in any other context, adding a domain requires additional tasks:

- Associate the new domain with an attribute in the Database Configuration application.
- Configure the database in the Database Configuration application.
- Use the Application Designer application to modify the user presentation as needed. For example, if you add an ALN domain to a field, you must add a Select Value control. New crossover domains might require new fields in the destination application.

Adding numeric domains

You add a numeric domain when you want to add a domain that uses one of the numeric data types.

About this task

Because you can use a domain with multiple fields, the length that you specify here must be less than or equal to the length of the shortest field with which you use the domain. For example, if you want to use the domain with three fields of lengths 8, 10, and 12, specify a length of 8 or less for the domain. If you specify a length greater than the field the domain is used in, you are not able to assign the domain to the attribute in the Database Configuration application. Alternatively, you can specify a greater length in the Domains application. You can use the Database Configuration application later to change the length of the field that uses the domain.

Procedure

1. In the Domains application, in the Domains table window, add a domain and select Add New NUMERIC Domain.
2. Specify a name, description and data type.
3. Depending on the data type the Length field might or might not be editable. If editable, specify a length that is equal to or less than the length of the field that uses the domain.
For example, if you are adding a domain for a field in the Assets application that has a length of 12, then specify a length of 12.
4. For Decimal data type only, in the Scale field, specify a scale value if different from the default, 2.
5. Insert a row for a new range segment, and add a segment name, range minimum and maximum values, and interval for that segment.
6. Optional: Apply a domain value to a specific organization or site by specifying values in the Organization and Site fields.
If no organization or site is specified, the domain is available to all users.
For example, if you enter a value 100 with no organization specified, a value 300 with Organization A specified, and a value 500 with Organization B specified, then records in Organization A have access to 300 only. Records that are in Organization B have access to 500 only. Records that are in other organizations have access to 100 only. Once you specify an organization and/or site for one value, records in that organization and/or site no longer has access to values that have no organization/site specified.
7. Optional: Insert rows for more segments.
8. Save your changes.

What to do next

After you add a domain, you might still have several tasks to perform, depending on the domain and how you want to display it. In the Classifications application, you can associate a domain with an attribute in the Attributes table window, and no further configuration is needed.

If you use a domain in any other context, adding a domain requires additional tasks.

- Associate the new domain with an attribute and apply changes in the Database Configuration application.
- Configure the database in the Database Configuration application.
- Use the Application Designer application to modify the user interface as needed. For example, if you add an ALN domain for a field, you must add the Select Value control. New crossover domains might require new fields in the destination application.

Adding numeric range domains

You add a numeric range domain when you want to add a domain that uses one of the numeric data types. However, you specify a range rather than specific values.

About this task

Because you can use a domain with multiple fields, the length that you specify here must be less than or equal to the length of the shortest field you use the domain with. For example, if you want to use the domain with three fields of lengths 8, 10, and 12, specify a length of 8 or less for the domain. If you specify a length greater than the field the domain is used in, you cannot assign the domain to the attribute in the Database Configuration application. Alternatively, you can specify a greater length in the Domains application. You can use the Database Configuration application later to change the length of the field that uses the domain.

Procedure

1. In the Domains table window of the Domains application, add a domain and select Add New NUMERIC RANGE Domain.
2. Specify a name and description for the domain.
3. Specify a data type for the domain.
4. Depending on the data type, the Length field might or might not be editable. If the field is editable, specify a length that is equal to or less than the length of the field that uses the domain.
For example, if you are adding a domain for a field in the Assets application that has a length of 12, then specify a length of 12.
5. For DECIMAL data type only, in the Scale field, specify a scale value if different from the default, 2.
6. Click New Row and fill the following fields.

Each row defines a range.

Field	Description
Range Segment	Specify an identifying number for the segment. For example, 1 if the range has just one segment, or 1, 2, or 3 if the domain has three segments. For a range with regular intervals or a simple continuous range, you need only one segment.
Range Minimum	Specify the lowest value in the range, for example, 10 in the range 10 - 50. You can leave either the Range Minimum field or the Range Maximum field empty (null value), but not both.
Range Maximum	Specify the highest value in the range, for example, 50 in the range 10 - 50. You can leave either the Range Minimum field or the Range Maximum empty (null value), but not both.
Interval	For a range with discrete values, specify the value of the interval that separates the values you want to appear in the list. For example, the interval is 10 in the range 10 - 50 if you want the values 10, 20, 30, 40, and 50 to be valid. For a continuous range of values between the minimum and maximum values, leave this field null (empty). Continuous is relative to the data type. For example, if the data type is INTEGER and the range is 1 - 5, then only 1, 2, 3, 4, and 5 are valid values.

7. Optional: Apply a domain value to a specific organization or site by specifying values in the Organization and Site fields.
Domains are applied at the system level by default.
You might want to leave the Organization and/or Site fields empty for all range segments so that users in all organizations and sites can access them. Or you might specify an organization and/or site for all range segments so that only users in the specified organizations and/or sites can access them.
8. Optional: Click New Row again to add ranges for more segments.
9. Save your changes.

What to do next

After you add a domain, you might have several tasks to perform, depending on the domain and how you want to display it.

- Associate the new domain with an attribute in the Database Configuration application.
- Configure the database in the Database Configuration application.
- Use the Application Designer application to modify the user interface as needed. For example, if you add an ALN domain for a field, you must add the select value button. New crossover domains might require new fields in the destination application.

Adding table domains

You add a table domain when you want to draw a single, dynamic value directly from a column in the database. This process creates a dynamic value list because the values it draws from the database might change. For example, you want to associate a lookup list with an extra field that the product provides.

About this task

Table domains differ from crossover domains in that crossover domains are used for copying multiple dynamic values from a table.

Procedure

1. In the Domains application, in the Domains table window, add a domain and select Add New TABLE Domain.
2. Specify a unique identifier and a description for the domain.
3. Insert a row and complete the following fields.
You can learn more about the data structures and relationships in the product in the Object structures application.

Field	Description
Object	Specify the name of the object that contains the attribute from which you want to create a domain. For example, to obtain values from the ASSET object, specify ASSET.
List Where Clause	The filter that specifies additional criteria that limits the values returned to the lookup list. For example, to select asset records that begin with the numbers 114, type: <code>assetnum like '114%'</code> Note: Your entry is not validated now for syntax or any other errors. Be sure that you specified a valid WHERE clause. If you make errors, errors do not become apparent until you configure the database.

Field	Description
Validation Where Clause	<p>The 1:1 relationship to a value in the child object, which is specified in the Object field. In the WHERE clause, specify the child attribute first. Then specify the source attribute, prefixed with a colon.</p> <p>Be aware of the level at which data is used. For example, an asset is added at the site level, so it is possible that identical asset identifiers are used in more than one site. The clause to select the assetnum should also specify a site identifier.</p> <p>For example, if you want a field named Z (attribute Z) to contain values from the assetnum field in the Assets application for the Concord site, type: <code>assetnum = :z and siteid =:Concord</code>.</p>

- Optional: Specify a group value and a key value to select an error message to display when domain validation fails.
You define values for error messages in the Database Configuration application.
 - In the Error Message Group field, specify the group value of the error message.
 - In the Error Message Key field, specify the key value of the error message.
- Optional: Apply a domain value to a specific organization and site by specifying values in the Organization and Site fields.
Domains are applied at the system level by default. You can allow users in all organizations and sites to access the values by leaving the Organization and Site fields empty.
- Optional: Add more rows.
- Save your changes.

What to do next

After you add a domain, you might still have several tasks to perform, depending on the domain and how you want to display it.

In the Classifications application, you can associate a domain with an attribute in the Attributes table window. Specify the table attribute and lookup name. No further configuration is needed.

If you use a domain in any other context, adding a domain requires any of the following tasks:

- Associate the new domain with an attribute in the Database Configuration application.
- Configure the database in the Database Configuration application.
- Modify the presentations as needed with the Application Designer application. For example, if you add an ALN domain for a field, you must add a Select Value control. New crossover domains might require new fields in the destination application.

Adding crossover domains

You add a crossover domain when you want to return a value from a field in one application to a field in another application.

About this task

Ensure that the SQL statements that you use in this procedure are valid. The application does not validate SQL statements.

Procedure

- Open the Domains application.
- In the Domains table window, add a domain and select Add New CROSSOVER Domain.
- Specify a name and description for the domain.
- In the Crossover Domain table window, insert a row and define details for the crossover domain:

Field	Description
Object	Select the name of the object that contains the attribute that you want to create a domain from. For example, to obtain values from the ASSET object, select ASSET.
Validation Where Clause	<p>The 1:1 relationship to a value in the child object, which is specified in the Object field. In the WHERE clause, specify the child attribute first. Then specify the source attribute, prefixed with a colon.</p> <p>Be aware of the level at which data is used. For example, an asset is added at the site level, so it is possible that identical asset identifiers are used in more than one site. The clause to select the assetnum should also specify a site identifier.</p> <p>For example, if you want a field named Z (attribute Z) to contain values from the assetnum field in the Assets application for the Concord site, type: <code>assetnum = :z and siteid =:Concord</code>.</p>
List Where Clause	<p>The filter that specifies additional criteria that limits the values returned to the lookup list.</p> <p>For example, to select asset records that begin with the numbers 114, type: <code>assetnum like '114%'</code></p>

- Optional: Specify a group value and a key value to select an error message to display when domain validation fails.
You define values for error messages in the Database Configuration application.
- Optional: To apply a domain to a specific organization or site, specify values in the Organization and Site fields. To allow access to users in all organizations and sites, clear all values from these fields.
- Select fields for the crossover domain:
 - In the Crossover Fields table window, add a row.
 - In the Source Field list, select an attribute of the object that you specified in the Object field.
This attribute represents the field from which you want to return values.
 - In the Destination Field text box, specify the field to which you want values to be returned.
 - Optional: Select the Accept NULL Value checkbox to copy the value from the source field when the value of the target attribute is empty.
This function overwrites the previous value.
 - Optional: Select the No Overwrite checkbox to copy the value of the source attribute when it is null.
- Optional: Specify conditions for the source object or the destination object, or both:

- a. In the Condition on Source field, select a condition or use the Conditional Expression Manager to build the condition for the source object of the crossover.
If a condition is specified, the source object must meet the condition before the crossover occurs.
 - b. In the Condition on Destination field, select a condition or use the Conditional Expression Manager to build the condition for the destination object of the crossover.
If a condition is specified, the destination object must meet the condition before the crossover occurs.
 - c. In the Sequence field, type a numeric value to specify the order that the crossover occurs when multiple crossovers are defined.
Crossovers with lower values occur before crossovers with higher values.
9. Save your changes.

What to do next

After you add a domain, you might still have several tasks to perform, depending on the domain and how you want to display it.
In the Classifications application, you can associate a domain with an attribute in the Attributes table window, and no further configuration is needed.

If you use a domain in any other context, adding a domain requires additional tasks.

- In the Database Configuration application, associate the new domain with an attribute and configure the database. After you onboard a tenant, the tenant can change the domains that you provide or create their own domains. These domains are tenant-specific and are not available to other tenants.
- In the Database Configuration application, associate the new domain with an attribute and configure the database.
- In the Application Designer application, modify the user interface as needed. For example, if you add an ALN domain for a field, you must add a Select Value control. New crossover domains might require new fields in the destination application.

Associating domain values with conditions

You can associate ALN, synonym, and numeric domain values with a condition to limit the number of values available to users for conditions such as status, priority, and asset. This association ensures that only users determined by you can set certain statuses, change the priority of work orders, and so on.

Before you begin

Before you associate a domain value with a condition, you must set up the domain values for the ALN, synonym, and numeric domains. You must then define a condition for when particular domain values appear in a domain. You can create conditions in the condition library of the Conditional Expression Manager application.

About this task

If you modify the condition for a domain value after the value was selected for a field, the existing values are not revalidated. When you associate a condition with a domain value, you can specify an object name. Conditional values are not supported in the List or Search tab.

Procedure

1. Open the Domains application and select the Edit Detail icon for the domain that contains the values that you want to associate with a condition.
Depending on the domain type that is selected, an ALN, numeric, synonym, table, or crossover window opens from where you can add or change conditions.
2. Select View/ Modify Conditions and add or change the conditions as necessary. If you are adding a condition, you must associate the condition with an object.
3. Optional: If you want to add the same conditions for multiple domain values, select Set Conditions and select a condition from the condition library.
You can apply the same condition to all of the selected values.
4. Optional: If you want domain values to be used by multiple objects, specify the objects in the Object Name field.
5. Save the record.

Creating synonyms of internal values

You can create synonyms of internal values so that you can present different values to users based on your business needs.

About this task

Procedure

1. In the Domains application, select the synonym domain for which you want to add a synonym value, such as WOSTATUS.
2. Click Edit Detail to open the Synonym Domain table window.
The Internal Value field is used by the product and must be unique. The value and its description are what users see.
3. Optional: Specify an organization or organization and site for which an existing domain value is valid. For more information about the effect of changing this data, refer to the important note that follows.
4. Add new values for an internal domain by inserting a row and entering values in the fields:

Field	Description
-------	-------------

Field	Description
Internal Value	Specify the existing internal value for which you want a synonym. For example, in the WOSTATUS domain, if you want to create a synonym for WAPPR called WAIT, you would specify the WAPPR internal value.
Value	Specify the synonym value that you want a user to see. For example, WAIT.
Description	Type a description of the synonym to differentiate it from the existing value.

- Optional: Select the Default checkbox to make the new synonym value the default.

Each internal value can have only one default synonym value.

For example, the status of WAPPR (Waiting for Approval) is added when you create a work order. You add a synonym value, WAIT. If you want the system to insert WAIT instead of WAPPR, then make WAIT the default.

- Optional: Apply a domain value to a specific organization or site by specifying values in the Organization and Site fields.

Domains are applied at the system level by default.

Leave the Organization and Site fields empty if you want users in all organizations and sites to access them. Or specify organization and site for all values so that only users in the specified organizations and sites can access them.

If you create a synonym value and specify a site or organization, and then click OK, duplicate rows are inserted for the other values. The duplicate rows have the site or organization you specified for the new value that you created. For example, the MRTYPE domain has three values: RECURRING, STANDARD, and TRANSFER (each with an internal value of the same name). If you create a synonym value, REGULAR, with the internal value of STANDARD and specify Organization B, the synonym values RECURRING and TRANSFER are added with Organization B specified.

Important: After you implement the system and inserted records, you generally must not add a synonym value with a site or organization specified. This action can invalidate existing data. If you must add a synonym value and specify a site or organization, you must also add synonym values for all the existing values. For example, if you added a synonym value for STANDARD with an organization or site specified, you must also add synonym values for RECURRING and TRANSFER (if they are used on records) with the same organization or site specified.

- Optional: Add more synonym values.
- Save your changes.

Deleting synonyms of internal domain values

You can delete a synonym of an internal value when it is no longer useful.

About this task

In synonym domains, you can delete synonym values, with the following conditions:

- You can delete only non-default synonym values.
- If you delete one synonym value for which you have specified an organization or site, you must delete all other values for which you have specified that organization or site.
- Do not delete synonym values if you have records referencing them.

Procedure

- In the Domains table window of the Domains application, select the domain with the synonym value that you want to delete and click Edit Detail.
- In the SYNONYM Domain table window, mark one or more rows for deletion.
- Save your changes.

Deleting domains

You can delete most domains when they are no longer useful.

About this task

You cannot delete a synonym domain. You can delete other types of domains, but not if the domain is assigned to an attribute. To delete the domain, you must first disassociate the attribute.

Deleting a domain does not affect values that have already been inserted on records. For example, if a user inserts a value in a field using a domain select value list, that value remains on the record. The value remains on the record even if the domain is later disassociated from the attribute and deleted.

Procedure

- In the Domains application in the Domains table window, select the domain that you want to delete and click the Mark Row for Delete icon.
- In the warning message, click Yes.
- Save your changes.

Applications associated with domains

After you create a domain, you need to apply the domain to an attribute. You use the Classifications, the Database Configuration, and the Application Designer applications to apply and to modify domains.

The table that follows lists the applications that are used to apply or to modify domains.

Table 1. Applications used to apply or to modify domains

Application	Description	Example
Classifications	Associate a domain with an attribute in the Attributes table window.	In the Domains application, add an ALN domain with three values. In Classifications, add a classification for assets. Specify an attribute to classify assets with and associate the new domain with the attribute. The next time that the new classification is applied to an asset, the three classification values are available for selection from that attribute.
Database Configuration	Associate a domain with an attribute. Most domains also have a default value, which you would specify in Database Configuration. If the attribute is required, a default value for the domain is also required.	An amount field might be bound to a NUMERIC domain or a status field might be bound to a SYNONYM domain. When you configure the database, the system does not validate the value you insert as the default field value. For example, you can have an Organization called EAGLENA, where the only acceptable domain value is CREW4. You can make the crewid attribute required in the Preventive Maintenance application, give it the default value of CREW2, and configure the database without error. The error, such as CREW2 is not a valid value, appears only when you return to the Preventive Maintenance application to insert a record.
Application Designer	Modify the user interface as needed.	Add one of the extra attributes to an application presentation. Associate the extra attribute with a domain. If you added an ALN domain for a field, you add a select value control by using the application designer application. New CROSSOVER domains might require new fields in the destination application.

Linear assets management

A linear asset is an asset that is defined and maintained using a linear referencing method. Roads, pipelines, and railroad tracks are examples of linear assets. Using measurements along the linear asset, you can locate maintenance activities, identify where characteristics change, and plan monitoring and metering.

Linear assets enhance your ability to maintain large and complex systems, such as:

- Roads and railways that carry transportation assets
- Water, waste water lines, and streets that connect facilities
- Gas and electric lines that support production assets
- Fiber optic trunk lines that connect IT and communications assets

A linear asset can contain additional assets, including a combination of linear and point assets. For example, you can create a linear asset for a road that has additional linear assets for segments of the road. You can manage each segment separately. You can specify physical features for linear assets, such as mile posts and guard rails on a road. You can classify linear assets so that you can search for and report on data. You can specify relationships between linear assets, such as road intersections. You can apply relationship hierarchies and relationships. The Features application is available to help you manage the physical objects that are associated with linear assets.

Linear asset components are available in the following applications. Some components are visible only when you are working with a linear asset.

- Assets
- Relationships
- Work Orders
- Preventive Maintenance
- Service Requests
- Condition Monitoring
- Routes

The product also contains features that enable you to develop and conduct asset inspections. Data from inspection and maintenance activities can be reported and analyzed to look for trends that have an impact on asset cost and availability.

- [Linear components](#)
Linear asset components include components that are enabled for use after security authorization. Other components are visible only if you are working with a linear asset.
- [Configuring security](#)
The product provides components that are enabled for use after security authorization. Other components are visible only if you are working with a linear asset.
- [Configuring a linear reference](#)
Before you configure a linear reference, you must create the units of measure and any conversion measures that the linear reference uses. Then create a linear referencing method that specifies how to locate work on a linear asset. You cannot create a linear asset until at least one linear referencing method is available to apply to it.
- [Configuring a linear asset segment](#)
A linear asset segment (or span) can contain one or more assets that includes at least one linear asset and a combination of other linear and point assets. The segment can also contain asset attributes, features, classifications, relationships, and work items.
- [Organizing work on a linear asset](#)
You can organize work by working on segments of a linear asset. You can plan your work by creating a route and preventive maintenance of one or more linear segments, and conduct work on those same linear segments. You can track the progress against your linear assets in the Work Progress table.

- [Importing linear assets from an external system](#)
You can import linear assets from an external application through the integration framework.
- [Reference information for linear asset controls](#)
Use this reference information as a checklist of linear asset controls and to clarify the terminology that is used when working with linear assets.

Linear components

Linear asset components include components that are enabled for use after security authorization. Other components are visible only if you are working with a linear asset.

- [Linear referencing](#)
Linear referencing enables you to locate points and spans along linear assets. There can be many linear referencing methods, such as absolute, relative, percent, addressing, time, and stationing.
- [Features application](#)
A feature is a physical object, such as a guard rail or a mile marker, that you associate with one or more linear assets. Features are not tracked with unique identifiers. You apply costs associated with a feature to the linear asset that has a unique identifier.
- [Relationships and linear assets](#)
The product supports two types of relationships: hierarchical relationships and user-defined relationships. A user-defined relationship uses basic terms, such as intersects, or contains to describe the dependency or connectivity between assets.
- [Linear asset classifications](#)
When you classify a nonlinear asset, the attribute applies to the entire asset. When you classify a linear asset, you can enter different values for the same attribute and identify the start and end measures where the values for that attribute change.
- [Linear segment details](#)
You use the Linear Segment Details section to locate a linear segment or point on a linear asset. The Linear Segment Details section, which displays on tabs in several applications, appears only if you are working with a linear asset.

Linear referencing

Linear referencing enables you to locate points and spans along linear assets. There can be many linear referencing methods, such as absolute, relative, percent, addressing, time, and stationing.

This topic describes an absolute linear referencing method but the product also supports reference points that are created using features but store absolute measure even when reference points are used. This type of referencing allows workers in the field to use relative linear referencing such as mile posts, while also ensuring accurate maintenance history is recorded against the asset.

Use linear referencing to locate point assets, relationships to locations or other assets (linear and nonlinear), features, attributes, and assigned work.

Linear referencing uses distance measures from known points along X, Y, and Z axes.

- X axis. A distance along the center line of the linear asset. This distance, the measure, is the distance from the beginning of the linear asset. You can also use an X offset to reference the distance from a known reference point along a linear asset, such as the distance from an intersection or a mile post.
- Y axis. A distance to the right or left side of the linear asset. This distance is the Y offset. You measure it from reference values that you define, such as the center line or right pavement edge.
- Z axis. A distance above or below the linear asset. This distance is the Z offset. You measure it from reference values that you define, such as the road surface.

To work with your linear assets, define one or more linear reference methods (LRMs) that fit your business practices. To define an LRM, specify units of measure and reference points for each of the axes. For example, you might define an LRM that uses miles for the measure, X axis, and feet for all the offset measurements.

Examples of linear referencing uses

The following examples illustrate how various enterprises use LRMs. The examples provide a general description, not specific units of measure for all axes.

- For roadways:
 - Kilometers
Measures are in kilometers from the start of the linear asset. This method is also known as distance measuring instrument (DMI), absolute LRM, or the document-oriented method.
 - Miles
Measures are in miles from the start of the linear asset. This method is also known as distance measuring instrument (DMI), absolute LRM, or the document-oriented method.
 - Milepost
Measures are from previously defined mile posts. This method is also known as a relative LRM or a sign-oriented method. Some roadways that do not have mile posts use roadside landmarks.
 - Station-Offset
An engineering method that establishes stations every 100 feet or every 200 feet and that adds an offset to identify the exact location.
- For railways:
 - Milepost

Measures are from previously defined mile posts. Railway mileposts, unlike road mileposts, rarely exist at the labeled mileage. Mile Post 2 might be 5420 feet beyond Mile Post 1, and so on.

Chain Marker

A chain unit, used in land measurement before 1960, exists as a means to identify linear locations. Originally 66 feet, it is also used today to identify a distance of 100 feet.

- For pipelines:

Stationing

An engineering method that establishes stations every 100 feet or 200 feet and adds an offset to identify the exact location.

Absolute Stationing

Station and offset values are converted to absolute measures. This method is also known as calculated measure. For example, if a pipeline segment starts at 10 + 100 (station 10 with an offset of 100), the calculated measure (with stations every 100 feet) is 1100.

Features application

A feature is a physical object, such as a guard rail or a mile marker, that you associate with one or more linear assets. Features are not tracked with unique identifiers. You apply costs associated with a feature to the linear asset that has a unique identifier.

A road is a linear asset. The features of a road include guard rails, mile posts, signs, traffic lights, pavement, culverts, intersections, and so on. Features that are associated with assets are unique, based on their start and end measures, and can also have labels. Typically a label is used only when that label can be reference in the field. For example guardrails typically don't have labels, but mile posts, such as MP 27, have labels. In some cases, such as railways, the same label can exist more than once for a single linear asset, for example if a segment of track was acquired from another organization. This arrangement is acceptable, and the two labeled features are identified using both their labels as well as their start and end measures.

You use the Features application to create, to modify, and to delete the features used with linear assets. Use the Assets application to associate features with linear assets, and to specify a classification for the feature. You cannot delete a feature after it has been associated with a linear asset.

Relationships and linear assets

The product supports two types of relationships: hierarchical relationships and user-defined relationships. A user-defined relationship uses basic terms, such as intersects, or contains to describe the dependency or connectivity between assets.

With a hierarchical relationship, a location can be the parent of other locations or of assets, and an asset can be the parents of other assets. With user-defined relationships, you can create relationships that establish a contextual link between related assets. User-defined relationships reflect the associations between assets and locations in networks, where objects contain, connect to, or are dependent on other objects. User-defined relationships can be used in conjunction with hierarchical relationships.

You can configure user-defined relationships to establish the contextual relationships between the components of a linear asset. If a railroad worker must perform some work on a railroad track at mile point 47, you can use relationships to see what else is located on this span of track that may impact the work.

You define and work with relationships in these ways:

- In the Relationships application, you create the formal definitions and accompanying rules for relationships.
- In the Relationships tab of the Assets application, you associate relationships with assets. The tab lists only user-defined relationships and does not list any hierarchical relationships.

If you use a GIS application that provides geographical context or a schematic viewer that provides operational context, user-defined relationships may be unnecessary for your business processes. User-defined relationships are provided for business that are not using such applications, or that want the additional value in defining operational context within the product.

You can configure user-defined relationships for use in conjunction with traditional hierarchies, because assets still have financial or organizational context. A linear asset must reside within a single location to use it with a traditional hierarchy. If you have a linear asset that spans multiple work sites, you can either segment that asset and place each segment in a different site, or you can place the asset in a single site, and use the Repair Facility functionality to allow teams from other sites to work on the linear asset. The cost of the work is still charged to the asset, but the work history shows that the work was conducted in another site.

Linear asset classifications

When you classify a nonlinear asset, the attribute applies to the entire asset. When you classify a linear asset, you can enter different values for the same attribute and identify the start and end measures where the values for that attribute change.

For example, the material for a 100 foot pipe can be PVC from measure 0 to 50, and IRON from 50 to 100.

Ensure that you specify the Linear Type attribute as Linear to make it visible for a linear asset. This option exists to allow the same classification to be applied to linear and nonlinear assets.

If you want to ensure that you have a single value for an attribute for the entire span of the linear asset, identify it as Continuous. Running the Gaps and Overlap report identifies any continuous attributes or features that have overlapping values, or any spans that are without a value. An example of a continuous attribute is a speed limit for a road, since the entire road has a speed limit, yet only a single speed limit for any span.

Linear segment details

You use the Linear Segment Details section to locate a linear segment or point on a linear asset. The Linear Segment Details section, which displays on tabs in several applications, appears only if you are working with a linear asset.

For example, if you specify a linear asset in the Asset field on a preventive maintenance record, the PM tab displays a Linear Segment Details section. If you enter a point asset, the PM tab does not display this section. The Linear Segment Details section includes fields for both the start point and the end point. If you locate a point, such as a stop sign, the start and the end points are the same.

The following terms are associated with linear segments:

Measure

The absolute distance from the start of a linear asset. You can specify a measure manually. The measure is calculated for you if you enter a reference point and a reference point offset. In the example, using Mile Post 27 and an offset of -528, the calculated measure is 26.9 miles (528 feet = .1 mile).

Offset

A measure from a previously defined reference point. The possible kinds of offsets are the following:

Reference Point Offset

The distance before or after the reference point. Specify an offset value if the segment start or end is before or after the reference point. The value can be negative (before) or positive (after). For example, if the start of the segment is 528 feet before Mile Post 27, type -528.

You cannot specify an offset that, when combined with the reference point, yields a measure that is outside the boundaries of the linear asset. For example, if reference point Mile Post 1 is at 1.0 miles on a linear asset that begins at 0.0 miles, you cannot enter an offset of -2 miles.

Y-Offset

A distance perpendicular to the direction of the linear asset. For example, a speed limit sign is located 10 feet from the right edge of the road. "Right" is positive and "left" is negative. Therefore, the Y offset is 10.

Z-Offset

A distance above a linear asset or below a linear asset. For example, an exit sign is located 18 feet above the surface of the road, and a culvert is 4 feet below the surface of the road. The Z offset for the sign is 18, and the Z Offset for the culvert is -4.

Reference point

A feature instance that you can use as a starting point or as an ending point for a linear segment. A reference point is a means of communicating a work location. For example, it can be more useful to workers to say that roadside plowing on Route 96 begins at the intersection of Routes 96 and 75, and ends at Exit 34. It would be less useful to say the work begins at Mile 27.85 and ends at Mile 33.8.

The use of reference points varies according to department practices and to individual variation among linear assets. Some roads might have accurate and persistent mile post markers and workers use the absolute measure in conjunction with the referencing method. For example, a worker can use MP 27.32 to reference a pot hole. In this case, the worker is actually saying mile 27.32, but because the mile posts are all accurate, he uses a combination of the mile post and an absolute measure. Other roads might have few markers or no accurate markers, and users must rely on reference points. This issues is common in the rail industry, where mile posts and chain markers are no longer at their original measures and is sometimes referred to as short or long miles or kilometers. Use labels that maintenance workers in the field can easily identify.

Click Select Value to select the reference point.

Y Reference

The point from which the Y Offset is measured.

The system administrator creates the set of Y Reference values by creating a domain in the Domains application. For roads, some common examples include midline, outer pavement edge, and inner pavement edge. For example, a stop sign is located not just 20 feet from a road, but 20 feet from the midline of a road.

Z Reference

The point from which the Z Offset is measured.

The system administrator creates the set of Z Reference values by creating a domain in the Domains application. For roads, some common examples include road surface and road bed. For example, an exit sign is located 18 feet above the road surface, or a culvert is 12 feet below the road bed.

Configuring security

The product provides components that are enabled for use after security authorization. Other components are visible only if you are working with a linear asset.

License-based component

The license-based component does not become available until you grant access to it in the Security Groups application. The Add/Modify Linear Referencing Methods action in the Select Action menu of the Assets application, is an example of this type of component. You must configure a linear referencing method before you can start creating linear assets. Therefore, configuring security access to this component is the first task that you must perform after installation.

Conditional components

After a user defines an asset as linear, conditional controls become visible. These components are visible only when the user is working with an asset that is defined as a linear asset. For example, when a user creates a work order on a linear asset, the following linear components are visible in the Work Order Tracking application:

- Feature field
- Feature Label field

- Linear Segment Details section

If the user creates a work order on an asset that is not linear, these components are not visible.

These conditional components are configured with signature option security. Each of these conditional components has a signature option that determines when to show or hide it, based on whether a linear asset is in use or not. The signature option is linked to a condition that looks for the linear indicator on the asset. If the indicator is set to TRUE, then the component is displayed. These signature options are linked to the MAXEVERYONE security group, or the group that is configured to act as the MAXEVERYONE group for your organization.

- **Enabling application components**

You must manually enable the Add/Modify Linear Referencing Methods menu option in the Security Groups application. You can also enable several other license-based components at the same time.

Enabling application components

You must manually enable the Add/Modify Linear Referencing Methods menu option in the Security Groups application. You can also enable several other license-based components at the same time.

Procedure

1. In the Security Groups application, specify EVERYONE in the Group field and then click the Applications tab.
2. Select the Assets application.
3. In the Options for Assets table, select the Grant Access check box for the Add/Modify Linear Referencing Method option.
4. Ensure that the check boxes to grant access to the Add/Modify Conversions and the Add/Modify Units of Measure options are also selected.
These menu options must be enabled because you must configure units of measure and conversion factors to use in your linear referencing methods.
5. Filter for the following options and grant access to them also:
 - Filter by Linear Assets
 - Relationships tab
 - View Relationship History
6. Click Grant Listed Options for this Application to commit the changes that you configured.

What to do next

Use the same procedures to grant access to the Filter for Linear Assets option in the following applications:

- Work Order Tracking
- Service Requests
- Quick Reporting
- Preventive Maintenance

Configuring a linear reference

Before you configure a linear reference, you must create the units of measure and any conversion measures that the linear reference uses. Then create a linear referencing method that specifies how to locate work on a linear asset. You cannot create a linear asset until at least one linear referencing method is available to apply to it.

- **Creating units of measure**

You create a unit of measure to measure assets, such as miles in a road or items in a box. You can associate a unit of measure with a conversion factor that converts one unit of measure to another, such as converting miles to kilometers.

- **Configuring conversion factors**

If you intend to use related units of measure, configure the conversion factor to apply to them. The conversion factor to use, for example, between a kilometer and a meter is 1000 (one thousand).

- **Creating a linear referencing method**

You must create at least one linear referencing method before you can start working with linear assets. A linear referencing method (LRM) determines the position of a linear asset, based on a start point, a measure, and a direction.

Creating units of measure

You create a unit of measure to measure assets, such as miles in a road or items in a box. You can associate a unit of measure with a conversion factor that converts one unit of measure to another, such as converting miles to kilometers.

Procedure

1. In the Assets application, click Unit of Measure and Conversion > Add/Modify Units of Measure in the Select Action menu.
You can create units of measure and conversion factors in many applications.
2. Click New Row.
3. In the Unit of Measure field, specify an identifier for the unit of measure.
4. Optional: Enter values in the following fields:

- Abbreviation
- Description

The abbreviation value along with an asset classification is used to create descriptions for assets, locations, and items.

5. Click OK.

Results

The unit of measure is now available for use in many applications. You can delete a unit of measure only when it is not used in a conversion, on a specification template, or on a meter record.

Configuring conversion factors

If you intend to use related units of measure, configure the conversion factor to apply to them. The conversion factor to use, for example, between a kilometer and a meter is 1000 (one thousand).

Before you begin

You must configure the relevant units of measure before you can configure a conversion factor to apply to them.

Procedure

1. In the Assets application, click Unit of Measure and Conversion. > Add/Modify Conversions in the Select Action menu.
You can create units of measure and conversion factors in many applications.
2. Click New Row.
3. Specify values in the From Unit of Measure and To Unit of Measure fields.
If you enter a unit of measure that has not been configured, an error is indicated.
4. In the Conversion Factor field, specify an appropriate value.
The conversion factor from meter to centimeter, for example, is .001 but the conversion factor from centimeter to meter is 100.
5. Click OK.

Creating a linear referencing method

You must create at least one linear referencing method before you can start working with linear assets. A linear referencing method (LRM) determines the position of a linear asset, based on a start point, a measure, and a direction.

About this task

To configure a linear referencing method, you specify units of measure for the length of the linear asset and for three offset measures. You can define multiple linear referencing methods, but you can apply only one of them to an individual linear asset. You cannot modify a linear referencing method after you add it to an asset.

Procedure

1. From the Select Action menu in the Assets application, select Add/Modify Linear Referencing Methods.
2. Click New Row.
3. Enter values in the following fields:

Option	Description
LRM	Identifies the linear referencing method.
Unit of Measure	The unit of measure used to measure the length of the linear asset, for example miles or kilometers. The unit of measure must exist in the database.
Base Unit of Measure	By default, this field uses the value in the Unit of Measure field, but you can specify a different value.
Offset Unit of Measure	The unit of measure for the start and end reference points of the linear asset. The unit of measure for a linear asset can be miles, for example, but you can use feet to measure distances from a reference point, such as 300 feet from Mile Post 12.

4. Optional: You can also specify values in the following fields:

Option	Description
Y-Offset Unit of Measure	The perpendicular distance from the linear asset, for example, a speed limit sign located 10 feet from the right edge of a road.
Z-Offset Unit of Measure	The distance above or below a linear asset for example, an exit sign located 18 feet above the surface of the road, or a culvert located four feet below the surface of the road.
Y Reference	The point from which the Y offset is measured, for example, a stop sign is located not just 20 feet from a road, but 20 feet from the midline of a road.
Z Reference	The point from which the Z offset is measured, for example, an exit sign is located 18 feet above the road surface, or a culvert is 12 feet below the road bed.

5. Click OK.

Configuring a linear asset segment

A linear asset segment (or span) can contain one or more assets that includes at least one linear asset and a combination of other linear and point assets. The segment can also contain asset attributes, features, classifications, relationships, and work items.

- [Creating linear assets](#)
A linear asset, also known as a continuous asset, is an asset that you maintain in segments, such as a road, a pipeline, or a railroad track. You make measurements along the linear asset to specify work, monitoring, metering, placement of signs, and so on.
- [Classifying a linear asset](#)
You classify a linear asset in much the same way that you classify a nonlinear asset. The key difference is that the values for linear asset attributes can change over the span of a linear asset.
- [Creating features](#)
A feature is a physical object, such as a guard rail or a mile marker, that you associate with one or more linear assets. Features are not tracked with unique identifiers. When you associate a feature with a specific asset, you can then apply a label to it that can be used as a reference point.
- [Associating features with linear assets](#)
You use the Assets application to associate features with linear assets. For example, for roads, you can associate mile posts, guard rails, pavement types, speed limit signs, and other objects and properties. You can associate a feature with a linear asset multiple times. Each association is a feature instance.
- [Example of reference points that are outside the span of a linear asset feature](#)
Reference points such as mileposts are used to define other features, attributes, relationships, and work order spans. When the start and end points of an asset feature do not correspond to reference points, you can select reference points outside the span of the asset feature. Default values are used for the offset to ensure that the measurement is within the boundaries of the reference points.
- [Creating relationships](#)
You can configure user-defined relationships to establish the context of the relationship between linear assets. You create relationships to define rules to determine how configuration items relate to each other. These rules affect how you deploy and manage configuration items and how you search for configuration items.
- [Retrieving related assets](#)
You can use advanced search features to retrieve assets that are related to a selected asset.
- [Creating a route based on relationships](#)
You can create a route based on user-defined relationships.
- [Linear segment label and balloon tip formatting](#)
Special tags, attributes, and properties can be used to format the text that is used in the label and balloon tip for linear segments.
- [Locating Linear features on the map from the Linear Visual table](#)
You can locate a Linear feature for an asset on the map from the Linear Visual table.
- [Deleting Linear segments on maps](#)
You can delete linear record information directly from a map.
- [Managing data by using the Linear Visual Control grid on the map](#)
You can use the Linear Visual Control map tool to manage Linear features while you view the map.
- [Configuring the appearance of Linear object symbols in the Linear Visual Control display](#)
Configure how Linear objects appear in the Linear Visual Control to quickly identify traits for the object. For example, you can color-code work orders for a segment by status, or the speed limit for a street.
- [Configuring the appearance of Linear object symbols in maps](#)
Customize how linear features appear in the map to quickly identify traits for the feature. For example, you can color-code multiple segments to group them in a collection.

Creating linear assets

A linear asset, also known as a continuous asset, is an asset that you maintain in segments, such as a road, a pipeline, or a railroad track. You make measurements along the linear asset to specify work, monitoring, metering, placement of signs, and so on.

Before you begin

Before you create a linear asset, you must define the linear referencing method (LRM) to apply to it and configure the units of measure for working with the LRM, such as kilometers, meters, miles, or feet.

Procedure

1. In the Assets application, click New Asset, and specify a value. If you use auto numbering for assets, the Asset field displays a number. For linear assets, you might want to use a different naming convention. Change the value to match the convention. It is unlikely that you will move a linear asset from one site to another site, but a move can occur for accounting reasons. To move a linear asset from one site to another, the asset number must be unique at the organization level. If you want to move an asset from one organization to another organization, the asset number must be unique at the system level. If an asset has the same number as an asset at the site or organization to which you want to move the selected asset, provide another number for the asset being moved. The move history is maintained regardless of asset number changes.
2. In the Asset Description field, type a description.
3. Select the Linear check box.
4. In the Details section, specify values as needed. Some fields are not used with linear assets, for example, Rotating Item. There are exceptions based on industry requirements and business practices. Note the following fields regarding their possible use with linear assets:
 - a. Parent. Defines a physical relationship that is hierarchical, for example, intersects with, merges with, and parallels. You can also use this field to identify an organizational or a financial relationship. A parent relationship does not use start and end measures. A parent linear asset is the parent of the entire child linear asset.

- b. Location. Identifies the physical location of a point asset. Linear assets are geographically dispersed and the concept of location might not be useful. However, some facilities contain linear assets within a physical structure that you can identify by location.
- 5. In the Linear Referencing Details section, type values as needed. Note the following considerations for specific fields:
 - a. Direction. Select a direction if relevant to the linear asset. This value is informational only and is not used in calculations.
 - b. LRM. Click Select Value and select the linear referencing method you want to use with this asset.
 - c. Start Measure and End Measure. The start measure can be any value. It does not have to be zero. For example, you might create multiple linear assets for multiple sections of an interstate highway, but use continuous mileage across the sections. The first section might start at zero, the second section might start at 48, and so on. Adjust the end measure to account for whatever value is specified for the start measure. For example, if a linear asset is 50 miles long and the start measure is 20, the end measure is 70. You can adjust the start and end measures at a later time. Shorten the length only if the segment you want to remove has no feature instances or attributes associated with it. In the Description fields, provide short explanations for why you specified those measures.
- 6. In the Purchase Information section, in the Costs section, in the Downtime section, and in the Modified section, specify values as needed.
- 7. Click Save Asset.

Classifying a linear asset

You classify a linear asset in much the same way that you classify a nonlinear asset. The key difference is that the values for linear asset attributes can change over the span of a linear asset.

Before you begin

Map out a classification hierarchy. For example, if you are classifying roads, you can have a Roads classification that has attributes that apply to all roads. You can then configure child classifications for road classes whose attributes are specific to each child class. Creating a classification hierarchy can ensure that only those attributes that are important to each asset class are applied. Use domains, which are predefined lists of values, to enhance the quality of data by restricting options and removing the possibility of data entry errors. With table domains, you can access data directly from a table column, making domain values dynamic.

Procedure

1. In the Assets application, select the asset that you want to classify.
2. In the Specifications tab, select the Detail menu for the Classification field and either:
 - Select Classify if the classification you want to use already exists.
 - Select Go To Classifications, to create a classification and then return with the value.
3. Click New Row to create an attribute and add values, including start and end measures.
4. Repeat the previous step to create all of the attributes required to properly classify the asset.

When you classify a road, for example, you can add a different County attribute for each county that is traversed by the road, and a different Area attribute for urban and rural sections of the road.
5. Click Save Asset.

Example

This example classifies a road. You create a classification called Road and select this classification. Create an attribute called Alias because most roads are known by other names by maintenance teams and external agencies. The road is called the Memorial Highway from mile 10 to 20, so specify this as the value for attribute Alias, and enter 10 as the start measure and 20 as the end measure. The road is known as the Northeast Corridor from mile 15 to 40, so click New Row, specify Alias as the attribute, and repeat the process, entering Northeast Corridor as the value and 15 and 40 as the start and end measures respectively. These entries overlap which is acceptable. If the attribute is defined as Continuous (in the Classifications application), the overlap is identified when you run the Gaps and Overlap report.

Creating features

A feature is a physical object, such as a guard rail or a mile marker, that you associate with one or more linear assets. Features are not tracked with unique identifiers. When you associate a feature with a specific asset, you can then apply a label to it that can be used as a reference point.

About this task

You create features in the Features application and you associate features with linear assets in the Assets application.

Procedure

1. From the Feature tab of the Assets application, click New Feature.
2. In the Feature field, type a name for the feature.
3. In the Feature Description field, type a description.
4. In the Details section, specify a type in the Type field.
 - a. Specify LINEAR if the feature has length and you want to associate the length with measurements on the linear asset. For example, you associate a guard rail with beginning measurement points and ending measurement points on a roadway, such as miles 7.6 to 7.8.
 - b. Specify POINT if you want to associate the feature with a single measurement point on a linear asset. For example, you associate a speed limit sign with a single measurement point on a roadway. Even if a feature has length, if you only associate the feature with a single point on a linear asset, then specify the type POINT. For example, the feature power line has length, but it crosses a road at a single point.

5. If the type is linear, check the Continuous box to specify whether the feature is continuous with the linear asset. Select the check box if the feature runs the entire length of the linear asset. The feature can be a single instance that runs the entire length, or it can be multiple instances that run through the entire length. Clear the check box if the feature runs for only part of the length of the linear asset. Run the Gap and Overlap Report to identify gaps in continuous features.
6. Select the Shared check box if you want the feature to be shared among multiple linear assets for which you have created a relationship. For example, two related linear assets share a segment. You associate the feature with one of the assets and it displays on the record for the other asset. Clear the check box if you want to associate the feature manually each time, even if multiple linear assets share a segment.
7. Select the Is Reference Point check box if you want to use the feature as a start or end point for a linear segment. For example, you specify a mile post to be a reference point because you want to use it to locate other features. If you clear the check box, you cannot use the feature as a reference point. Use the Relationships application to create relationships between linear assets.
8. Select the Specifications tab and specify information in the following fields as needed:
 - a. In the Classification field, type a value, or click Detail Menu to select an option and to retrieve a value. The attributes for that classification are inserted in the Specifications window.
 - b. If a class description for the classification exists, the Class Description field is automatically filled in. Use the Classifications application to create classifications and to define attributes for them.
9. To add attributes for the feature, click New Row in the Specifications tab.
 - a. In the Attribute field, specify a value.
 - b. Optional: Type values in other fields, as needed. Some fields are read-only, depending on the values in the other fields.
10. Click Save Feature .

Associating features with linear assets

You use the Assets application to associate features with linear assets. For example, for roads, you can associate mile posts, guard rails, pavement types, speed limit signs, and other objects and properties. You can associate a feature with a linear asset multiple times. Each association is a feature instance.

Procedure

1. From the Assets application, display the record of the linear asset with which you want to associate a feature.
2. Click the Features tab, and in the Features window, click New Row.
3. In the Feature field, specify a feature.
4. In the Label field, type a label if the feature name and measures are not sufficient to identify the feature instance. Use labels in the following situations:
 - a. When multiple instances of an asset feature reside at the same measures. The labels allow you to differentiate between the asset features.
 - b. When you plan to use the feature as a starting point or as an ending reference point to locate work. Reference points must be identifiable by maintenance workers in the field. For example, a label can be the text on a sign, or a label can be a point of interest, such as a named hilltop. A label can also be a relationship with another asset or with a location, such as an intersection or a rest area.
 - c. When you want to do work on a feature. The feature must be identifiable in the field, which requires some form of visible label. If the feature has been classified, the Classification field displays the classification. The Class Description field displays the class description.
5. Select the Share With Related Assets check box if you want the feature to be visible on related linear assets when the relationship span includes the location of this feature instance. For example, a mile post might be located between two linear assets. You want the feature to appear on both linear asset records. Use the Relationships application to define the relationships between linear assets. This option is useful for parallel linear assets that share the same measures. For example, multiple parallel tracks on a railway.
6. Select the Is Reference Point check box if you want to use this feature instance as a reference point, such as a work location. For example, a mile post is typically used as a reference point. Some features, however, are not suitable as reference points. You can use pavement as a feature that spans the length of a road, but you would not specify it as a reference point.
7. In the Linear Segment Details section, specify measures and specify offsets to identify the location of the feature instance.
8. The Attributes window displays the attributes associated with the classification for this feature. You can add values and measures to these attributes. To add additional attributes, click New Row.
9. Click Save Asset.

Example of reference points that are outside the span of a linear asset feature

Reference points such as mileposts are used to define other features, attributes, relationships, and work order spans. When the start and end points of an asset feature do not correspond to reference points, you can select reference points outside the span of the asset feature. Default values are used for the offset to ensure that the measurement is within the boundaries of the reference points.

Example

You create a linear asset such as a 100 mile train track. You add mileposts to the track at mile intervals to act as reference points. You label the mileposts MP 1 to MP 100. You create a guardrail as an asset feature. The guardrail starts at MP 10 with an offset of 250 feet, and ends at MP 10 with an offset of 500 feet. You create a guardrail classification with an attribute of MATERIAL because at a point along the guardrail the material changes from wood to aluminum. You can use MP 10 as a reference point, even though it is outside the span of the guardrail. If MP 10 is selected for the start or end measure of the MATERIAL attribute value, the offset defaults to 250. The default ensures that the calculated absolute measure is brought within the span of the guardrail asset feature. You can override the offset with the correct value. For example, the Wood value might start from MP 10 offset 250 and end at MP 10 offset 375. The Aluminum value would then start at MP 10 offset 375 and end at MP 10 offset 500.

Creating relationships

You can configure user-defined relationships to establish the context of the relationship between linear assets. You create relationships to define rules to determine how configuration items relate to each other. These rules affect how you deploy and manage configuration items and how you search for configuration items.

Procedure

1. In the Relationships application, click New Relationship.
2. Optional: Specify a classification.
You create the classification in the Classifications application.
3. In the Use with field, select ASSET.
4. Optional: Select the Is Reference Point check box if you intend to use this relationship as a reference point on a linear asset.
5. Optional: You can create one or more rules to apply to the relationship in the Asset Relationship Rules section.
6. Save the new relationship.

Retrieving related assets

You can use advanced search features to retrieve assets that are related to a selected asset.

Procedure

1. In the List tab of the Assets application, select the Filter by Linear Assets option in the Advanced Search menu.
2. Specify the asset that you want to search and specify start and end measures or the start and end reference points.

Results

The search retrieves the following assets:

- All assets whose relationship start measures are within the entered span
- All assets whose relationship end measures are within the entered span
- All assets whose relationship covers the entire span entered

Creating a route based on relationships

You can create a route based on user-defined relationships.

Procedure

1. In the Routes application, click New Route.
2. Click Path Selector.
3. Specify the asset that is at the start of the route and click Refresh.
4. Check the respective rows to select one or more assets to use as route stops, and click Select.
5. Click Select and Return if you want to select assets and return them to the route.
6. Click Close.

Linear segment label and balloon tip formatting

Special tags, attributes, and properties can be used to format the text that is used in the label and balloon tip for linear segments.

You can use special character tagging for Asset and Feature specifications that have multiple attributes. Only attributes that have values appear in the label or balloon tip. Use the `#{ [-- and --] }` tags to bracket a series of attributes. The following example shows a list of attributes in a text format.

```
#{ [--  
  ${assetattrid}: ${numvalue} ${measureunitid}  
  ${assetattrid}: ${numvalue}  
  -- ] }
```

The following example shows a list of attributes in an HTML format.

```
<div>#{ [--</div>  
  <div>${assetattrid}: ${numvalue}  
    ${measureunitid}</div>  
  <div>${assetattrid}: ${numvalue}</div>  
  <div>-- ]</div>
```

If one or more of the attributes that are listed in the first line do not have values that are assigned to them, then the second line is checked. This process continues until a line is found where all attributes that are listed have values that are assigned to them. The text that is generated from those attributes is used for the label or balloon tip. If no suitable lines are found, then no information that appears between the tags is used.

The `parentAssetIsSource` and `parentAssetIsTarget` attributes can be used with the Relationship layer to determine whether the main asset is either the source or the target to the related asset, for example:

```
#{[--
${parentAssetIsSource}##{attributeTitle|targetassetnum} ${targetassetnum}
${parentAssetIsTarget}##{attributeTitle|sourceassetnum} ${sourceassetnum}
--]}
```

Based on that assessment, contextual information can be included in the label or balloon tip. The attributeTitle property can retrieve the given title of an attribute, for example:

```
#{attributeTitle|STARTMEASURE}: ${startmeasure}
```

This property can be useful to retrieve the globalized version of the title of the attribute.

- [Configuring balloon tips and label messages for Linear Visual Control segments](#)
You can configure the text that is displayed in the label and balloon tip for a linear segment to provide context and historical information for the segment.
- [Customizing the default label and balloon tip information for new organizations](#)
You can add information directly in the product database to customize the default label and balloon tip information for linear objects.

Configuring balloon tips and label messages for Linear Visual Control segments

You can configure the text that is displayed in the label and balloon tip for a linear segment to provide context and historical information for the segment.

Procedure

1. In the Organizations application, select an organization and select an organization action, for example, Asset Options.
2. In the Linear Visual Control Message Configuration table, select a Linear Layer object type.
3. In the Label field, use the field selection tool to specify attributes that you want to display in the object label.
4. In the Balloon Tip Message template field, Use the field selection tool to specify attributes that you want to display in the object balloon tip message.
5. Click OK to save your changes.

Customizing the default label and balloon tip information for new organizations

You can add information directly in the product database to customize the default label and balloon tip information for linear objects.

Procedure

1. Log in to the database server by using a user ID that has permission to modify Maximo® Asset Management database tables.
2. In the LVCMSGINFODFLT table, add the following columns:
 - INFOATTRIBUTETEMPLATE
 - LABEL
3. To customize a balloon tip for a layer name, create a CLOB object in the INFOATTRIBUTETEMPLATE column.
Each object must be defined by using HTML tags. At a minimum, you must use division tags for each line, for example:

```
<div><b>${workorder.description}</b></div>
<div>#{attributeTitle|recordclass}: ${recordclass}</div>
<div>#{attributeTitle|workorder.status}: ${workorder.status}</div>
<div>#{attributeTitle|workorder.statusdate}: ${workorder.statusdate}</div>
<div>#{attributeTitle|STARTMEASURE}: ${startmeasure}</div>
<div>#{attributeTitle|ENDMEASURE}: ${endmeasure}</div>
```

4. To customize a label for a layer name, create a CLOB object in the LABEL column.
Each object must be defined as text, for example:

```
${workorder.description}
```

Locating Linear features on the map from the Linear Visual table

You can locate a Linear feature for an asset on the map from the Linear Visual table.

Before you begin

The location function for Linear features in the product is available when you also have deployed Maximo® Spatial Asset Management, and you have selected Spatial as the map provider for the asset record.

Procedure

1. Open the Assets application and select a Linear asset.
2. Select any tab that includes Linear segment details, Specifications, Features, Relationships and Work, and then locate the Linear Visual table.
The location function is not accessible from the Linear Visual table located on the Map tab.
3. Right-click a feature in the table and select Open map.
A new window displays the map at the location of the feature you selected, which is highlighted.

What to do next

You can also locate a Linear feature from the map tab of an application by opening Linear Visual Control tool on the map toolbar and selecting a feature from the list. Alternatively, you can open the Linear Visual Control tool on the map, select a linear feature on the map, and the feature will be highlighted in the Linear Visual Control tool.

The appearance of the feature highlight can be changed from the Map Symbology tab of the Map Manager application. Configure attributes of the `lvcTargetMapLayer` object to modify the color, thickness, and style of Linear feature highlights.

Deleting Linear segments on maps

You can delete linear record information directly from a map.

Procedure

1. Open a map that includes linear layers with features.
2. Open the Identify tool and select a linear feature on the map.
3. Use the navigation arrows in the Identify tool results window to locate the linear segment that you want to delete.
4. Click the Delete linear segment button.
If this option is not available, you cannot delete this type of information directly from the map.
5. Confirm that you want to delete the current linear segment.

Results

The linear segment is removed from the linear feature. The linear layer and the Identify tool results window are refreshed. Information about the deleted segment is removed from any relevant tables shown for specifications, features, relationships, work orders, and tickets.

Managing data by using the Linear Visual Control grid on the map

You can use the Linear Visual Control map tool to manage Linear features while you view the map.

Procedure

1. Open a record that includes Linear data that is linked to a GIS feature.
2. Select the Map tab to open the map for the record.
3. From the map toolbar, select the Linear Visual Control tool to display the Linear Visual Control grid.
The grid displays information for the current record. You can move and size the grid as required.
4. Select a linear feature in the Linear Visual Control grid to highlight it in the map.
5. Open the Identify tool and select the highlighted linear feature to view its details.
6. Select the Features list from the feature details window.
7. Select an object from the features list to highlight it on both the map and the Linear Visual Control grid.

Configuring the appearance of Linear object symbols in the Linear Visual Control display

Configure how Linear objects appear in the Linear Visual Control to quickly identify traits for the object. For example, you can color-code work orders for a segment by status, or the speed limit for a street.

About this task

You use JSON to configure the appearance of Linear objects that are defined for specifications, features, relationships, and work, including work orders and tickets.

Procedure

1. Open the Organizations application.
2. Select an organization, and then select Asset Options from the list of More Actions.
3. In the Linear Visual Control Symbolism section, click Configure.
4. Locate an object you want to modify and use the JSON editor to update one or more attributes.
For example, you can update the `cssClass` attribute to display the object in a different color. The help option provides object configuration assistance by defining objects and attributes that can be used in the JSON editor.
5. Click Update to validate and save your changes.
Updates are saved to the MAPSYMBOLOLOGYCONFIG column of the MapManager table in the database. You can restore the default symbol appearance by clicking Restore .
6. Open a Linear record to verify that the Linear objects shown in the Linear Visual Control display have updated.

Configuring the appearance of Linear object symbols in maps

Customize how linear features appear in the map to quickly identify traits for the feature. For example, you can color-code multiple segments to group them in a collection.

About this task

You configure the appearance of features in a map by using a JSON editor. The JSON editor can be used either in code view mode or a hierarchical tree view mode. Use the code view mode to create and modify JSON information through a code editor with code formatting assistance. In the tree view, you can browse the object hierarchy, search, rearrange existing object elements by dragging them, or create new objects and attributes.

Procedure

1. Open a Map Manager record and then select the Map Symbology tab.
2. Use the JSON editor to configure the appearance of linear objects that appear in the **linearSymbologies** section.
The help option provides object configuration assistance by defining objects and attributes that can be used in the JSON editor.
3. Click Update to validate and save your changes.
Updates are saved to the MAPSYMBOLGYCONFIG column of the MapManager table in the database. You can restore the default symbol appearance by clicking Restore .
4. Open a Maximo® record that includes linear data and then select the Map tab to verify that your changes were applied.

Organizing work on a linear asset

You can organize work by working on segments of a linear asset. You can plan your work by creating a route and preventive maintenance of one or more linear segments, and conduct work on those same linear segments. You can track the progress against your linear assets in the Work Progress table.

1. [Creating start and end features](#)
Not all work zones can be identified using absolute measures. Most maintenance workers identify work zones using start and end reference points. Reference points are simply features that have been identified as reference points.
2. [Creating a work order with multiple assets](#)
Linear assets are typically part of a linear network or infrastructure. You can attach multiple assets to a single work order.
3. [Searching for work orders using linear measures](#)
You can search for work orders based on linear measures.
4. [Creating a work order on an asset feature](#)
After you apply a feature to an asset, you can create a work order on that feature. The work can apply to all features of a particular type that are associated with an asset or the work can apply to a specific instance of feature that has a label.
5. [Tracking the progress of work on a linear asset](#)
You can track the progress of work on both linear and nonlinear assets.

Creating start and end features

Not all work zones can be identified using absolute measures. Most maintenance workers identify work zones using start and end reference points. Reference points are simply features that have been identified as reference points.

Procedure

1. In the Features application, create a feature.
2. Select the Is Reference Point check box.
3. Save the feature.

What to do next

If you are working on city streets, you can also create reference points automatically by identifying a relationship as a reference point. When you apply that relationship, then both linear assets in the relationship will have a feature created that can be used subsequently to define work zones.

Next topic: [Creating a work order with multiple assets](#)

Creating a work order with multiple assets

Linear assets are typically part of a linear network or infrastructure. You can attach multiple assets to a single work order.

About this task

If railway tracks require grinding, the work order can often include one track, a crossover track, and a parallel track. Signal inspections often include multiple assets as well. When you add multiple assets to a work order, all cost of work is applied to the asset, location or G/L account at the header of the work order. If you to distribute the costs to each asset, place them on separate child or task work orders.

Procedure

1. You can apply multiple assets to a work order in the multiple asset table.
2. You can apply multiple assets from a route that has Entries in the Work Order's Multi Asset, Location and CI Table selected.

Previous topic: [Creating start and end features](#)

Next topic: [Searching for work orders using linear measures](#)

Searching for work orders using linear measures

You can search for work orders based on linear measures.

Procedure

1. In the List tab of the Work Orders application, select the Filter by Linear Assets option in the Advanced Search menu.
2. Specify the linear asset that you want to search along, including either the start and end measures or the start and end reference points.

Results

The following work orders will be retrieved:

- All work orders whose start measures are within the entered span
- All work orders whose end measures are within the entered span
- All work orders whose span covers the entire span entered

Previous topic: [Creating a work order with multiple assets](#)

Next topic: [Creating a work order on an asset feature](#)

Creating a work order on an asset feature

After you apply a feature to an asset, you can create a work order on that feature. The work can apply to all features of a particular type that are associated with an asset or the work can apply to a specific instance of feature that has a label.

About this task

The cost of any work done is applied to the asset with which the feature has been associated.

Procedure

1. In the Work Orders application, add the linear asset to the work order.
The window refreshes to include the Feature and Feature Label fields.
2. Specify a value in either the Feature or the Feature Label field.
The start and end measures for the specified feature are used to populate the start and end measures for the work order.

Previous topic: [Searching for work orders using linear measures](#)

Next topic: [Tracking the progress of work on a linear asset](#)

Tracking the progress of work on a linear asset

You can track the progress of work on both linear and nonlinear assets.

Procedure

1. When you add a single linear asset to a work order, in the Progress table you can specify segments that identify where work has been completed.
Progress can exceed the planned span, and the work order status is not based on the spans entered.
2. If multiple linear assets are specified for a work order in the Multiple Assets, Locations and CIs table, in the Progress table you can enter segments that identify where work has been completed on any of the assets.
3. Optional: Where multiple assets are specified for a work order, you can select the Progress check box for an asset in the Multiple Assets, Locations and CIs table window.

Previous topic: [Creating a work order on an asset feature](#)

Importing linear assets from an external system

You can import linear assets from an external application through the integration framework.

- [Import of linear assets from an external application](#)
You can automate the import of linear assets from an external system and map this data to the data formats and structures used by the product.
- [Performing the import](#)
To perform the import, you must create an object structure for the data, create the import files, run the import, and perform some additional configurations.

Import of linear assets from an external application

You can automate the import of linear assets from an external system and map this data to the data formats and structures used by the product.

You can use the integration framework to import of linear asset data from an external system. You provide flat files containing the data to import, such as text files containing commas-separated values. The integration framework processes this data and maps it to object structures (or interface objects) that organize the data for use by the product.

The integration framework includes some predefined object structures, including the MXAsset object structure. The integration framework does not include object structures for Features, AssetFeatures, Relationships, and AssetRelationships objects. You must configure additional object structures for these objects in the Object Structures application.

The objects in an object structure are arranged in a hierarchy. For example, in the MXAsset object structure, the parent object is Asset and it includes child objects such as AssetMeter and AssetSpec. If you import using the XML format, the hierarchy is retained. If you use a flat file structure, the hierarchy is also flattened, putting data such as asset header, specification and status all in one file. To simplify the data, create a separate flat file for each object, and import the files in a sequence that insures that data from parent objects is imported before data from dependent child objects.

After creating the flat files to import, you configure a cron task to run the imports. The same validation is used for data import as applies when a user manually enters data in an application. The import process also validates that the data in the flat files conforms to the xml defined for the integration object structures.

The integration framework also provides an option of importing or exporting directly from the product applications.

Performing the import

To perform the import, you must create an object structure for the data, create the import files, run the import, and perform some additional configurations.

- [Configuring the asset object structure](#)
The integration framework includes a predefined object structure for assets, MXASSET. You can add the ASSETFEATURE object to this object structure, and set it to support the import of data in flat file structures.
- [Creating import files](#)
Create a separate spreadsheet for each object that you are importing.
- [Running the import](#)
You can configure a cron task to import linear asset data from an external system. Before running the import, you can preview some of the data and check that the integration is working.
- [Configuring features and relationships for import](#)
The integration framework does not include predefined integration components for the FEATURES object or the RELATIONSHIPS object. You must create object structures for these objects and configure enterprise services to use them before you can import data to them.

Configuring the asset object structure

The integration framework includes a predefined object structure for assets, MXASSET. You can add the ASSETFEATURE object to this object structure, and set it to support the import of data in flat file structures.

Procedure

1. Filter for MXASSET in the Object Structures application.
2. Check the Support Flat Structure checkbox in the header information for the object structure
3. Click New Row in the Source Objectssection.
4. Specify the following values:
 - a. ASSETFEATURE in the Object field
 - b. ASSET in the Parent Object field
 - c. ASSETFEATURES in the Relationships field
5. Click the Add Modify Alias option in the Select Action menu to check if any attributes are duplicated in the object structure.
If duplicates are identified, provide an alias, for example by adding a prefix before the attribute name.

Creating import files

Create a separate spreadsheet for each object that you are importing.

About this task

If you create a separate spreadsheet for each source object it is easier to import data from a flat file and organize it within an object hierarchy. You must structure the data in the spreadsheet in the format required by the integration framework. The example in this procedure uses the EXTSYS1 external system, a predefined component provided with the integration framework. You can configure a different external system in the External Systems application.

Procedure

1. Specify the header information in the first row. This information is required, must be in the first row, and must be in the format *<External system>,<Enterprise service>,<Action>,<Language>*
To import new records into the Asset object structure, the first row header information is EXTSYS1, MXASSETInterface,Add,EN.
All of the values are required except the action value. Include the Add action only when you are importing new records so that a new record is automatically created. When you are updating existing records, do not include the Add action in the header information.
2. Specify column headings in the second row that match the aliases specified for the object structure.
Open MXASSET in the Object Structure application and use the Add Modify Alias action if you want to check the aliases to enter in the spreadsheet.
3. Specify data to import in the third row and all subsequent rows.
4. Save the spreadsheet.
5. Import the data to a CSV file.
6. Open the CSV file in a text editor to correct any formatting errors that occurred when you converted the data to a CSV file:
 - a. If there are quote marks surrounding the content of the first row, delete the quote marks.
 - b. If there are additional commas between values in the first or second row, delete them.
Each value must be separated by just one comma.
 - c. Check for unintended spaces between the column headers in the second row and remove any that you find.

What to do next

Create additional spreadsheets for the other objects in the MXASSET object structure.

Running the import

You can configure a cron task to import linear asset data from an external system. Before running the import, you can preview some of the data and check that the integration is working.

Procedure

1. Filter for the JMSQSEQCONSUMER cron task in the Cron Task Setup application.
2. Select the Active checkbox for the SEQQIN cron task instance, to enable the cron task.
3. Filter for EXTSYS1 in the External Systems application.
Substitute another name if you configured a different external system for the import.
4. Select the Enabled check box to enable communication during the import.
5. Select the MXASSETInterface record in the Enterprise Services tab and deselect the Continuous Queue checkbox.
6. To preview the import, click Data Import and specify the following values:
 - a. Select the Flat File option.
 - b. Select the Import Preview check box to review the process without importing data.
If errors are encountered, you can review error messages in the Message Reprocessing application and fix the input file before you import any data.
 - c. Specify , (comma symbol) in the Delimiter field.
 - d. Click Browse to navigate to the CSV file to import.
 - e. Click OK.
7. When the import preview is successful, click Data Import again.
8. Deselect the Import Preview check box but use the same values for all other fields.
9. Click OK to enable the import as soon as the cron task runs.
The default setting is for the cron task to run every 30 minutes but you can change this setting.
10. Repeat these steps to import flat files of data to other objects in the MXASSET object structure and for the objects in the MXFEATURES and MXRELATIONSHIPS object structures.

Configuring features and relationships for import

The integration framework does not include predefined integration components for the FEATURES object or the RELATIONSHIPS object. You must create object structures for these objects and configure enterprise services to use them before you can import data to them.

- [Creating an object structure](#)
You must create two object structures to enable integration, one for the FEATURES object and another for the RELATIONSHIPS object.
- [Creating an enterprise service](#)
Create an enterprise service for each new object structure and use it to manage integration activities with external systems.

Creating an object structure

You must create two object structures to enable integration, one for the FEATURES object and another for the RELATIONSHIPS object.

About this task

The procedures for creating the two object structures are the same, but ther

Procedure

1. Click the New Object Structure icon in the Object Structures application.
2. Specify a name for the object structure, either MXFEATURE or MXRELATIONSHIP.
3. Specify INTEGRATION in the Consumed by field.
4. Check the Support Flat Structure check box to enable processing of data provided in flat files.
5. Click New Row in the Source Details section and specify the name of the object, either FEATURE or RELATIONSHIP.
The object structures are now configured but you must perform two additional steps to add the FEATURESPECS object to the MXFEATURES object structure.
6. Optional: In the MXFEATURES object structure only, click New Row in the Source Details section and specify the following values:
 - a. Specify FEATURESPECS as the object.
 - b. Specify FEATURES as the parent object.
 - c. Specify FeatureSpecClass in the Relationship field.
 - d. Specify 2 in the Object Order field. to indicate that this object is the second to be processed during integration.
Object structures can contain many child objects. The number in this field determines the order in which child objects are processed during integration.
7. Save the object structure.
8. Optional: In the MXFEATURES object structure only, click Add/Modify Alias in the Select Action menu.
 - a. Select FEATURESPEC.
 - b. Add FS_ as a prefix to FEATURESID, to create an alias of FS_FEATURESID
 - c. Add FS_ as a prefix to CLASSSTRUCTUREID to create an alias of FS_CLASSSTRUCTUREID

What to do next

Configure enterprise services to manage integration transactions between the new object structures and the external system.

Creating an enterprise service

Create an enterprise service for each new object structure and use it to manage integration activities with external systems.

About this task

After you create enterprise services for the MXFEATURES and MXRELATIONSHIPS object structures, you can import features and relationships data for your linear assets.

Procedure

1. Click New Enterprise Service in the Enterprise Services application.
2. Specify MXFEATUREInt in the Enterprise Service field.
3. Specify MXFEATURE in the Object field.
4. Save the enterprise service.
5. Repeat these steps to create an enterprise service for the MXRELATIONSHIPS object structure. Substitute MXRELATIONSHIPInt and MXRELATIONSHIPS as the values in the Enterprise Service and Object fields.

What to do next

You can now use the new enterprise services to run an import that adds features and relationships data to the linear assets you imported earlier.

Reference information for linear asset controls

Use this reference information as a checklist of linear asset controls and to clarify the terminology that is used when working with linear assets.

- [Conditional components](#)
The product provides some components that are enabled for use after security authorization. Other components are visible only if you are working with a linear asset.
- [Visual control tools](#)
Use the tools available in the visual control space to manage how you view linear asset grid data.

- [Linear asset terminology](#)
A linear asset is an asset whose length plays a critical role in its maintenance.

Conditional components

The product provides some components that are enabled for use after security authorization. Other components are visible only if you are working with a linear asset.

- [Linear components in the Assets application](#)
The product includes a number of linear management components in the Assets application. Some must be enabled by using the Security Groups application, and some are visible only when a linear asset is selected.
- [Linear components in the Classifications application](#)
The product includes several linear management components that are visible in the Classifications application.
- [Linear components in the Condition Monitoring application](#)
The product includes a linear management component in the Condition Monitoring application. It is visible only when a linear asset is selected.
- [Linear components in the Features application](#)
The product provides a Features application that enables you to work with physical objects that are associated with linear assets. You can view feature history if you have the correct security authorization and you are working with a linear asset.
- [Linear components in the Preventive Maintenance application](#)
The product includes a number of linear management components in the Preventive Maintenance application. Some components must be enabled using the Security Groups application, and some are visible only when a linear asset is selected.
- [Linear components in the Quick Reporting application](#)
The product includes a number of linear management components in the Quick Reporting application. Some components must be enabled using the Security Groups application, and some are visible only when a linear asset is selected.
- [Linear components in the Routes application](#)
The Routes application contains linear asset components that are visible only when a linear asset is selected.
- [Linear components in the Work Order Tracking application](#)
The product includes a number of linear management components in this application. Some components must be enabled using the Security Groups application, and some are visible only when a linear asset is selected.
- [Linear components in the Create Service Request application](#)
This application includes several linear management components that are visible only when a linear asset is selected.
- [Linear components in the View Service Request application](#)
The application provides components that are enabled for use after security authorization. Other components are visible only if you are working with a linear asset.
- [Linear components in the Service Requests application](#)
The application provides components that are enabled for use after security authorization. Other components are visible only if you are working with a linear asset.
- [Nonlinear components used by the product](#)
The product uses some components that are not linear components and are used by other applications. These components must be enabled in the Security Groups application.

Linear components in the Assets application

The product includes a number of linear management components in the Assets application. Some must be enabled by using the Security Groups application, and some are visible only when a linear asset is selected.

Table 1. Linear components in the Assets application

Tab or window	Control type	Control name		Security enabled	Linear asset selected
List tab	Field	Linear			
List tab, Advanced Search	More Search Fields menu option	Linear			
List tab, Advanced Search	Filter by Linear Asset menu option	Filter by Linear Asset		X	
All tabs	Select Action menu option	Add/Modify Linear Referencing Methods		X	
All tabs	Select Action menu option	View Feature History		X	X
Meters tab	Field	From			X
Meters tab	Field	To			X
Meters tab	Section	Linear Segment Details			X
Enter Meter Reading, Select Action menu option	Enter Meter Reading window, Section	Linear Segment Details			X
Manage Meter Reading History, Select Action menu option	Manage Meter Reading History window, Section	Linear Segment Details			X
Features tab	Tab	All fields			
Specifications	Field	From			X
Specifications	Field	To			X
Specifications	Section	Linear Segment Details			X

The Relationships tab in the Assets application can be used with linear assets. The Relationships tab must be enabled in the Security Groups application.

Linear components in the Classifications application

The product includes several linear management components that are visible in the Classifications application.

Table 1. Linear components in the Classifications application

Tab or window	Control type	Control name		Security enabled	Linear asset selected
Main tab	Select Value menu	Use with Object, Features option			
Main tab	Field	Linear Type			
Main tab	Field	Continuous			

Linear components in the Condition Monitoring application

The product includes a linear management component in the Condition Monitoring application. It is visible only when a linear asset is selected.

Table 1. Linear components in the Condition Monitoring application

Tab or window	Control type	Control name		Security enabled	Linear asset selected
Main tab, Measurements table	Section	Linear Segment Details			X

Linear components in the Features application

The product provides a Features application that enables you to work with physical objects that are associated with linear assets. You can view feature history if you have the correct security authorization and you are working with a linear asset.

Table 1. Linear components in the Features application

Tab or window	Control type	Control name		Security enabled	Linear asset selected
Features tab in the Assets application	Application	Features			
	Select Action menu option	View Feature History		X	X

Linear components in the Preventive Maintenance application

The product includes a number of linear management components in the Preventive Maintenance application. Some components must be enabled using the Security Groups application, and some are visible only when a linear asset is selected.

Table 1. Linear components in the Preventive Maintenance application

Tab or window	Control type	Control name		Security enabled	Linear asset selected
List tab, Advanced Search	Menu option	Filter by Linear Asset		X	
Main	Section	Linear Segment Details			X
Main	Field	Feature			X
Main	Field	Feature Label			X

Linear components in the Quick Reporting application

The product includes a number of linear management components in the Quick Reporting application. Some components must be enabled using the Security Groups application, and some are visible only when a linear asset is selected.

Table 1. Linear components in the Quick Reporting application

Tab or window	Control type	Control name		Security enabled	Linear asset selected
List tab, Advanced Search	Menu option	Filter by Linear Asset		X	
Main	Section	Linear Segment Details			X
Main	Field	Feature			X
Main	Field	Feature Label			X
Main	Section	Progress Table			X

If a linear asset exists anywhere on the work order, the Progress table is visible.

Linear components in the Routes application

.The Routes application contains linear asset components that are visible only when a linear asset is selected.

Table 1. Linear components in the Routes application

Nonlinear components used by the product

The product uses some components that are not linear components and are used by other applications. These components must be enabled in the Security Groups application.

Table 1. Nonlinear components used by the product

Component	Description
Relationships tab in the Assets application	This tab must be enabled for the Assets application in the Security Groups application. Includes all fields in the main tab, and the View Asset Relationship History option in the Select Action menu. The component is not conditional and can be used for linear and nonlinear assets.
View Asset Relationship History	This option must be enabled for the Assets application in the Security Groups application. When enabled, the option is available in the Select Action menu, and opens the View Asset Relationship History window.
View Asset Specification History	This option must be enabled for the Assets application in the Security Groups application. When enabled, the option is available in the Select Action menu, and opens the View Asset Specification History window.
Add/Modify Units of Measure option in the Select Action menu, Assets application	This option must be enabled for the Assets application in the Security Groups application. You must configure units of measure to use when you create a linear referencing method. The component is not conditional and can be used for linear and nonlinear assets and several other applications.
Add/Modify Conversion Factors option in the Select Action menu, Assets application	This option must be enabled for the Assets application in the Security Groups application. You configure conversion factors to apply to units of measure to use when you create a linear referencing method. The component is not conditional and can be used for linear and nonlinear assets and several other applications.

Visual control tools

Use the tools available in the visual control space to manage how you view linear asset grid data.

Table 1. Linear visual control tools

Tool	Description
Print	Print the current visual control view. To print graphic elements, ensure that your browser is configured to print background graphics.
Expand all rows	Expand all rows that are displayed on the tree grid.
Collapse all rows	Collapse all rows that are displayed on the tree grid.
Zoom in	Zoom in to view more detail for an element. You can also right-click an element to access the zoom feature.
Zoom out	Zoom out to view hierarchical detail for an element. You can also right-click an element to access the zoom feature.
Zoom to fit	Fit all elements into a single screen view.
Debug tool	Open the debug tool to view debug information for the visual control.

Linear asset terminology

A linear asset is an asset whose length plays a critical role in its maintenance.

Purpose

The following terms are associated with linear assets:

Attribute

A property of a linear asset or of a feature. For example, speed limit is an attribute of a highway (a linear asset) with multiple possible values (40 miles per hour, 50 miles per hour, and so on). A guardrail (a feature) comes in different types. You can specify "Type" to be an attribute of a guardrail, and specify a value for each type of guardrail.

You can apply an attribute to an entire linear asset or to part of a linear asset. For example, a 50 miles per hour speed limit might apply to all or to part of Route 96.

Dynamic segmentation

The ability to analyze a linear asset multiple ways without affecting its underlying geometry. For example, you define a road as a linear asset. The road starts at mile zero and ends at mile 60. You assign a speed limit of 55 miles per hour to miles 0 - 20, and a speed limit of 65 miles per hour to miles 20 - 60. At the same time, the number of lanes might be three lanes from miles 0 - 40, and four lanes from miles 40 - 60.

Do not split a linear asset into multiple assets to accommodate changing properties. Define the properties in the context of one linear asset. Segment the linear asset virtually to analyze it and to work with it.

Feature

A physical object that you associate with a linear asset, but which itself is not an asset. Use features, such as, mile posts, to locate where work takes place. Create feature records using the Assets > Features application.

You can associate one or more feature instances with a linear asset. Apply costs associated with a feature instance against the linear asset where the feature instance occurs. For example, you create a feature called Mile Post, and you create a feature instance labeled MP 27 on Route 95. If you repair MP 27, the cost for the repair is charged to Route 95.

The use of features varies based upon your business model. If you want to track costs against an object, create an asset record for the object instead of creating a feature record.

You can also create features by using the relationships that you define in the IT Infrastructure > Relationships application. For example, a municipality uses intersections to locate work. By relating two streets and by specifying that the relationship is a reference point, a feature instance is created each time the relationship is applied to those linear assets.

Feature instance

A feature that you have associated with a linear asset. For example, you create a feature called Mile Post. When you associate Mile Post with a linear asset in a location, it is a feature instance.

Linear referencing

Define the location of a point along a linear asset. Linear referencing uses distance measures from known points along the X, Y, and Z axes. The X axis is the length of the linear asset. The Y axis is the distance to the right or to the left of the linear asset. The Z axis is the distance above the linear asset or below the linear asset.

Linear referencing method

A method of determining a position by using a known starting point, a measure, a direction, and offset values. To define a linear referencing method, specify units of measure for the length of the linear asset, and for three offset measures (see offset). You can define multiple linear referencing methods.

Linear segment

A span of a linear asset defined by a starting measure and by an ending measure. The span can be the entire length of the linear asset or it can be any continuous part of it. The starting measure and ending measure for the linear segment must be within the starting measure and ending measure of the linear asset. A linear segment cannot overlap two linear assets.

Measure

The absolute distance from the start of a linear asset. You can specify a measure manually. The measure is calculated for you if you enter a reference point and a reference point offset.

Offset

A measure from a previously defined reference point. The three kinds of offsets are as follows:

Reference Point Offset

A distance along the length of the asset measured from a previously defined reference point. For example, a speed sign is 0.2 miles from Mile Post 10.

Y-Offset

A distance perpendicular to the direction of the linear asset. For example, a speed limit sign is located 10 feet from the right edge of the road. Right is positive and left is negative. Therefore, the Y offset is 10.

Z-Offset

A distance above a linear asset or below a linear asset. For example, an exit sign is located 18 feet above the surface of the road, and a culvert is 4 feet below the surface of the road. The Z offset for the sign is 18, and the Z Offset for the culvert is -4.

Point asset

An asset whose length does not play a critical role in its maintenance. For example, a pump, a railway switch, or a camera. With a point asset, you do not assign work to a particular length of the asset, but rather to the entire asset or to its parts.

Reference point

A feature instance that you can use as a starting point or as an ending point for a linear segment. A reference point is a means of communicating a work location. For example, it can be more useful to workers to say that roadside plowing on Route 96 begins at the intersection of Routes 96 and 75, and ends at Exit 34, rather than to say that the work begins at mile 27.85 and ends at mile 33.8.

The use of reference points varies according to department practices and to individual variation among linear assets. Some roads might have accurate and persistent mile post markers and workers can rely on them to locate work. Other roads might have few markers or no accurate markers, and users can rely on reference points.

Relationship

A defined interdependency between two linear assets: a linear and a point asset, or a linear asset and a location. Define relationships using the IT Infrastructure > Relationships application. Relationships can be physical. For example, intersects with or is parallel to. Relationships can also be abstract. For example, belongs to or is owned by.

Planning and scheduling work

You can plan and schedule upcoming work in a graphical view.

You can manage upcoming work and assignments by creating schedules. By using the graphical view, maps, and calendars, you can see the work and resource requirements that are in the schedule. For unplanned work, you can respond to requirements by graphically assigning work to the appropriate labors and crews based on their availability. You can create street-level routes for work lists to visually manage work progress on maps that show work, crews and labor based on their Maximo® service addresses.

The following applications are used to plan and schedule upcoming work.

Table 1. Scheduling applications

Application	Description
Graphical Scheduling	Maintenance planners and schedulers can manage and schedule upcoming work.
Graphical Scheduling - Large Projects	Maintenance planners and schedulers can manage and schedule upcoming work in large projects.
Scheduling dashboard	Maintenance planners and schedulers can see upcoming work, fix scheduling issues, and view resource utilization all from one convenient location.
Graphical Assignment	Supervisors and dispatchers can assign the work records to resources.

Application	Description
Graphical Assignment - Repair Facility	Repair facility planners can assign the work records to repair facilities.
Graphical Work Week	Schedule and assign work while you manage resources over a short period of time.
Graphical Resource View	Manage resource hours over one week or one month at a time.
Graphical Crew Management	Supervisors and dispatchers can assemble crews to complete the work assignments.
<ul style="list-style-type: none"> Graphical Appointment Book Appointment Book Manager 	Customer service representatives can schedule appointments with customers to complete the work.
Scheduler Data Manager	Validate a schedule or work list's data before scheduling or assigning work, while ensuring that data best practices are followed.
Scheduling Alternate Resources	Define alternate availability for resources in your schedules.
Configure Tooltips	Modify tooltip text for work records and resources in the graphical view.
<ul style="list-style-type: none"> Configure Weather Forecast Configure Weather Alerts 	If you have a subscription to Weather.com®, you can display weather data in Maximo Manage. Supervisors and dispatchers can configure notifications that are sent to technicians and customers to warn them about weather conditions that might affect work.

If your labor and crew resources have mobile devices that can access Maximo Mobile, they can remotely complete their daily tasks, such as preparing resources, and reviewing and updating work orders.

- [Scheduling roles](#)
Each role in your organization uses specific applications to manage the scheduling process.
- [Scheduling terms](#)
This section describes common terminology used when scheduling work in Maximo Manage.
- [Best practices: Data preparation for scheduling](#)
Many factors affect the ease and effectiveness of scheduling. By preparing your data ahead of time, you can ensure that your work can be scheduled effectively.
- [Performance considerations for scheduling work](#)
You can improve performance when scheduling work by limiting the query size of your schedules and adjusting other settings.
- [Graphical view](#)
The graphical view helps you to schedule and assign work more efficiently. When you view your projects in the graphical view, the information is divided by category.
- [Managing schedules](#)
You can create and maintain schedules that are based on work record, asset, or location hierarchies. The queries you use determine which hierarchy the work records in your schedule reflect.
- [Managing assignments](#)
You can assign work to labor, crews, or repair facilities based on their skills and availability.
- [Managing short term work](#)
You can manage work in one week increments by using the Graphical Work Week application.
- [Managing resources](#)
You can manage your resources in the Graphical Resource View application in order to see all resource availability and assignments in a single view.
- [Managing crews graphically](#)
You can manage the labor and assets that are assigned to positions in crews visually by using the Graphical Crew Management application.
- [Validating data](#)
You can validate the data in your schedules and work lists in the Scheduler Data Manager application.
- [Managing appointment books](#)
You can create and manage appointment books for customer service representatives to use when they schedule customer appointments.
- [Managing weather](#)
You can configure and enable weather forecasts and alerts to notify users about weather events that might affect work.
- [Optimizing schedules](#)
You use IBM® Maximo® Optimizer to automate efficient decisions for long-range planning, scheduling, and dispatching of resources for asset maintenance while balancing competing objectives and constraints.

Scheduling roles

Each role in your organization uses specific applications to manage the scheduling process.

The following table describes how roles correspond with the applications.

Table 1. Scheduler roles

Role	Description	Applications used
Planner	<ul style="list-style-type: none"> Model work steps in job plans and routes. Define PM frequencies. Forecast long term work and costs. Use historical data to adjust the plan. 	Graphical Scheduling
Scheduler	<ul style="list-style-type: none"> Create rolling work schedules. Resource level and capacity plan. Define schedule windows. Define dependencies and the critical path. Monitor schedule compliance. 	Graphical Scheduling
Supervisor or dispatcher	<ul style="list-style-type: none"> Assign work to people or crews. Monitor and assign emergency work. Manage crew resources. Monitor dispatched people and crews. 	<ul style="list-style-type: none"> Graphical Assignment Graphical Crew Management
Repair facility planner	<ul style="list-style-type: none"> Assign mobile assets to a facility. Manage repair facility capacity. 	Graphical Assignment – Repair Facility
Customer service representative	Book appointments that are based on customer preference, technician availability, work zone, and weather.	Graphical Appointment Book

Scheduling terms

This section describes common terminology used when scheduling work in Maximo® Manage.

- [Rolling schedules](#)
You can set your schedules to refresh automatically at predefined intervals.
- [Date calculation and display](#)
The graphical view shows work dates based on a work record's scheduled start and scheduled finished dates, if they are available. If no dates that are defined for the work, the segments are shown based on other criteria.
- [Date constraints in schedules](#)
When you set date constraints on work records, the constraints appear in the Gantt view.

Rolling schedules

You can set your schedules to refresh automatically at predefined intervals.

You use the Rolling Schedule check box to designate a scheduling project as a rolling schedule. You set the interval at which you want the schedule to refresh in the Rolling Schedule window, available from the Actions menu. For example, you want to refresh the work records in the schedule every day at 7:00 AM.

The values in the Rolling Frequency and Duration in Days fields generate the project start and end dates. The start and end dates determine which dates are shown in the graphical view, and an additional 14 days before and after the schedule dates are included as a buffer. You can configure the buffer to be more or less than 14 days.

Rolling is best used for a moving time frame, in which most work is expected to occur within the start and end range of the schedule. For example, a 4-week rolling schedule gets refreshed on Monday to show forward planning. Scheduling and rescheduling are done in the 4-week planning range. Resource counts and the visible date range are restricted to the schedule's width (plus or minus 14 days), although all work can be seen if needed. Scrolling backward in the graphical view is limited.

Date calculation and display

The graphical view shows work dates based on a work record's scheduled start and scheduled finished dates, if they are available. If no dates that are defined for the work, the segments are shown based on other criteria.

Start and end dates and project offset dates

The Start Date and End Date fields control the work period calendar that shows in the graphical view. If a value is defined in the Rolling Offset in Days field in the Roll Schedule window, it is added to either side of the date range in the graphical view. You cannot move work segments outside the graphical view date range as calculated by these fields.

Initial scheduling

The following rules are used to calculate dates for work records in schedules:

1. If both schedule dates exist (scheduled start and scheduled finish), they are used.

2. If one schedule date exists (scheduled start or scheduled finish), the other date is calculated by adding (to schedstart) or subtracting (from schedfinish) the duration.
3. If target dates exist (targetstartdate and/or targcompdate), they are used.
4. If no dates exist, the records are scheduled by their duration, beginning at the current system date.

Parent-child relationships

If a child work order or task has no dates that can be used, it uses its parent's dates if they exist. If a child work order or a task has dates that can be used, they override the parent's dates. The parent's dates are a summary of the start of the earliest child or task through the end of the latest finish date of any of the children.

Completed, closed, and canceled work

Completed records are shown in the schedule as gray read-only bars, using their actual start and actual finish dates.

Closed and canceled work orders are not included in the schedule, even if the work order query on the schedule's main tab includes them.

Precedence constraints

Precedence constraints determine the order of scheduling by establishing dependencies between work orders or tasks. Precedence constraints can be inserted, edited, and deleted directly in the graphical view.

Precedence constraints can be finish-to-start, finish-to-finish, start-to-start, or start-to-finish. They can have lead time (overlaps or head starts) or lag time (gaps or delays).

The constraints can come from a job plan or from work orders that were linked to their predecessors beforehand. Inserting or changing a link does not immediately change the schedule dates. They are processed as part of critical path method (CPM) scheduling when it is run.

Only links between work orders at the same level under the same parent or between tasks of the same work order, are allowed. To graphically manage links between your work orders, you can organize them into a work package under a parent work order in Work Order Tracking. Your work query can fetch that one work order, and all children and tasks automatically become part of the schedule.

To graphically manage links between your work orders, you can organize them into a work package under a parent work order in Work Order Tracking. Your work query can fetch that one work order, and all children and tasks automatically become part of the schedule.

CPM

In graphical scheduling applications, CPM is a process that determines the schedule dates for the work records. CPM uses durations, precedence constraints, and working time to schedule work. It does not consider resource availability.

1. The schedule begins at the overall schedule start date (or today). Records without predecessors are scheduled. If the Preserve Schedule Start Dates check box is selected, the dates are unchanged from the last saved session. If the Preserve Schedule Start Dates check box is cleared, the start dates move to the schedule start (or today).
2. If a record has a start date, CPM considers its interruptible state. If a record is interruptible, its duration is scheduled to occur only during working time according to the schedule's calendar and shift. An interruptible work record can result in the record splitting around a non-work period. It can also result in a record's start date moving forward to the next working period, if its original date fell in a non-work period. If the work is not interruptible, the record is scheduled as soon as possible, regardless of calendar and shift.
3. Successor records are evaluated. The precedence type and lead or lag time is applied to the predecessor's start or finish date to derive the successor's start or finish date. Duration is added (to the start) or subtracted (from the finish) to calculate the other date. The record's successors are then scheduled, and so on, until there are no successors. The total span of that work is rolled up to its parent record. Parent schedule dates are always calculated from the children and are not editable in the graphical view.

Date constraints in schedules

When you set date constraints on work records, the constraints appear in the Gantt view.

Work date constraints are set in work management applications, for example, Work Order Tracking, Activities and Tasks, Changes, and Releases. The values in the Start No Earlier Than and Finish No Later Than fields on the work records are the date constraints.

After you create a schedule and save the data, you can view the work in the Gantt view. When you click a work record in the Gantt view, date constraints on the work record appear as red lines. The thin red line indicates the Start No Earlier Than date, and the thick red line indicates the Finish No Later Than date. If no date constraints are defined for a task, the task shows the date constraints of its parent work record.

In the Graphical Assignment - Repair Facility application, date constraints on the availability of the repair location show as well. The constraints appear as blue lines, the thin blue line indicating the start of the repair location schedule window, and the thick blue line indicating the end of the window.

You can adjust the dates in the Gantt view by dragging and dropping the work records, or by extending their duration. When you adjust the work dates, the Gantt view indicates whether the dates that you provided conflict with date constraints placed on the work or repair location. If you move the work to a date that conflicts with a constraint, the color of the work record changes to red. You can readjust the schedule dates to fall within the defined constraints, or you can override them and save the schedule.

Best practices: Data preparation for scheduling

Many factors affect the ease and effectiveness of scheduling. By preparing your data ahead of time, you can ensure that your work can be scheduled effectively.

Calendar and shift information

Set up your calendar with shift and shift break information. Include all shifts that you want to schedule work for. Ensure that your calendar extends far enough into the future. For example, if you want to plan your work out for the next six months, ensure that your calendar information extends out for six months.

Craft, crew, and labor information

Set up your crafts and crew types so that they can be specified on job plans and work plan labor. Set up labor and crews with their appropriate shifts and ensure that they are available for assignments.

Work orders and tasks

Divide your work orders and other work records into smaller tasks so that each task can be scheduled and divided between resources as needed. Plan your resources at the level that they are managed. For example, if you assign entire work orders, the resource requirement must be at the work order level. If you assign individual tasks within a work order, the resource requirement must be at task level. If you require resources at the task level, you must include tasks in the schedule to see them in the Gantt view.

Use the Interruptible check box to schedule work only during work time. If a task or work order is not interruptible, it is scheduled in a single block that might include non-work time.

Job plan information

Review your job plans to ensure that they require the appropriate craft and crew types. Also, carefully review job plan durations.

Durations affect scheduling and cost calculations. Ideally, all durations for craft requirement should be for the entire length of the job plan. For example, a 2 hour job plan for fire hydrant maintenance would require 2 hours for a plumber and 2 hours for a mechanic. Job plan and work order durations are synchronized in the Gantt view.

Service addresses

Create service addresses for assets and locations. When you enter an asset or location as a service address, XY coordinates are calculated for each asset and location. You can then view work graphically on the Dispatch tab in the Gantt view of the Graphical Assignment application.

Performance considerations for scheduling work

You can improve performance when scheduling work by limiting the query size of your schedules and adjusting other settings.

The following suggestions can improve performance:

- Break schedules up into smaller queries. Work on smaller data groups within a larger schedule. Only the information that changed is saved. For example, assume that you are working on a group of 20 work orders in the middle of a schedule that contains 300 work orders. Click Perform Critical Path Method on Selected Rows instead of Perform Critical Path Method on All Rows when adjusting the dates and links for the work. There are fewer changes to save and commit.
- Create the schedule at a work order level if the tasks are descriptive in nature and do not affect schedule scope. Clear the Include Tasks in Schedule check box in the Work Order Tracking application to bring only the work order into the schedule. If you want to see resources used by that work order, plan them at the work order level rather than at the task level.
- Limit the number of records that can be retrieved by a saved query at a time. Limiting the number of records can prevent users from inadvertently creating queries that retrieve too many records into the Gantt view (the default is 1000). To limit the record count, in the System Properties application, open the mxe.skd.populatecount record. In the Global Value field, enter the number of records that you want to allow Scheduler to retrieve at a time. From the Select Action menu, choose Live Refresh to activate the new setting.
- When modifying multiple work records at the same time in the graphical view (by using right-click options), limit the number of records you select at one time. Changes to large groups of work records affect performance.
- Specify when the commit operation is run in the background by configuring asynchronous processing. You can limit the number of records that can be committed at a time before the commit transaction is sent to a background, or asynchronous, process. You can then continue to work on other schedules. The schedule that is being committed remains in a read-only state until the commit is complete. To limit the record count, in the System Properties application, open the mxe.skd.changeount record. In the Global Value field, enter the number of records that you want to allow Scheduler to commit while running in real time (the default is 500). From the Actions menu, choose Live Refresh to activate the new setting.
- In Graphical Scheduling projects, clearing the Enable Related Attributes? check box can significantly reduce time when rendering the graphical view. Including attributes from related tables affects performance.

Graphical view

The graphical view helps you to schedule and assign work more efficiently. When you view your projects in the graphical view, the information is divided by category.

Interface layout

In the Graphical Scheduling applications, the graphical view is divided into four sections:

Activity table

The Activity table lists all work records in a table view.

Activity chart

The Activity chart shows the work to be performed on a timeline.

Resource table

The Resource table lists the resources that are needed for the work, in a table view.

Resource chart

The Resource chart shows the resources that are needed for the work on a timeline.

You can resize the panes in the graphical view. For example, you can limit the size of the Activity table so that your Activity chart is maximized. Changes that you make to the panes are saved with the schedule.

Colors in the graphical view

Colors in the graphical view are defined by system properties in the System Properties application. For more information on colors in the graphical view, see the [Maximo® Manage Scheduling Community](#). You will need to join the community in order to view content. This process can take several minutes.

- [Graphical view navigation](#)
The graphical view navigation tools help you to schedule and assign work more efficiently. You can use zoom features, resource planning charts, and toolbar buttons to focus on specific aspects of the work while you create your schedule.
- [Graphical view tips](#)
You can use several shortcuts in the graphical view to make scheduling and assigning work easier.
- [Graphical view customization](#)
You can modify the default values of system properties to determine what information appears in the graphical view. The properties are located in the System Properties application.

Graphical view navigation

The graphical view navigation tools help you to schedule and assign work more efficiently. You can use zoom features, resource planning charts, and toolbar buttons to focus on specific aspects of the work while you create your schedule.

- [Record movement in the graphical view](#)
You can move records individually or in groups in the graphical view. You can modify start dates, finish dates, and durations by dragging the task bars with your mouse.
- [Sorting columns in the graphical view](#)
You can sort columns in the graphical view to focus on specific data.
- [Filtering data in the graphical view](#)
To search for specific data, you can filter the data in the graphical view.
- [Zoom options in the graphical view](#)
When scheduling and assigning work, you can adjust the zoom level of the graphical view to focus on work that is scheduled during a specific time, and view tasks and job plans in detail.
- [Refreshing data in the graphical view](#)
When you refresh the information in your schedule, you update the schedule with changes that were made to the work records in the applications where the work records originated.
- [Uncommitted work](#)
Uncommitted work is work that was modified in the graphical view without being saved to the originating work record applications.

Record movement in the graphical view

You can move records individually or in groups in the graphical view. You can modify start dates, finish dates, and durations by dragging the task bars with your mouse.

You can move records in the graphical view in two ways:

- You can drag work to a new date in the Activity chart.
- You can right-click on the work record and move it to predefined intervals.

When you move and drag a summary bar, all children move accordingly.

You can only move and resize work requirements and assignments that appear in the assignment node.

Dragging work in the graphical view

Each task bar (at the lowest level of the hierarchy) has three edit points:

- The edges of the bar represent the scheduled start and finish dates of the work. You can click and drag the edges to change the start date, end date, and duration.
- Click the middle of the bar to drag the record to a new start and finish date while preserving duration.

You can stretch the ends of the task bar to the preferred start and end dates, modifying the duration of the work record. If you move the start or end date of a work record outside of any date constraints that exist for that record, a red line appears, indicating where the date constraint falls. The work record turns red, indicating it

is in violation of its date constraints. You can move the work back to comply with the date constraints, or override them. You can drag the work record from the middle of the task bar to reschedule dates without changing duration.

Dragging multiple records

You can select multiple work records at the same time and reschedule them as a group. You can multiselect task bars in the graphical view in the following ways:

- Click outside of the tasks, then group them with a border.
- Use Ctrl-click to select individual tasks of a noncontiguous group.

The task bars that you select have edit markers visible on both ends of the bar. The task row in the Activity table is highlighted. When multiple rows are selected, only the start and finish dates can be moved, preserving duration. Dragging any of the selected rows moves them all proportionally. Moving a group of tasks or child records moves the parent record with them. Parents always span their children and tasks.

Moving records using right-click options

You can move work in the graphical view by right-clicking on the work record in the Activity table or chart. The following options are available from the right-click menu:

- Move to Next Hour: Moves the work record one hour ahead.
- Move to Today: Moves the work record to the current date.
- Move to Next Day: Moves the work record one day ahead.
- Move to Day: Opens a calendar from which you can choose the date that you want to move the record to, keeping the time in tact.
- Set Work to Day: Opens a calendar from which you can choose the date and time that you want to move the record to.

You can select multiple records at the same time and use the right-click options to move their dates.

Moving PM records

In the Graphical Scheduling application, you can modify the dates for PM forecasts in the same way. If the Forecast Dates Locked? check box is selected, the PM segment is gray and cannot be moved. If the Reforecast Subsequent Dates? check box is selected, the PM segments are blue and can be moved. After you change the date, the segment turns red and the entire forecast row becomes read-only pending reforecast. To reforecast the PM, click PM Reforecast All in the toolbar.

PM segments cannot be moved past the next PM segment. If the PM is meter-based, only the first segment can be modified.

Sorting columns in the graphical view

You can sort columns in the graphical view to focus on specific data.

Procedure

1. In the table portion of the graphical view, click the arrow in the header of the column that you want to sort by. You can sort in ascending or descending order.
2. Add an additional sort column by pressing Shift while clicking the arrow for the second column that you want to sort by.
You can sort by up to three columns by using this method. To change the number of columns you can sort by, modify the `skd.max.sort.columns` system property in the System Properties application.

Filtering data in the graphical view

To search for specific data, you can filter the data in the graphical view.

Procedure

1. In the graphical view, click the Filter icon .
A search box opens for each column heading.
 2. Type the text that you want to search for in the search box.
 3. Click the X next to the search box to choose the operator that you want to use in the filter.
For example, you can filter for values that are equal to, less than, or end with your search text.
After you specify filter criteria, the graphical view contains only the data that you filtered for. Any text that is contained anywhere in a hierarchy affects search results.
For example, if you search for AIR in the description, work records that do not contain AIR in their description appear if they have tasks that contain AIR in the description.
 4. To view the entire schedule again, click the Clear Filter and Show All Activities icon .
 5. Optional: You can also search for records in the Quick Filter field, or limit the records by hierarchy level by clicking the hierarchy levels at the beginning of the Description column.
- **Quick filter**
You can use the Quick Filter field to locate records in your schedule or work list.

Quick filter

You can use the Quick Filter field to locate records in your schedule or work list.

Type text in the Quick Filter field and press Enter. Work rows that contain the text that you specified in any column are shown. Parent records are included if tasks meet the search criteria. Tasks are always shown in the context of their parent.

You can use the following advanced techniques to further filter data:

Table 1. Quick filter searches

Search type	Example of returned records	Example of search terms
And search	Approved work records for asset 14300	APPR 14300
Exact phrase search (use quotes)	Work records for reciprocating pumps	"reciprocating pump"
Or search	Work records for pumps or for location BR410	Pump OR BR410
Exclusion search (use minus sign)	All work records that are not related to asset 14300	-14300
Search within a specific column	Work records that have Kelly Hose Maintenance in the Description column	Description=Kelly Hose Maintenance
Greater than (>), less than (<)	Tasks that have task numbers that are higher than 50	Task > 50
And search with mathematical search (&&)	Tasks that have task numbers that are less than 80 and that have a priority that is greater than 6	Task < 80 && Priority > 6

Zoom options in the graphical view

When scheduling and assigning work, you can adjust the zoom level of the graphical view to focus on work that is scheduled during a specific time, and view tasks and job plans in detail.

The following zoom options are available in the graphical view:

- Zoom In : Expands the calendar scale so that you can see more detailed information.
- Zoom Out : Contracts the calendar scale so that you can see a larger time frame.
- Zoom to Week : Sets the calendar scale to show one week.
- Go to Day : Opens a calendar so that you can select a single date for the calendar to show.

You can also focus in on specific time frames by placing your cursor on the calendar bar, and clicking a starting point. The cursor switches to a double-ended arrow. Click an end point, and then double-click the highlighted area to zoom in on it.

- Double-click a month to see a four week view.
- Double-click a week to get a seven day view.
- Double-click a day to get the view in hours.

Changes you make to the calendar scale are saved with the schedule.

Refreshing data in the graphical view

When you refresh the information in your schedule, you update the schedule with changes that were made to the work records in the applications where the work records originated.

Refreshing data for work records

When you update work records in the work management applications, you can refresh your schedule data to include the updates. The following business rules apply:

- Any new work records that you add in the work management applications that fit your query criteria appear in your schedule. Corresponding tasks and resources also appear.
- If you change the Scheduled Start or Scheduled End dates in the work management application where the record originated, the dates are updated in the schedule, providing that the segments were not edited in the schedule. If changes were made in the schedule but not committed back to the work management application, no updates are made to the schedule.
- If you change the precedence relationships between tasks in the work management application, the precedence constraints are updated in your schedule, providing that no changes were made to the constraints in the Graphical Scheduling application. If changes were made in the application but not committed back to the work management application, no updates are made.
- If you change the status or priority of a work record in the work management application, the schedule is updated. If a work record changes to a status of CANCELLED or CLOSED, it is deleted if the Preserve Existing Records on Refresh check box is cleared.

Refreshing data for preventive maintenance forecasts

For preventive maintenance (PM) forecasts, changes made in the Preventive Maintenance application to the forecasted PMs are brought into the schedule, and the forecasts are updated accordingly. The following business rules apply:

- If edits were made to a PM forecast in the scheduling application, and no edits were made in the PM application, the data in the schedule is not refreshed.
- If edits were made in the scheduling application, and new forecast dates appear on the PM record, the new forecast dates are added to the schedule, but the dates that you modified in the scheduling application are not changed.
- If a forecast is deleted in the PM application, it is deleted from the schedule upon refresh.
- When a PM is deleted or its status changed to INACTIVE in the PM application, it is removed from the schedule upon refresh.
- If a forecast was deleted and regenerated in the PM application, all forecast dates are updated and overwritten in the schedule.

Uncommitted work

Uncommitted work is work that was modified in the graphical view without being saved to the originating work record applications.

When you change work records in the graphical view, their appearance in the Activity table changes. Uncommitted work is indicated with an asterisk, and is italicized in blue.

You can commit work (at the PM or work order level) by using the Commit Selected Work action, or you can commit all changes at once by using the Commit All button. The edits can be changes that you made in the Gantt view, or changes that came from a child work record. (The graphical view always recalculates the duration of the parent work record to span the duration of its children.) You cannot commit a task without its parent work record. However, when you commit a work order, its tasks are also committed.

If you want to erase all uncommitted changes, you can refresh the graphical view. The uncommitted changes are overwritten by data from the work records in the database.

In the Graphical Scheduling application, the following changes are considered uncommitted work.

- Start Date
- End Date
- Duration
- Precedence constraints

In the Graphical Assignments applications, the following changes are considered uncommitted work.

- Work that was assigned, unassigned, or reassigned, split, or deleted
- Start Date
- End Date
- Duration

Graphical view tips

You can use several shortcuts in the graphical view to make scheduling and assigning work easier.

Work record hover information

You can press ALT-click while hovering over a work record to get a full description of the work.

Selecting all work records under a parent

You can select all work records under a parent work record in the graphical view. Press Shift-Click on the check box next to the parent record to highlight the entire work hierarchy.

Right-click options

You can right-click on most areas of the graphical view to see a list of actions that you can perform on the selected records. The right-click options include the following:

- From the activity table, right-click on the work record number to modify the work record. For example, you can change the status of the record or create a job plan for it.
- From the activity table or chart, right-click on the work description to highlight the work in the Gantt view. You can expand the work hierarchy, or move the work to another hour or day.
- From the resource table, right-click to see where a labor or resource is already assigned, see their craft and skill level, or change their availability.
- From the resource table, you can split work into multiple segments, or create or delete an assignment.

Zoom in on selected work

You can show work segments in the graphical view by double-clicking the work in the activity table.

Resource Filter

You can use the resource filter to show only the labor and crew resources that are required for the selected work records.

Resizing the chart

You can resize the windows of the graphical view by dragging the arrow at the bottom corner.

Lock scrolling while assigning work

Using keyboard keys, you can restrict where you can drag assignments in the graphical view. Click Shift while dragging to move tasks up and down on the graphical view, locking the time. Click Alt while dragging to move tasks left to right, locking the labor, craft, or crew assignment.

Graphical view customization

You can modify the default values of system properties to determine what information appears in the graphical view. The properties are located in the System Properties application.

Changing property values

You can change a display property by modifying its value in the System Properties application. You can search the System Properties application for properties that are related to the graphical view by using the following prefixes:

- skd
- map
- lbs

Displaying shift colors

You can enable shifts to display in certain colors in the System properties application. Use the `skd.shift.enable.colors` system property to display shifts by color in the graphical view. Choose the colors in which the shifts display in the `skd.shift.colors` property.

Modifying drag increment settings

In the Graphical Scheduling and Graphical Assignment applications, when you drag a work record in the graphical view, it moves in 15 minute increments. You can change the increment by modifying the `skd.gantt.view.snap_to_interval_mins` property in the System Properties application. If you want to plan and schedule in more precise detail, make the setting smaller.

Modifying column sorting settings

In the repair facilities and Asset/Location Graphical Scheduling applications, you can sort up to three columns of data in the graphical view . You can change the number of columns you can sort by modifying the `skd.max.sort.columns` property in the System Properties application.

Modifying the work action menu order

System administrators can change the order in which the right-click menu for work record actions display by updating the Maximo® database. Using any database tool, update the MENUORDER column in the SKDACTION table. You must restart the Maximo server for changes to take effect.

Modifying resource availability display options

You can choose to consider person/crew modified availability when calculating hourly totals by modifying the `mxe.skd.resourceavail` property in the System Properties application.

You can remove modified availability from the sum of the Hours-based view and the Resource & Availability tab calculations. In the System Properties application, change the value of the `mxe.skd.resourcesummedview` property to 0. The default value is 1, which shows the modified availability.

Modifying work record display options

The `mxe.skd.availabilitydaterange` property determines the length of time that asset availability displays for in the Other Resources window. By default, it is set to display for 7 days past the end of the work order start date. It can be modified in the System Properties application.

You can choose to mark work records without dates as modified once they are scheduled in the Graphical Scheduling application by modifying the `mxe.skd.setactivitymodified` property in the System Properties application.

Modifying notification options

You can turn off notifications from the emergency work crontask if no emergent work is found by modifying the `mxe.skd.setsendemailfornoemwo` property in the System Properties application.

Modifying performance options

You can set the number of changed rows that initiate a background commit to the database by modifying the `mxe.skd.changecount` property in the System Properties application.

You can limit the number of work list records that tables can populate at once by modifying the `mxe.skd.populatecount` property in the System Properties application.

Modifying colors

You can modify the default color settings in the graphical view by using the System Properties application. Search the System Properties application for properties that are related to the graphical view by using the following prefixes:

- `skd`
- `map`
- `lbs`

For more information on colors in the graphical view, see the [Maximo Asset Management Scheduler Community](#). You will need to join the community in order to view content. This process can take several minutes.

Modifying colors for resource availability

Modifications to resource availability display in the graphical view in different colors, depending on the reason. You can modify the default color settings, or add additional reason codes.

Modify existing reason codes using the following system properties:

Table 1. Modified availability display colors

System property	Reason code	Default color code
<code>skd.modavail.color.EXTRATIME</code>	Extra time	<code>#b0ecde</code>
<code>skd.modavail.color.MEET</code>	Meeting	<code>#79e5b2</code>
<code>skd.modavail.color.PERS</code>	Personal time	<code>#eae8c6</code>
<code>skd.modavail.color.SICK</code>	Sick time	<code>#311151</code>
<code>skd.modavail.color.TRAIN</code>	Training	<code>#dfc78e</code>
<code>skd.modavail.color.VAC</code>	Vacation time	<code>#8c769f</code>

You can also add additional reason codes to account for different types of modified availability in the Domains application. Search for the `RSNCODE` domain and additional codes as necessary.

Defining colors for synonym statuses

If your organization uses synonyms for work record statuses, you can define specific color settings for the synonyms in the System Properties application. Add a new system property in the System Properties application using the syntax: `skd.syn.<OBJECTNAME>.<STATUS>.background` and enter a hexadecimal color code in the Global Value field.

For example, you have a synonym for approved work orders called `APPR_S1`.

1. In the System Properties application, enter a new system property called: `skd.syn.workorder.APPR_S1.background`.
2. In the Global Value field, enter the hexadecimal color code for the color you want the work orders to be in the graphical view.
3. From the Actions menu, click Live Refresh.

Defining critical path indicators

When CPM is run on a schedule, the critical path is highlighted. The critical path indicate the records that have no float, meaning if their dates slip, the entire project slips. You can configure the color of the highlight in the `skd.criticalpath.color` system property in the System Properties application. To enable warning messages that alert users to changes in the critical path, enable the `skd.cp.impactwarning.enabled` system property.

- [Defining shift colors](#)
You can enable resource shift calendars to appear in the resource view to assist you in scheduling work when resources are available.
- [Configure Tooltips application](#)
You can modify tooltip text for work records and resources in the graphical view.
- [Configuring default settings in the graphical view](#)
You can specify the work and resources that appear in the data table of the Gantt view. The settings specified in the Configure Gantt Properties: Default Settings window apply to all schedules or work lists.

Defining shift colors

You can enable resource shift calendars to appear in the resource view to assist you in scheduling work when resources are available.

Procedure

1. In the System Properties application, search for the `skd.shift.enable.colors` property. Change the Current Value to 1 to enable the property. Save the record.
2. Define the colors that you want the shifts to display in the `skd.shift.colors` property. Save the record.

Return to the Graphical Scheduling application to see your changes. The maintenance and operation shifts are shown in the top portion of the graphical view. The shifts are shown in the resource section.

Configure Tooltips application

You can modify tooltip text for work records and resources in the graphical view.

Tooltips are shown when you hover over work or resource bars in the graphical view. The following tooltip types can be configured:

Table 1. Configurable tooltips

Application	Tooltip type
Graphical Scheduling	<ul style="list-style-type: none">• Work record• PM• Resource
Graphical Scheduling - Large Projects	<ul style="list-style-type: none">• Work record• Resource
Graphical Assignment	<ul style="list-style-type: none">• Work record or assignment• Resource
Graphical Assignment - Repair Facility	Work record or assignment

- [Configuring tooltips](#)

You can modify the text that is shown when you hover over a work or resource record in the graphical view. This text is called a tooltip.

Configuring tooltips

You can modify the text that is shown when you hover over a work or resource record in the graphical view. This text is called a tooltip.

About this task

The Configure Tooltips application contains the default values for tooltips that are shown in the graphical view. You can modify the default values to change the text.

Procedure

1. In the Configure Tooltips application, search for the tooltip template that you want to modify. You can enter the first few letters in the Template Name search field or press Enter to display all values. Open the tooltip template for the tooltip that you want to modify.
2. Edit the HTML. Click Tooltip Preview to see your changes.
You can reset the tooltip text to the default value by clicking Reset to Default.
3. Save the record.

Configuring default settings in the graphical view

You can specify the work and resources that appear in the data table of the Gantt view. The settings specified in the Configure Gantt Properties: Default Settings window apply to all schedules or work lists.

Only data that you specify in the Configure Gantt Properties: Default Settings window can be shown in the Gantt view.

You define the data that appears in the graphical view on the following tabs:

Table 1. Tabs that can contain graphical view data

Tab	Description
Work Properties	Specify the work that shows in schedules. Select data from the Activity, Change, Release, or Work Order applications.
Resource Properties	Specify the resource data that shows in schedules. Select data from the Crafts application.

You can specify a business object and attribute, such as a database table and column, to associate with each property that you enter. You can specify the order in which data appears in the data table in the Display Order field. You can set certain data to appear on all schedules by selecting Always Visible.

Managing schedules

You can create and maintain schedules that are based on work record, asset, or location hierarchies. The queries you use determine which hierarchy the work records in your schedule reflect.

- [Schedules overview](#)

Schedules allow maintenance planners to optimize the resources used to complete work. You can create multiple scenarios of schedules, run optimization

templates on them, and choose the preferred version to save to the work records.

- [Graphical Scheduling application](#)
You use the Graphical Scheduling application to manage and schedule work and resources at your organization. The schedules you create are based on work record, asset, or location hierarchy. You can view the schedules in the graphical view to manage them visually.
- [Graphical Scheduling - Large Projects application](#)
You use the Graphical Scheduling - Large Projects application to manage schedules that are too large for the Graphical Scheduling application.
- [Scheduling dashboard](#)
On the Scheduling dashboard, you can see all your schedules at a glance and view upcoming work.

Schedules overview

Schedules allow maintenance planners to optimize the resources used to complete work. You can create multiple scenarios of schedules, run optimization templates on them, and choose the preferred version to save to the work records.

- [Graphical view for schedules](#)
When you view your schedule in the graphical view, the information is divided by work record type.
- [Resource planning in schedules](#)
You can use the graphical view to help you schedule work based on resource requirements and their availability. You can prioritize and adjust your schedule by balancing the resource load.
- [Status of schedules](#)
The status of a schedule indicates whether the record is in draft form, is approved for use, or is closed.
- [Schedule duplication](#)
You can duplicate a schedule to take an existing schedule and add additional work and resources to it while you maintain a copy of the original.
- [Time zones in the graphical view](#)
Time zones display in the graphical view differently for work and PM forecasts.
- [CPM in schedules](#)
Schedules use the standard critical path method (CPM) algorithm to assign schedule dates to each work record. Critical path method logic adjusts scheduling dates by factoring in precedence relationships, calendar information, specified start dates, and other factors.
- [Percent complete display and calculations](#)
In the Graphical Scheduling application, you can display percent complete for work orders and tasks, and then calculate the percent complete for the parent work records and the schedule, helping your planner to keep projects on track.
- [Schedule compliance calculation](#)
A maintenance planner needs to track metrics to ensure that maintenance projects in the department are on track.
- [Scheduling work in the graphical view](#)
After you create a project schedule, you use the graphical view to visually manage and schedule work and resources in your organization. The graphical view shows you the available resources for work, and allows you to make schedule changes.

Graphical view for schedules

When you view your schedule in the graphical view, the information is divided by work record type.

Schedule information for work and PM forecasts is shown separately:

- Work schedules are shown in the Activity and Resource tables.
- PM forecasts appear in the lower portion of the tables, in the PM section. The PMs and jobplans within the PM forecasts are segmented bars. If there is no job plan associated with a PM, the graphical view gives a default duration of one hour. The bars can be moved to new dates, but the durations of the job plans cannot be changed. When you edit a forecast or a job plan that is associated with a forecast, the edited segment becomes a striped bar.

Work records whose status is CANCELLED or CLOSED are not included in the graphical view.

Resource planning in schedules

You can use the graphical view to help you schedule work based on resource requirements and their availability. You can prioritize and adjust your schedule by balancing the resource load.

In the graphical view, resources are displayed in the two lower panes: the Resource table and the Resource chart. You can resize the panes to customize your view.

Resource hours and availability

Craft and crew type resources that are required for the work are shown in the resource view. The resource hours that are listed in blue represent the number of craft hours that the work requires for a shift. The hours in yellow are the total craft hours that are available for the shift.

In the resource view, resource load and availability is displayed by craft. Alt-click on the yellow or blue bar to display resource information for that craft. It shows available hours, number of labor records working, and total number of hours assigned. When you make changes to the scheduled work above in the graphical view, the resource buckets are automatically updated as well. You can choose which day the resources display from by changing the value in the Start Week Day field on the schedule tab. By default, it starts on Sunday. You can also choose whether you want to see your resource load and availability displayed by shift, or in daily, weekly, or monthly segments in the Resource Load and Availability Display Mode field.

You can filter the graphical view to show the specific craft and crew type requirements and availability required for specific work records. In the Activity table.

Select the work record you want to see the craft requirements for. Click the Filter resources based on the selected work orders  button. The resources required for the work are shown in the Resource chart.

You can filter the graphical view to show the work that requires specific craft resources. In the Resource table, select the craft or crew type record that you want to see the work records for. Click the Filter work orders based on the selected resources  button. The work records that require the selected craft or crew type are shown in the Activity table.

To clear the filters, click  again.

Availability of other resources

Asset, locations, items, and tools that are required for work are available in the Other Resource Availability window. Right-click a work record in the activity chart and select Other Resources Availability to see the availability of resources that are required for the work.

Asset and location availability are displayed based on their operating and maintenance schedules, and the appropriate asset or location calendar. The schedules appear as follows:

- An orange bar shows the calendar for the site of the asset or location.
- A green bar shows the maintenance schedule for the asset or location. It is the best time to schedule work.
- A red bar shows the operational schedule for the asset or location, when it is unavailable for maintenance.

Item and tool availability are shown in the following way:

- A green bar indicates that the item or tool is available during the scheduled work time.
- An orange bar indicates one of the following circumstances:
 - If the work record is in WAPPR status, indicates that the item or tool is partially available, and can be reserved.
 - If the work record is not in WAPPR status, indicates that a soft reservation was made for this tool or item.
- A red bar indicates that the item or tool is unavailable during the scheduled work time.

Unlike labor and crew availability, tool and item availability show only for the task that is selected in the Activity table. You cannot view item and tool availability for multiple tasks at the same time.

Alternate availability

You can define alternate availability for resources in your schedules in the Scheduling Alternate Resources application.

- [Scheduling Alternate Resources application](#)
You can define alternate availability for resources in your schedules.
- [Asset and location availability](#)
A maintenance planner must consider many factors when scheduling work. These factors include the availability of specialized labor and crews, the availability of the asset or location itself, and the nature of the maintenance work.

Scheduling Alternate Resources application

You can define alternate availability for resources in your schedules.

You can override resource availability for the entire duration of the project, or for specific dates in the project.

For example, a project schedule is eight weeks long. During that period, 20 mechanics are available for the first four weeks. During the next two weeks, 15 mechanics are available. For the final two weeks, 18 mechanics are available. You can define the craft availability for each time period in the application. You can also define alternate availability for crew types and tools.

- [Defining alternate resource availability](#)
You can modify the availability of craft, crew type, and tool resources for specific dates in a schedule, or for the entire duration.

Defining alternate resource availability

You can modify the availability of craft, crew type, and tool resources for specific dates in a schedule, or for the entire duration.

Procedure

1. In the Scheduling Alternate Resources application, click the Detail menu to select a schedule.
2. Click Modify. The Modify Alternate Availability table lists the craft, crew type, and tool resources that are used in the schedule that you selected. Each shift has its own resource entry.
3. In the row for the correct resource and shift combination, modify the quantity of the available resource. Enter a start and end date for the modification.
4. To enter a second row for the same resource and shift, click Add New Alternate Availability . In the new row, enter the new start and end dates.
You can have as many entries per resource and shift combination as necessary.
5. When you are finished making modifications, save the record.

Example

For example, a schedule ABC is 8 weeks long. During that period, 20 mechanics are available for the first four weeks. During the next two weeks, 15 mechanics are available. For the final two weeks, 18 mechanics are available. All mechanic work takes place in the day shift.

In the Scheduling Alternate Resources application, open the record for schedule ABC. In the Modify Alternate Availability table, find the row for mechanics in the day shift. Enter 20 in the Quantity field, and the start and end dates for the first four weeks of the schedule. Click Add New Alternate Availability. In the new row, enter 15 in the Quantity field, and the start and end dates for those two weeks. Click Add New Alternate Availability again. In the new row, enter 18 in the Quantity field and the start and end dates. Save the record.

Asset and location availability

A maintenance planner must consider many factors when scheduling work. These factors include the availability of specialized labor and crews, the availability of the asset or location itself, and the nature of the maintenance work.

Maintenance schedule

The maintenance schedule is the time during the day when your maintenance crew can work on an asset or location. Certain assets and locations require specialized labor or crews to perform maintenance on them. A crew might be available in a location only on certain days, or at certain times. The crew's schedule is defined in the maintenance schedule windows, so that this information is available to the maintenance planner. A maintenance schedule is not required for regular assets and locations that do not require a specialized crew or skill.

In the Define Maintenance Schedule dialog box, you define the asset or location maintenance schedule. In the Manage Maintenance Schedule dialog box, you can add, delete, or modify entries for specific assets or locations.

Operational schedule

The operational schedule for an asset or location is the time during the day when the asset or location is in use, and is unavailable for maintenance. This information can be entered in the Operational Schedule dialogs or can be imported from the Maximo® integration framework.

In the Define Operational Schedule dialog box, you define the operational schedule for the asset or location. In the Manage Operational Schedule dialog box, you can add, delete, or modify entries for specific assets or locations.

For example, an X-ray device requires a specialized maintenance crew, including a technician and a radiation inspector, for annual maintenance. The specialized maintenance crew is at the location on Tuesdays, from 7 a.m. to 10 a.m. The operating schedule for the X-ray device is 9 a.m. to 5 p.m., daily. The maintenance can be performed on Tuesday between 7 a.m. and 9 a.m.

Status of schedules

The status of a schedule indicates whether the record is in draft form, is approved for use, or is closed.

The following statuses are used for schedules.

Draft

The draft status is the default status for new schedules. A draft schedule is being developed or reviewed. In draft status, you can define the schedule details, like calendar information, the start date for work, and the queries that define the work and required resources. You can also modify the schedule details, the queries, and the work in the Gantt view.

Approved

When a schedule is in approved status, the schedule details and the work queries are read-only. You can modify the resource queries, and you can modify the work records in the Gantt view. You can create multiple scenarios for an approved schedule, if your schedule allows it (by using the Scenario Allowed check box).

Closed

A schedule can be closed when all the work is complete, or when it is no longer used. A closed schedule does not show in the list view. It can be accessed only from the Advanced Search window. It can be changed back to approved status if necessary.

If more scenarios exist for the schedule, it cannot be changed to draft status.

Schedule duplication

You can duplicate a schedule to take an existing schedule and add additional work and resources to it while you maintain a copy of the original.

You can duplicate schedules in two ways. Both options are available from the Action menu:

Duplicate Schedule Definition

Duplicates just the schedule information, including the query that was used, calendar information, and other data that you entered on the Schedule tab.

Duplicate Schedule

Duplicates the entire schedule record, including data on the Schedule tab, and changes you made in the Gantt view.

Time zones in the graphical view

Time zones display in the graphical view differently for work and PM forecasts.

Time zones for work records

Work records are shown in the local time zone of the user. When you create a schedule, select the calendar and shift information for where the work will be performed (which might differ from the database date and time). The craft requirements for those work orders also are shown in the local time zone of the user. Craft availability is shown based on the calendar and the shift specified in the schedule. For example, if the shift is from 7:00 AM to 3:00 PM, the availability is shown for that duration.

Your Maximo® database is set to Eastern Standard Time (EST). A work order is scheduled to start today at noon (12:00 PM), EST. If the locale settings of the user are in Pacific Standard Time (3 hours earlier than EST), the Gantt view shows the work starting at 9:00 AM. However, the work order start time at the database level (on EST) is still noon. Therefore, select the shift information based on the locale of the user, not the database.

Time zones for PM forecasts

PM segments are shown with a start time of 12:00 AM, regardless of the time zone of the user. If the user moves a segment to another time, the segment returns to 12:00 AM when the schedule is saved. If the segment was moved to a different date, the new date saves with 12:00 AM as the start time.

CPM in schedules

Schedules use the standard critical path method (CPM) algorithm to assign schedule dates to each work record. Critical path method logic adjusts scheduling dates by factoring in precedence relationships, calendar information, specified start dates, and other factors.

When precedence constraints exist between work orders or tasks, you want the schedule dates to honor those relationships. Critical path method logic schedules the work to ensure that work is performed in the correct order. Critical path method logic follows certain rules to set optimal schedule dates for the work records in a schedule. The logic is based upon durations, precedence constraints, and working time, and not on resource availability.

You can apply critical path method logic in the Scheduler application by clicking the critical path method toolbar buttons in the graphical view.

How critical path methodology adjusts schedule dates

All work that has no dependencies is scheduled to start on the earliest scheduled start date. If the Preserved Scheduled Start Dates check box is selected for a schedule, the logic does not change the start date of tasks that are not dependent on others. However, independent tasks that are interruptible are moved to the earliest working time.

Interruptible work is scheduled only during work hours, as defined by the calendar in the schedule. Uninterruptible work is scheduled at the first available time. If no calendar information is associated with the schedule, all work is treated as interruptible.

Critical path method logic evaluates precedence relationships. For example, in a Finish-to-start relationship between Task 1 and Task 2, the start date for Task 2 is moved to the end date of Task 1.

Lead and lag time are added to the schedule dates as needed. For example, in the Finish-to-start relationship in the previous example, if Task 2 has a lead time of three hours, Task 2 is scheduled three hours after Task 1 finishes.

When critical path method logic adjusts the work dates, a Start-to-finish relationship can move work to a date that is earlier than the current date. To avoid the conflict, enter a value in the Start Date field on the schedule. The logic does not schedule any work earlier than the specified start date. This date is also used in cases when the work records have no target or schedule dates.

When CPM is run on a schedule, the critical path is highlighted. The critical path indicates the records that have no float, meaning if their dates slip, the entire project slips. You can configure the color of the highlighting (skd.criticalpath.color) and enable warning messages (skd.cp.impactwarning.enabled) for CPM in the System Properties application.

Critical path method logic does not affect preventive maintenance forecasts in the schedule.

Identifying the critical path

After running CPM, the critical path is highlighted in the graphical view. A backward pass calculates the late dates and float to determine the critical path, allowing users to focus on the important tasks that drive the schedule finish date. You can filter to show only the critical path by clicking Filter by Critical Path .

Percent complete display and calculations

In the Graphical Scheduling application, you can display percent complete for work orders and tasks, and then calculate the percent complete for the parent work records and the schedule, helping your planner to keep projects on track.

The percent complete for work can be determined in three ways.

Physical percent complete

The physical percent complete is manually entered, and is an estimation by the user.

Actual percent complete

The actual percent complete is calculated by dividing actual hours that were entered on the work record by planned hours (total actual hours / total planned hours).

- The value can exceed 100%.
- The value is time-based by labor transactions (duration of work completed / total duration)
- The value is updated when labor hours are reported in work record applications.

Task percent complete

The task percent complete can be calculated either on an average of completed tasks or on work time completed.

- For the average, it is calculated by dividing the number of the completed work segments by the total number of segments in the work (tasks completed / total # of tasks).
- For time-based calculations, it divides the number of work hours completed / number of total work hours required for the segment.

Percent calculation system property

The `skd.percentcomplete.rollup` system property determines how the calculation methods are rolled into the Graphical Scheduling application. By default, the property is set to 0, making the calculations time-based (based on reported hours). You can change the value to 1 to make the calculations based on averages.

For example, a schedule with task percent complete calculation has three tasks complete out of six total tasks. However, the span of the schedule is 19 hours, and the three task complete span 1 hour each. A value of 0 (time-based) in the `skd.percentcomplete.rollup` system property makes the Task Percent Complete 15% (3 hours / 19 hours). A value of 1 (average-based) in the `skd.percentcomplete.rollup` system property makes the Task Percent Complete 50% (3 tasks / 6 tasks).

- [Displaying percent complete in the graphical view](#)
You can view the percentage of a schedule that is complete in the Graphical Scheduling application.

Displaying percent complete in the graphical view

You can view the percentage of a schedule that is complete in the Graphical Scheduling application.

Procedure

1. In the Graphical Scheduling application, open the schedule that you want to display and calculate the percent complete for.
2. On the Schedule tab, select a value in the Percent Complete Calculation Method field.
For example, select Actual to calculate actual percent complete.
The graphical view now shows percent complete at the task level.
3. From the Actions menu, select Calculate % Complete.
The values in the Percent and Last Calculated fields for parent work records and the schedule are updated.
4. In the graphical view, click Display menu to choose visible columns . Select the Percent Complete column for the method that you chose. For example, select the Actual Hours Percent Complete column. Click OK to close the menu.
The percent complete column appears in the graphical view. If you chose Physical Percent Complete, you can update the value directly in the graphical view.

Results

The work records in the graphical view show percentage complete in the segments that represent them. For example, a work record that is 50% complete appears half green. If you entered a Physical Percent Complete and chose another calculation method as well, the calculated percentage appears. You can click the Show/Hide Actuals icon to display both values.

Schedule compliance calculation

A maintenance planner needs to track metrics to ensure that maintenance projects in the department are on track.

The planner might evaluate any of the following items:

- The cost of work over a specific time period
- Whether work is being completed on time
- The accuracy of the planning process
- [Viewing costs associated with scheduled work](#)
A maintenance planner needs to see the cost of work over a period to ensure that the department is not over budget. For example, the monthly maintenance cost for a certain location must not exceed \$10,000.
- [Forecast costs for preventive maintenance](#)
When budgeting for long-term work, you need to review upcoming work and its associated costs. You can use the Forecast Cost tab to see upcoming

preventive maintenance forecasts and the costs that are associated with each one.

- [Evaluating project performance](#)
A maintenance planner wants to evaluate overall project performance, comparing target and actual dates against the current maintenance schedule. The planner reviews the current scheduling project, and wants to anticipate problems that might be caused if date slippages occur.
- [Evaluating maintenance planning](#)
A maintenance manager wants to evaluate the accuracy of project planning in the maintenance department by using the schedule compliance factor. The manager wants to compare projected and actual hours for planned work on a schedule.
- [Evaluating resource load and availability](#)
For a certain day, a maintenance planner wants to see the number of hours of planned work that each craft has, compared to the number of resource hours that are available.
- [Calculating schedule compliance with a cron task](#)
You can set up a cron task to calculate schedule compliance automatically, at predefined intervals.

Viewing costs associated with scheduled work

A maintenance planner needs to see the cost of work over a period to ensure that the department is not over budget. For example, the monthly maintenance cost for a certain location must not exceed \$10,000.

Procedure

1. In the Graphical Scheduling application, open the record that you want to view costs for.
2. On the Cost and Usage tab, enter the date that you want the cost calculation to begin on.
3. In the Start Week Day field, select the day of the week that should be considered starting day for work cost calculations. Weekly work costs will calculate from this day forward.
4. Click Calculate Cost.
5. In the Work Cost table on the Week, Month, or Year tab, open the time period that you want to view costs for.
The totals are broken down into three categories.

Committed estimated total

The total cost of the work scheduled during the time period and committed to the database. The committed cost is saved in the work record applications.

Saved estimated total

The total cost of the work scheduled during the time period that was saved to the schedule. The saved cost is not saved to the work record applications.

Actual total

The total cost of the scheduled work incurred during the time period.

Forecast costs for preventive maintenance

When budgeting for long-term work, you need to review upcoming work and its associated costs. You can use the Forecast Cost tab to see upcoming preventive maintenance forecasts and the costs that are associated with each one.

You can calculate the projected costs for upcoming work by using the Forecast Cost tab. When you generate a forecast, forecasted work is displayed on the Forecast tab. On the Forecast Cost tab, you can click Calculate Cost to see the cost that is associated with each projected work order. All forecasted work is listed with the labor, material, tool, and service costs for each projected forecast. You can see a combined total for all the projected work to ensure that you budget for the work.

On the following subtabs, you can view the detailed costs for each category in the projected cost:

- On the Labor subtab, you can review craft, skill, and labor rate information to see how the labor costs were calculated.
- On the Material subtab, you can review item quantities and associated costs.
- On the Tool subtab, you can review tool rates and quantities for each tool that the work requires.
- On the Service subtab, you can review details for any service costs that are associated with the work.

Evaluating project performance

A maintenance planner wants to evaluate overall project performance, comparing target and actual dates against the current maintenance schedule. The planner reviews the current scheduling project, and wants to anticipate problems that might be caused if date slippages occur.

About this task

A maintenance planner reviews the current scheduling project, and wants to anticipate problems that might be caused if date slippages occur. The planner wants to take steps to correct possible problems before they occur.

Procedure

1. In the graphical view of the Graphical Scheduling application, select the row in the activity table that you want to view details for.
2. Click the Show / Hide Compliance toolbar button.
In the activity chart, the graphical view shows an orange segment that represents the target time span for the work. The graphical view shows a light green bar representing actuals.
3. From the activity table, right-click on the work record and navigate to the application that the work record originated in.
For example, for a work order, select Go To Work Order Tracking.
4. View the details of the work record, including the owner, priority, supervisor, and actual labor hours.
5. Return to the Graphical Scheduling application. In the activity table, right-click on the work record and take the following actions.
 - Select Owner: Select an owner for the work record that you can follow up with later.
 - Initiate Workflow: Set a workflow process in motion to notify management of the delay.
 - Create Communication: Send an email to the labor or crew resource responsible for their work, or to their manager, alerting them to the problem.

Evaluating maintenance planning

A maintenance manager wants to evaluate the accuracy of project planning in the maintenance department by using the schedule compliance factor. The manager wants to compare projected and actual hours for planned work on a schedule.

Procedure

1. In the Graphical Scheduling application, open the schedule that you want to evaluate.
2. On the Compliance tab, enter the start and end dates for the time period that you want to evaluate. Click Start Compliance.
3. In the Schedule Compliance Factor table window, select the time period that you want to review.
The table shows the planned hours for the time period.
4. Click Finish Compliance.
5. Save the record.

Results

The compliance details show in the Schedule Compliance Factor table. The Plan Work Records column lists the number of work records you planned to completed during the selected time period. The Actual Work records column list the number of work records you completed during the time period. The number of break-in and break-out work records are also listed. Break-in work is work that was not in the original schedule, but was later added. Break-out work is work that was included in the original schedule, but was later removed.

The Dashboard tab displays compliance information for each compliance period.

Evaluating resource load and availability

For a certain day, a maintenance planner wants to see the number of hours of planned work that each craft has, compared to the number of resource hours that are available.

Procedure

1. In the Graphical Scheduling application, open the schedule that you want to evaluate.
2. On the Resource Load and Availability tab, enter the start day for your work week.
3. Click Calculate Labor Hours.
4. In the Labor Hours table window, select the time period that you want to review.

Results

The resource hours details for each craft show in the Labor Hours table. The Planned Duration Hours column lists the planned duration of the work that is contained in the schedule. For example, all work must be completed in 3 hours. The Planned Labor Hours column lists the number of labor hours that are required to complete the work. For example, the planned duration of an electrical job is 3 hours, but the work takes 6 hours to complete, you allocate two electricians. The Available Labor Hours column lists the total number of craft hours that you have available for the selected time period.

Calculating schedule compliance with a cron task

You can set up a cron task to calculate schedule compliance automatically, at predefined intervals.

About this task

The *schedule compliance factor* measures adherence to the maintenance schedule, measuring the effectiveness of the work scheduling process. You can measure compliance on a weekly, monthly, or any user-defined basis. The schedule compliance factor is a percentage. It is derived by dividing the actual hours spent on work planned at the beginning of the time period, by the total planned work hours. For example, if the week starts on Monday, the compliance factor reflects work that is scheduled for that week as of Monday morning. The schedule compliance factor does not factor in unplanned work that was scheduled and performed during the time period.

Procedure

1. In the Graphical Scheduling application, open the schedule that you want to evaluate.
2. Click the Compliance tab. Enter the length of time for which you want the schedule compliance calculated in the duration fields.
3. Select the Cron Active check box to activate the cron task.
4. Define the frequency with which you want the schedule compliance calculation to run in the Schedule Frequency field.
5. Save the record.

Example

For example, you want to calculate the schedule compliance factor every week, from Monday to Friday. Enter the start date in the Schedule Compliance Start field. Enter 5 in the Duration field, and select Days in the Duration Units field. In the Schedule Frequency field, select every 1 week, on Monday at 8:00 AM. Click OK.

Scheduling work in the graphical view

After you create a project schedule, you use the graphical view to visually manage and schedule work and resources in your organization. The graphical view shows you the available resources for work, and allows you to make schedule changes.

Before you begin

You can customize your schedule display settings in the graphical view in the Configure Gantt Properties: Default Settings window. You can also adjust display properties on the Activity and Resource chart.

About this task

The following restrictions apply when scheduling work in the graphical view:

- Canceled, completed, or closed tasks are read-only in the graphical view. The dates for the task cannot be changed and the task cannot be moved in the schedule.
- You cannot set or manage date constraints from the graphical view. Date constraints originate from, and are managed in, the work record. You can, however, manage task-precedence constraints in the graphical view. For example, a task has a date constraint, and you move the task scheduled dates beyond that date in the graphical view. The color of the task changes to red, indicating it is in violation of the date constraint. You can schedule the work to occur at any time, but the date constraint remains in place in work management applications.
- Forecasts cannot be deleted in the graphical view.

Procedure

1. To modify the scheduled dates for a work record, select the work record in the Activity chart of the graphical view.
2. Review the information in the resource table to determine when to schedule the work.
3. Click the center of the work segment that represents the work, and drag it to the new date.
If you move the start or end date of a work record outside of any date constraints that exist for that record, a dashed line appears, indicating where the date constraint falls. The work record turns red, indicating it is in violation of its date constraints. You can move the work, or override the date constraints.
4. Save the schedule. To save your changes to the work management applications, such as Work Order Tracking or Activities and Tasks, commit the changes.

- [Creating schedules](#)

Creating a schedule in the Graphical Scheduling application helps you to see upcoming work based on work record, asset, or location hierarchy, and optimize the resources that are needed for the work. The schedule is prioritized and logically structured by work record. By default, schedules can be updated or deleted only by the user who created them. Use the Manage Commit Access action to control who can commit the schedule back to the database.

- [Sample queries](#)

You must use the proper query to populate your schedule or work list with relevant data.

- [Scheduling work based on resource availability](#)

When you are scheduling upcoming work, you must ensure that you schedule it when craft, asset, location, item, and tool resources are available.

- [Managing precedence constraints in the Graphical Scheduling application](#)

You can manage precedence constraints in the graphical view to ensure that tasks are completed in a designated order.

- [Interruptible and uninterruptible tasks](#)

Interruptible and uninterruptible work records are scheduled differently in the graphical view.

- [Committing schedule and work list data](#)

When you commit your schedule or work list, you update the work management records in the applications where they originated.

- [Scenarios](#)

You can create multiple scenarios for a schedule or work list to compare how different parameters and constraints change work completion dates. Creating multiple scenarios allows you to keep multiple working copies of a schedule without publishing the data to the work records.

Creating schedules

Creating a schedule in the Graphical Scheduling application helps you to see upcoming work based on work record, asset, or location hierarchy, and optimize the resources that are needed for the work. The schedule is prioritized and logically structured by work record. By default, schedules can be updated or deleted only by the user who created them. Use the Manage Commit Access action to control who can commit the schedule back to the database.

Procedure

1. In the Graphical Scheduling application, click New Schedule .
2. In the Schedule field, specify a name for the schedule, and then use the Description field to briefly describe the schedule.
3. In the Type field, specify the schedule type that you want to create. Choose Asset, Location, or Work.
4. In the Calendar field, specify the shift calendar for when the work is to be performed.
5. In the Shift field, specify the work shift when the work is to be scheduled.
If you do not enter calendar or shift information, the schedule assumes that resources are unavailable.
6. If you want your project to automatically refresh at predefined intervals, select the Rolling Schedule check box. You set up the rolling schedule by selecting Roll Schedule from the Actions menu. For example, you want to refresh the work records in the schedule every day at 7:00 AM.
7. Enter start and end dates for the schedule.
The Start Date and End Date control the work period calendar that shows in the graphical view. If Project Start Offset Days and Project End Offset Days exist, they are added to either side of the date range in the graphical view. You cannot move work segments outside the graphical view date range as calculated by these four fields.
8. Use the Restrict Work to Dates? check box to further filter your work query to include only work with a start or finish date between the schedule start and finish dates. This means that any work records without schedule dates is not included in the graphical view at all.
9. In the queries section, select the asset or location records that you want to schedule for. You can choose from existing queries, create a new one, or select certain assets or locations. Choose from the following options:

Option	Description
Select assets or locations	Click New Row. In the details section that appears, select the Detail menu for the Assets or Locations field. Select the assets or locations that you want to include in the schedule.
Retrieve a saved query	Click Copy Query to produce a list of queries to choose from. Select the query that you want to use.
Create a query	Click New Row. In the details section that appears, complete the required fields to specify the details for the query.

Click the Detail menu for the Data Objects field. In the Select Objects window, select the database tables that you want your query to pull data from. You can select multiple tables.

10. You can choose either work orders or PMs that you want to exclude from your schedule by adding a Work Query Restriction.
11. In the Restrict Resource Availability section, you can restrict which labor and crew resources are available in the schedule. For example, you may have 30 electricians, but you only want to include the ones in a particular work location in the schedule. You can choose from existing craft, labor, crew, or crew type queries, or create a new one.
12. Click the More Information subtab. In the Additional Resources section, find any resources that you want to include in the schedule that are not required by the work or PMs in the schedule. You can choose from existing craft, labor, crew, or crew type queries, or create a new one. Choose from the following options:

Option	Description
Retrieve a saved resource query	Click Copy Query to produce a list of resource queries to choose from.
Create a resource query	Click New Row. In the details section that appears, complete the required fields to specify the details for the resource query.

13. Click Save Schedule.

Sample queries

You must use the proper query to populate your schedule or work list with relevant data.

Work queries for a schedule or work list

The following queries are examples of common queries you might use to populate a schedule or work list. These queries are to be used as templates for your actual production queries, which should be tested thoroughly before deployment. Your database syntax might vary.

You can also create queries using the relevant application's list page, in the Advanced Search window. You can do a query by example on the field combinations of interest. Once executed, you can see and modify the SQL statement in the Where Clause window, available from the dropdown menu in the Advanced Search window.

All work orders scheduled for a two week period

```
((woclass = 'WORKORDER' or woclass = 'ACTIVITY') and schedstart <= '2010-04-16 09:08:24.000' and historyflag = 0 and siteid = 'BEDFORD' and istask = 0 and schedstart >= '2010-04-05 09:08:04.000' )
```

All work orders that a specific user owns, and are approved or in progress

owner = (select personid from person where personid = (select personid from maxuser where userid = 'WILSON')) and status in ('APPR','INPRG') note that the attribute owner could just as easily be supervisor or lead, or any field that resolves to a person id.

All work orders that are scheduled for this week

```
((woclass = 'WORKORDER' or woclass = 'ACTIVITY') and historyflag = 0 and siteid = 'BEDFORD' and istask = 0 and schedstart >= sysdate and schedstart <= (sysdate + 7))
```

All work orders targeted to be complete that are not (backlog)

((woclass = 'WORKORDER' or woclass = 'ACTIVITY') and historyflag = 0 and siteid = 'BEDFORD' and istask = 0 and targcompdate <= sysdate and status != 'COMP')

All in progress work for a group of assets with a similar prefix, found anywhere on a work order (as the primary asset or an entry in the Multiple Asset, Locations, and CIs table window)

((woclass = 'WORKORDER' or woclass = 'ACTIVITY') and status = 'INPRG' and historyflag = 0 and siteid = 'BEDFORD' and istask = 0) and (exists (select 1 from maximo.multiassetloci where ((assetnum like 'A80%')) and (recordkey=workorder.wonum and recordclass=workorder.woclass and worksiteid=workorder.siteid)))

Scheduling work based on resource availability

When you are scheduling upcoming work, you must ensure that you schedule it when craft, asset, location, item, and tool resources are available.

About this task

A maintenance planner is creating a schedule for the next three months. The maintenance planner wants to ensure that the dates meet start and end date requirements, and that it is scheduled when all resources that are required to complete the work are available.

Procedure

1. In the Graphical Scheduling application, open the appropriate schedule.
2. In the Activity table of the graphical view, drag the work segment to the timeframe that you want to schedule it for.
The resource chart shows craft or crew type requirements for the work, and their availability on that day.
3. Check for the availability of other resources. Right-click on the work record in the Activity chart and choose Other Resources Availability. The Other Resources Availability window opens.
The window shows the assets, locations, items, and tools that are required for the work, along with their availability. An orange segment indicates time when the resource is not available for maintenance. Green segments indicate the maintenance schedule associated with an asset or location. The asset and location are available to be worked on during this period.
4. Ensure craft and crew type availability during the newly scheduled work time. On the Resource Load and Availability tab below the work list, confirm that the craft and crew resources that are needed for the work are available on the scheduled work date.
5. Make schedule adjustments as necessary.
6. Save the schedule.

Managing precedence constraints in the Graphical Scheduling application

You can manage precedence constraints in the graphical view to ensure that tasks are completed in a designated order.

About this task

A *precedence constraint* is a relationship between two work records that indicates when one task begins or ends in relation to another. You can define precedence relationships between any tasks that are siblings under the same parent work record. Some precedence relationships are defined in the work management application where the work record originated. You can edit constraints or add new ones in the Gantt view. You cannot add constraints to preventive maintenance forecasts.

Procedure

1. To insert a precedence constraint, press Ctrl-click on the work records that you want to link, then click Create constraints for selected work . All of the selected work records are now linked by constraints. The constraints are start-to-finish, in order. If a constraint does not violate any finish-to-start work requirements, the line connecting the records is blue. If a constraint violates finish-to-start work requirements, the line connecting the records is red.
 2. To modify or delete the constraint, right-click on the line for the constraint that you inserted. Select Edit Constraint or Delete Constraint.
 3. Click Save Schedule .
 4. To save your changes to the work records in the work management applications, click Commit Changes  from the Actions menu.
- **Predecessor relationships**
Predecessor relationships indicate when successor work records and tasks can begin to ensure that tasks are completed in a designated order.

Predecessor relationships

Predecessor relationships indicate when successor work records and tasks can begin to ensure that tasks are completed in a designated order.

You can define the following relationships:

Table 1. Descriptions of predecessor relationships

Relationship	Description
Finish-to-finish	When the status of a predecessor changes to COMP (Complete), its successor changes to INPRG (In Progress). You can change the status of the successor. However, you can only change the status of the successor to COMP if the status of the predecessor is COMP or beyond.
Finish-to-start	When the status of a predecessor changes to COMP (Complete), its successor changes to INPRG (In Progress). The status of the successor cannot be changed to INPRG until the status of the predecessor is COMP.
Start-to-finish	When the status of a predecessor status changes to INPRG (In Progress), the status of its successor changes to INPRG. You can change the status of the successor. However, you can only change the status of the successor to COMP (Complete), if the status of the predecessor is INPRG or beyond.
Start-to-start	When the status of a predecessor status changes to INPRG (In Progress), the status of its successor changes to INPRG. The status of the successor cannot be changed to INPRG until the status of the predecessor is INPRG.

Your work record statuses might be different, depending on the values that you defined in the Organizations application.

For example, Work Order 1 (WO1) has a Finish-to-start relationship with Work Order 2 (WO2). WO1 contains three tasks, the duration of which total 12 hours. WO2 cannot start until all tasks for WO1 are complete (12 hours). The status of WO2 changes to INPRG when all three tasks for WO1 are complete, making WO1 complete.

Lead and Lag time do not affect status changes that occur through flow control.

Interruptible and un interruptible tasks

Interruptible and un interruptible work records are scheduled differently in the graphical view.

If no calendar or shift information is defined on the schedule, there is no distinction between interruptible and un interruptible work in the graphical view.

Interruptible work

Interruptible work can be performed during work hours only. When interruptible work appears for the first time in the graphical view, it is scheduled for the first available work time in the calendar. The duration of the work is added to the start date and time to arrive at the work end date and time. If any portion of the work occurs during nonwork time, the unfinished portion is moved forward to the next work time. The nonwork portion of the work is shaded differently in the graphical view, indicating that no work is being performed.

The duration for an interruptible task is not always the difference between the start date and time and end date and time. The duration is the sum of the work hours between the start and end date and time. For example, a task starts on 06/01/2010, at 7:00 AM and ends on 06/02/2010, at 9:00 AM. Work time is between 7:00 AM and 3:00 PM. The duration is 10 hours (eight hours of work time on June 1, and two hours on June 2).

Uninterruptible work

Uninterruptible work can be performed at any time, regardless of work hours. The work is completed without interruption. When un interruptible work appears for the first time in the graphical view, it is scheduled for the first available time on the schedule. The work continues, uninterrupted, until finished. The duration of the work is always the difference between the start date and time, and end date and time.

Committing schedule and work list data

When you commit your schedule or work list, you update the work management records in the applications where they originated.

Committing data from work records

When you commit a schedule or work list that contains work records, changes that were made in the schedule are saved to the appropriate work management application. The following business rule applies:

- If the work order was canceled or closed in the work management application, it is not updated by the schedule or work list.

Committing data from PM forecasts

When you commit a schedule that contains PM forecasts, changes that were made in the schedule are saved to the Preventive Maintenance application. The following business rules apply:

- If a forecast, or any portion of a forecast, was deleted from the Preventive Maintenance application, changes made in the schedule are not saved.
- If a work order was generated from the Preventive Maintenance application, and a forecast date was dropped, and then added, some forecasted dates for the PM will not match the data in the schedule. Changes that were made in the schedule to the forecasts that still exist in both places are updated in the Preventive Maintenance application. Changes that were made in the schedule to forecast dates that no longer exist are not saved to the PM. To add the new PM forecast date from the Preventive Maintenance application into the schedule, refresh your data.
- If a forecast was deleted and regenerated in the Preventive Maintenance application, no changes from the schedule are saved to the PM.

Scenarios

You can create multiple scenarios for a schedule or work list to compare how different parameters and constraints change work completion dates. Creating multiple scenarios allows you to keep multiple working copies of a schedule without publishing the data to the work records.

You can create scenarios in the following applications:

- Graphical Scheduling
- Graphical Assignment

A schedule or work list includes information such as calendar information, the start date for work, and the queries that define the work and required resources. Every schedule has one main scenario, which is a reflection of the work record data at the time that the schedule was created or last refreshed.

You can create multiple scenarios to compare how changes in resources, priority, and date constraints change the work order dates. For example, you can create a scenario to see how additional resources affect the schedule dates. You can create another scenario that focuses on getting higher priority work completed first, and a third that strictly enforces the start no later than and finish no earlier than dates. You can create a scenario from the Action menu.

The active scenario is shown on the List View. You view other scenarios from the Action menu. When you publish a scenario, it becomes the new active schedule record.

- [Comparing scenarios](#)
You can compare multiple scenarios of a schedule or work list to determine which version best fits your needs.
- [Published schedules](#)
When you publish a schedule, you commit the schedule data to the work records in the database.
- [Snapshots](#)
A snapshot is a read-only view of a schedule and its graphical view, which represents the schedule data when the snapshot was taken. You can compare snapshots to other snapshots and to scenarios.

Comparing scenarios

You can compare multiple scenarios of a schedule or work list to determine which version best fits your needs.

About this task

You can compare any two scenarios of the same schedule or work list in the Compare Scenarios tab. You can compare the work dates and the labor load for each scenario. Two graphical charts show when work is scheduled, or you can switch views to compare resource loads. Differences between the two scenarios are highlighted, including work records that are scheduled for different dates, or that appear in only one scenario. You can also compare the current schedule with a baseline, or snapshot, of the original schedule. When you compare a scenario to your baseline, you can see break-in and break-out work. Break-in work is work that was not in the original schedule, but was later added. Break-out work is work that was included in the original schedule, but was later removed.

Procedure

1. In the graphical view, view a scenario (or snapshot) that you want to compare.
2. Select Compare Scenarios from the Action menu, or click the Compare Scenarios tab. The Select Scenarios window opens, listing all scenarios and snapshots for the schedule. The current scenario is automatically selected. Choose another scenario from the list to compare it to.
3. Click Compare. The scenario window displays the Gantt view of both scenarios, with work dates. Break-ins, break-outs, and differences in work dates are highlighted. You cannot move or modify any dates in the graphical view when you compare scenarios.
4. Click the Next Change button to move the focus to the next difference in schedules, or click the Display Differences Only button to filter the view to show only differences.
5. Click the Compare Cost tab. Click Calculate Cost to update the costs for both scenarios. Select a tab to display the weekly, monthly, or yearly costs for each scenario.
6. Click the Compare Costs Chart tab. From the charts menu, choose the comparison chart that you want to view. For example, click Saved Estimated Total (Weekly) to view the comparison chart for total costs for the week that the work is scheduled for.
7. Open the graphical view. Click the scenario name to return to the graphical view of the original record.

Published schedules

When you publish a schedule, you commit the schedule data to the work records in the database.

When you publish a scenario, it becomes the main schedule record, and commits the changes that you made in the graphical view to the work records in the database. A snapshot of the graphical view is created, and can be viewed later by using the Manage Snapshots and Scenarios window.

You can publish a schedule by selecting Publish from the Actions menu.

You cannot publish a schedule that is in draft status.

Snapshots

A snapshot is a read-only view of a schedule and its graphical view, which represents the schedule data when the snapshot was taken. You can compare snapshots to other snapshots and to scenarios.

Snapshots are available in the Graphical Scheduling application.

You create a snapshot by selecting Create Snapshot from the Actions menu.

A snapshot is also created when a scenario is published.

You can view and delete snapshots in the Manage Snapshots and Scenarios window, available from the Actions menu.

Graphical Scheduling application

You use the Graphical Scheduling application to manage and schedule work and resources at your organization. The schedules you create are based on work record, asset, or location hierarchy. You can view the schedules in the graphical view to manage them visually.

You can identify possible scheduling conflicts that might arise from multiple concurrent work orders that need the same resources. You can move work records in bulk. For example, you can reschedule all unfinished work from the previous week to the next week. You can also match resources to requirements so that you can address exceptions rather than manually schedule all assignments.

After you create a work schedule, you can view the schedule in a graphical view. At a glance, you can see all the work in the schedule, and the resource requirements for that work. You can reschedule work so that resources are not overloaded or underutilized, and compare various work schedules by creating different scenarios. You can change the schedule with the drag-and-drop capability of the graphical view, and save the changes to the Maximo® database.

The Graphical Scheduling application manages constraints to ensure that your work is scheduled properly. For example, you can use task-precedence constraints to specify that some work (such as painting a wall) cannot be started until other work (sanding the wall) is complete. Similarly, you can use the date constraint feature to ensure that tasks that are scheduled to start on a certain date do not supersede tasks that are scheduled to start on an earlier date. Critical path methodology (CPM) can be used to track these dependencies while you make schedule changes, and recalculate the schedule accordingly.

Graphical Scheduling - Large Projects application

You use the Graphical Scheduling - Large Projects application to manage schedules that are too large for the Graphical Scheduling application.

The application is similar to the Graphical Scheduling application, with the following enhancements in the graphical view to facilitate large project performance (schedules containing 10,000 or more records):

- Work records are loaded in pages, 50 records at a time. The pages are created on the server rather than fetching and updating all work records in the project at once. The status at the bottom of the graphical view indicates the total number of records, the number of pages, and the start and end dates of the schedule.
- Child work records are collapsed by default. They can be opened as needed.
- Work records that have dependencies that are not on the same data page have an icon that indicates a dependency. If the work has an incoming dependency (for example, start to finish), the icon is on the left of the work record. If the work record has an outgoing dependency (for example, finish to start), the icon is on the right. You can ALT+click on the icon for the details of the constraint.
- The resource section of the graphical view is collapsed by default. If you open the resource section, resource information displays that is specific to the zoom level of the graphical view. A refresh button becomes available when changes are made to the work. You can refresh as needed by clicking the icon. The resource view also refreshes every time that it is opened.
- Changes made in the graphical view are automatically saved back to the work records.
- Critical Path Methodology (CPM) functionality and optimization run on the entire project, and display for the current page of records.
- The filter, sorting, and search functions query the entire project. Quick sort is not available.
- PM forecasting is not supported.

Scheduling dashboard

On the Scheduling dashboard, you can see all your schedules at a glance and view upcoming work.

Key performance indicators show important information, including scheduling problems and resource utilization. You can update work records, view resource allocation, fix scheduling problems, and run optimization from one convenient location. You can publish your changes when your adjustments are complete.

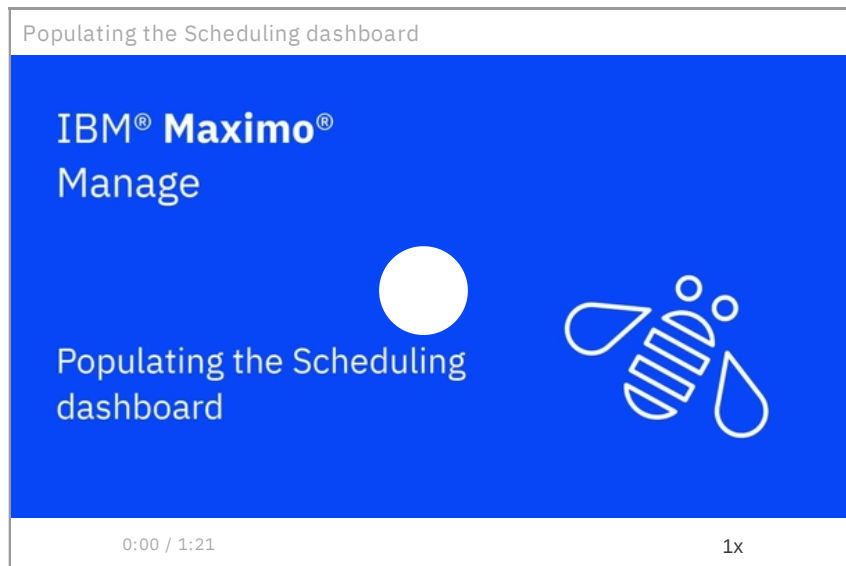

You choose which schedules appear on your dashboard in the Graphical Scheduling application.

- **[Adding schedules to the Scheduling dashboard](#)**
In order for schedules to appear on the Scheduling dashboard, they must be prepared for the dashboard in the Graphical Scheduling application. You can choose which schedules appear on the dashboard by creating a schedule scenario and preparing it for the dashboard.
- **[Viewing resource utilization on the Scheduling dashboard](#)**
You can see the percentage of your resources that are being used in each schedule on your dashboard.
- **[Viewing resource leveling on the Scheduling dashboard](#)**
You can view resource allocation and planned work by craft on the Scheduling dashboard.
- **[Fixing scheduling issues on the Scheduling dashboard](#)**
When optimization runs, sometimes work records cannot be scheduled because they do not meet the scheduling criteria that are defined in the optimization settings. You can update these work records on the dashboard to better align with the scheduling rules that you defined, or you can change the scheduling optimization rules.
- **[Monitoring optimization progress on the Scheduling dashboard](#)**
You can view optimization progress and results for your schedules on the Scheduling dashboard.
- **[Removing schedules from the Scheduling dashboard](#)**
You can remove schedules from the Scheduling dashboard by changing their settings in the Graphical Scheduling application.

Adding schedules to the Scheduling dashboard

In order for schedules to appear on the Scheduling dashboard, they must be prepared for the dashboard in the Graphical Scheduling application. You can choose which schedules appear on the dashboard by creating a schedule scenario and preparing it for the dashboard.

About this task

Procedure

1. On the Scheduling dashboard, click Prepare Schedules.
The Graphical Scheduling application opens.
2. In Graphical Scheduling, open the schedule that you want to include on the Scheduling dashboard.
3. Create a scenario for the schedule, if one does not exist. From the Actions menu, select Create Scenario and choose which kind of scenario you want to create.
If you want to use an existing scenario instead, open the scenario in Graphical Scheduling.
4. From the Actions menu, select Prepare for Dashboard.
5. In the Prepare Schedule for Dashboard window, select the scenario that you want to appear on the dashboard. If you want to apply a template, click Select Template and choose a template from the list.
6. Click OK.
The schedule scenario now appears on the Scheduling dashboard.
7. To add more schedules to the dashboard, in the My schedules table, click Add schedules.
The Graphical Scheduling application opens, where you can prepare more schedules for the dashboard.

Viewing resource utilization on the Scheduling dashboard

You can see the percentage of your resources that are being used in each schedule on your dashboard.

About this task

The Resource utilization KPI on the header shows the utilization rate for all crafts that are included in the schedule. The resources table shows utilization by craft.

Procedure

1. On the Scheduling dashboard, click the name of the schedule that you want to view.
2. In the Resources table, click the cell for the date and craft resource that you want to view resource utilization details for.
The scheduled hours, available hours, and utilization percentage are displayed. To view resource leveling data for that date and craft, click Resource leveling.
3. Click a different cell to view resource utilization for that date and craft.

Viewing resource leveling on the Scheduling dashboard

You can view resource allocation and planned work by craft on the Scheduling dashboard.

Procedure

1. On the Scheduling dashboard, click the name of the schedule that you want to view.
2. Click the Resource leveling tab.
3. From the craft menu, select the craft that you want to view resource levels for.
4. In the date selection field, choose the date from which you want assigned work to show. Work is shown on the Resource leveling tab for two weeks, beginning on the date that you choose.

Fixing scheduling issues on the Scheduling dashboard

When optimization runs, sometimes work records cannot be scheduled because they do not meet the scheduling criteria that are defined in the optimization settings. You can update these work records on the dashboard to better align with the scheduling rules that you defined, or you can change the scheduling optimization rules.

About this task

You can view scheduling issues from the main dashboard, or from within individual schedules.

Procedure

1. On the Scheduling dashboard, open the schedule that you want to view.
2. On the Scheduling issues tile, click the number.
The Issues tab opens. Use the table filter to group issues by category.
3. For each row in the Results table, expand the error message to determine why the work record was not scheduled. Update the values to fix the scheduling issue. Repeat for each row in the Results table.
4. From the Actions menu, select Optimize schedule.
5. In the Optimize schedule window, update scheduling rules as needed. Click Optimize schedule.
The optimization runs, and schedules the work records that had scheduling issues.
6. When you are satisfied with the schedule, publish it to the Work Order Tracking application. From the Actions menu, select Publish schedule.

Monitoring optimization progress on the Scheduling dashboard

You can view optimization progress and results for your schedules on the Scheduling dashboard.

Procedure

1. After fixing scheduling issues or refreshing your schedule, from the Actions menu, select Optimize schedule to run optimization.
The Optimize Schedule page opens. On the Optimize Schedule page, you can see optimization progress, including the solutions, the solve status, and any alerts or warnings that were encountered. You can watch the progress or click Run in background to return to the Scheduling dashboard.
2. When optimization is complete, click Go to schedule to return to the Issues tab for the schedule, where you can fix any unresolved issues. You can also view the latest optimization report at any time by clicking the Last ran link in the schedule header, or from the Optimization status column on the Scheduling dashboard.

Removing schedules from the Scheduling dashboard

You can remove schedules from the Scheduling dashboard by changing their settings in the Graphical Scheduling application.

Procedure

1. In the Graphical Scheduling application, open the scenario for the schedule that you want to remove from the Scheduling dashboard.
2. In the Scheduling Dashboard Ready field, turn off the toggle switch.
3. Save the schedule.
The schedule is removed from the Scheduling dashboard.

Managing assignments

You can assign work to labor, crews, or repair facilities based on their skills and availability.

- [Assignments overview](#)
You use assignments to assign work to labor, crews, or repair facilities based on their skills and availability.
- [Graphical Assignment application](#)
You assign work to labor and crews at your facility based on their skills and availability. In the Graphical Assignment application, you view upcoming work and assign the work graphically to the appropriate labor or crew resource, and respond to dynamic work situations.

- [Graphical Assignments - Repair Facility application](#)

In the Graphical Assignments - Repair Facility application, you can assign work directly to your facilities based on their availability. For example, you can assign work directly to an aircraft hangar.

Assignments overview

You use assignments to assign work to labor, crews, or repair facilities based on their skills and availability.

- [Assigning work](#)
You use the Assignment view to assign upcoming work to labor and crews based on their availability.
- [Splitting work between people and shifts](#)
You can split work into multiple assignments to complete the work as efficiently as possible. For example, if a job takes more time than anticipated, you can continue it into a second shift with another labor or crew resource.
- [Rescheduling assignments](#)
In reviewing the weekly schedule for the organization, a maintenance planner sees that some work must be reassigned because of upcoming emergency work. The maintenance planner wants to leave a particular labor or crew resource available for the upcoming work.
- [Assigning emergency work](#)
You can check for emergency work in your organization and assign the work as it comes in. You can assign the work to available resources automatically or manually.
- [Exporting assignment calendars](#)
In the Graphical Assignment and Graphical Work Week applications, you can export the assignment calendars for resources to keep a separate record of them. You can download the resource calendars or send them in an email.
- [Resource availability for assignments](#)
You use the Assignment view in the Graphical Assignment and Graphical Assignment - Repair Facility applications to assign work to available resources.

Assigning work

You use the Assignment view to assign upcoming work to labor and crews based on their availability.

About this task

Assignments typically originate from a job plan, but can be added to work records at any time. Job plans specify the crafts and crew types that are required to do the work.

The Assignment View tab displays labor and crew availability as it is defined in the Calendars application, where you can define calendar, shift, and break information. Non-work time appears in the assignment view as a shaded area on the resource table. The assignment view also shows the modified availability of the resources, including overtime, sick, and vacation time.

If you have filters applied for the work segments in the work view, you can carry the filter results into the assignment view by clicking Enable Filtering from the

Work View .

Procedure

1. On the Assignment View tab, select the orange bar representing the work record that you want to assign. You can shift-click to select multiple records. Resources that match the requirements of the work exactly (both craft and skill) are shaded dark blue. Resources that partially match the requirements (craft only) are shaded light blue. A multiple skills icon indicates that the labor or crew possesses multiple skills. You can right-click on the resource and select View Craft/Skill to see all of its associated skills. You can assign work by using one of the following methods:
 - Drag the work record to the resource that you want to assign it to in the resource chart.
 - Right-click on the bar representing the work that you want to assign. Select Available Labor. In the Available Labor window, select the labor or crew resource that you want to assign the work to. Click OK.
 - Right-click on the resource that you want to assign the work to. Select Assign Available Labor/Crew. The work is assigned to the selected resource based on their availability. It is split to accommodate shifts, etc.
 - To assign only top or bottom level work records to a resource, you can use the CTRL and ALT keys while drawing a border around the work you want to assign.
 - Press the CTRL key and draw a border around the work to select only the top level work records in the hierarchy. Right-click on a work segment for any selected work order and select Available Labor/Crew. Choose the labor or crew resource you want to assign the work to.
 - Press the ALT key and draw a border around the work to select only the bottom level work records in the hierarchy. Right-click on a work segment for any selected task and select Available Labor/Crew. Choose the labor or crew resource you want to assign the tasks to.

Using keyboard keys, you can restrict where you can drag assignments. Click Shift while dragging to move tasks up and down on the Gantt view, locking the time. Click Alt while dragging to move tasks left to right, locking the labor, craft, or crew assignment.

When work is properly assigned, the bar that represents the assigned work is green. If you selected a resource that does not match the work requirements, the bar is red. If you have double-booked a resource, the bar is yellow. Alt-click on the bar to get work details, including an explanation of any assignment violations.

 - a. If an appointment is required (in the work record application), an icon indicates that an appointment has not been made. Right-click on the assignment and choose Lock to set the appointment. Appointments that are locked cannot be rescheduled due to optimization or manual edits. To change the scheduled time manually, right-click on it and choose Unlock.
2. Save the work list.

Splitting work between people and shifts

You can split work into multiple assignments to complete the work as efficiently as possible. For example, if a job takes more time than anticipated, you can continue it into a second shift with another labor or crew resource.

Procedure

1. In the resource chart of the Assignment view, right-click on the work record that you want to split.
2. Split the work by either segment or shift. For example, if the work duration spans more than one work shift, you can split the work by shift. If you want to break the work up into smaller segments that can be assigned simultaneously, split the work into two or three segments.
3. Assign each segment of the work.
 - Drag the work to the appropriate labor or crew resource.
 - Right-click on the bar representing the work that you want to assign. Select Available Labor. In the Available Labor window, select the labor or crew resource that you want to assign the work to. Click OK.
4. Save the record.
To merge the assignments in the future, right-click on any segment of the assignment and select Merge Split Assignments.

Rescheduling assignments

In reviewing the weekly schedule for the organization, a maintenance planner sees that some work must be reassigned because of upcoming emergency work. The maintenance planner wants to leave a particular labor or crew resource available for the upcoming work.

Procedure

1. In the Graphical Assignments application, click the Assignment View tab. In the resource table, locate the labor or crew entry to make available for emergency work.
2. Drag the assignments that you want to reassign to another labor or crew resource. You can also reassign all the work assigned to a resource to a different day by selecting multiple records (Ctrl-click) and dragging them to a different day.
3. Save the record.

Assigning emergency work

You can check for emergency work in your organization and assign the work as it comes in. You can assign the work to available resources automatically or manually.

Procedure

1. In the Graphical Assignment application, from the Action menu, choose Define Emergency Work.
2. Enter a SQL WHERE clause to query for incoming work that qualifies as emergency work. Select Assign Automatically to assign the work to available resources automatically. Clear the Assign Automatically check box to choose from a list of available labor resources and assign the work yourself.
3. Select the frequency with which you want the query to run.
4. Click Submit to run the query immediately. Click Save to run it at the scheduled time.

Results

You can preview emergency work that matches your query in the Emergency Work Orders table window. You can see any assignments that were made.

If you chose not to automatically assign work, the Emergency Work Resource Availability window opens. From the list, select the resource that you want to assign the work to. For queries set to run in the future, email notifications are sent. You can also see a list of new emergency work by clicking View Available Resources for Emergency Work Orders on the Scheduler toolbar.

Whenever emergency work is added to a work list, travel time is recalculated by your map service provider.

Exporting assignment calendars

In the Graphical Assignment and Graphical Work Week applications, you can export the assignment calendars for resources to keep a separate record of them. You can download the resource calendars or send them in an email.

Before you begin

To send an assignment calendar in an email, you need to specify an email address on the person or crew record of the resource.

About this task

The calendar is exported into an .ICS file. You can export assignments for a single resource or a group of resources, and send them to your team to import into their external calendar applications.

Procedure

1. In the Graphical Assignment or Graphical Work Week application, open the work list that contains the assignments that you want to export.
2. In the Resource chart, right-click on the labor or crew record whose calendar you want to export.
3. Select Export to Calendar.
4. In the Export to Calendar window, in the Start Date field, enter the date that you want the exported calendar to start on.
5. In the Number of Days field, specify the length of the exported calendar, in days.
6. In the Method field, choose how you want to export the calendar, either by file download or email.
7. Click OK.

The calendar information is exported by using the delivery method that you selected.

Resource availability for assignments

You use the Assignment view in the Graphical Assignment and Graphical Assignment - Repair Facility applications to assign work to available resources.

Labor and crew availability

In the Graphical Assignment application, labor and crew resources that meet your query criteria are shown on the Assignment View tab. The tab shows their availability, as well as their craft and skill level.

Labor and crew availability are shown as follows:

- A white section on the calendar represents the working shift of the labor or crew resource. It also indicates any planned overtime.
- A light gray section on the calendar indicates that the labor or crew is not working during the shift.
- A dark gray section on the calendar indicates that the resource is assigned to other work that is not included in this work list.
- A light blue section on the calendar indicates that the labor or crew is unavailable for work during their regular shift due to modified availability, like sick or vacation time.

Repair facility availability

In the Graphical Assignment - Repair Facility application, facilities that meet your query criteria are shown on the Assignment View tab.

Repair facility availability is shown as follows:

- A white section on the calendar indicates available time.
- A light gray section on the calendar indicates unavailable time.
- A dark gray section on the calendar indicates that the facility is being used for other work that is not included in this work list.

Work assignments

Work assignments display in the Assignment view as follows:

- An orange bar indicates that the work requirement that is unassigned.
- A green bar indicates that the work is assigned to a labor or crew resource.
- A red bar indicates the labor or crew resource that you assigned the work to does not meet the craft and skill requirements of the work.

Graphical Assignment application

You assign work to labor and crews at your facility based on their skills and availability. In the Graphical Assignment application, you view upcoming work and assign the work graphically to the appropriate labor or crew resource, and respond to dynamic work situations.

On the Work List tab, you can create a list of scheduled work orders and the available labor and crews, and apply a street level route.

The graphical view consists of two tabs. On the Assignment View tab, you can review unassigned work and the resources that are available to do the work. You see the daily availability of your crews and technicians, including shifts and breaks, and exceptions such as sick leave and vacation time. You can access resource details, such as skill, rate, and certifications. You can also see current assignments and balance the workload. You can reassign work, or split work between resources or across shifts. In the Work View tab, you can see work details, such as assets and priority. You can also modify work details, such as status, work priority, and target start and end dates.

In the Dispatch view, you can see work and work routes in maps and calendars. These tools also provide a graphical view of the requirements, availability, and work assignments of labor and crews. You can use these tools to view detailed information about labor and crews to monitor their work progress more precisely in the short term, such as during a work shift.

In the Dispatch view, you can do the following tasks to respond more effectively to dynamic work situations:

- Sequence and assign work to labor and crews based on the priority, status, and locations of work orders
- Determine travel time between work orders

- Locate labor and crews using their mobile devices or global positioning system (GPS)

All assignment information can be saved to the associated work records.

- **[Creating work lists](#)**
You can create a list of upcoming work that needs to be assigned, and assign it to labor and crews based on their skills and availability. Work lists can be updated or deleted only by the user who created them. Use the Manage Commit Access action to control who can commit the work list back to the database.
- **[Dispatching work to crews and labor](#)**
You dispatch work to assign resources, such as labor resources or assets, to work orders. After you configure queries to define street-level routes, you dispatch labors and crews to unplanned work, such as when a labor is sick or for emergency work orders.

Creating work lists

You can create a list of upcoming work that needs to be assigned, and assign it to labor and crews based on their skills and availability. Work lists can be updated or deleted only by the user who created them. Use the Manage Commit Access action to control who can commit the work list back to the database.

Before you begin

You can set up shift patterns in the Calendars application to reflect rotating shifts. You can then pull the shift pattern into the work list to reflect the rotation.

Procedure

1. In the Graphical Assignments application, in the Work List tab, create a new work list.
2. Enter a name for the work list and specify calendar and shift information for when the work is to be performed.
3. If you want your project to automatically refresh at predefined intervals, select the Rolling Project? check box and define the frequency in the Roll Date Schedule field. For example, you want to refresh the work records in the schedule every day at 7:00 AM.
4. Enter start and end dates for the work list.
The Start Date and End Date control the work period calendar that shows in the graphical view. Enter a value in the Rolling Offset in Days field if you want to add days to both sides of the date range in the graphical view. You cannot move work segments outside the graphical view date range as calculated by these four fields.
5. You can filter the work query to include only work with a start or finish date between the schedule start and finish dates. This means that any work records without schedule dates is not included in the graphical view at all. To include only work within the schedule dates, select the Restrict Work to Dates? check box.
6. Create a work query based on the work records that you want to include in your work list.
7. In the Restrict Resource Availability section, you can restrict which labor and crew resources are available in the graphical view. For example, you may have 30 electricians, but you only want to include the ones in a particular work location in the schedule. You can choose from existing craft, labor, crew, or crew type queries, or create a new one. If you do not enter anything in this section, all resources for the calendar and shifts that you selected will be included.
8. Apply the street-level route, if applicable, and save the work list.

Dispatching work to crews and labor

You dispatch work to assign resources, such as labor resources or assets, to work orders. After you configure queries to define street-level routes, you dispatch labors and crews to unplanned work, such as when a labor is sick or for emergency work orders.

About this task

Work is planned several weeks ahead of time in the Graphical Scheduling application. Work is planned by coordinating new and unassigned work orders with the available resources, which can be individual labor resources or crews and their tools. Any shift breaks for crews are entered in the Calendar application.

Dispatching is required closer to the time of the scheduled work, when the dispatcher must manage unplanned scheduling issues. For example, an electrician is not available today due to illness. All of the work that is assigned to the electrician needs to be reassigned to another labor resource for the work to be completed today. Or an emergency work order needs to be completed within the next two hours.

The dispatcher needs to find a labor resource to replace the sick labor resource, create a route for the new labor resource, and then delete the street-level route of the sick labor resource. Then, the emergency work order must be located on a map to find a nearby crew or labor resource to do the unplanned work. The street-level route for the crew needs to be redrawn to include the emergency work order.

- **[Preparing to dispatch labor and crews](#)**
Before you dispatch labor or crews, you must create a list of scheduled work orders and apply a street-level route before dispatching labor and crew resources.
- **[Responding to labor and crew unavailability](#)**
You must be able to reassign work from absent labor and crew resources to other labor and crews so that work is completed on schedule. You must also update the street-level routes provided to the replacement labor and crews.
- **[Responding to emergency work](#)**
A dispatcher assigns labor and crews to emergency work. After the work order is created, the dispatcher views the location of the emergency work on a map and finds nearby labor or crews to it. Then street-level route is updated to include the emergency work.
- **[Geolocation of labor and crews](#)**
Geolocation uses various types of signals to approximate the location of a user. You can enable the geolocation of labor and crews so that you can view maps to monitor their work and route progress.

- [Street level route cron task](#)

The street level route cron task is scheduled to run daily on the system server. Cron tasks are behind-the-scene jobs that run automatically and on a fixed schedule.

- [Work zones](#)

You can divide a geographic area into smaller work zones and reduce travel time between work orders. Work is then assigned to resources based on the work zones that they are associated with.

Preparing to dispatch labor and crews

Before you dispatch labor or crews, you must create a list of scheduled work orders and apply a street-level route before dispatching labor and crew resources.

Procedure

1. In the Graphical Assignment application, on the Work List tab, complete the fields to create a work list.
2. Define a work query in the SQL Expression Builder to retrieve the relevant work and labor or crew records. For example, create the following query to find all open work orders that are scheduled for the next week:

Option	Description
Db2®	<code>((woclass = 'WORKORDER' or woclass = 'ACTIVITY') and historyflag = 0 and schedstart >= CURRENT_TIMESTAMP and schedstart <= (CURRENT_TIMESTAMP + 7 DAYS) and (status != 'COMP'))</code>
Microsoft SQL Server	<code>((woclass = 'WORKORDER' or woclass = 'ACTIVITY') and historyflag = 0 and schedstart >= GetDate() and schedstart <= GetDate()+7 and (status != 'COMP'))</code>
Oracle Database	<code>((woclass = 'WORKORDER' or woclass = 'ACTIVITY') and historyflag = 0 and schedstart >= sysdate and schedstart <= sysdate+7 and (status != 'COMP'))</code>

3. Filter by resources, such as labor and crews.
4. Apply the street-level route.

Responding to labor and crew unavailability

You must be able to reassign work from absent labor and crew resources to other labor and crews so that work is completed on schedule. You must also update the street-level routes provided to the replacement labor and crews.

Procedure

1. In the Graphical Assignment application, on the Dispatch View tab, view the work orders of the absent labor or crew resource on a map and on a calendar.
2. Click each work order on the map to view the work order details. Check which labor or crews can complete the work orders based on their location and skills.
3. Reassign the work to the most suitable labor or crews resource.
 - If a single labor or crew resource cannot complete all the work orders, then you must divide the work between several labor and crew resources. Assign each work order to the most suitable labor or crew resource.
 - If you can find one replacement to reassign all the work for that labor resource, you must create a street level route. Select the Apply Street Level Routes action, and specify the date of the work, the start and end location, and the labor or crews record.
4. Delete the street-level route for the absent labor or crew resource. From the Action menu, select Delete Street Level Routes, and specify the date of the absence, the labor record, and the start and end location for the work.

Responding to emergency work

A dispatcher assigns labor and crews to emergency work. After the work order is created, the dispatcher views the location of the emergency work on a map and finds nearby labor or crews to it. Then street-level route is updated to include the emergency work.

Before you begin

The emergency work order is created in the Work Order Tracking application.

Procedure

1. In the Graphical Assignment application, on the map on the Dispatching tab, select the icons to view the unassigned work orders and nearby labor and crews.
2. In the calendar, ensure that a nearby labor and crew resource has the availability and required skills for the work order.
3. On the map, select the work order and assign it to the labor or crew resource.

The street-level route for the crew is updated.

Geolocation of labor and crews

Geolocation uses various types of signals to approximate the location of a user. You can enable the geolocation of labor and crews so that you can view maps to monitor their work and route progress.

The following table describes the map geolocation symbols that might be associated with the labor and crews.

Table 1. Geolocation symbols

Symbol	Description
	Indicates that the location data was refreshed was less than an hour ago. You can change the interval time between date refreshes in the <code>mxe.lbs.lastupdate.tolerance</code> system property.
	Indicates that the location data was refreshed was over an hour ago.
	Indicates that the location of the labor or crews is estimated to be outside of the defined radius. You can change the radius in the <code>mxe.lbs.maximumAccuracy</code> system property.
	Indicates the accuracy of the geolocation of the labor and crews. The smaller the radius, the more accurate the geolocation. If the accuracy is less than 2000 meters, then the image is not displayed.

Street level route cron task

The street level route cron task is scheduled to run daily on the system server. Cron tasks are behind-the-scene jobs that run automatically and on a fixed schedule.

The SLROUTECLEANUP cron task deletes street level routes that were scheduled for dates two or more days in the past. For example, on the 11th November, 2012 all street level routes from the 9th November, 2012 or before, are deleted. The SLROUTECLEANUP cron task runs every day at 12 am.

Work zones

You can divide a geographic area into smaller work zones and reduce travel time between work orders. Work is then assigned to resources based on the work zones that they are associated with.

You create a work zone in the Work Zone application. You choose a work zone type for the work zone, for example, WATER, to indicate the utility category for that zone. You can then assign specific labor resources, crews, assets, and locations to that work zone, ensuring that all work that must be completed in that area is assigned appropriately. A specific geographic location can be in multiple work zones. Depending on the type of work that is required, different resources are assigned the work.

For example, a city block might be in electrical work zone A, but in water zone 3, and sewer zone SEW1. Electrical crew EL1 might respond to electrical outages, while water crew W46 responds to water maintenance needs.

You can assign crews and labor to specific work zones, so that they are assigned work that occurs in that zone. You can assign a crew or labor record can be assigned to multiple work zones, but each record has only one default work zone.

Graphical Assignments - Repair Facility application

In the Graphical Assignments - Repair Facility application, you can assign work directly to your facilities based on their availability. For example, you can assign work directly to an aircraft hangar.

In the Assignment view, you review a list of all the facilities within a location. You can review when they are available for work and plan accordingly.

On the Work List tab, you can create a list of scheduled work orders and the available labor and crews for your repair facility.

The graphical view consists of two tabs. On the Assignment View tab, you can review unassigned work and the facilities available to do the work. You can review current assignments in your repair facilities and balance the workload. On the Work View tab, you can review work details, such as assets and priority. You can also modify work details, such as status, work priority, and target start and end dates.

All assignment information can be saved to the associated work records.

- [Repair facilities](#)
A repair facility is a facility where assets are brought for maintenance. You can assign work to resources that are associated with the repair facility, or to the repair facility itself.
- [Creating work lists](#)
You can create a list of upcoming work that needs to be assigned, and assign it to repair facilities based on their availability. Work lists can be updated or deleted only by the user who created them. Use the Manage Commit Access action to control who can commit the work list back to the database.
- [Assigning work to repair facilities](#)
You use the Assignment view to assign upcoming work to repair facilities based on their availability.
- [Asset availability in repair facilities](#)
You can view the availability of assets, items, and tools that are required for work in the Work View tab.

Repair facilities

A repair facility is a facility where assets are brought for maintenance. You can assign work to resources that are associated with the repair facility, or to the repair facility itself.

A repair facility can take many forms, including automotive bays, aircraft hangars, and workshops. Planning for these facilities is done for short time periods when work emerges or becomes due simultaneously. For example, you might schedule work for a repair facility for two weeks in advance.

Creating work lists

You can create a list of upcoming work that needs to be assigned, and assign it to repair facilities based on their availability. Work lists can be updated or deleted only by the user who created them. Use the Manage Commit Access action to control who can commit the work list back to the database.

Procedure

1. In the Graphical Assignment - Repair Facility application, on the Work List tab, create a new work list.
2. Enter a name for the work list and specify calendar and shift information for when the work is to be performed.
3. Specify a repair facility.
4. Create a query based on the work records that you want to include in your work list. Resources that are required to complete the work are included in the Assignment view.
Facilities that match your repair facility are listed.

Assigning work to repair facilities

You use the Assignment view to assign upcoming work to repair facilities based on their availability.

About this task

The Assignment view displays the availability of your repair facilities. Unavailable time appears in the Gantt view as a shaded area on the resource table.

Procedure

1. On the Assignment View tab, select the work record that you want to assign. An orange bar represents unassigned work. You can assign work by using one of the following methods:
 - Drag the work record to the resource that you want to assign it to in the resource chart.
 - Right-click on the bar representing the work that you want to assign. Select Available Location. In the Available Location window, select the labor or crew resource that you want to assign the work to. Click OK.When work is properly assigned, the bar that represents the assigned work is green. If you selected a resource that does not match the work requirements, the bar is red.
If an appointment is required (in the work record application), an icon indicates that an appointment has not been made. Right-click on the assignment and choose Lock to set the appointment. Appointments that are locked cannot be rescheduled due to optimization or manual edits. To change the scheduled time manually, right-click on it and choose Unlock.
2. Save the work list.

Asset availability in repair facilities

You can view the availability of assets, items, and tools that are required for work in the Work View tab.

Assets, items, and tools that are required for work are available in the Other Resource Availability window. Right-click on a work record in the Work View tab to see the availability of resources required for the work.

Asset availability is displayed based on operating and maintenance schedules, and the appropriate asset calendar. The availability displays as follows:

- An orange bar shows the calendar for the site of the asset.
- A green bar shows the maintenance schedule for the asset. It is the best time to schedule work.
- A red bar shows the operational schedule for the asset, when it is unavailable for maintenance.

Item and tool availability are shown in the following way:

- A green bar indicates that the item or tool is available during the scheduled work time.
- An orange bar indicates one of the following:
 - If the work record is in WAPPR status, it indicates that the item or tool is partially available, and can be reserved.
 - If the work record is not in WAPPR status, it indicates that a soft reservation has been made for this tool or item.
- A red bar indicates that the item or tool is unavailable during the scheduled work time.

Tool and item availability show only for the task selected in the work view. You cannot view item and tool availability for multiple tasks at the same time.

Other resource availability appears for the date or the work record, plus 7 days in the future. You can change the calendar view to span different days using right-click options.

- [Checking asset availability in repair facilities](#)

A maintenance planner needs to reschedule assignments based on changes in asset availability.

Checking asset availability in repair facilities

A maintenance planner needs to reschedule assignments based on changes in asset availability.

About this task

In reviewing the schedule for the organization, a maintenance planner notices that an asset that is scheduled to be worked on is not available for maintenance. The operating schedule for the asset was modified, and now conflicts with the scheduled work.

Procedure

1. In the Work View tab of the Graphical Assignments application, locate the correct date in the resource chart.
2. In the Activity table on the left of the chart, select the appropriate work record. Right-click and select Other Resources Availability . The asset availability displays.

What to do next

You can also check item and tool availability in the Other Resources Availability window.

Managing short term work

You can manage work in one week increments by using the Graphical Work Week application.

- [Graphical Work Week application](#)
You use the Graphical Work Week application to schedule and assign work while you manage resources over a short period of time.

Graphical Work Week application

You use the Graphical Work Week application to schedule and assign work while you manage resources over a short period of time.

In the Graphical Work Week application, you can schedule and assign work to resources. The graphical view displays scheduled work time and shift hours in one week increments. You can scroll forward and backward one week at a time between the start and end dates that you define on the Work tab.

All assignments and work records without assignments are included in the graphical view, without a hierarchy structure. For work records without assignments, you can create assignment records and assign them to resources.

- [Creating work lists in the Graphical Work Week application](#)
You can create a list of upcoming work that needs to be assigned, and assign it to labor and crews based on their skills and availability.
- [Modifying availability in the Graphical Work Week application](#)
You can modify the availability of resources in the graphical view of the Graphical Work Week application.
- [Balancing resource loads and assigning work](#)
In the Graphical Work Week application, you can reschedule and assign work to balance your resources and workload.

Creating work lists in the Graphical Work Week application

You can create a list of upcoming work that needs to be assigned, and assign it to labor and crews based on their skills and availability.

Before you begin

You can set up shift patterns in the Calendars application to reflect rotating shifts. You can then include the shift pattern into the work list to reflect the rotation. For more information, see [Shift patterns for calendars](#).

Procedure

1. In the Graphical Work Week application, on the Work List tab, create a new work list.
2. Enter a name for the work list and specify calendar and shift information for when the work is to be performed.
3. If you want your work list to automatically refresh at predefined intervals, select the Rolling schedule check box. You set up the rolling schedule by selecting Roll Schedule from the Actions menu. For example, you want to refresh the work records in the schedule every day at 7:00 AM.
4. Enter start and end dates for the work list.
The start and end dates control the work period calendar that is shown in the graphical view. Including an extra week beyond your current scheduling plans allows for room to move work out a week in the graphical view.

If you want to add days to both sides of the date range in the graphical view, you can enter value in the Rolling Offset in Days field in the Roll Schedule window. You cannot move work segments outside the graphical view date range as calculated by these fields.

5. Create a work query that is based on the work records that you want to include in your work list. If you want to include all work that is scheduled between the start and end dates of your work list, you can leave this field blank.

Any work records without scheduled dates are not included in the graphical view.

- To include work without scheduled dates, select the Include Work Orders Without Dates check box. Scheduled start dates are automatically created in the Work Order Tracking application for these records.
 - To include work only within the schedule dates, clear the Include Work Orders Without Dates check box.
6. In the Restrict Resource Availability section, restrict which labor and crew resources are available in the graphical view. For example, you might have 30 electricians, but you want to include only the ones in a particular work location in the schedule. You can choose from existing craft, labor, crew, or crew type queries or create a new one. If you do not enter anything, all resources for the calendar and shifts that you selected are included.
 7. Optional: Use the actions that are available in the More Actions menu to create a work list that is based on an existing work list or schedule in the Graphical Assignment or Graphical Scheduling application.

Modifying availability in the Graphical Work Week application

You can modify the availability of resources in the graphical view of the Graphical Work Week application.

About this task

The reason codes that are displayed in the graphical view of the Graphical Work Week application are defined in the Domains application. You can add new reason codes as necessary in the RSNCODE domain.

The colors that are used in the graphical view are defined by system properties. For more information, see [Graphical view customization](#).

Procedure

1. In the Resource chart of the graphical view, select the reason for modifying availability from the Reason Code menu in the toolbar.
2. From the Availability Type menu, select the length of time that you want to modify availability for. For example, you can modify availability for a full day, a partial day, or a full week.
If you select Partial, enter values in the Start Time and End Date fields in the Modify Availability window.
3. To modify the availability of a single resource, double-click the date cell that corresponds with the resource and the date that you want to modify availability for.
To modify the availability of multiple resources, select the check boxes at the beginning of each resource row that you want to apply the modified availability to. In one of the selected rows, double-click the date cell that you want to modify availability on.
The modified availability is shown in the graphical view, and the changes are saved back to the person or crew record. If a resource has multiple modifications for the same day, an indicator appears in the corner of the date cell. To see details about the modifications, right-click on the resource in the resource table and select Modify Person Availability. In the Modify Person Availability window, scroll to the Modify Work Dates table.

Balancing resource loads and assigning work

In the Graphical Work Week application, you can reschedule and assign work to balance your resources and workload.

About this task

In this example, you created a work list in the Graphical Work Week application that includes all scheduled work and resources for the day shift for this week (Work List XYZ). In the graphical view, you can see that you have too much work scheduled for Monday that requires first class electricians. Your total workload for Monday shows 56 hours of electrical work that requires first-class electricians. However, your total labor hours for electricians on Monday is 40 hours (five labor resources at 8 hours each). You need to move some of the work to next week, and then assign all the work to available resources.

Procedure

1. In the Graphical Work Week application, open the graphical view for work list XYZ.
2. Scroll to the Resource chart at the bottom of the page.
You notice that the Electrician-First Class entry for Monday is displayed in red, which indicates that more work is scheduled than you have resources to complete it. The text in red reads 56:00/40.00, which indicates that you are over scheduled by 16 hours (56 hours are scheduled out of 40 available hours).
3. In the Resource chart, select the row for Electrician-First Class. Click the Filter Work Orders Based on the Selected Resources button.
The Activity table filters the work records to show the electrical work.
4. Select the check boxes for multiple work records to reschedule. You can also draw a border around the work in the Activity chart, or use Shift-click to select multiple records.
5. Right-click on the segments and select Set to Day. Choose a date next week to schedule the work.
To be able to schedule the work next week, those dates must be included in the schedule on the Work tab.
If the work records have date constraints (Start No Earlier Than or Finish No Later Than dates), the constraints appear in the Activity chart, on either side of the work segment .
6. Scroll down to the Resource chart and check your load balance.
7. Repeat steps 3-6 until all load balances appear blue.

What to do next

Assign work to resources.

1. In the Activity chart of the graphical view, select the work segment that you want to assign.
2. In the Resource chart, double-click the date cell for the labor or crew resource that you want to assign the work to.

If all of the selected work (or work that has a long duration) cannot fit into a single shift, it is automatically split between days for that resource.

Assignment records are automatically saved to the database. If the `mxe.skd.syncwodataes` property is set to 1, work order changes are also saved back to the work records. The schedule start and end dates are updated to match the new assignments.

Managing resources

You can manage your resources in the Graphical Resource View application in order to see all resource availability and assignments in a single view.

- [Graphical Resource View application](#)
You use the Graphical Resource View application to manage resource hours over a period of time. You can choose to see one week or one month at a time.

Graphical Resource View application

You use the Graphical Resource View application to manage resource hours over a period of time. You can choose to see one week or one month at a time.

In the graphical view, you can see scheduled work time per shift, as well as modified availability in a single view. You can see total resource hours by craft, and you can also access assignment records.

You can enter new availability modifications, and see modified availability totals by resource. You can also see rotating shift patterns, which are defined in the Calendars application.

- [Creating resource lists](#)
You can create a resource list to see the availability of all required resources in a particular week.
- [Modifying availability in the Graphical Resources View application](#)
You can modify the availability of resources in the graphical view of the Graphical Resources View application.

Creating resource lists

You can create a resource list to see the availability of all required resources in a particular week.

Before you begin

You can set up shift patterns in the Calendars application to reflect rotating shifts. You can then include the shift pattern into the resource list to reflect the rotation. For more information, see [Shift patterns for calendars](#).

Procedure

1. In the Graphical Resource View application, on the Resource List tab, create a new resource list.
2. Enter a name for the resource list and specify calendar and shift information for when the work is to be performed. A maximum of five shifts is allowed.
3. Select the Show Labor in Resource Chart Check box to include labor records in your resource list. Select the Show Crews in Resource Chart? check box to include crews.
4. Optional: In the Restrict Resource Availability section, restrict which labor and crew resources are available in the graphical view. For example, you might have 30 electricians, but you want to include only the ones in a particular work location in the schedule. You can choose from existing craft, labor, crew, or crew type queries, or create a new one. If you do not enter anything, then all resources for the calendar and shifts that you selected are included.

Modifying availability in the Graphical Resources View application

You can modify the availability of resources in the graphical view of the Graphical Resources View application.

About this task

The reason codes that are displayed in the graphical view of the Graphical Resources View application are defined in the Domains application. You can add new reason codes as necessary in the RSNCODE domain.

The colors that are used in the graphical view are defined by system properties. For more information, see [Graphical view customization](#).

Procedure

1. In the toolbar of the graphical view, select the reason for modifying availability from the Reason Code menu.
2. From the Availability Type menu, select the length of time that you want to modify availability for. For example, you can modify availability for a full day, a partial day, or a full week.
If you select Partial, enter values in the Start Time and End Date fields in the Modify Availability window.
3. To modify the availability of a single resource, double-click the date cell that corresponds with the resource and the date that you want to modify availability for.
To modify the availability of multiple resources, select the check boxes at the beginning of each resource row that you want to apply the modified availability to. In one of the selected rows, double-click the date cell that you want to modify availability on.
The modified availability is shown in the graphical view, and the changes are saved back to the person or crew record. If a resource has multiple modifications that are scheduled for the same day, an indicator appears in the corner of the date cell. To see details about the modifications, right-click on the resource in the resource table and select Modify Person Availability. In the Modify Person Availability window, scroll to the Modify Work Dates table.

Managing crews graphically

You can manage the labor and assets that are assigned to positions in crews visually by using the Graphical Crew Management application.

You can view crews and their details, including assigned labor and assets. You can also see whether all qualifications and requirements for the crew are met. You can modify crew assignments as necessary, and update the labor, asset, and crew records in the background.

- **[Resources in the Graphical Crew Management application](#)**
You assign labor and assets to crews in the Graphical Crew Management application.
- **[Creating crew lists](#)**
You create a list of crews so that you can view the resources that are assigned to crews. You can then make daily adjustments as necessary. Crew lists can be updated or deleted only by the user who created them.
- **[Adjusting crew assignments](#)**
As a dispatcher, you often must adjust the daily assignments of your crews based on changes in the availability of your resources. For example, if a driver is sick, you must assign a new driver to that crew for that day. You can perform this daily shuffle by using the Assignments tab of the Graphical Crew Management application.

Resources in the Graphical Crew Management application

You assign labor and assets to crews in the Graphical Crew Management application.

The Gantt view consists of two tabs. On the Crew View tab, you can see crew requirements, status, craft/skill information of resources, and whether the crews have been properly configured.

On the Assignments tab, you can view resources available for crew assignment and make the assignments. You see the daily availability of your crews and technicians, including shifts and breaks, and exceptions such as sick leave and vacation time. You can access resource details, such as skill, rate, and certifications. You can also see current assignments.

Labor and assets that match the query that you ran are shown in the Assignments tab.

Labor availability

Labor availability is shown as follows:

- A white section on the calendar indicates that the labor resource is available during the shift.
- A light gray section on the calendar indicates that the labor resource is unavailable for work during the shift.
- A dark gray section on the calendar indicates an existing work order or crew assignment that is not included in the schedule.
- A light blue section on the calendar indicates that the labor resource is unavailable due to modified availability, like sick or vacation time.

Asset assignments

A light blue section on the calendar indicates an existing work order or crew assignment for an asset.

Crew assignments

The crew assignments display in the Assignments tab as follows:

- A green bar indicates that the crew requirements are met.
- An orange bar indicates that the crew has outstanding requirements.
- A yellow bar indicates that the crew's assigned labor and assets do not meet all requirements or qualifications for the crew. If the labor or asset record is yellow in the resource chart, a requirement was not met. For example, your work requires a first class mechanic, and you assigned a second class mechanic. If the crew record in the resource chart is yellow, a crew qualification was not met. For example, the crew is required to have one member with CPR training and no one assigned to the crew does. You can right-click on the crew resource and select Crew Assignment Status to determine the problem.

Creating crew lists

You create a list of crews so that you can view the resources that are assigned to crews. You can then make daily adjustments as necessary. Crew lists can be updated or deleted only by the user who created them.

Procedure

1. In the Graphical Crew Management application, in the Crew List tab, create a new crew list.
2. Enter a name for the crew list and specify calendar and shift information for when the crew is needed. The labor and crew resources that work during those shifts are shown in the Gantt view.
3. Enter the start date that you want to assign crew requirements on. If you do not enter a date, the graphical view shows today's date.
4. In the queries table windows, create queries to define the crew and resource information that you want to see. The available labor and asset resources that match the crew requirements show in the resource table in the graphical view.
5. Save the crew list.

Results

On the Assignments tab, you can see the list of resources by type (labor/craft and tool type/asset). You can assign labor resources and assets to crews in the Crew View tab or in the Crews application. Changes that are made in both places appear when you refresh the graphical view.

On the Crew View tab, crews that have all crew requirements met are green. Crews that have outstanding assignments are orange. Crews with assigned labor and assets that do not meet all requirements or qualifications for the crew are yellow. For example, your work requires a first class mechanic, and you assigned a second class mechanic. If the crew record in the crew requirements chart is yellow, a crew qualification was not met. For example, the crew is required to have one member with CPR training and no one assigned to the crew does. You can right-click on the crew in the crew requirements table and select Crew Assignment Status to determine the problem.

Adjusting crew assignments

As a dispatcher, you often must adjust the daily assignments of your crews based on changes in the availability of your resources. For example, if a driver is sick, you must assign a new driver to that crew for that day. You can perform this daily shuffle by using the Assignments tab of the Graphical Crew Management application.

About this task

On the Assignments tab, you can assign labor and assets to crews for any single day.

Procedure

1. In the Graphical Crew Management application, on the Crew List tab, display the crew list whose assignments you want to adjust. Enter the start date that you want to assign crew requirements on. If you do not enter a date, the graphical view shows today's date.
2. On the Crew View tab, review the status of the crew list for the start date specified in step 1. An orange crew bar signifies an open requirement.
3. Expand the crew to find out which position or positions have open requirements, for example, CREW1/LEADER/ELECTRICIAN. Check the skill level.
4. On the Assignments tab, open the corresponding list of resources, for example, ELECTRICIAN. Select the requirement in the header row and drag it to a resource that is available and has a matching skill level, or right-click on the requirement and choose Create Assignment.
 - When the requirement is assigned, you can split the assignment into two segments and assign each segment to a different resource. Right-click on the requirement in the Resource chart and choose Split Work.
5. Crews with assigned labor and assets that do not meet all requirements or qualifications for the crew are yellow. Reassign requirements as necessary. Drag the requirement to the appropriate resource. When all requirements are met and qualifications are satisfied, the bar is green.
 - To reassign resources for multiple days, right-click on the crew name in the Crew Requirements table and select Adjust Crew Assignments.
6. Save the crew list.

Validating data

You can validate the data in your schedules and work lists in the Scheduler Data Manager application.

- **[Scheduler Data Manager application](#)**
By using the Scheduler Data Manager application to validate a schedule or work list's data before scheduling or assigning work, you can ensure that data best practices are followed.

Scheduler Data Manager application

By using the Scheduler Data Manager application to validate a schedule or work list's data before scheduling or assigning work, you can ensure that data best practices are followed.

You can access the application from the Administration application menu, or from within the following applications:

- Graphical Scheduling
- Graphical Scheduling - Large Projects
- Graphical Assignment

- Graphical Work Week

Sometimes, data that is valid in an IBM® Maximo® Asset Management environment might not be conducive to scheduling. For example, the following work records might cause scheduling issues:

- Work records that have no planned labor.
- Work records that have a schedule window, like a Start No Earlier Than or Finish No Later Than date, that is in the past or outside the schedule calendar.
- Work records that have planned labor requirements that do not match your schedule. For example, the work requires three electricians, but your schedule only has access to two.

By validating the data in a schedule, you ensure that the included work records have better scheduling results. When a violation is found you can take corrective action in the Schedule Data Manager application to update the work record and correct the error.

Only work records can be validated by the Schedule Data Manager application. Preventive maintenance records are not evaluated.

- [Validating schedule data](#)
You can validate the work record data contained in your schedule to adhere to best practices for scheduling. Validation can be run on work, dependencies, and required resources for all work records included in the schedule.
- [Troubleshooting data validations](#)
The Scheduler Data Manager application validates the data that you include in your schedules and work lists. When errors are found in the data that is included, you can make corrections or exclusions as needed.

Validating schedule data

You can validate the work record data contained in your schedule to adhere to best practices for scheduling. Validation can be run on work, dependencies, and required resources for all work records included in the schedule.

About this task

You can access the Scheduler Data Manager application directly in the following applications:

- Graphical Scheduling
- Graphical Scheduling - Large Projects
- Graphical Assignment
- Graphical Work Week

You can navigate to the Scheduler Data Manager application by clicking the detail menu for the schedule or work list name, or by navigating to it through the Go To menu. If you access the application through the Go To menu, use the List tab to select the schedule or work list to validate.

Procedure

1. In the Scheduler Data Manager application, select the schedule or work list whose data you want to run validation on. The Schedule tab displays read-only information that is copied from the Maximo® Asset Manager Scheduler applications. The one exception is the Duration Threshold field, which you can edit on the Schedule tab.
2. On the Work tab, select the check boxes for the validations that you want the process to check. You can select any combination of options.
3. Click Validate Work. A notification window displays the status of the validation progress. Click OK to close the window.
You can monitor the progress of validation jobs by selecting Show Validation Jobs from the More Actions menu.
When validation is complete, all work rows that are contained in the schedule are displayed in the work record table. Key data about the work, including duration, priority, and restraint dates is included.
4. Review any errors or warnings that the validation process found for each work record. You can select the Show Errors/Warnings Only check box to narrow your results. You can also filter for specific errors and warnings in the Filter By Error/Warning field. To correct violations, you can update work data directly in the table, or by clicking the icons next to the error or warning. Changes that you make are saved in the work records. You must refresh the schedules in order to see the changes.
5. Repeat steps 2 through 4 on the additional tabs to validate the following:

Tab	Validations
Calendar	Calendar information
Queries	Work and resource queries
Dependencies	Work record dependencies
Resources	Required resources
Assignments	Assignment data

The tabs that are visible in the Scheduler Data Manager application depend on which application you are validating data from.

Troubleshooting data validations

The Scheduler Data Manager application validates the data that you include in your schedules and work lists. When errors are found in the data that is included, you can make corrections or exclusions as needed.

You use the Scheduler Data Manager application to test your data for scheduling and assignment best practices. You can check your data before you view it in the graphical view, or at any time to catch and change any potential problems. The application looks at the key data components of the schedule or work list, specifically the following items:

- Calendar
- Queries
- Work
- Dependencies
- Assignments
- Resources

Table 1. Example: Key indicators (partial list)

Tab	Parameters
Calendar	<ul style="list-style-type: none"> • Does the calendar cover the entire schedule? • Are there work periods for the shifts defined? • Are the shift patterns sequential and named?
Queries	<ul style="list-style-type: none"> • Does the SQL clause affect performance? • Does the clause retrieve a reasonably sized data set?
Work	<ul style="list-style-type: none"> • Do the work orders have defined durations? • Does non-interruptible work exceed the shift length? • Do work orders have work plans? • Is work prioritized? • Do work plans have resource quantities that exceed availability?
Dependencies	<ul style="list-style-type: none"> • Are the precedence relationships between work records and tasks non-circular? • Are they affected by work status or actual dates?
Resources	<ul style="list-style-type: none"> • Are crafts, crews, and rotating tools available in a sufficient quantity to be able to schedule work at a specific point in the schedule?

For each category, click Validate, review the data rows in the table, and review any errors or warnings. In many cases you can fix the issue in the table, which updates the associated records and improves your schedule.

For larger or rolling schedules, consider running validation through a scheduled a cron task, so you can review the results regularly.

- [Calendar validations](#)
You can validate the calendar that your schedules and work lists use and troubleshoot the results.
- [Query validations](#)
You can validate the queries that your schedules and work lists use and troubleshoot the results.
- [Work validations](#)
You can validate the work that your schedules and work lists include and troubleshoot the results.
- [Dependency validations](#)
You can validate the work dependencies that your schedules and work lists use and troubleshoot the results.
- [Assignment validations](#)
You can validate the assignments in your work lists and troubleshoot the results.
- [Resource validations](#)
You can validate the resources that your schedules and work lists use and troubleshoot the results.

Calendar validations

You can validate the calendar that your schedules and work lists use and troubleshoot the results.

Table 1. Calendar/shift validations

Field	Validation	Level	Warning/Error	Solution
Schedule	Too many shifts can affect performance in the graphical view.	Schedule	W – nn shifts are selected. Performance can be affected when the number of shifts for a schedule is greater than four.	Go to the schedule or work list application and edit the shifts.
Work Periods	All shifts require work periods that span the schedule start and end dates.	Shift	E – Shifts must be applied for the entire span of the schedule.	Go to the Calendars application and select Define/Apply Shifts.
Work Periods	Shifts must be applied on the calendar.	Shift	E – Work periods do not exist for the shift.	Go to the Calendars application and select Define/Apply Shifts.
Shift Pattern	The shift is too short or too long, or pattern days overlap.	Shift	W - Shifts cannot be less than 2 hours or greater than 13 hours for labor and crews.	Go to the Calendars application and redefine the shift pattern.
Schedule	The end date of the schedule is before or the same as the end date of the calendar.	Schedule	E – The calendar start and end dates do not align with the schedule start and end dates.	Go to the Calendars application and update the calendar start and end dates.
Shift Pattern	Check the shift pattern definition for overlapping times. For example, day one is from 11 PM to 7 AM and day two is 6 a.m. to 2 PM.	Shift	E – Pattern day 1 and day 2 times overlap.	Go to the Calendars application and select Define/Apply Non-Working Time.

Field	Validation	Level	Warning/Error	Solution
Shift Pattern	Pattern day name	Shift	W – Pattern day name was not provided. “W” will be displayed in the graphical resource view for all working days.	Go to the Calendars application and select Define/Apply Nonworking Time.

Query validations

You can validate the queries that your schedules and work lists use and troubleshoot the results.

Validations can be run on the following query types:

- Work
- Asset
- Location
- Resources
- Additional resources

Table 1. Query validations

Field	Validation	Object/Type	Warning/Error	Solution
SQL Best Practices	Dates in query (schedule dates/target dates)	WORKORDER/WOACTIVITY	W – Consider using restrict work to dates.	Return to the schedule and modify the query.
SQL Best Practices	%xxx%	All	W – %xxx% contains queries that might cause performance issues.	Return to the schedule and modify the query.
SQL Best Practices	Is task	WORKORDER/WOACTIVITY	W – Istask is added by Maximo® Asset Manager Scheduler. If it is included in the query, it can affect performance.	Return to the schedule and modify the query.
SQL Best Practices	History	WORKORDER/WOACTIVITY	W – History is added by Maximo Asset Manager Scheduler. If it is included in the query, it can affect performance.	Return to the schedule and modify the query.
Records	Number of work records if using the Graphical Scheduling application and count is greater than 3000 records and less than 5000 records.	WORKORDER/WOACTIVITY	W – Consider using the Graphical Scheduling-Large Projects application for schedules of this size.	In the Graphical Scheduling-Large Projects application, choose the Create Schedule from Graphical Scheduling application action.
Records	Number of work records if using the Graphical Scheduling application and count is greater than 5000 records.	WORKORDER/WOACTIVITY	E – Use the Graphical Scheduling-Large Projects application for a record count of <i>nnnn</i> .	In the Graphical Scheduling-Large Projects application, choose the Create Schedule from Graphical Scheduling application action.
Records	Number of work records if using the Graphical Assignment or Graphical Work Week application and count is greater than 500 records.	WORKORDER/WOACTIVITY WORKORDER/ASSIGNMENTS	W – Consider breaking the work list into multiple work lists in order to match work and resources.	Make changes in the Graphical Assignments or Graphical Work Week application.

Work validations

You can validate the work that your schedules and work lists include and troubleshoot the results.

Table 1. Work validations

Validation	Warning/Error	Solution
A task or work order with no children has 0 duration.	W – 0 duration for planned work.	Modify the value in Duration field.
Interruptible work has a specified shift that is not included in the schedule.	W – The interruptible shift selected is not included in this schedule.	Modify the value in the Interruptible field by using the Select Value icon.
The Start No Earlier Than date plus the duration is greater than or equal to the schedule end date.	E – This work cannot be successfully scheduled with the current Start No Earlier Than date.	Modify the Start No Earlier Than date.
The Finish No Later Than date minus the duration is less than or equal to the schedule start date.	E – This work cannot be successfully scheduled with the current Finish No Later Than date.	Modify the Finish No Later Than date.
The location assignment dates do not fall within the schedule dates.	E – Location assignment exists outside of schedule dates.	In the Work Order Tracking application, open the parent work record and change the assignment.
The location assignment is shorter than the parent work order duration.	E – Location assignment is not long enough to complete all work in this work package.	In the Work Order Tracking application, open the parent work record and change the assignment.

Validation	Warning/Error	Solution
Bottom level work records and operations do not have planned resources (craft, crew type, tool)	W – There are no required resources to determine schedule dates.	In the Work Order Tracking application, adjust the planned labor.
Craft: A single work record or operation has a planned craft quantity greater than the available craft quantity on any shift	E – Work cannot be scheduled without enough resources in a single shift.	In the Work Order Tracking application, adjust the planned labor or the resources.
Crew Types: A single work record or operation has a planned crew type quantity greater than the available crew type quantity on any shift.	E – Work cannot be scheduled without enough resources in a single shift.	In the Work Order Tracking application, adjust the planned labor or the resources.
Rotating Tools: A single work record or operation has a planned tool quantity greater than the available tool quantity.	E – Work cannot be scheduled without enough resources.	In the Work Order Tracking application, adjust the planned labor or the resources.
Planned labor exists on the parent work order when planned labor also exists at the task level.	W – Labor can be planned at the task or work record level, but not both.	In the Work Order Tracking application, adjust the planned labor or the resources.
Duration is negative or over the threshold of 24*100 (quantity*duration).	E – Duration is negative or unreasonably high.	Modify the value in Duration field.
Task is missing a parent work record.	E – Tasks must have a parent work record.	In the Activities and Tasks application, add a parent work record.
Work record does not have a priority.	W – Work records must have a priority.	Modify the value in Priority field.

Dependency validations

You can validate the work dependencies that your schedules and work lists use and troubleshoot the results.

Table 1. Dependency validations

Validation	Error	Solution
Circular dependency.	E – You cannot have a circular dependency.	Modify the dates in the Edit Constraints window.
Actual dates break the dependency.	E – Actual dates break the dependency.	Modify the dates in the Edit Constraints window, or modify the actuals in the Work Order Tracking application.
Dependency Lead/Lag incorrect – lag time is longer than the threshold 24*100 (quantity*duration).	E – Dependency lead/lag time is too long.	Modify the dates in the Edit Constraints window.
Dependency missing target.	E – The dependency target is missing.	Delete the constraint.
Dependency missing origin.	E – The dependency origin is missing.	Delete the constraint.

Assignment validations

You can validate the assignments in your work lists and troubleshoot the results.

The tabs that are visible in the Scheduler Data Manager application depend on which application you are validating data from. The Assignments tab is only available when validating work lists from the Graphical Assignment and Graphical Work Week applications.

Table 1. Assignment validations

Field	Validation	Warning/Error	Solution
Hours	Assignment hours are longer than the work record hours.	W – Assignment hours are longer than the work order or task duration.	In the Work Order Tracking application, modify the assignment hours.
Schedule Date	The schedule date of the assignment is different from the work record.	W – Work record schedule date does not include the assignment start or end date.	In the Work Order Tracking application, modify the assignment hours or start date.
Craft/Crew Type	Required craft and skill level or crew type is not available on shifts in the work list.	E – Cannot assign craft %xxx% for shifts in work list.	In the Work Order Tracking application, modify the craft, skill level, or crew type.
Work Zone	A work zone exists on the assignment when no labor or crews with that value exist.	E – Cannot assign for work zone %xxx%.	Modify the work zone in the Work Order Tracking, Labor, or Crews applications.
Crew Work Group	A required work plan does not match the assignment.	W - Work Plan required %xxx% craft or crew, but was signed to %yyy% craft or crew.	Modify the labor using the Available Labor icon.
Crew Work Group	A crew work group appears on the assignment when no labor or crews with that value exist.	E – Cannot assign for crew work group %xxx%.	Modify the crew work group.

Resource validations

You can validate the resources that your schedules and work lists use and troubleshoot the results.

The tabs that are visible in the Scheduler Data Manager application depend on which application you are validating data from. The Resources tab is only available when validating schedules from the Graphical Scheduling applications.

Table 1. Resource validations

Validation	Error	Solution
Craft: The total number of planned craft hours exceeds all available craft in all shifts.	E – All work cannot be scheduled with the limited number of resources.	Modify the craft hours in the Scheduling Alternate Resources application.
Crew types: The total number of planned crew type hours exceeds all available crew type in all shifts.	E – All work cannot be scheduled with the limited number of resources.	Modify the crew type hours in the Scheduling Alternate Resources application.
Rotating tools: The total number of planned tool hours exceeds all available rotating assets.	E – All work cannot be scheduled with the limited number of resources.	Modify the tool hours in the Scheduling Alternate Resources application.

Managing appointment books

You can create and manage appointment books for customer service representatives to use when they schedule customer appointments.

- [Appointment Book Manager application](#)
In the Appointment Book Manager application, you can create and update appointment books for customer service representatives to use when they schedule customer appointments.
- [Graphical Appointment Book application](#)
You use the Graphical Appointment Book application to schedule appointments in appointment windows that you defined in the Appointment Book Manager application.

Appointment Book Manager application

In the Appointment Book Manager application, you can create and update appointment books for customer service representatives to use when they schedule customer appointments.

An *appointment book* is a calendar view of the daily time slots in which an appointment for on-premise work can be done.

You set up appointment windows in which the work can be completed based on calendar and shift information, and determine how many appointment slots are available within each range. Appointments can then be made in the Graphical Appointment Book application by customer service representatives at your organization.

- [Creating appointment books](#)
You can create an appointment book for customer service representatives to use when scheduling appointments with customers.
- [Viewing appointments in an appointment book](#)
You can view available and scheduled appointments in the View tab of the Appointment Book Manager application.
- [Modifying available appointments in an appointment book](#)
You can modify how many appointments are available in an appointment book.
- [Managing access to appointment books](#)
You can grant users and groups access to specific appointment books in the Appointment Book Manager application.

Creating appointment books

You can create an appointment book for customer service representatives to use when scheduling appointments with customers.

About this task

An *appointment book* is a calendar view of the daily time slots in which an appointment for on-premises work can be done.

Procedure

1. In the Appointment Book Manager application, create a new record.
2. Enter a name for the appointment book, and a Start Date and End Date. Representatives can schedule appointments within the defined date range.
3. Enter values in the Calendar, Shift fields for the appointment book.
4. In the Start Day field, select the day of the week that you want the appointment book to start on. Then, enter a value in the Days in Pattern field. For example, enter Sunday in the Start Day field and 7 in the Days in Pattern field for a typical 7 day weekly shift.
5. Enter a work zone for the appointment book, if appropriate.
6. If you want to allow users to request a specific person to complete the work when they create an appointment, select the Allow Labor Assignment check box.
7. In the Work Order Dates and Work Order Status fields, specify the criteria that you want work orders that are created in the Graphical Appointment Book application to have.
8. In the Job Plans table window, select the job plans that you want to associate with the appointment book. The job plans that you specify are copied to the work records created when an appointment is made in the Graphical Appointment Book application. You can modify the value in the Number of Appointments field as necessary.
9. In the Appointment Windows table window, click New Row to create an appointment window.
You can create multiple appointment windows for an appointment book. For example, you can create one appointment window for the morning and one for the afternoon.
10. Enter a name for the appointment window.
11. Specify values in the Start Time and End Time fields. The start and end times for the window must occur within the defined shift for the appointment book.

12. In the Appointments field, define the number of appointments that are available in the appointment window.
13. Modify the values in the Effective Start Date and Effective End Date fields as needed. If the Effective End Date field is blank, the appointment window is in effect indefinitely.
14. In the Pattern Exceptions table window, enter any exceptions for appointment availability within the appointment windows. For example, if two technicians are attending training on a specific day, you can modify the number of appointments that are available on that day.
15. Save the record.

Viewing appointments in an appointment book

You can view available and scheduled appointments in the View tab of the Appointment Book Manager application.

About this task

After you set up an appointment book, you can use the View tab to see all appointments that are associated with the appointment book.

Procedure

1. In the Appointment Book Manager application, open the appointment book record that you want to view.
2. On the View tab, the Graphical View subtab shows an overview of all appointments, and how many in each appointment window are scheduled.
3. Click the Appointments Available subtab to see appointment information in a list view.
4. Click the Appointments Made subtab to view appointments that were scheduled by a customer service representative in the Graphical Appointment Book application.

Modifying available appointments in an appointment book

You can modify how many appointments are available in an appointment book.

About this task

You can change the number of available appointments within an appointment window as long as those appointments are not already booked.

Procedure

1. On the Graphical View subtab of the Appointment Book Manager application, right-click on the green segment representing the day and appointment window that you want to modify.
 2. Select Modify Available Appointments. In the Modify Appointment Book Availability window, enter the new number of appointments for that day/window. Click OK. The number of total available appointments for that segment is updated.
- You can also modify the number of available appointments by selecting Modify Appointment Book Availability in the Actions menu.

Managing access to appointment books

You can grant users and groups access to specific appointment books in the Appointment Book Manager application.

Procedure

1. In the Appointment Book Manager application, open the appointment book record that you want to grant access to.
2. Select Manage Appointment Book Access from the Actions menu.
3. In the Manage Appointment Book Access window, click the Select Person and Select Group buttons to select the person or group records that you want to enable to access the appointment book.
4. Click OK.

Graphical Appointment Book application

You use the Graphical Appointment Book application to schedule appointments in appointment windows that you defined in the Appointment Book Manager application.

An *appointment book* is a calendar view of the daily time slots in which an appointment for on-premise work can be done.

In the Appointment Book Manager application, you set up appointment windows in which the work can be completed based on calendar and shift information. You also determine how many appointment slots are available within each range.

In the Graphical Appointment Book application, customer service representatives can make appointments for customers within pre-defined appointment windows. They can schedule additional work records for affected locations at the same time.

- [Scheduling appointments](#)
Customer service representatives can make appointments for customers within pre-defined appointment windows.
- [Rescheduling appointments](#)
You can reschedule appointments that were previously made in the Graphical Appointment Book application.
- [Canceling appointments](#)
You can cancel appointments that were previously made in the Graphical Appointment Book application.
- [Enabling communication templates for appointments](#)
Communication templates are available for you to use when scheduling and rescheduling appointments in the Graphical Appointment Book application.

Scheduling appointments

Customer service representatives can make appointments for customers within pre-defined appointment windows.

Before you begin

You create appointment books in the Appointment Book Manager application. An *appointment book* is a calendar view of the daily time slots in which an appointment for on-premise work can be done. You set up appointment windows in which the work can be completed based on calendar and shift information, and determine how many appointment slots are available within each range. Appointments can then be made in the Graphical Appointment Book application by customer service representatives at your organization.

Procedure

1. In the Graphical Appointment Book application, enter the location or service address where you want to schedule the appointment.
2. In the Appointment Book field, select the appointment book that you want to use when you make the appointment.
3. In the Job Plan field, select the job plans that you want completed during the appointment. Only job plans associated with the appointment book are available to be selected.
4. Click Find.
In the graphical appointment view, available appointment windows are shown.
5. Right-click on the green segment that represents the appointment window when you want to schedule the appointment. Select Make Appointment.
In the Create Work Order with Appointment Window window, enter any additional information and click OK.

If additional work records are outstanding for the selected location, you can schedule appointments for them as well.

6. In the Other Work for Location table window, select the work record that you want to make an appointment for.
7. Right-click on the green segment that represents the appointment window when you want to schedule the appointment. Select Make Appointment for Selected Work Order.

Rescheduling appointments

You can reschedule appointments that were previously made in the Graphical Appointment Book application.

Procedure

1. In the Graphical Appointment Book application, search for the appointment that you want to reschedule. Enter values in the Location, Appointment Book, and Job Plan fields to locate the appointment.
2. Click Find.
3. In the Existing Appointments table window, select the appointment that you want to reschedule.
4. In the graphical appointment view, right-click on the green segment that represents the appointment window when you want to schedule the appointment. Select Reschedule Selected Appointment.

Canceling appointments

You can cancel appointments that were previously made in the Graphical Appointment Book application.

Procedure

1. In the Graphical Appointment Book application, search for the appointment that you want to cancel. Enter values in the Location, Appointment Book, and Job Plan fields to locate the appointment.
2. Click Find.
3. In the Existing Appointments table window, select the appointment that you want to cancel.
4. Click Cancel Appointment.

Enabling communication templates for appointments

Communication templates are available for you to use when scheduling and rescheduling appointments in the Graphical Appointment Book application.

About this task

Email and SMS notifications can be sent to customers to inform them of upcoming appointments and relevant updates. The notifications must be enabled in the Communication Templates and Escalations applications.

Procedure

1. In the Communication Templates application, search for "appointment" in the Description field of the List tab.
The following results are returned:
 - APPTTECHES
 - APPTNEW
 - APPTRESCHED
 - APPTCANCEL
2. For each communication template that you want to enable, change the status to ACTIVE.
3. Save the records.
4. In the Escalations application, search for "appointment" in the Description field of the List tab and then open the APPTTECHES record.
5. From the Actions menu, select Activate/Deactivate Escalations.
6. Save the record.

Managing weather

You can configure and enable weather forecasts and alerts to notify users about weather events that might affect work.

- [Configure Weather Forecast application](#)
You use the Configure Weather Forecast application to enable and configure weather forecast panels in applications.
- [Configuring Weather Alerts application](#)
You can configure and enable weather alerts so that work records in the graphical and map views are highlighted when they are at risk because of weather events.

Configure Weather Forecast application

You use the Configure Weather Forecast application to enable and configure weather forecast panels in applications.

Weather information can be configured for the following applications:

- Graphical Appointment Book
- Graphical Assignment
- Graphical Scheduling
- Graphical Scheduling - Large Projects
- [Enabling weather panels in applications](#)
You can enable weather information for certain applications in the Configure Weather Forecast application.
- [Configuring weather panels](#)
You can configure the front and back panels of your weather panel in the Configure Weather Forecast application.

Enabling weather panels in applications

You can enable weather information for certain applications in the Configure Weather Forecast application.

About this task

Weather information can be configured for the following applications:

- Graphical Appointment Book
- Graphical Assignment
- Graphical Scheduling
- Graphical Scheduling - Large Projects

You can enable up to four weather properties for each view: Current®, Hourly, and Daily.

Procedure

1. In the Configure Weather Forecast application, select the application that you want to enable weather data for.
2. On the main tab, select the Enable Weather check box.

3. For the Graphical Assignment and Graphical Scheduling application, select the Enable Back Panel check box if you want an additional weather panel to show.
4. On the Current, hourly, and Daily subtabs, select the weather property that you want to enable on the panels. For example, select Heat Index. Select the Enable in Front Panel or Enable in Back Panel check boxes to determine where to show that weather property.
5. Enter the display order in the Attribute Order in Panel field. For example, enter 1 for the weather property that you want to display first.
6. Optional: Enter a display style in the Style Name field.
You can choose from predefined weather styles to apply to the weather attribute. The predefined styles are defined in the cascading stylesheet (.css). For example, large, align_start, align_end, center, etc.
7. Optional: Select the Suppress Label check box to hide the weather attribute label in the panel. For example, 25°C rather than Temperature: 25°C.
8. Enable other weather properties as needed.
9. Save the record.

Configuring weather panels

You can configure the front and back panels of your weather panel in the Configure Weather Forecast application.

You can select up to four weather properties to appear on each weather panel. Pick the minimum amount necessary to maximize display space.

The following table describes display options that you can configure:

Table 1. Weather panel configuration

Display option	Description
View Order	Specifies the order in which weather properties appear. A view order of '0' indicates that there is no specific ordering. When properties have the same view order, they are ordered by the field label.
Suppress Label	Indicates whether to hide the weather attribute label in the panel. For example, 25°C rather than Temperature: 25°C . This option applies only to the front weather panel.
Style Name	<p>Style name properties are defined in the cascading stylesheet. The following list contains valid style name properties:</p> <ul style="list-style-type: none">• center• right• left• small• medium• large• space-top• space-bottom <p>You can use multiple Style Name properties per item. This option applies only to the front weather panel.</p> <p>Some styles apply only if the weather label is suppressed. For example, center, left, right apply only if no weather label is present.</p>

- [Weather data customization](#)
You can modify the default values of system properties to determine how your weather data appears. The properties are located in the System Properties application.

Weather data customization

You can modify the default values of system properties to determine how your weather data appears. The properties are located in the System Properties application.

Changing property values

You can change the weather panel width and height, the number of panels to show, and the unit of measure to display weather data in. You change a display property by modifying its value in the System Properties application. Search the System Properties application for properties that are related to the weather data by using the following prefix:

- skd.weather
- mxe.weather

Configuring Weather Alerts application

You can configure and enable weather alerts so that work records in the graphical and map views are highlighted when they are at risk because of weather events.

Weather alerts are configured in the Configuring Weather Alerts application (when a subscription is purchased) and enabled with a cron task. When enabled, an icon appears on work records that might be affected by the specified weather conditions. A work tooltip explains the peril.

Example

When a peril or alert is received from The Weather Company®, a cron task looks for work that is scheduled or assigned in the affected area during that timeframe.

In the Graphical Scheduling application and the work view of the Graphical Assignment application, work records that can be impacted by the alert are flagged with an icon. The work order tooltip shows the alerts, allowing the planner to decide whether the job needs to be rescheduled.

In the Graphical Assignment application, the dispatching map displays current weather alerts and all affected assignments show within the radius of the alert map marker. The dispatcher can reschedule the work and notify the crews.

A technician in the field is notified by SMS or email to seek shelter because of bad weather in the area.

In the Graphical Appointment Book application, customer locations are checked to see if there are any alerts for that area. If there are, an icon displays in the calendar with a tooltip that describes the peril. The customer service representative can reschedule the work if needed.

- [Configuring weather alerts](#)
You configure weather alerts based on weather conditions and zones affected in the Configure Weather Alerts application.

Configuring weather alerts

You configure weather alerts based on weather conditions and zones affected in the Configure Weather Alerts application.

Procedure

1. In the Configure Weather Alerts tool, open the Service Configuration page.
2. Add weather perils to your organization in the Weather Perils table. You can add up to 22 weather perils. (The perils can be downloaded and sent to create your weather subscription).
3. Click Alert Endpoint.
4. Create endpoints for the weather alerts. Enter the URL, user name, and password for each endpoint.
5. Register the endpoints with the weather service by clicking Register All. Save your changes.
6. On the Weather Zone page, enter the Service Address or the longitude and latitude of the center of each weather zone, and specify the radius of the zone.
7. Register each weather zone with the weather service by clicking the Register icon. Save your changes.

What to do next

For the weather alerts to appear in Maximo® Asset Management Scheduler applications, you must enable the POPULATEWOWEATHERALERT cron task.

Note:

If you are using Weblogic and are not using application server security (for instance, you are using LDAP in Maximo), you need to bypass Weblogic basic authentication, which can be done with the following configuration change:

To set the enforce-valid-basic-auth-credentials flag, perform the following steps:

1. Add the <enforce-valid-basic-auth-credentials> element to config.xml within the <security-configuration> element as follows:

```
<enforce-valid-basic-auth-credentials>false</enforce-valid-basic-auth-credentials>
```

```
</security-configuration>
```
2. Start or restart all of the servers in the domain.

- [Enabling weather alerts by using cron tasks](#)
In order for weather alerts to be displayed for affected work records in graphical and map views, you must enable the weather alert cron tasks.

Enabling weather alerts by using cron tasks

In order for weather alerts to be displayed for affected work records in graphical and map views, you must enable the weather alert cron tasks.

Procedure

1. In the Cron Task Setup application, search for the POPULATEWOWEATHERALERT cron task.
2. In the Cron Task Instances table, select the Active check box.
3. Save the record.

What to do next

To clear expired alerts on work records, open the REMOVEWOWEATHERALERT cron task and set the cron task to Active. When the cron task runs, expired weather alerts are removed.

Optimizing schedules

You use IBM® Maximo® Optimizer to automate efficient decisions for long-range planning, scheduling, and dispatching of resources for asset maintenance while balancing competing objectives and constraints.

Maximo® Optimizer is purchased separately through one of the following plans:

Maximo® Optimizer plan

The Maximo® Optimizer plan with no restrictions on the deployment of virtual processor cores (VPCs), parallel execution of jobs, or number of custom models.

Maximo® Optimizer Limited plan

The Maximo® Optimizer Limited plan limits the deployment to two VPCs and a serialized execution of jobs for only one model. The model is a default model or a customized version of the default model that is provided by IBM.

For more information on deploying and activating Maximo Optimizer, see [Deploying IBM Maximo Optimizer](#).

- [IBM® Maximo® Optimizer optimization models](#)

You can run optimization models to schedule or assign work within a scenario. When you run an optimization model, the work is scheduled and assigned based on the criteria that you specify. Each model provides results that are tailored to a specific business need.

- [Optimization templates](#)

A template is a default set of values that can be used across multiple schedules to optimize work that is based on your objectives. You create a template to define which work details are most important to you during scheduling.

- [Running optimization](#)

Using optimization templates, you can run optimization on your schedule scenarios and work lists to enhance scheduling results.

- [Monitoring optimization processes](#)

You can monitor the progress of completed, scheduled, or ongoing optimization processes by using options from the Actions menu.

- [Example of comparing optimization scenarios](#)

You can create multiple scenarios to perform an analysis of how resource allocation affects schedule dates. You can create the scenarios manually, or you can use predefined resource leveling options to automate the scheduling of work.

IBM® Maximo® Optimizer optimization models

You can run optimization models to schedule or assign work within a scenario. When you run an optimization model, the work is scheduled and assigned based on the criteria that you specify. Each model provides results that are tailored to a specific business need.

Some models provide information for long term planning, while others focus on short term planning and assigning work. You can run multiple optimization models and compare the results by creating multiple scenarios.

Table 1. Optimization model options

Planning type	Applications	Optimization scenarios
Long term planning	<ul style="list-style-type: none">• Graphical Scheduling• Graphical Scheduling - Large Projects	<ul style="list-style-type: none">• Resource leveling• Capacity planning• Maintenance scheduling optimization
Short term assignment	<ul style="list-style-type: none">• Graphical Assignment	<ul style="list-style-type: none">• Labor and crew assignment• Spatial scheduling

Resource leveling optimization

You can optimize your schedule to balance your resource use, balancing your work demands with the resource pool that is available. Resource leveling optimization ensures that you are not under-utilizing labor resources, or over-allocating work to a specific craft.

Resource leveling ensures that you are not over-scheduling the amount of work that you can get accomplished. When you level resources, you can also meet other objectives, such as minimizing task interruption or labor costs. For example, you can match a work record's required skill level, rather than assigning it to a resource with a higher skill level.

Capacity planning optimization

You can optimize your schedule to ensure that you can complete as much work as possible in the allotted time period.

In planning work, you can identify whether additional labor resources are necessary to complete work in a specific timeframe. For example, 100 work orders must be completed this week. Capacity planning optimization ensures that you are using all available labor resources to accomplish your goal. When you set the optimization parameters, you can set other criteria that must be met. For example, you can ensure that work is scheduled only when the asset is available for maintenance.

Labor and crew assignment optimization

You can optimize your schedule to automatically assign people and crews to work based on their availability and required skills.

Assigning work can be time consuming for supervisors and planners. Factors to consider include resource availability and the skill level that the work requires. You can set the labor and crew optimization model to accommodate these factors, which are based on your preferences. For example, you can set the optimization model to respect appointments that were made, or use the same labor or crew resource throughout a job.

You can then review the assignments, adjust them as needed, and publish them.

Spatial scheduling optimization

You can optimize your schedule to automatically assign work to people and crews based on their geographic location.

When you use spatial scheduling optimization to assign work, work is assigned based on the locations and work zones of labor and crew resources. Crew types are evaluated and assigned appropriate work, and efficient routes are created. You can then review the assignments in the Gantt view and adjust them as needed, or view them spatially on the Dispatch View tab. You can publish the assignments when ready.

Optimization templates

A template is a default set of values that can be used across multiple schedules to optimize work that is based on your objectives. You create a template to define which work details are most important to you during scheduling.

Optimization templates contain the parameter values that you want the optimization model to take into account when it schedules work. The parameter values include objectives, constraints, and variables. For example, you can define one template whose primary objective is to minimize cost and another whose objective is to schedule high-priority work first.

When you work with a schedule, you can select which optimization template to use. Templates exist for the following optimization use cases:

- Resource leveling
- Capacity planning
- Labor and crew assignments
- Spatial dispatching
- Maintenance scheduling optimization

Running optimization

Using optimization templates, you can run optimization on your schedule scenarios and work lists to enhance scheduling results.

About this task

If you have a multilanguage environment, optimization results (messages, conflicts, and alerts) are returned in the language of the current user. For example, if a user in a Japanese environment runs optimization, the results are returned in Japanese. A user in an Italian environment who viewed the results would also see them in Japanese.

Procedure

1. In the scheduling or assignment application, display the scenario or work list that you want to run optimization for.
2. Optional: Review or create a new template.
 - a. From the More Actions menu, select the optimization template that you want to run.
 - b. In the template window, select an existing template or click New Template to create a new one.
 - c. Review the parameters on the Template Main Parameters and Additional Parameters tabs. Include or exclude parameters that you want the optimization to consider by using the check boxes.
 - d. Click OK to save your template and return to the schedule.
3. From the Common Actions menu, select Run Optimization.
4. Define the parameters for the optimization on the Variables tab and other tabs.
5. Choose when you want the optimization to run.
 - a. To run optimization immediately, click Run
 - b. To set up optimization to run by using a cron task, click Set Cron Tasks. In the Optimization Parameters for Cron Tasks window, define when you want to the cron task to run. You can set it up to run at specific date and time, to run at a specific recurring interval, or both. Click Save to save your settings, then click Run.
6. In the graphical view, review the results, and adjust the schedule or work list manually as necessary.

What to do next

You can monitor optimization processes and their progress by using the following optimization options in the More Actions menu:

- View Optimization Processes
- View Scheduled Optimization Processes
- View Optimization Progress

For scheduling optimization, the View Optimization Progress window displays key performance indicator (KPI) information. Depending on the KPI value, you can terminate the optimization process by clicking Terminate.

Monitoring optimization processes

You can monitor the progress of completed, scheduled, or ongoing optimization processes by using options from the Actions menu.

To see optimization processes that are currently running, select View Optimization Processes from the Actions menu. You can see the status of each process, and how long it took to complete. You can also see an optimization summary, a conflict report for failed optimizations, and a list of records that were not optimized or

assigned. These records appear in the Gantt view in red at the end of the scheduled dates. (You can set a system property to move these to the beginning of the schedule instead.)

To view optimization processes that are scheduled to run but not running currently, select View Scheduled Optimization Processes.

To see a log of current optimization processes, select View Optimization Progress.

For scheduling optimization, the View Optimization Progress window displays key performance indicator (KPI) information. You can terminate the optimization process by clicking Terminate.

Example of comparing optimization scenarios

You can create multiple scenarios to perform an analysis of how resource allocation affects schedule dates. You can create the scenarios manually, or you can use predefined resource leveling options to automate the scheduling of work.

About this task

In this example, you have many work orders that must be completed with limited resources. You have an existing schedule that contains both current maintenance and emergent work and work from a substantial backlog. You must assign the work in order of priority to the resources that are available. You want to see whether allocating 100% of your resources to the schedule affects the dates significantly over allocating 75%.

Procedure

1. With the schedule open, from the Actions menu, create a resource leveling scenario. Select OK and Move to open the new scenario.
2. From the Actions menu, click Run Optimization.
3. In the Resource Leveling Optimization window, select Immediate.
4. On the Variables tab, in the Percentage Availability field, enter 100. Click Submit.
5. In the Gantt view, review the results, and adjust the schedule manually as necessary.
6. Run the resource leveling scenario again by repeating steps 1-5. Use 75 in the Percentage Availability field.
7. Compare the scenarios.
8. Publish the scenario that best fits your needs.

Managing calibration assets and standards

You can manage your calibration assets and the standards that are used to calibrate them.

You can ensure regulatory compliance with FDA (21 CFR part 11 for support of electronic signatures and electronic audits), calibration of instruments, tools and measurement equipment and standards. Compliance Assistance Documentation provides support for asset-related CAPA processes, and support in validation projects.

You can manage the calibration of instruments that measure process variables such as temperature, pressure, and flow. You can maintain a historical record of calibration measurements for instruments and measurement and test equipment. You can also track historical records of the calibration instrument or the standard that is used to calibrate an instrument or measurement and test equipment.

You can create data sheet templates to document your instrument specification and apply the templates to multiple instruments. You can select or define tolerance levels and input-range limits for each data sheet and associate the data sheet with job plans and work orders. You can then use the data sheets in work orders to gather calibration as-found and as-left data to record and analyze the performance of the instrument.

By creating performance maintenance intervals, you can automatically create calibration work orders to ensure that the calibration of assets is completed on time. Calibration job plans define the procedures that you use to calibrate an instrument. You can use revision control to update the information of a job plan or a data sheet and maintain records of the previous revisions.

To comply with industry regulations, your calibration history is recorded to ensure that your calibration assets are fully traceable. You can identify which standard or measurement and test equipment was used to calibrate an asset. You can apply reverse traceability to identify all assets that were calibrated with a specific standard.

- [Documenting instrument specifications by using data sheets](#)
You document your instrument specifications using the data sheet template. These specifications are typically defined by the manufacturer of the instrument.
- [Defining calibration procedures, assets, tools, and locations](#)
You can create asset records to define your instruments, measurement and test equipment (M&TE), and standards. You can also manage your instruments as locations and M&TE as tools.
- [Configuring calibration features](#)
You must complete configuration tasks in order to use calibration features.
- [Recording calibration data in work orders](#)
You document your calibration data results using calibration work orders.

Documenting instrument specifications by using data sheets

You document your instrument specifications using the data sheet template. These specifications are typically defined by the manufacturer of the instrument.

- [Data sheet templates](#)
Data sheets are templates that define the calibration process for one or more asset functions. You use the Data Sheet Template application to create data sheets for calibration assets.
- [Data sheets](#)
Data sheets provide technicians with the information that they need to perform a calibration. A data sheet is a template that defines the specifications of an asset for the calibration process.
- [Non-linear instruments in data sheets](#)
Non-linear instruments are analog instruments that have their tolerance limits calculated based on the desired output value and not the nominal input value.
- [Tolerance limits on data sheets](#)
Tolerance is an acceptable value or value range for a specified output value. You define the tolerance limits for accuracy of a calibration point on a data sheet.
- [Creating data sheets](#)
A data sheet is a template that defines the specifications of an asset for the calibration process. Data sheets give a technician the information necessary to calibrate an analog or discrete asset function.
- [Associating work assets with data sheets](#)
When you associate an asset with a data sheet, you are attaching a template with predefined calibration points for the work asset.
- [Duplicating the asset function of a data sheet](#)
When you create multiple data sheets with similar information, you can duplicate the asset function information to save time.
- [Calibration calculations](#)
During the calibration of an asset, calculations are used to determine whether the asset passes or fails the calibration. These calculations are based on the values that you specify on the data sheet.
- [Data sheet templates](#)
Data sheets are templates that define the calibration process for one or more asset functions. You use the Data Sheet Template application to create data sheets for calibration assets.
- [Data sheets](#)
Data sheets provide technicians with the information that they need to perform a calibration. A data sheet is a template that defines the specifications of an asset for the calibration process.
- [Non-linear instruments in data sheets](#)
Non-linear instruments are analog instruments that have their tolerance limits calculated based on the desired output value and not the nominal input value.
- [Tolerance limits on data sheets](#)
Tolerance is an acceptable value or value range for a specified output value. You define the tolerance limits for accuracy of a calibration point on a data sheet.
- [Creating data sheets](#)
A data sheet is a template that defines the specifications of an asset for the calibration process. Data sheets give a technician the information necessary to calibrate an analog or discrete asset function.
- [Associating work assets with data sheets](#)
When you associate an asset with a data sheet, you are attaching a template with predefined calibration points for the work asset.
- [Duplicating the asset function of a data sheet](#)
When you create multiple data sheets with similar information, you can duplicate the asset function information to save time.
- [Calibration calculations](#)
During the calibration of an asset, calculations are used to determine whether the asset passes or fails the calibration. These calculations are based on the values that you specify on the data sheet.

Data sheets

Data sheets provide technicians with the information that they need to perform a calibration. A data sheet is a template that defines the specifications of an asset for the calibration process.

A data sheet defines the asset function specifications and the calibration point of an asset. The data sheet also defines the functional checks and dynamics checks of an asset, if required.

Data sheets are associated with assets and are copied to calibration work orders for the asset. On the work order data sheet, the technician enters calibration As Found and As Left data. This data is used to analyze asset performance and calibration frequency.

The data sheet also records uncertainty measurement data for instruments and measuring and test equipment (M&TE). This uncertainty data is calculated and imported from an external source into the Data Sheet Template application and the Work Order Tracking application.

- [Asset functions](#)
The asset function specifies the calibration data for the function of an asset. You can specify calibration data about one or more asset functions.
- [Calibration points](#)
A calibration point is the test information that is used to calibrate an asset. The amount of calibration points that are required for a calibration process is determined by business requirements.
- [Dynamic checks](#)
A dynamic check is additional data about the instrument being calibrated.
- [Functional checks](#)
A functional check is an additional check point that is required to calibrate an instrument.
- [Uncertainty measurement for calibration](#)
The results from the calibration of an asset can vary when the asset is measured multiple times. In calibration, the uncertainty measurement helps determine the reliability of the asset by comparing the recorded value to its real value.
- [Asset functions](#)
The asset function specifies the calibration data for the function of an asset. You can specify calibration data about one or more asset functions.
- [Calibration points](#)
A calibration point is the test information that is used to calibrate an asset. The amount of calibration points that are required for a calibration process is

- determined by business requirements.
- [Dynamic checks](#)
A dynamic check is additional data about the instrument being calibrated.
- [Functional checks](#)
A functional check is an additional check point that is required to calibrate an instrument.
- [Uncertainty measurement for calibration](#)
The results from the calibration of an asset can vary when the asset is measured multiple times. In calibration, the uncertainty measurement helps determine the reliability of the asset by comparing the recorded value to its real value.

Asset functions

The asset function specifies the calibration data for the function of an asset. You can specify calibration data about one or more asset functions.

Calibration data includes the input and output values of an asset, the tolerance limits of an asset, and the uncertainty measurement data of an asset. The combination of these values is calculated to determine whether the calibration of an instrument passes or fails performance tests.

You can configure a data sheet for the following types of devices:

Analog device

An *analog device* is an instrument that provides continuous results, such as a pressure gauge.

Discrete device

A *discrete device* is an instrument that has only two settings. For example, a discrete device can be a switch that is either on or off or a valve that is either open or closed.

- [Asset function parameters](#)
The asset function specifies the calibration data for an asset. There are two types of asset functions: an analog asset function and a discrete asset function.
- [Asset function parameters](#)
The asset function specifies the calibration data for an asset. There are two types of asset functions: an analog asset function and a discrete asset function.

Asset function parameters

The asset function specifies the calibration data for an asset. There are two types of asset functions: an analog asset function and a discrete asset function.

Asset function parameters

The following table lists the parameters that are enabled for analog asset functions and asset discrete functions.

Parameter	Analog	Discrete
Technician Can Insert Points	✓	✓
No Adjustment Limit	✓	✓
Input Minimum Field Resolution	✓	✓
Limits clipped at calibration ranges:	✓	
Input Limits Clipped		
Output Limits Clipped		
Input range limits:	✓	
Input Range From		
To		
Input Units	✓	✓

Uncertainty tolerance range and criteria: Guardband From To As	✓	✓
Status when Exceeded	✓	✓

Calibration points

A calibration point is the test information that is used to calibrate an asset. The amount of calibration points that are required for a calibration process is determined by business requirements.

A calibration point defines the nominal input value and the desired output value for an analog asset function.

A calibration point defines the set point and set point action for a discrete asset function.

Dynamic checks

A dynamic check is additional data about the instrument being calibrated.

A dynamic check point does not affect the calibration of an instrument, but is relevant to the calibration of an instrument. For example, a dynamic check can record the reading of gear settings or controller tuning of an instrument.

Functional checks

A functional check is an additional check point that is required to calibrate an instrument.

The options for a functional check are either pass or fail. For example, a functional check can record a temperature setting that contributes to either a pass or fail.

Uncertainty measurement for calibration

The results from the calibration of an asset can vary when the asset is measured multiple times. In calibration, the uncertainty measurement helps determine the reliability of the asset by comparing the recorded value to its real value.

Any measurement is subject to imperfections. Some of these imperfections are caused by random effects, such as short-term fluctuations in temperature, humidity, and air-pressure, or variability in the performance of the measurer. Repeated measurements show variation because of these random effects.

Other imperfections are caused by systematic effects. These systematic effects can be the offset of a measuring instrument or a change in its characteristics between calibrations. Other systematic effects can be personal bias in reading an analog scale or the uncertainty of the value of a standard.

The uncertainty measurement data for calibration is calculated externally to Maximo® Calibration. Information about calibration assets is exported from Maximo Calibration to the external system, where the information is calculated to determine the correct uncertainty data. The information is then imported into the calibration data sheet tables and the data sheet work order tables. When a data sheet is attached to a work order, the uncertainty measurement data is imported from the Data Sheet Template application.

You use the Manage integration framework to link Maximo Calibration to the external system. Before you configure Maximo Calibration for uncertainty data, you must complete the basic configuration tasks to set up your environment. See the information about basic configuration in the *IBM Maximo Asset Management Integration Guide*.

Non-linear instruments in data sheets

Non-linear instruments are analog instruments that have their tolerance limits calculated based on the desired output value and not the nominal input value.

To indicate that an instrument is non-linear, select the Non-linear check box. If calibration points are already entered, they must be cleared before you can select non-linear.

When an instrument is selected as non-linear, the Engineering Unit (EU) is the only tolerance that is used. Also, the desired output value of the calibration point must be within the output range of the asset function.

Tolerance limits on data sheets

Tolerance is an acceptable value or value range for a specified output value. You define the tolerance limits for accuracy of a calibration point on a data sheet.

You can specify up to four tolerance levels on a data sheet. Tolerance 1 is the tightest (or narrowest) tolerance and Tolerance 4 is the widest. Typically, the manufacturer of the asset establishes the tolerance limits.

Example of using tolerance limits

Tolerance 1 is the output limit range that does not require adjustment for the asset. An asset passes calibration if the actual output value for the asset is within the limit range of Tolerance 1. No additional action is required.

The asset requires adjustment if the actual output value exceeds the limit range of Tolerance 1 but is within the limit range of Tolerance 2. The asset owner is also notified.

Tolerance limits are validated as tightest to widest by using the following criteria:

- Tolerance 1 lower limits > Tolerance 2 lower limits > Tolerance 3 lower limits > Tolerance 4 lower limits
- Tolerance 1 upper limits < Tolerance 2 upper limits < Tolerance 3 upper limits < Tolerance 4 upper limits

Tolerance limits are also validated by using the following criteria:

- The lower tolerance limit value, the From field, must be less than or equal to zero.
- The upper tolerance limit value, the To field, must be greater than or equal to zero.

When a technician enters As-found and As-left values on the work order data sheet, these values are validated to ensure that they are within the specified range.

Creating data sheets

A data sheet is a template that defines the specifications of an asset for the calibration process. Data sheets give a technician the information necessary to calibrate an analog or discrete asset function.

About this task

When you create a data sheet, the status default value is draft.

If you enter a value for an asset function using the comma as the thousand separator, the value becomes a decimal number. For example, if you enter 1,000 and your minimum field resolution is 3, then the value converts to 1.000 (one). If you enter 1000 and your minimum field resolution is 3, then the value converts to 1000.000 (one thousand).

Procedure

1. In the Data Sheet Template application, click New Data Sheet and specify a data sheet name.
2. Create an asset function and specify the type of asset function.
3. Specify whether the asset function is a calibration point, a functional check point, or a dynamic check point.
4. Optional: To allow a field technician to add calibration point rows to a work order data sheet while performing a calibration, select the Technician Insert Points check box.
5. Specify the asset function information.
6. Specify either the calibration point information, the functional check point information, or the dynamic check point information of the asset function.
This checkpoint information is according to the business rules for your company.
7. Save the data sheet.

What to do next

Change the status of the data sheet to approved to add it to a work asset. You can then associate the data sheet to a job plan or to a work order.

- [Revising the version of a data sheet](#)

Changes that are made to data sheets are saved by using revision control. Revision control maintains a historical record to troubleshoot calibration issues with assets when data sheet values have changed.

- [Revising the version of a data sheet](#)

Changes that are made to data sheets are saved by using revision control. Revision control maintains a historical record to troubleshoot calibration issues with assets when data sheet values have changed.

Revising the version of a data sheet

Changes that are made to data sheets are saved by using revision control. Revision control maintains a historical record to troubleshoot calibration issues with assets when data sheet values have changed.

About this task

You can revise data sheets that are in approved status only. Data sheet revision numbers increment by 1. You can view the revision history of a data sheet from the Select Action menu. Work orders that the data sheet is attached to are not automatically updated.

When the status of the revised data sheet is set to approved, the status of the previous data sheet is set to Revised. The revised data sheet cannot be edited or reopened.

Job plans that are associated with the data sheet are automatically updated to the revised version.

Procedure

1. In the Data Sheet Template application, select the data sheet that you want to revise.
2. From the Select Action menu, select Revise Data Sheet.
3. Enter a revision description and click OK.
The status of the data sheet is set to Pending Revision.
4. Update the data sheet for this revision and save the changes.

What to do next

You can change the status of the revised data sheet to either Waiting on Approval or Approved.

Associating work assets with data sheets

When you associate an asset with a data sheet, you are attaching a template with predefined calibration points for the work asset.

About this task

You can link one or more assets to a data sheet. You can use the current data sheet for multiple assets that have identical calibration data sheet requirements.

Procedure

1. In the Data Sheet Template application, select the data sheet you want to associate with a work asset.
2. On the Work Assets tab, insert a row.
3. Specify either a location, an asset, or an item.
If you select a location as the work asset, the Asset field is automatically populated.
4. Save the data sheet.

Duplicating the asset function of a data sheet

When you create multiple data sheets with similar information, you can duplicate the asset function information to save time.

About this task

You can duplicate the asset function information of a data sheet that is in draft status and pending revision status only.

Procedure

1. In the Data Sheet Template application, select the asset function of the data sheet that you want to duplicate.
2. Click Duplicate Row.
3. Specify the asset function number and description.
4. Update any fields as required.
5. Save the record.

Calibration calculations

During the calibration of an asset, calculations are used to determine whether the asset passes or fails the calibration. These calculations are based on the values that you specify on the data sheet.

The results of these calculations depend on the type of asset that is being calibrated. The results also depend on whether the tolerance levels are based on the input or the output information of the asset. Your desired output is the result that you want for your asset. The desired output is based on the direction of the values and whether the value is increasing or decreasing.

These calculations are processed on the Data Sheet tab in the Data Sheet application and the Work Order application.

- [Symbols used in calibration formulas](#)

The calibration formulas use specific symbols. These symbols define the algorithms that are used in the calibration calculations.

- [Tolerance criteria for calibration calculations](#)

The tolerance criteria in a data sheet determines which algorithm is used to calculate the lower and upper output limits for each tolerance level. Each tolerance criterion represents a specific calculation formula to calculate tolerance limits.

- [Single tolerance for calibration calculations](#)

You can use a single tolerance criterion for each tolerance level. The single tolerance calculates the desired output.

- [Summed tolerance for calibration calculations](#)

You can use summed tolerance criteria for each tolerance level. Summed tolerance is the total of single tolerance expressions.

- [Square root tolerance for calibration calculations](#)

The square root calculation is used to perform the input limits and output tolerance calculations for differential pressure producing flow meters.

- [Reverse flow calculation for calibration calculations](#)

The reverse flow calculation is used to perform the input limits and output tolerance calculations for linear assets, for example flow indicators in reverse flow.

- [Symbols used in calibration formulas](#)

The calibration formulas use specific symbols. These symbols define the algorithms that are used in the calibration calculations.

- [Tolerance criteria for calibration calculations](#)

The tolerance criteria in a data sheet determines which algorithm is used to calculate the lower and upper output limits for each tolerance level. Each tolerance criterion represents a specific calculation formula to calculate tolerance limits.

- [Single tolerance for calibration calculations](#)

You can use a single tolerance criterion for each tolerance level. The single tolerance calculates the desired output.

- [Summed tolerance for calibration calculations](#)

You can use summed tolerance criteria for each tolerance level. Summed tolerance is the total of single tolerance expressions.

- [Square root tolerance for calibration calculations](#)

The square root calculation is used to perform the input limits and output tolerance calculations for differential pressure producing flow meters.

- [Reverse flow calculation for calibration calculations](#)

The reverse flow calculation is used to perform the input limits and output tolerance calculations for linear assets, for example flow indicators in reverse flow.

Symbols used in calibration formulas

The calibration formulas use specific symbols. These symbols define the algorithms that are used in the calibration calculations.

List of the symbols used in calibration formulas

i	Input value: nominal or actual.
i_{lower}	Input range, lower limit.
i_{upper}	Input range, upper limit.
i_a	Actual input value (as found input).
i_{calc}	Calculated input value (input as calculated from the as found output).
o_{lower}	Output range lower limit.
o_{upper}	Output range upper limit.
o_a	Actual output value (as found output).
o_{calc}	Calculated output value (output as calculated from the input).

Δi
Input range span.

Δo
Output range span.

r_{lower}
Range limit From value (lower limit).

r_{upper}
Range limit To value (Upper limit).

Tolerance
Tolerance value entered, for example, +/- 2.5, +2.5 or -2.5.

Tolerance criteria for calibration calculations

The tolerance criteria in a data sheet determines which algorithm is used to calculate the lower and upper output limits for each tolerance level. Each tolerance criterion represents a specific calculation formula to calculate tolerance limits.

Table 1. Criteria definitions and calculations

Criterion	Criteria definition	Tolerance calculation based on input	Tolerance calculation based on output
Engineering Units (EU)	Tolerances that are based on input are expressed in input units. The tolerance levels are always expressed in output units; therefore, a conversion must occur. The conversion is $\left(\frac{\Delta o}{\Delta i}\right)$ If the tolerance is based on output, then no conversion is required.	$Tolerance * \left(\frac{\Delta o}{\Delta i}\right)$	Tolerance
%Span	The values for the %Span criterion are calculated from the calibrated input span of the asset. The values are then converted to output units and are added to or subtracted from the desired output value to determine the range limits. The span is the algebraic difference of the input upper and lower range values divided by 100. If the tolerance is based on output, then no conversion is required.	$Tolerance * \left(\frac{\Delta i}{100}\right) * \left(\frac{\Delta o}{\Delta i}\right)$	$Tolerance * \left(\frac{\Delta o}{100}\right)$
%URV	The %URV criterion is the upper range value divided by 100. If the upper input range value is used, the value must be converted to output units before the tolerance is calculated. The converted tolerance is then added to or subtracted from the desired output value to determine the range limits. If the tolerance is based on output, then no conversion is required.	$Tolerance * \left(\frac{r_{upper}}{100}\right) * \left(\frac{\Delta o}{\Delta i}\right)$	$Tolerance * \left(\frac{O_{Upper}}{100}\right)$
%Reading	The values for the %Reading criterion are calculated from the nominal input value applied to the asset. The values are then divided by 100, converted to output units, and added to or subtracted from the desired output value to determine the range limits. These values are not constant, but vary with nominal input. If the tolerance is based on output, then no conversion is required.	$Tolerance * \left(\frac{i}{100}\right) * \left(\frac{\Delta o}{\Delta i}\right)$	$Tolerance * \left(\frac{o}{100}\right)$

Single tolerance for calibration calculations

You can use a single tolerance criterion for each tolerance level. The single tolerance calculates the desired output.

You use one of two calculations to calculate the desired output. The calculation that is used depends on the direction of the input and the output. The desired output is calculated and then applied to the formulas to calculate tolerance limits.

Table 1. Single tolerance calculations

Description	Input and output	Calculation
Same direction increasing	If Input From to Input To < 0 and Output From to Output To <= 0	Desired output $= (i - i_{Lower}) * \left(\frac{\Delta o}{\Delta i}\right) + O_{Lower}$
Same direction decreasing	If Input From to Input To > 0 and Output From to Output To >= 0	Desired output $= (i - i_{Lower}) * \left(\frac{\Delta o}{\Delta i}\right) + O_{Lower}$
Opposite direction increasing/decreasing	If Input From to Input To < 0 and Output From to Output To >= 0	Desired output $= O_{Upper} - (i - i_{Lower}) * \left(\frac{\Delta o}{\Delta i}\right)$

Description	Input and output	Calculation
Opposite direction decreasing/increasing	If Input From to Input To > 0 and Output From to Output To <= 0	Desired output $= O_{Upper} - (i - i_{Lower}) * \left(\frac{\Delta o}{\Delta i} \right)$

Summed tolerance for calibration calculations

You can use summed tolerance criteria for each tolerance level. Summed tolerance is the total of single tolerance expressions.

The calculation converts the individual terms to corresponding output units and then adds all the output units together.

Summed Tolerance = Desired Output + EU + %Span + %URV + %Reading

The following figure shows the formula based on input (where T = tolerance):

Figure 1. Summed tolerance formula based on input

$$= (i - i_{Lower}) * \left(\frac{\Delta o}{\Delta i} \right) + O_{Lower} + \left[T * \left(\frac{\Delta o}{\Delta i} \right) \right] + \left[T * \left(\frac{\Delta i}{100} \right) * \left(\frac{\Delta o}{\Delta i} \right) \right] + \left[T * \left(\frac{i_{Upper}}{100} \right) * \left(\frac{\Delta o}{\Delta i} \right) \right] + \left[T * \left(\frac{i}{100} \right) * \left(\frac{\Delta o}{\Delta i} \right) \right]$$

The following figure shows the formula based on output (where T = tolerance):

Figure 2. Summed tolerance formula based on output

$$= (i - i_{Lower}) * \left(\frac{\Delta o}{\Delta i} \right) + O_{Lower} + \left[T * \left(\frac{\Delta o}{100} \right) \right] + \left[T * \left(\frac{O_{Upper}}{100} \right) \right] + \left[T * \left(\frac{o}{100} \right) \right]$$

Square root tolerance for calibration calculations

The square root calculation is used to perform the input limits and output tolerance calculations for differential pressure producing flow meters.

Square root calculations

You select the Square Root of Input check box to use this calculation.

The formula for calculating the desired output is included in the square root equations.

The following figure shows the desired output calculation:

Figure 1. Desired output calculation

$$\sqrt{\left(\frac{i}{i_{Upper}} \right)} * \Delta o + O_{Lower}$$

Table 1 shows the positive square root equation and negative square root equation for each criterion.

Table 1. Single square root equations for input

Criterion	Description	Positive square root equations	Negative square root equations
EU	When the Square Root of Input check box is selected, the positive square root equation is used for the engineering unit criterion. The negative square root equation is used if the input + tolerance is a negative number.	$\sqrt{\left(\frac{i + Tolerance}{i_{Upper}} \right)} * \Delta o + O_{Lower}$	$O_{Lower} - \sqrt{\left(\frac{i + Tolerance}{i_{Upper}} \right)} * \Delta o$
%Span	When the Square Root of Input check box is selected, the positive square root equation is used for the %Span criterion. The negative square root equation is used if the input + tolerance is a negative number.	$\sqrt{\left(\frac{i + Tolerance(\Delta i / 100)}{i_{Upper}} \right)} * \Delta o + O_{Lower}$	$O_{Lower} - \sqrt{\left(\frac{i + Tolerance(\Delta i / 100)}{i_{Upper}} \right)} * \Delta o$
%URV	When the Square Root of Input check box is selected, the positive square root equation is used for the %URV criterion. The negative square root equation is used if the input + tolerance is a negative number.	$\sqrt{\left(\frac{i + Tolerance(i_{Upper} / 100)}{i_{Upper}} \right)} * \Delta o + O_{Lower}$	$O_{Lower} - \sqrt{\left(\frac{i + Tolerance(i_{Upper} / 100)}{i_{Upper}} \right)} * \Delta o$
%Reading	When the Square Root of Input check box is selected, the positive square equation is used for the %Reading criterion. The negative square root equation is used if the input + tolerance is a negative number.	$\sqrt{\left(\frac{i + Tolerance(i / 100)}{i_{Upper}} \right)} * \Delta o + O_{Lower}$	$O_{Lower} - \sqrt{\left(\frac{i + Tolerance(i / 100)}{i_{Upper}} \right)} * \Delta o$

Table 2 shows the positive square root equation and negative square root equation for a summed square root.

Table 2. Summed square root equations for input

Description	Summed square root equation
Positive square root equations	$\sqrt{\left(\frac{i + Tolerance + Tolerance(\Delta i / 100) + Tolerance(i_{Upper} / 100) + Tolerance(i / 100)}{i_{Upper}} \right)} * \Delta o + O_{Lower}$

Description	Summed square root equation
Negative square root equations	$O_{Lower} - \sqrt{\left(\frac{i + Tolerance + Tolerance\left(\frac{\Delta i}{100}\right) + Tolerance\left(\frac{i_{Upper}}{100}\right) + Tolerance\left(\frac{i}{100}\right)}{i_{Upper}} \right)^2 * \Delta o}$

Reverse flow calculation for calibration calculations

The reverse flow calculation is used to perform the input limits and output tolerance calculations for linear assets, for example flow indicators in reverse flow.

You select the Reverse Flow check box to use this calculation.

The formula for calculating desired output is included in the following equations.

The following figure shows the desired output calculation:

Figure 1. Desired output calculation

$$\left(\left(\frac{i - i_{Lower}}{\Delta i} \right)^2 * \Delta o \right) + O_{Lower}$$

Table 1. Single squared equation for reverse flow

Criterion	Description	Squared equations
EU	When the Reverse Flow check box is selected, the squared equation is used for the engineering unit criterion.	$\left(\left(\frac{i - i_{Lower} + Tolerance}{\Delta i} \right)^2 * \Delta o \right) + O_{Lower}$
%Span	When the Reverse Flow check box is selected, the squared equation is used for the %Span criterion.	$\left(\left(\frac{(i - i_{Lower}) + Tolerance\left(\frac{\Delta i}{100}\right)}{\Delta i} \right)^2 * \Delta o \right) + O_{Lower}$
%URV	When the Reverse Flow check box is selected, the squared equation is used for the %URV criterion.	$\left(\left(\frac{(i - i_{Lower}) + Tolerance\left(\frac{i_{Upper}}{100}\right)}{\Delta i} \right)^2 * \Delta o \right) + O_{Lower}$
%Reading	When the Reverse Flow check box is selected, the squared equation is used for the %Reading criterion.	$\left(\left(\frac{(i - i_{Lower}) + Tolerance\left(\frac{i}{100}\right)}{\Delta i} \right)^2 * \Delta o \right) + O_{Lower}$

Figure 2. Summed squared equations. This equation calculates the reverse flow for summed squared criteria.

$$\left(\frac{(i - i_{Lower}) + Tolerance + (Tolerance\left(\frac{\Delta i}{100}\right) + (Tolerance\left(\frac{i_{Upper}}{100}\right) + (Tolerance\left(\frac{i}{100}\right)))}{\Delta i} \right)^2 * \Delta o + O_{Lower}$$

Defining calibration procedures, assets, tools, and locations

You can create asset records to define your instruments, measurement and test equipment (M&TE), and standards. You can also manage your instruments as locations and M&TE as tools.

- [Calibration procedures](#)
You create calibration job plans to define calibration procedures. You can also apply revision control to a job plan and associate data sheets to a job plan.
- [Calibration assets](#)
Calibration assets include *instruments*, which are the devices that do the work, and *measuring and test equipment* (M&TE), which are the devices that measure and test the instruments.
- [Tools used for calibration](#)
When you create a tool for calibration, you configure the tool as a rotating item to track the tool as an asset and create work orders.
- [Loop locations](#)
A loop is a set of instruments that are grouped and calibrated together. The input and output of the entire group determines whether the calibration is successful.

Calibration procedures

You create calibration job plans to define calibration procedures. You can also apply revision control to a job plan and associate data sheets to a job plan.

- [Calibration job plans](#)
You create calibration job plans to define the procedures that calibrate instruments and measuring and test equipment (M&TE). You can also revise these job plans and maintain a historical record of the changes that were made.
- [Revising calibration job plans](#)
You create calibration job plans so that you can apply revision control to a job plan. When you revise calibration job plans, a record of the changes that are made is saved.
- [Associating data sheets to a work asset on a job plan](#)
You can associate one or more data sheets with a work asset of a calibration job plan. Information from the data sheets is used to analyze data and evaluate asset performance.

Calibration job plans

You create calibration job plans to define the procedures that calibrate instruments and measuring and test equipment (M&TE). You can also revise these job plans and maintain a historical record of the changes that were made.

Job plans contain tasks and information about estimated labor, labor hours, materials, services, and tools that are required for the work. To ensure a safe working environment, you can add work assets and associate safety plans that can be used when work is performed. You can associate one or more data sheets with a work asset of a calibration job plan.

You can specify which organizations and sites can use the information that is on the job plan and its tasks. If you do not specify this information, the job plan can be used in any site of any organization.

You can apply job plans to preventive maintenance records, routes, and work orders. After a job plan becomes a work plan on a work order, you can change the work plan without affecting the job plan. You also can create a job plan from a work plan that you use frequently.

Revision control allows you to revise a calibration job plan. You can track and compare job plans and view the history of the changes made to each job plan.

Revising calibration job plans

You create calibration job plans so that you can apply revision control to a job plan. When you revise calibration job plans, a record of the changes that are made is saved.

About this task

You can revise job plans that are in active status only. When you revise a job plan, the current job plan is duplicated with the same name. The revision number increments by 1. Work orders with an existing job plan attached are not updated with the revised version.

You can enable revision control in the Organizations application.

Procedure

1. On the Job Plans application, select the job plan that you want to revise.
2. From the Select Action menu, select Revise Job Plan.
3. Enter a description for the revised job plan in the Revision Description field and click OK.
The revised job plan has a status of pending revision. The original job plan remains in active status.
4. Update the revised job plan.
5. After all changes are completed, change the revised job plan to active status.
The original job plan automatically changes to revised status and it can no longer be changed.
6. Save the revised job plan.

What to do next

You can view all changes that have been made to the job plan, including who was responsible and when the changes were made.

Associating data sheets to a work asset on a job plan

You can associate one or more data sheets with a work asset of a calibration job plan. Information from the data sheets is used to analyze data and evaluate asset performance.

About this task

When a job plan is attached to a work order and has the same primary asset as the work order, then the data sheet is also attached to the work order.

Job plans are not updated when data sheets are revised. Only approved data sheets are attached to a Work Order.

Procedure

1. In the Job Plan application, select the job plan to attach the data sheet to.
2. On the Work Assets tab, insert a new row in the Data Sheets table window and specify a data sheet.
3. Save the job plan.

Calibration assets

Calibration assets include *instruments*, which are the devices that do the work, and *measuring and test equipment (M&TE)*, which are the devices that measure and test the instruments.

Measuring and test equipment is also referred to as standards by technicians who perform calibrations. Instruments are periodically calibrated with measuring and test equipment to certify that they perform within specified limits. Measuring and test equipment is also periodically calibrated to certify that it performs within its specified limits.

You can identify whether an asset is measuring and test equipment and assign an owner and status for that asset. You can then identify which measuring and test equipment was used to calibrate an instrument. You can also identify all instruments that were calibrated with a specific measuring and test equipment .

You can define whether the asset is calibrated internally or by a vendor and define the operating range and accuracy measurements of the asset.

Use the Assets application to define and uniquely identify calibration assets. You can also determine the next calibration due date of an instrument and associate assets with loop calibrations.

- [Rotating and nonrotating measuring and test equipment](#)
Measuring and test equipment (M&TE) can be either rotating or nonrotating. Rotating measuring and test equipment is an asset that can move in and out of storerooms. Nonrotating measuring and test equipment remains in one location throughout its lifecycle.
- [Creating an asset record for measuring and test equipment](#)
Measuring and test equipment (M&TE) test the performance of instruments. When you create an asset record, you can indicate that the asset is M&TE.

Rotating and nonrotating measuring and test equipment

Measuring and test equipment (M&TE) can be either rotating or nonrotating. Rotating measuring and test equipment is an asset that can move in and out of storerooms. Nonrotating measuring and test equipment remains in one location throughout its lifecycle.

Rotating measuring and test equipment has both a unique asset number and an inventory tool number.

You can use the tool number to track measuring and test equipment as a group, as it moves in and out of inventory and other types of locations. You can use the asset number to track individual instances of the measuring and test equipment as they move between locations and between sites.

A nonrotating piece of measuring and test equipment has a unique asset number, but does not have a tool number because you do not track nonrotating assets in inventory.

Example of a rotating measuring and test equipment

A company has four identical gauges (same make, same model), therefore all four gauges have the same tool number. Each gauge also has its own unique asset number. so you can track the use, the repair, and the location of each individual gauge. Before you can create a record for a rotating piece of measuring and test equipment, you must create the rotating tool record in the Tools application.

Creating an asset record for measuring and test equipment

Measuring and test equipment (M&TE) test the performance of instruments. When you create an asset record, you can indicate that the asset is M&TE.

Procedure

1. In the Assets application, click New Asset.
2. Enter a unique asset number.
3. Enter the description and status of the asset.
4. If the asset is a rotating asset, specify a value in the Rotating Item field.
5. If this asset has a parent, specify a value in the Parent field.
If the parent asset is associated with a location, the location identifier is copied to the Location field.
6. Select the Is M&TE check box to indicate that the asset is M&TE.
7. Specify the M&TE classification.
8. Specify whether the calibration of the M&TE is completed internally or externally:
 - Select the Internal Calibration check box to indicate that you calibrate the M&TE internally.
 - If the tool is calibrated externally, specify the calibration vendor.

9. Save the asset record.

Tools used for calibration

When you create a tool for calibration, you configure the tool as a rotating item to track the tool as an asset and create work orders.

You can assign qualifications to the calibration tool to ensure that technicians are trained and qualified to use the tool when they complete a work order.

You can define calibration measuring and test equipment (M&TE) as a tool and identify if the tool is calibrated internally or externally.

To uniquely identify a tool, you can also record the following attributes:

- Commodity group and commodity code
- Meter and meter group
- Issue unit
- Lot type
- Material safety data sheet (MSDS)
- Whether to inspect the tool on receipt, which means that you require the tool to be examined during the receiving process before it is accepted
- Whether the tool is outside, which means that it is owned by an outside supplier
- Whether the tool is calibrated internally
- [Creating a tool record](#)
A tool record defines a tool and allows you to associate information with the tool. Tools are used to perform work, such as building, maintenance, and repairs.

Creating a tool record

A tool record defines a tool and allows you to associate information with the tool. Tools are used to perform work, such as building, maintenance, and repairs.

Procedure

1. In the Tools application, click New Tool.
2. Specify a tool and lot type.
3. If the tool is part of measurement and test equipment, select the Is M&TE check box.
4. Specify whether the calibration of the M&TE is completed internally or externally:

Option	Description
If the tool is calibrated in internally	Select the Internal Calibration check box.
If the tool is calibrated externally	Specify the calibration vendor.

5. Save the record.
- [Adding alternate tools to a tool record](#)
Alternate tools can be used to perform the same work if a shortage of a particular tool occurs.
 - [Associating data sheets to a tool record](#)
You can associate one or more data sheets to a tool record. Information from the data sheets is used to analyze data and evaluate performance.

Adding alternate tools to a tool record

Alternate tools can be used to perform the same work if a shortage of a particular tool occurs.

About this task

If you want two tools to be alternates for each other, you must assign each as an alternate for the other. Measuring and test equipment (M&TE) tools can only be alternate tools to other M&TE.

Procedure

1. In the Tools application, open an existing tool record.
2. On the Tool tab, insert a row and specify the alternate tool.
3. Save your changes.
4. If this tool is the alternate for the tool that you specified in step 2, repeat these steps for the other tool.

Associating data sheets to a tool record

You can associate one or more data sheets to a tool record. Information from the data sheets is used to analyze data and evaluate performance.

Procedure

1. In the Tools application, select the tool to attach the data sheet to.
2. From the Select Action menu, select Attach Data Sheet and insert a row.
3. Specify the data sheet plan number.
4. Click Done to return to the current record.

Loop locations

A loop is a set of instruments that are grouped and calibrated together. The input and output of the entire group determines whether the calibration is successful.

You identify a location as part of a loop in the Locations application by selecting the Loop Calibration check box on the Locations tab. You associate assets with the loop in the Assets application using the Location field for each asset.

You associate data sheets with locations in the Work Order Tracking application.

When assets are added in the Assets application, they are listed on the Assets tab in the Locations application. You use the Locations application to view the history of a loop calibration.

If a data sheet, which is part of a loop calibration, is marked as required, then all data on that data sheet is required. This data includes all asset functions for calibration points, function checks, or dynamic checks.

- [Adding a location to a loop calibration](#)

A loop calibration is a set of instruments that are grouped and calibrated together. The input and output results of the entire group determines the pass or fail status of the calibration.

Adding a location to a loop calibration

A loop calibration is a set of instruments that are grouped and calibrated together. The input and output results of the entire group determines the pass or fail status of the calibration.

Procedure

1. In the Locations application, select the location that you want to add to a loop calibration.
2. Select the Loop Calibration check box.
3. Save the location.

What to do next

You can associate assets with the loop in the Assets application.

- [Attaching data sheets to a location record](#)

You can associate one or more data sheets to a location record. Information from the data sheets is used to analyze data and evaluate performance.

Attaching data sheets to a location record

You can associate one or more data sheets to a location record. Information from the data sheets is used to analyze data and evaluate performance.

Procedure

1. In the Location application, select the location to attach the data sheet to.
2. From the Select Action menu, select Attach Data Sheet and insert a row.
3. Specify the data sheet.
4. Click OK to return to the current record.

Configuring calibration features

You must complete configuration tasks in order to use calibration features.

- [Configuring options for organizations](#)

You can configure specific calibration options and define edit rules for your organizations.

- [Configuring calibration features for uncertainty data](#)

You configure Maximo Manage to link to an external system that calculates uncertainty measurement data.

Configuring options for organizations

You can configure specific calibration options and define edit rules for your organizations.

- [Configuring calibration options for organizations](#)
You can configure calibration options for an organization, such as displaying warning messages or controlling the number of times a user can extend a PM record.
- [Configuring edit rules for calibration work orders](#)
You can configure each work order status to define when a data sheet on a work order can be edited. The edit rules apply to all calibration work orders for the selected organization.

Configuring calibration options for organizations

You can configure calibration options for an organization, such as displaying warning messages or controlling the number of times a user can extend a PM record.

About this task

These calibration options apply to the Work Order Tracking application and the Preventive Maintenance application.

Procedure

1. In the Organizations application, select the organization.
2. From the Select Action menu, select Calibration Options, > Work Order - Other Organization Options.
3. Specify the options to configure your organization.
4. Click OK to apply the changes.

Configuring edit rules for calibration work orders

You can configure each work order status to define when a data sheet on a work order can be edited. The edit rules apply to all calibration work orders for the selected organization.

About this task

You can specify the edit rules for editing As Found and As Left values, adding new data sheets, and editing calibration points.

Procedure

1. In the Organizations application, select the organization.
2. From the Select Action menu, select Calibration Options, > Work Order - Edit Rules.
3. In the Edit Rules window, choose the status for each value to indicate that the property can be changed.
4. Click OK to apply the changes.

Configuring calibration features for uncertainty data

You configure Maximo Manage to link to an external system that calculates uncertainty measurement data.

1. [Creating the data sheet template object structure](#)
An object structure is the common data layer that the integration framework uses for data processing. You create an object structure for the data sheet template to configure Maximo Manage for uncertainty data. You specify source objects in the object structure.
2. [Creating the work order data sheet object structure](#)
An object structure is the common data layer that the integration framework uses for data processing. You create an object structure for the work order data sheet to configure Maximo Manage for uncertainty data. You specify source objects in the object structure.
3. [Creating publish channels for the object structures](#)
A publish channel is the link for sending data to the external system. You create one publish channel for the data sheet template object structure and another publish channel for the work order data sheet object structure.
4. [Creating enterprise services for the object structures](#)
An enterprise service is the link for importing data from the external system. You create one enterprise service for the data sheet template object structure and another enterprise service for the work order data sheet object structure.
5. [Configuring the external system](#)
The external system calculates the uncertainty data that is required for the calibration process. You configure the external system to link to Maximo Manage.

Creating the data sheet template object structure

An object structure is the common data layer that the integration framework uses for data processing. You create an object structure for the data sheet template to configure Maximo Manage for uncertainty data. You specify source objects in the object structure.

Procedure

1. In the Object Structure application, create an object structure and specify a name.
2. In the Consumed By field, select Integration.
3. Specify the source objects for the data sheet template.
4. Save the object structure.

What to do next

Create the work order data sheet object structure.

- [Source object information: Data sheet template object structure](#)
You define the data sheet template source objects in the data sheet template object structure.

Next topic: [Creating the work order data sheet object structure](#)

Source object information: Data sheet template object structure

You define the data sheet template source objects in the data sheet template object structure.

Specify the following source object information in the data sheet template object structure.

Source object name	Parent Object field	Relationship field	Alternate Key field	Include Persistent fields
PLUSDSPLAN			PLUSDSPLAN_NDX2	<ul style="list-style-type: none">• CONFIDLEVEL• DSPLANNUM• GBMETHOD• GUARDBAND• KFACTOR• REVISIONNUM• SYSTEMID• SYSTEMIDDESC• UNCERTFREQ• UNCERTUNITS
PLUSCDSINSTR	PLUSDSPLAN	PLUSCDINSTR	PLUSCDSINSTR_NDX2	<ul style="list-style-type: none">• ASSETFUNCTION• CONFIDLEVEL• DSPLANNUM• GBFROM1• GBTO1• GBSUMDIRECTION1• GBFROM2• GBTO2• GBSUMDIRECTION2• GBFROM3• GBTO3• GBSUMDIRECTION3• GBFROM4• GBTO4• GBSUMDIRECTION4• GBMETHOD• GUARDBAND• INSTRSEQ• KFACTOR• REVISIONNUM• UNCERTFREQ• UNCERTUNITS
PLUSCDSPPOINT	PLUSCDSINSTR	PLUSCDSINSTRPOINTS	PLUSCDSPPOINT_NDX2	<ul style="list-style-type: none">• DSPLANNUM• INSTRSEQ• POINT• REVISIONNUM

Creating the work order data sheet object structure

An object structure is the common data layer that the integration framework uses for data processing. You create an object structure for the work order data sheet to configure Maximo Manage for uncertainty data. You specify source objects in the object structure.

About this task

You specify source object information in the object structure.

Procedure

1. In the Object Structure application, create an object structure and specify a name.
2. In the Consumed By field, select Integration.
3. Specify the source objects for the work order data sheet.
4. Save the object structure.

What to do next

After you create the two object structures, you configure a publish channel for each object structure.

- **Source object information: Work order data sheet object structure**
You define the work order data sheet source objects in the work order data sheet object structure.

Previous topic: [Creating the data sheet template object structure](#)

Next topic: [Creating publish channels for the object structures](#)

Source object information: Work order data sheet object structure

You define the work order data sheet source objects in the work order data sheet object structure.

Specify the following source object information in the work order data sheet object structure.

Source object name	Parent Object field	Relationship field	Alternate Key field	Include Persistent fields
PLUSCWODS			PLUSCWODS_NDX5	<ul style="list-style-type: none">• CONFIDLEVEL• DSPLANNUM• GBMETHOD• GUARDBAND• KFACTOR• REVISIONNUM• SITEID• SYSTEMIDDESC• SYSTEMID• TUR• UNCERTFREQ• UNCERTUNITS• WONUM• WODSNUM
PLUSCWODSINSTR	PLUSCWODS	PLUSCWODSINSTR	PLUSCWODSINSTR_NDX5	<ul style="list-style-type: none">• CALIBFUNCTION• CALIBFUNCTIONTIME• COMSTDUNCERT• DSPLANNUM• GBFROM1• GBTO1• GBSUMDIRECTION1• GBFROM2• GBTO2• GBSUMDIRECTION2• GBFROM3• GBTO3• GBSUMDIRECTION3• GBFROM4• GBTO4• GBSUMDIRECTION4• GBMETHOD• GUARDBA• INSTRSEQ• KFACTOR• REVISIONNUM• SITEID• TUR• UNCERTFREQ• UNCERTUNITS• WODSNUM• WONUM

Source object name	Parent Object field	Relationship field	Alternate Key field	Include Persistent fields
PLUSCWODSPOINT	PLUSCWODSINSTR	PLUSCWODSINSTRPOINTS	PLUSCWODSPOINT_NDX5	<ul style="list-style-type: none"> • DSPLANNUM • EXPECTDRIFT • EXPECTDRIFTEU • INPUTUNCERT • INPUTUNCERTEU • INSTRSEQ • POINT • REVISIONNUM • SITEID • UNCERTVALUE • UNCERTVALUEEU • WODSNUM • WONUM

Creating publish channels for the object structures

A publish channel is the link for sending data to the external system. You create one publish channel for the data sheet template object structure and another publish channel for the work order data sheet object structure.

Procedure

1. In the Publish Channel application, create a publish channel record.
2. Specify a publish channel name.
3. Specify the object structure.
4. Optional: To automatically generate XML files for all events, from the Select Action menu, select Enable Event Listener.

What to do next

Create an enterprise service for both object structures.

Previous topic: [Creating the work order data sheet object structure](#)

Next topic: [Creating enterprise services for the object structures](#)

Creating enterprise services for the object structures

An enterprise service is the link for importing data from the external system. You create one enterprise service for the data sheet template object structure and another enterprise service for the work order data sheet object structure.

Procedure

1. In the Enterprise Services application, create an enterprise service record.
2. Specify an enterprise service name.
3. Specify the object structure.

What to do next

Configure the external system for the uncertainty calculation system.

Previous topic: [Creating publish channels for the object structures](#)

Next topic: [Configuring the external system](#)

Configuring the external system

The external system calculates the uncertainty data that is required for the calibration process. You configure the external system to link to Maximo Manage.

Procedure

1. In the External System application, create the external system record and specify the external system name.
2. Select the End Point as MXXMLFILE.
3. To enable the external system, select the Enabled check box.
4. Specify the queues for the external system.
5. Specify the publish channels that you created.
6. Specify the enterprise services that you created.

What to do next

Now, you can import and export the xml file information.

Previous topic: [Creating enterprise services for the object structures](#)

Recording calibration data in work orders

You document your calibration data results using calibration work orders.

- [Work order tracking in calibration](#)
When you create a work order, you initiate the maintenance process and create a historical record of work that is being performed.
- [Associating data sheets to a work order](#)
When you create a work order to calibrate an instrument, you can associate the data sheet necessary to perform the calibration process to the work order.
- [Checking the status of a tool](#)
Tools that are used to calibrate an instrument must be in active status. You can view the status of a tool before it is added to a work order to ensure that it is in active status.
- [Entering calibration results on a work order data sheet](#)
When you calibrate an asset, you enter the results of the As Found and As Left values on the data sheet of a work order. These values determine the calibration status of the asset.
- [Extending due dates of calibration PM records](#)
You extend the date of a preventive maintenance (PM) record to override the typical next due date for generating PM work orders. You can extend the due date of a PM for a calibration asset a specified number of times.

Work order tracking in calibration

When you create a work order, you initiate the maintenance process and create a historical record of work that is being performed.

You use the Work Order Tracking application to create and manage calibration work orders.

When you create a calibration work order, you specify the work order with one of the following work types:

- CAL
- PMCAL
- CMCAL
- EMCAL

You use data sheets that are associated with a work order to calibrate an asset. A data sheet contains the specifications of an asset that is required for the calibration of the asset.

The data sheet also records uncertainty measurement data for instruments and measurement and test equipment. When a data sheet is attached to a work order, the uncertainty measurement data is imported from the Data Sheet Template application. Alternatively, uncertainty measurement data can be entered or imported directly into the work order data sheet.

On calibration work orders, you can view the calibration history of an asset and check the status of a tool associated with a work order. You can also record the result of a spot check for a tool associated with a work order and review data sheets that are attached to work orders.

Work order data sheets

You use the work order data sheet to enter data that is gathered during the calibration of an asset. Calibration assets are instruments and measuring and test equipment (M&TE).

Data sheets are created in the Data Sheet Template application and associated with assets. When a work order is created for a work asset with one or more associated data sheets, the data sheets are copied to the work order. You can also associate data sheets with job plans or attach them directly to a work order.

Only approved data sheets can be processed on work orders. During the calibration of an asset, you can enter the results of the as-found and as-left data. This data is used to analyze asset performance and calibration frequency.

As-found and as-left data

As Found and *As Left* are standard industry terms. The As-found and As-left data determines the calibration status of the asset.

When an asset is calibrated, the As-found data is recorded. As-found data is the calibration results before the asset is adjusted. In Maximo® Calibration, the As-found values are calculated to ensure that they are within the established range that is specified on the data sheet. If the values are outside the limit range, the asset is adjusted and the As-left results are recorded. As-left data is the calibration results after the asset is adjusted.

You must complete all As-found and As-left values before you can close a work order.

Associating data sheets to a work order

When you create a work order to calibrate an instrument, you can associate the data sheet necessary to perform the calibration process to the work order.

Before you begin

The data sheet that you want to associate to a work order must have a status of approved.

Procedure

1. In the Work Order Tracking application, select the calibration work order.
2. On the Data Sheet tab, click New Row in the Associated Data Sheets table window.
3. Specify the data sheet and save the work order.

- [Viewing the calibration history of data sheets](#)

You can view a list of completed data sheets of an asset that is associated with a work order. Calibration information about the asset is displayed.

Viewing the calibration history of data sheets

You can view a list of completed data sheets of an asset that is associated with a work order. Calibration information about the asset is displayed.

About this task

You can also view a list of data sheets for a specific date range.

Procedure

1. In the Work Order Tracking application, select the work order.
2. From the Select Action menu, select View Calibration History.
Data sheet information, including asset calibrations, location calibrations, and loop calibrations, is displayed.

Checking the status of a tool

Tools that are used to calibrate an instrument must be in active status. You can view the status of a tool before it is added to a work order to ensure that it is in active status.

Procedure

1. In the Work Order Tracking application, select the work order record for which you want to check a tool.
2. From the Select Action menu, select Check Tool Status.
3. Specify the tool and click Refresh.
The status information of the tool is displayed.

- [Recording tool spot check results](#)

Before you assign a tool to a work order, you can verify that the tool is operating within its correct range. You record the results of the verification using the Tool Spot Check action.

Recording tool spot check results

Before you assign a tool to a work order, you can verify that the tool is operating within its correct range. You record the results of the verification using the Tool Spot Check action.

Procedure

1. In the Work Order Tracking application, select the work order record that contains the associated tool that you want to check.
2. From the Select Action menu, select Tool Spot Check and click New Row.
3. Specify the tool information.
4. Specify the results of the spot check in the Status field.
5. Specify the check type and enter comments.
6. Click OK to save the tool spot check results.

Entering calibration results on a work order data sheet

When you calibrate an asset, you enter the results of the As Found and As Left values on the data sheet of a work order. These values determine the calibration status of the asset.

Procedure

1. In the Work Order Tracking application, select the work order.
2. Select the Data Sheet tab.
3. Specify the As Found results for the calibration point.
4. Optional: If the results are outside the specified limit range, adjust the asset.
5. Specify the As Left results for the calibration point.
6. Save the work order.

- [Adding a calibration point to a work order data sheet](#)

Calibration points are typically defined when you create a data sheet in the Data Sheet Template application. However, you can add calibration points to a data sheet on a work order if you need to check additional points for that asset.

Adding a calibration point to a work order data sheet

Calibration points are typically defined when you create a data sheet in the Data Sheet Template application. However, you can add calibration points to a data sheet on a work order if you need to check additional points for that asset.

Before you begin

You can add a calibration point only if the Technician Insert Points check box is selected on the data sheet in the Data Sheet Template application.

Procedure

1. In the Work Order Tracking application, select the calibration work order.
2. On the Data Sheet tab and in the Calibration Points table window, insert a row.
3. Enter a numeric value for the calibration point.
4. Specify either the discrete or analog asset function information.
5. Save the calibration point.

Extending due dates of calibration PM records

You extend the date of a preventive maintenance (PM) record to override the typical next due date for generating PM work orders. You can extend the due date of a PM for a calibration asset a specified number of times.

About this task

The number of times that you can extend the due date is configured in the Organizations application. The default number of times is 1. The due date of a calibration PM must be controlled so that the calibration schedule of an asset is completed on time.

If the allocated number of times to extend the due date is exceeded, you can override the extended date. Only users with security permissions can override the extended date.

When a calibration due date is extended on a preventive maintenance (PM) record, you can view this change on the associated master PM.

Procedure

1. In the Preventive Maintenance application, select the PM record.
2. On the Frequency tab, ensure the Estimated Next Due Date field contains a date.
3. In the Extended Date field, specify a value and enter a reason for extending the date.
The date must be later than the Estimated Next Due Date.
4. Optional: To adjust this date after the work order for the PM is generated, select the Adjust Next Due Date check box.
5. Save your changes.

- [Overriding extended dates of calibration PM records](#)

Users with security access can override the number of times that the due date of a preventive maintenance (PM) plan can be extended.

- [Viewing PM extended dates](#)

When a calibration due date is extended on a preventive maintenance (PM) record, you can view this change on the associated master PM.

Overriding extended dates of calibration PM records

Users with security access can override the number of times that the due date of a preventive maintenance (PM) plan can be extended.

About this task

The number of times that you can extend the due date of a PM plan for a calibration asset is configured in the Organizations application.

Procedure

1. In the Preventive Maintenance application, select the PM record for which you want to extend the date.
2. From the Select Action menu, select Override Extend Date.
3. Specify a new date and click OK.

Viewing PM extended dates

When a calibration due date is extended on a preventive maintenance (PM) record, you can view this change on the associated master PM.

Procedure

1. In the Master Preventive Maintenance application, select the master PM record.
2. From the Select Action menu, select View PM Extend Dates.
3. Click OK to close the window.

Administering and configuring attached documents

As an administrator, you can maintain attached documents for your applications in persistent storage or in cloud object storage.

- [Configuring attached documents](#)
Configuration for attached documents includes preparing a storage repository, specifying storage parameters when you deploy Maximo® Manage, and configuring the application after deployment.
- [Administering attached document libraries](#)
Administrators use the Attachment Library/Folders action in applications to create a document library and to organize documents into folders. Files and folders that you add are stored in the storage repository that you create for Maximo Manage.

Configuring attached documents

Configuration for attached documents includes preparing a storage repository, specifying storage parameters when you deploy Maximo® Manage, and configuring the application after deployment.

- [Preparing storage repositories](#)
Before you can store and view attached documents, you must determine a storage option and complete the configuration requirements for that option. Both persistent storage and cloud storage options are available.
- [Adding persistent storage parameters to deployments](#)
When you deploy Maximo Manage, you configure a persistent claim to the storage volume that was created to store attachments.
- [Configuring system properties for persistent storage](#)
To implement attached document features for persistent storage in Maximo Manage, administrators specify system properties to define parameters, such as a default file path, maximum file size, attachment security, and other relevant properties.
- [Configuring system properties for S3](#)
To implement attached document features for Simple Storage Service (S3) cloud object storage in Maximo Manage, administrators specify system properties to define parameters, such as the storage bucket, access key, and other relevant properties.
- [Converting file-based storage to S3 storage](#)
Maximo Manage provides you with a tool to convert file-based attachments to S3 attachments.

Preparing storage repositories

Before you can store and view attached documents, you must determine a storage option and complete the configuration requirements for that option. Both persistent storage and cloud storage options are available.

Preparing persistent storage repositories

If you want to use a Network File System (NFS) to provide storage for attached documents, you must provision a persistent storage volume for Maximo Manage using the Kubernetes persistent volume (PV) framework.

Setting up the storage is outside of the scope of the Maximo Manage deployment and must be completed before you deploy the application. Then, when you deploy the application, you can configure a persistent claim to the amount of storage that you need for attached documents.

While the detailed steps for preparing storage depend on your organization's specific implementation, the following guidelines provide a high-level summary of the tasks to complete when you set up NFS storage:

- Deploy an NFS server and ensure that the server is enabled and started.
- Export an NFS file share and ensure that it is accessible. In the file share, specify the directory to use for attached documents, the IP address for a method to access the directory, and the authorizations for accessing the folder. Ensure that everyone has read and write access to the directory. When you deploy Maximo Manage, you specify the mount path for the directory when you create the persistent volume claim for the storage. You also specify the directory when you configure system properties for attached documents in Maximo Manage.
- In Kubernetes, within Red Hat® OpenShift®, set up an NFS provisioner and class. Note the class name because you specify the class name for your persistent volume claim when you deploy Maximo Manage.
- Create a persistent volume storage resource. Note the volume name because you specify the volume name for your persistent volume claim when you deploy Maximo Manage.

For more information about setting up persistent storage, see [Understanding persistent storage](#) in Red Hat OpenShift documentation.

Preparing S3 storage

If you want to use Simple Storage Service (S3) cloud object storage for storing attachments, you must first create a bucket for storing the attachments.

Note the access key, secret key, S3 endpoint URI, and name of the storage bucket. You specify those values when you configure the following system properties:

- mxe.cosaccesskey
- mxe.cossecretkey
- mxe.cosendpointuri
- mxe.cosbucketname

Adding persistent storage parameters to deployments

When you deploy Maximo® Manage, you configure a persistent claim to the storage volume that was created to store attachments.

Before you begin

Ensure that you prepared a persistent storage volume and can provide the volume name, class name, mount path, and size for your persistent volume claim.

Procedure

1. Log in to Maximo Application Suite as a system administrator.
2. From the catalog, on the Applications tab, select the Manage tile.
3. On the application details page, click Actions and select Update configuration.
4. In the Persistent volume claims (PVCs) row on the Update Manage configuration window, click the Edit icon.
5. In the Persistent volume claims (PVCs) section of the configuration window, click Add PVC.
You might have to click System managed to view configuration options.
6. Add the following details for your persistent volume claim.

Option	Description
PVC name	User-defined name of the persistent volume claim for storage.
Volume name	Name of the volume that was provisioned for attached document storage.
Size	Amount of storage that is required for this persistent claim.
Mount path	Mount path for the volume within the Maximo Manage pod.
Storage class name	Storage class that describes and classifies the storage.

7. After you complete all configurations, select one of the following options:
 - If you are configuring a new deployment, click Activate.
 - If you are updating a deployment, click Apply changes.

Configuring system properties for persistent storage

To implement attached document features for persistent storage in Maximo® Manage, administrators specify system properties to define parameters, such as a default file path, maximum file size, attachment security, and other relevant properties.

About this task

This task describes how to configure the system properties that are needed to set up attachments if you provisioned storage for attachments by using the Kubernetes persistent volume (PV) framework. The topic describes the basic properties that you must configure after you deploy Maximo Manage. However, you might need to specify other properties for your implementation. For more information, see *Attached document properties*.

Before you begin

You must have authorization to edit system properties for attached documents.

Procedure

1. In the System Properties application, in the Property Name field, filter for attached document property or properties that you want to configure.
2. Configure the system properties for attached documents as shown in the following table.

Table 1. Required system properties for attached documents

Property	Description	Value
mxe.doclink.doc types.defpath	The default file directory to use for folders in the attached documents library. Specifies the default path for the directory that you set up for attached documents on your persistent storage volume. Your documents are stored in this directory. This value must be configured before you can attach documents and requires a live refresh.	Specify the path to the directory that you set up in your persistent storage volume. For example, /d01/doclinks
mxe.doclink.doc types.topLevelP aths	Specifies the top-level attachments directory that stores all document folders in your persistent storage volume. The Default File Path value that is entered in the Manage All Documents Folder window must be a subdirectory of this value. This value cannot be null. When you complete the system property configurations, restart the server bundle pod to implement the changes.	The default location is the top-level directory on the persistent storage volume. For example, \doclinks.
mxe.doclink.pat h01	The HTTP Server path to link documents that are attached to records. The server name in the path must be a fully qualified server name. This property requires a live refresh.	/d01/doclinks=https://hostname//maximo/oslc/doclinks For example: /d01/doclinks=https://host//maximo/oslc/doclinks
mxe.doclink.sec uredAttachment	The value that you specify for this property determines whether the application displays the file path of attached documents. Setting this property to <code>true</code> prevents the application from displaying the file path of attached documents. The application displays only the content root and the file name. Setting the property to <code>true</code> makes all attached document requests go through the Maximo Manage server instead of an HTTP web server and provides an extra layer of security to the stored documents.	The default value for this property is false. For Maximo Manage deployments on Red Hat® OpenShift®, set this property to <code>true</code> .
mxe.report.Atta chDoc.validateU RL	Determines whether the URL of the attached document needs to be validated before the document is printed.	The default value for this property is 1. For Maximo Manage, set this property to 0.

3. Restart the server bundle pod.
If you have multiple server bundles, restart all of them.

Configuring system properties for S3

To implement attached document features for Simple Storage Service (S3) cloud object storage in Maximo® Manage, administrators specify system properties to define parameters, such as the storage bucket, access key, and other relevant properties.

About this task

You can configure the system properties after you deploy Maximo Manage.

Before you begin

You must have authorization to edit system properties for attached documents.

Procedure

1. In the System Properties application, select the property that you want to edit. You can locate document properties for S3 attachments by specifying the following filters in the Property Name field:
 - mxe.cos
 - mxe.doclink
 - mxe.attachmentstorage
2. Configure the system properties for attached documents as needed.
For more information about the system properties for S3 storage, see *Attachment properties for S3 storage*.
3. Restart the server bundle pod.
If you have multiple server bundles, restart all of them.

Converting file-based storage to S3 storage

Maximo® Manage provides you with a tool to convert file-based attachments to S3 attachments.

About this task

When you deploy Maximo Manage, you can find a new shell script that is named file2s3.sh in \tools\maximo folder.

Procedure

Run the shell script file2s3.sh by using the following parameters:

Table 1. Listing of shell script parameters

Parameter name	Description	Example
-bBucketName	Bucket name	-bqabucket
-xAccessKey	Access key	-x6xg5v1EacUtyMLXgzXbg
-sSecretKey	Secret key	-siaAKhsSYKM51u39yyIH05l4jYzgCf5NH HJUUltm5
-rEndpoint	End point or URL of the S3 provider	-rs3.us.cloud-object- storage.appdomain.cloud
-wwhere clause for filtering docinfo table	A where clause for filtering docinfo table. The document information table stores links to all the documents.	-w"(document='TESTDOC')"

Note: The maxinst or admin pod must be able to access the folder locations of the attachments for the tool to work.

For example, `./files2s3.sh -bqabucket -x6xg5v1EacUtyMLXgzXbg -siaAKhsSYKM51u39yyIH05l4jYzgCf5NHJUUltm5 -rs3.us.cloud-object-storage.appdomain.cloud -w"(document='TESTDOC')"`

Administering attached document libraries

Administrators use the Attachment Library/Folders action in applications to create a document library and to organize documents into folders. Files and folders that you add are stored in the storage repository that you create for Maximo® Manage.

You can maintain the library, create folders as needed, and specify which folders are available for each application. The system includes default folders, including folders for attachments, diagrams, images, and websites. You can also create more folders or organize the folders into functional categories. Other folders might include permits, part sheets, photographs, procedures, and drawings.

To open an attachment, users must have the appropriate application for that document type that is installed on their computer. For example, you must have Microsoft Word installed to view a Word document.

- [Adding document folders](#)
Administrators can add folders to attached document libraries from within Maximo Manage applications.
- [Associating document folders with applications](#)
Administrators can associate document folders with Maximo Manage applications. By default, folders for attachments, images, and diagrams are associated with applications that have the attached documents action.
- [Adding file attachments to the library](#)
You can add a file attachment to your documents library.
- [Adding URLs to the library](#)
You can add a URL to your document library.
- [Modifying existing documents](#)
You can modify the information for documents that are stored in the document library.
- [Attaching documents to records](#)
You can attach relevant information to your records in the form of a file or a URL address. Documents can include text files, spreadsheets, and diagrams.

Adding document folders

Administrators can add folders to attached document libraries from within Maximo® Manage applications.

Before you begin

You must have administrative permissions to add folders.

About this task

Several default folders are provided with the Maximo Manage application, including folders for attachments, diagrams, images, and websites. When you are setting up your attachment library, ensure that you specify the appropriate file path to the storage repository for the default folders and for any other folders that you add.

Procedure

1. Open any Maximo Manage application that has the attached documents actions.
2. Select Attachment Library/Folders and then select the Manage Folders action.

3. Click Add a New Document Folder.
4. Specify the information for the new folder.
Ensure that you specify the file path to the directory that you set up for attached documents on your persistent storage volume.
5. Click OK.

Associating document folders with applications

Administrators can associate document folders with Maximo® Manage applications. By default, folders for attachments, images, and diagrams are associated with applications that have the attached documents action.

Before you begin

You must have administrator privileges to associate document folders with an application.

Procedure

1. Open a Maximo Manage application that has the attached documents actions.
2. Select Attachment Library/Folders, then select the Associate Folders action.
3. Click New Row.
4. In the Document Folder field, enter a value. The Document Folder Description field and the Application field contain default values, which you can change.
5. Click OK to save your changes.

Adding file attachments to the library

You can add a file attachment to your documents library.

Procedure

1. Open an application that has the attached documents actions.
2. Select the Attachment Library/Folders action, then select the Manage Library action.
3. Click Add a Document to the Library, then select Add New File.
4. Complete all necessary fields, and click OK.

Adding URLs to the library

You can add a URL to your document library.

Procedure

1. Open an application that has the attached documents actions.
2. Select the Attachment Library/Folders action, then select Manage Library.
3. Click Add a Document to the Library, then select Add New Web Page.
4. Complete all necessary fields, and click OK.

Modifying existing documents

You can modify the information for documents that are stored in the document library.

About this task

If you click View Details for a document, you can modify only the Document Description field and the URL/File Name field, and select the Print with Work Pack check box.

Procedure

1. Open an application that has the attached documents actions.
2. Select Attachment Library/Folders, then select the Manage Library action.
3. In the Manage Library window, expand the row for the document that you want to modify.
4. Modify editable fields that you want to change.
Fields with a white background are editable and fields with a gray background are read-only.
5. Click OK.

Attaching documents to records

You can attach relevant information to your records in the form of a file or a URL address. Documents can include text files, spreadsheets, and diagrams.

About this task

You can attach documents to records and to tasks on a record. You can upload a file attachment from your computer, or you can attach a file from your attached documents library.

Procedure

1. In an application that has the attached documents actions, click Attachments.
2. Select one of the following actions to attach documents:

Option	Description
To add an attachment from the library.	<ol style="list-style-type: none">a. Select Add from Library.b. Select one or more files in the library and click OK.
To add an attachment.	<ol style="list-style-type: none">a. Select Add New Attachments.b. Select Add New File or Add New Web Page.c. In either the Create a File Attachment window or the Create a URL Attachment window, specify the folder to add the attachment to.d. Enter the details for the file or URL attachment.e. If you want to add this file to the library, you can select the Add document to the document library for others to use checkbox.f. Click OK.

Restriction: Center for Internet Security (CIS) policies might prevent the upload of some HTML files as attachments. In such cases, convert the file to a PDF format, or contact your administrator about adjusting the CIS policies.

Enabling edit mode

You can enable edit mode for records, such as work orders and tickets, that are used frequently by multiple users. Edit mode reduces errors that occur when two users edit a record in the same application at the same time.

Edit mode does not eliminate all error occurrences when two users are editing a record. For example, errors can still occur when two users edit the same record in two different applications.

- [Edit mode for records that are used frequently by multiple users](#)
Examples of applications in which multiple users might concurrently access records include the Work Order Tracking application, the Problems application, the Incidents application, the Changes application, and the Activities and Tasks application.
- [Configuring edit mode](#)
You enable edit mode on an application-by-application basis. Edit mode is not enabled for any applications when the product is installed.
- [Releasing records from edit mode](#)
If records remain in edit mode erroneously, you can release the records in the Record Release application. You can filter the records to locate the records that you want to release.

Edit mode for records that are used frequently by multiple users

Examples of applications in which multiple users might concurrently access records include the Work Order Tracking application, the Problems application, the Incidents application, the Changes application, and the Activities and Tasks application.

When edit mode is enabled for an application but a record is not in edit mode, actions that update the underlying record are not available to the user. When the user places the record in edit mode, the actions become visible. An action that has a prerequisite of SAVE in Application Designer indicates that it might update the underlying record.

When a user selects records on an application's List tab and selects an action, the action does not run on records that are currently being edited by other users if the action causes an error. If the action will not cause an error, then the action takes place on the records in edit mode. For example, a user places a record in edit mode in the Item Master application. Another user selects that record on the application's List tab and selects the Add to Item Storeroom action while the first user is making changes on the Item tab. The action is allowed on the record as it does not cause an error for the first user.

The following actions release a record from edit mode:

- Starting another application by using the Go To menu.
- Returning to the List tab of the application.
- Paging through records by using the Next and Previous links.
- Logging out.

If a user closes the browser without logging out, the record remains in edit mode until session times out. Starting a child application does not take the record out of edit mode, nor does saving the record.

Configuring edit mode

You enable edit mode on an application-by-application basis. Edit mode is not enabled for any applications when the product is installed.

About this task

You enable edit mode for an application by using the Edit Mode Enabled? check box in Application Designer.

If you decide at a later point that edit mode is not needed for an application, you can clear the Edit Mode Enabled? check box. Disable edit mode outside of normal business hours. Users who are currently editing records in the application when you disable edit mode continue to have edit mode access until they log out and log back in.

Procedure

1. In Application Designer, open an application that you want to configure for edit mode.
2. Select the Edit Mode Enabled? check box.
3. Save the application.
4. Log out and log back in.

Results

Users who are members of security groups that have save permissions can open records in the application in edit mode after they log out and log back in.

Releasing records from edit mode

If records remain in edit mode erroneously, you can release the records in the Record Release application. You can filter the records to locate the records that you want to release.

Procedure

1. In the Record Release application, select the records that you want to release from edit mode.
2. Click Release Edit Mode.

Log management

You can create and manage log files that contain informational, warning, or error messages about various application activities. You also can view log data about for the Maximo® Manage server bundles and for processes that are handled by the administrative server.

- [Log output locations](#)
In Maximo Manage, output logs from administrative server processes or from the server bundles are directed to standard output (STDOUT) in Red Hat® OpenShift®. They also can be sent or redirected to a Simple Storage Service (S3) Cloud Object Storage location that you provision.
- [Sending log output to S3 Cloud Object Storage](#)
You can send server bundle logs for Maximo Manage to Simple Storage Service (S3) Cloud Object Storage. You also can redirect logs from the administrative server to S3 Cloud Object Storage.
- [Managing log files](#)
You create log files to save the informational, warning, or error messages about the system. You can also manage the logging process and the format of the log files across your organization.
- [Working with log files](#)
There are several tasks relating to managing your log files from applications, such as specifying log file formats and locations, and associating loggers with appenders.
- [Viewing Maximo Manage Logs](#)
View the IBM® Maximo Manage logs for Server, Maxinst and Update database, User sync, Workspace operator, and Build logs from the Red Hat OpenShift console.

Log output locations

In Maximo® Manage, output logs from administrative server processes or from the server bundles are directed to standard output (STDOUT) in Red Hat® OpenShift®. They also can be sent or redirected to a Simple Storage Service (S3) Cloud Object Storage location that you provision.

To view log files, select Workloads > Pods in the console menu. Open the pod for your project and select the Logs tab to view logs. Or, view or process the output with various tools, such as an aggregation of logs in a Red Hat OpenShift cluster-level logging stack, or kubectl, the Kubernetes command-line tool.

You also can send server bundle logs for Maximo Manage to Simple Storage Service (S3) Cloud Object Storage that you provision. You can redirect logs from the administrative server to S3 Cloud Object Storage.

For more information about logging to S3 Cloud Object Storage, see the related task.

Sending log output to S3 Cloud Object Storage

You can send server bundle logs for Maximo® Manage to Simple Storage Service (S3) Cloud Object Storage. You also can redirect logs from the administrative server to S3 Cloud Object Storage.

Before you begin

You must provision an S3 Cloud Object Storage location and note its S3 bucket name, endpoint URL, S3 access key properties, and the value of the S3 secret. If you intend to send server bundle logs to S3, you must have or obtain an API key in the Administrative Work Center.

About this task

The Maximo Manage application is deployed in one or more workloads, which are called server bundles. Server bundles include the ui, all, mea, reports, and cron types. Server bundle logs can be uploaded from your log location on WebSphere® Application Server Liberty to your S3 location.

The administrative server handles commands for the updatedb, maxinst, and the integrity checker utilities. Administrative server logs can be redirected to your S3 location.

Procedure

1. In your Red Hat® OpenShift® Container Platform deployment, go to Workloads > Secrets and add a key and value secret for your S3 configuration.
 - a. For the secret name, specify `s3secretkey`.
 - b. Set the key name to `accessSecretKey`.
 - c. Get the value from your S3 configuration.
2. In the Administration section, modify the custom resource (CR) for the ManageWorkspace custom resource definition (CRD) by taking the following steps:
 - a. Select the ManageWorkspace custom resource definition (CRD).
 - b. Select the Instance tab, then select the custom resource (CR).
 - c. On the YAML tab, add or modify the `spec.settings.deployment` section, and ensure that the custom resource (CR) for your instance contains the `loggingS3destination` property and the following child properties and values that match your S3 configuration:
 - `bucketName`: The S3 bucket name of the log destination.
 - `endpointURL`: The S3 endpoint URL. URLs for S3 can vary, depending on the S3 service that you use, such as a public, private, or regional URL service. Choose the URL that matches your deployment.
 - `accessKey`: The S3 access key.
 - `secretKey`: The name of the secret that contains the S3 access credential that you configured in Step 1.

After you modify the CR for your instance, the values are propagated to the CRs for the administrative server and the server bundle pods. If any property or value is not specified, logs are not sent to S3 Cloud Object Storage.

The following code sample for the CR shows the required properties and some fictitious values:

```
deployment:
  loggingS3Destination:
    accessKey: AQDNAWKXRTTY84LJ4G6YR
    bucketName: s3-bucket
    endpointURL: https://s3.us-area.amazonaws.com
    secretKey:
      secretName: s3secretkey
```

Logs that result from the running the maxinst, updatedb, or integrity checker utilities are now redirected to your S3 storage location. Each modified log is compressed and has a name that contains the source location and the timestamp of when the administrative command started to run.

3. To upload server bundle logs from your log location on WebSphere Application Server Liberty, make the following API request: **POST** `https://host:port/maximo/api/service/logging?action=wsmethod:submitUploadLogRequest`. Provide the API key in the header of the request. The body is empty.

The API request creates an entry in the LOGREQUEST table of Maximo Manage for each server bundle. A continuously running cron task uploads the compressed log files to your S3 storage location when the table is updated. The name of each file contains the source location and the timestamp of when the command started to run.

You can query the LOGREQUEST table to troubleshoot any issues. Clean up old table entries by configuring an instance of the LOGREQUESTCLEANUP cron task to run each day.

- [S3 buckets](#)
Maximo Manage 8.5 supports nested and other buckets for file backups.

Streaming WebSphere Application Server Liberty logs

You can stream WebSphere Application Server Liberty logs for server bundles by constructing a URL that you can use in a browser or other tool that you use for REST API calls.

Before you begin

Before you can stream logs, your administrator must grant you the STREAMLOG signature option for the Logging application. An API key is also required.

About this task

When you enter the URL in a browser, the browser displays the content of the WebSphere Application Server Liberty messages.log file for the server bundle that you specified.

Procedure

1. To stream the contents of the messages.log file for WebSphere Application Server Liberty, enter a URL in the following format in a browser or other API tool that you use for REST API calls:

```
https://<URL to the server bundle for which you want to stream logs>/maximo/api/service/logging?  
action=wsmethod:streamLog&apikey=<your API key>
```

For example,

```
https://mas.manage.ui.mydomain.com/maximo/api/service/logging?  
action=wsmethod:streamLog&apikey=n0sjvsv4m8495037r2baafag35r5qaoncps
```

2. Optional: To refresh the browser with the latest contents of the log, press Enter again.

Managing log files

You create log files to save the informational, warning, or error messages about the system. You can also manage the logging process and the format of the log files across your organization.

- **Logging application components**
The Logging application has the loggers, appenders, and layouts components that you configure.
- **Application of logger settings**
Log settings in the Logging application define the type of information that is logged. Before you can activate logging for applications or runtime components, you must apply log settings in the Logging application.

Logging application components

The Logging application has the loggers, appenders, and layouts components that you configure.

Loggers

Loggers prepare log statements to be written to console or log file.

Loggers are named entities or keys, such as log4j.logger.maximo.sql. Loggers also form a hierarchy. A logger is defined as an ancestor of another logger. This relationship is true only when the name of the logger is followed by a dot or is a prefix of the descendant logger name. If there are no ancestors between a logger and the descendant logger, a logger becomes the parent of a child logger. For example, log4j.logger.maximo.sql is the parent of log4j.logger.maximo.sql.WORKORDER.

Log levels indicate the type of event that the system logs. You can assign the following levels to Loggers: DEBUG, INFO, WARN, ERROR, and FATAL.

Appenders

Appenders specify the output definitions for loggers. For example, a rolling appender writes log statements to a specified file. Once a size limit for the file is reached, that file is renamed and a new file is created.

Appenders can exist for consoles or files. You can associate one or more loggers with a given appender. Alternatively, you can associate a single logger with multiple appenders.

The product provides the following types of appenders. You cannot delete any of the provided appenders.

Table 1. Appender types

Type	Description
Console appender	Writes log statements to the application server console.
Rolling appender	Writes log statements to the file specified in the File Name field. Once the file size limit is reached (5 MB by default), the current file is renamed and a new file is created. For example, if the current file is named maximo.log, then the renamed file is maximo.log.1.
Daily Rolling appender	Writes log statements to the file specified in the File Name field. The file is renamed and a new file is created at a specified rate. This rate depends on the Date Pattern attribute. For example, if you have configured the Date Pattern of your Daily Rolling Appender to yyyy-MM-dd , when the current file is named maximo_scheduled.log, the renamed file is maximo_scheduled.log.2007-06-18.

Layouts

A layout specifies the output format of the log statement and is always associated with an appender.

For example, a Conversion Pattern such as: `%d{dd MMM yyyy HH:mm:ss:SSS} [%-2p] %m%n`, results in the following log statement: `2007-05-07 14:07:41,508 [main] INFO MyApp - Entering application;`

Application of logger settings

Log settings in the Logging application define the type of information that is logged. Before you can activate logging for applications or runtime components, you must apply log settings in the Logging application.

If you create a logger or change the log settings, select the Apply Settings action.

Perform this action if you change the settings in the Log Level field or in the Active check box. You also perform this action if you add loggers.

Working with log files

There are several tasks relating to managing your log files from applications, such as specifying log file formats and locations, and associating loggers with appenders.

- [Specifying local log file locations](#)
You can specify a folder for storing your log files from activities such as escalations and integrations.
- [Managing appenders](#)
You can create, change, or delete appenders in the Logging application.
- [Automation scripts loggers](#)
All logging that is related to scripts is done by the autoscript logger. The log level is set, by default, to ERROR. Only errors that are encountered during script execution, are output to the system console or to the product log file.
- [Log control of individual scripts](#)
To help you identify errors in automation scripts, you can add child script loggers to the root logger for automation scripts. Then, you associate the new script logger with the script that you want to monitor and specify a log level that is more granular than the log level for root logger for automation scripts.
- [Cron task loggers](#)
When cron tasks fail to run successfully, the root logger cron task can be set to different levels to obtain more detailed logs. If a particular cron task fails to run successfully, additional loggers can be set up to isolate the cause of the failure.
- [Adding a rolling logger for the PMWoGen cron task](#)
You can limit the size and number of log files that are saved for the PMWoGen cron task. You add a cron task logger that rolls over to a new log file when the current log reaches a specified size. Older versions are deleted after a specified number of instances. The log level can be less granular than the level that is specified for the parent cron task logger.
- [Escalation loggers](#)
If an escalation fails to run, the failure can be caused by the escalation engine, the email notifications, or actions triggered by the escalation. You can troubleshoot the cause of the failure by setting the correct log level.
- [Integration framework loggers](#)
The integration framework has four root loggers: integration, REST, interaction, and Open Services Lifecycle Collaboration (OSLC). To receive the maximum amount of information set the root loggers to DEBUG.
- [Enabling the EventTracker filter](#)
To enable the EventTracker filter, uncomment the filter definition and filter mapping in the web.xml file, which is located in *Tpae root\applications\maximo\maximouiweb\webmodule\WEB-INF* directory.
- [Configuring custom log messages to help resolve bugs](#)
To identify the section of a log file that contains statements or messages that are relevant to product use, problem creation, or a debugging activity, you can configure custom log messages. You specify start and end messages that are included in the log file. You can review the statements or messages that are shown in between the custom log start and end messages in the log file to help you trace a scenario or resolve an issue.
- [Enabling thread logs](#)
In the System Configuration application, you can enable thread logs to track actions made by specified users in Maximo Manage, such as in the user interface.
- [Scenario: Interpreting log file statements to resolve errors](#)
Marco, a system administrator, wants to isolate and resolve an error that occurs when someone tries to save a work order. Marco can troubleshoot the problem by setting the Word Order Tracking root logger to DEBUG and the SQL root logger to INFO.

Specifying local log file locations

You can specify a folder for storing your log files from activities such as escalations and integrations.

Before you begin

You must ensure that the user account used to run the application server has both read and write permissions on the log file destination folder.

Procedure

1. In the Logging application, select the Set Logging Root Folder action.
2. In the Set Logging Root Folder window, specify a location in the Root Logging Folder field.

Managing appenders

You can create, change, or delete appenders in the Logging application.

Procedure

1. Select the Manage Appenders action.
2. In the Manage Appenders window, you can create, modify, or delete an appender.

Automation scripts loggers

All logging that is related to scripts is done by the autoscript logger. The log level is set, by default, to ERROR. Only errors that are encountered during script execution, are output to the system console or to the product log file.

Individual script log levels can be used to redirect output statements in the script code to the system console or to the product log file. To ensure that output statements are redirected, set the log level of the individual script to the same log level of the autoscript logger. For example, if the autoscript logger is set to INFO, then the individual script log level must also be set to INFO.

The log level can be changed so that more script execution information is written to the product log file. Some of the statements are from the scripting component while others can be the script code-specific output statements. Each individual script can be configured at different log levels.

Example

A system administrator enters a purchase price value. A field validation script that is associated with the Purchase Price field of the Asset application runs business rules that compute the replacement cost. The system administrator encounters an error that indicates that the script failed to run line number 17 of the script. If required, he can place the output statements in the script code to isolate the specific section of code that is failing. He can set up detailed DEBUG logging to determine the type of variable, either input or output, that was received into or calculated in the script.

Log control of individual scripts

To help you identify errors in automation scripts, you can add child script loggers to the root logger for automation scripts. Then, you associate the new script logger with the script that you want to monitor and specify a log level that is more granular than the log level for root logger for automation scripts.

In the Logging application, you can create a child logger of the autoscript logger and associate the child logger with a script that you want to monitor. In the Key field, append the name of the script in uppercase text to the root autoscript name. Then, for example, you can set the log level to Debug on the child logger and keep the level of the parent log set to Error.

This action can help you to find and troubleshoot script errors more easily.

Example

You add a script that is named ASSETCHG1 to send a notification whenever an asset identifier is changed.

You want to be sure that the action and notification complete successfully, so in the Logging application, you add a child logger to the log4j.logger.maximo.script Autoscript logger. In the Key field, you specify the logger name as log4j.logger.maximo.script.ASSETCHG1. You set the log level for this script to Debug, make the script active, and apply the settings. The parent Autoscript logger is set to Error.

You test changing an asset identifier and when the notification does not occur, you review the debug log for the ASSETCHG1 script. You find and correct an error in the script.

Cron task loggers

When cron tasks fail to run successfully, the root logger cron task can be set to different levels to obtain more detailed logs. If a particular cron task fails to run successfully, additional loggers can be set up to isolate the cause of the failure.

The following table lists the application area, the cron task, a description of the cron task, and the log levels to set each logger to. The list details the key cron tasks and not contain all of the cron tasks.

Table 1. Cron task loggers. Cron task logger details

Group / Area	Cron task	Description	Loggers and log level
Escalation	ESCALATION	Runs active escalation definitions and starts actions and notifications	To isolate execution errors with escalations, set the child logger of cron task root logger to DEBUG level.
Email listener	LSNRCRON	Runs periodically to process incoming emails and create or update Service Requests	To isolate execution errors with the email listener, set the child logger of cron task, EmailListnerCron to DEBUG level.

Group / Area	Cron task	Description	Loggers and log level
Integration	FLATFILECONS UMER	Automates the processing and loading of data contained in flat files	To isolate execution errors with the integration framework, set the integration root logger to DEBUG level. This logger supports log statements produced from all of the integration framework cron tasks.
Integration	IFACETABLECO NSUMER	Automates the processing and loading of data contained in interface tables	To isolate execution errors with the integration framework, set the integration root logger to DEBUG level. This logger supports log statements produced from all of the integration framework cron tasks.
Integration	JMSQSEQCONS UMER	Automates the processing of messages from the JMS sequential queue in the integration framework	To isolate execution errors with the integration framework, set the integration root logger to DEBUG level. This logger supports log statements produced from all of the integration framework cron tasks.
Integration	XMLFILECONSU MER	Automates the processing and loading of data contained in XML formatted files	To isolate execution errors with the integration framework, set the integration root logger to DEBUG level. This logger supports log statements produced from all of the integration framework cron tasks.
Reporting	REPORTLOCKRE LEASE	Determines whether locked report jobs continue, or are canceled and resubmitted to the reporting queue	To isolate execution errors with reporting, set the child logger REPORTLOCKRELEASE for the cron task root logger to DEBUG.
Reporting	REPORTOUTPUT CLEANUP	Automates the clean-up of previously output report entries that are stored	To isolate execution errors with reporting, set the child logger REPORTOUTPUTCLEANUP for the cron task root logger to DEBUG.
Reporting	REPORTSCHED ULE	Automates the removal of report usage entries that are created each time a report is run	To isolate execution errors with reporting, set the child logger REPORTSCHEDULE for the cron task root logger to DEBUG.
KPI	KPICronTask	Refreshes KPI values periodically	To isolate execution errors with KPI, set the child logger KPICronTask for the cron task root logger to INFO.
User group/synchroni zation	LDAPSYNC	Automates the synchronization of users and groups maintained in an LDAP directory	To isolate execution errors with security, set the child logger LDAPSYNC for the cron task root logger to DEBUG.
User group/synchroni zation	VMMSYNC	Automates the synchronization of users and groups maintained in an LDAP directory	To isolate execution errors with security, set the child logger VMMSYNC for the cron task root logger to DEBUG.
Inventory	ReorderCronTas k	Runs the reorder process for direct issue items	To isolate execution errors with inventory, set the child logger, INVENTOR for the application root logger to DEBUG.

Adding a rolling logger for the PMWoGen cron task

You can limit the size and number of log files that are saved for the PMWoGen cron task. You add a cron task logger that rolls over to a new log file when the current log reaches a specified size. Older versions are deleted after a specified number of instances. The log level can be less granular than the level that is specified for the parent cron task logger.

About this task

The PMWoGen cron task can be enabled to automatically generate work orders from preventive maintenance records. Logging activity can be extensive, depending on the number of sites and assets that you maintain.

Procedure

1. In the Logging application, select the Manage Appenders action and add an appender that is named PMWoGen.
2. Specify the class file name as `psdi.util.logging.MXFileAppender`.
3. Specify the log file name as `pmwogencronlog.log`.
4. Specify the maximum file size for the most current log and the number of most recent files to retain. Save your changes.
5. In the Root Loggers section, filter for the cron task logger and insert a child logger. Name the child logger `PMWoGenCronTask`.
6. In the Key field, specify `log4j.logger.maximo.crontask.PMWoGenCronTask`.
7. Set the log level to INFO.
8. Specify the PMWoGen appender and save your changes. Apply the settings.

Results

Logging for the PMWoGen cron task is directed to the new logger. The log file rolls over based on the information that you specified for the appender.

Escalation loggers

If an escalation fails to run, the failure can be caused by the escalation engine, the email notifications, or actions triggered by the escalation. You can troubleshoot the cause of the failure by setting the correct log level.

The following table lists the escalation loggers, a description of the logger, and the log level to set each logger to.

Logger	Description	Log level
crontask	Root logger that generates log statements for all cron tasks	DEBUG

Logger	Description	Log level
ESCALATION	Child logger that inherits from cron task root logger and generates log statements specifically for the escalation engine	DEBUG
sql	Root logger that generates log statements of SQL statements run in the application server	INFO
COMMTEMPLATE	Child logger that inherits from service root logger and generates log statements specifically for communication templates and notifications events	INFO
mail	Root logger that generates log statements for communication with the mail server when sending notifications.	DEBUG

Integration framework loggers

The integration framework has four root loggers: integration, REST, interaction, and Open Services Lifecycle Collaboration (OSLC). To receive the maximum amount of information set the root loggers to DEBUG.

The following table lists the loggers, a description of the log level, and log levels to set the logger to.

Table 1. Integration framework loggers. Integration framework logger details

Logger	Description	Log level
Integration	Logs information about the integration framework configuration, creation, management, and runtime processing.	DEBUG
REST	Logs information about the REST API components. REST API starts the integration with business objects. The REST API call from a client, runs the client request against the appropriate business object and returns a response.	DEBUG
Interaction	Logs information about both the design process, when a web service interaction is created, and the execution process, where a web service interaction is run. Designated users run web service interactions to receive data interactively from external systems."	DEBUG
OSLC	Logs information about both the design process, when an OSLC interaction is created, and the execution process, where an OSLC interaction is run.	DEBUG

Enabling the EventTracker filter

To enable the EventTracker filter, uncomment the filter definition and filter mapping in the web.xml file, which is located in *Tpae root*\applications\maximo\maximouiweb\webmodule\WEB-INF\ directory.

About this task

If your web.xml file does not contain the commented code, you can enable the EventTracker filter by adding the code, without the comments. Add the filter definition between the last filter definition and the first filter mapping in your web.xml file. Then, add the filter mapping so that it is the last entry in the filter mappings.

Procedure

1. Open the web.xml file from the *Tpae root*\applications\maximo\maximouiweb\ webmodule\WEB-INF\ directory.
2. Remove the comment from the following code for the filter:

```
<!-- Uncomment these lines to enable the EventTracking filter
  <filter>
    <filter-name>EventTrackingFilter</filter-name>
    <filter-class>psdi.webclient.system.filter.EventTrackingFilter</filter-class>
  </filter>
-->
```

3. Remove the comment from the following code for the filter mapping:

```
<!--! Uncomment these lines to enable the EventTracking filter
<filter-mapping>
  <filter-name>EventTrackingFilter</filter-name>
  <url-pattern>/ui/*</url-pattern>
</filter-mapping>
<filter-mapping>
  <filter-name>>EventTrackingFilter</filter-name>
  <url-pattern>/webclient/login/logout.jsp</url-pattern>
</filter-mapping>
-->
```

4. Save and rebuild the Tivoli®'s process automation engine enterprise archive (EAR) file.
5. Redeploy the EAR file.

What to do next

In the Logging application, a new row in the Root Loggers table lists the EventTracker filter as eventtracking with the key value log4j.logger.maximo.webclient.eventtracking. By default, the logging level is set to INFO, which logs all events. If the logging level is set to ERROR, change the logging level to INFO and select the Apply Settings action.

- [Logging events for specific applications or users](#)
You can add rows to the Logger table in the Logging application to enable the EventTracker filter to log the events of specific applications, specific users, or specific users in specific applications.
- [Enabling logging for application server security synchronization](#)
To troubleshoot application server security synchronization issues, enable logging for the VMMSYNC and LDAPSYNC cron tasks.
- [Stopping the logging of events](#)
You can stop logging events in the Logging application, which eliminates the need to edit the web.xml file and restart the application server.
- [Correlation of related events in logs](#)
Log correlation is the process of analyzing a set of related events. The analysis is based on rules that are used to interpret the event data. When log correlation is enabled, you can use the correlation ID to identify the UI request, cron task action, MXSCRIPT object, or REST call that produced a log entry.

Logging events for specific applications or users

You can add rows to the Logger table in the Logging application to enable the EventTracker filter to log the events of specific applications, specific users, or specific users in specific applications.

Procedure

1. In the Logging application, in the Root Logging table, set the logging level for log4j.logger.maximo.webclient.eventtracking to ERROR.
2. In the Logging table, add a new row.
3. Set the Logger field to one of the following:

Option	Description
To log a specific application	Specify the application ID, for example, wotrack.
To log a specific user	Specify the user ID, for example, wilson.
To log a specific application for a specific user	Specify the application ID.user ID, for example, wotrack.wilson.

The Key field is automatically populated based on the value in the Logger field.

4. Select the Apply Settings action.

Enabling logging for application server security synchronization

To troubleshoot application server security synchronization issues, enable logging for the VMMSYNC and LDAPSYNC cron tasks.

About this task

You must enable VMMSYNC and LDAPSYNC for both cron task sync and SQL logging. You can set logging levels for the entire cron task or just for specific instances. To set logging levels for specific instances, set the logging property *instancename* to DEBUG.

Procedure

1. In the Logging application, set the following logging properties to DEBUG:
 - log4j.logger.maximo.crontask.VMMSYNC
 - log4j.logger.maximo.crontask.LDAPSYNC
 - log4j.logger.maximo.sql.crontask.LDAPSYNC
 - log4j.logger.maximo.sql.crontask.VMMSYNC
2. To enable DEBUG SQL logging for business objects, set the log4j.logger.maximo.sql.servicename.objectname logging property to DEBUG.
For example:

```
log4j.logger.maximo.sql.SIGNATURE.MAXUSER=DEBUG
log4j.logger.maximo.sql.SIGNATURE.MAXGROUP=DEBUG
log4j.logger.maximo.sql.PERSON.PERSON=DEBUG
log4j.logger.maximo.sql.PERSON.EMAIL=DEBUG
log4j.logger.maximo.sql.PERSON.PHONE=DEBUG
```

3. Select the Apply Settings action.

Stopping the logging of events

You can stop logging events in the Logging application, which eliminates the need to edit the web.xml file and restart the application server.

Procedure

1. In the Logging application, in the Root Logging table, set the logging level for log4j.logger.maximo.webclient.eventtracking to ERROR.
2. Select the Apply Settings action.

Correlation of related events in logs

Log correlation is the process of analyzing a set of related events. The analysis is based on rules that are used to interpret the event data. When log correlation is enabled, you can use the correlation ID to identify the UI request, cron task action, MXSCRIPT object, or REST call that produced a log entry.

Correlation ID

When log correlation is enabled, identify the user interface (UI) request, cron task action, MXSCRIPT, or REST call that produced a log entry by using the correlation ID. All log entries for a single UI request or cron task action have the same correlation ID. The unique correlation ID applies to any group of log entries such as SQL logs or application logs.

The correlation ID is in the format of `[CID-TYPE-NUMBER]`. The type can be CRON, UI, MXSCRIPT, or REST. The number ensures uniqueness. The server name is also included when log correlation is enabled. For log entries that are not yet correlated, the correlation ID field in the log is empty. The server name field is empty for logs that are generated before the server name is available.

To enable log correlation, in the System Properties application, add the `mxe.logging.CorrelationEnabled` property.

To enable UI request correlation, in the System Properties application, add the `mxe.webclient.logging.CorrelationEnabled` property.

Example

The following example shows the correlation log for the UI requests that are associated with an SQL statement that is being debugged:

Interpret the log file

```
06 Jun 2012 16:12:38:360 [INFO] [MXServer] [CID-UI-993] Correlation started.
06 Jun 2012 16:12:38:534 [INFO] [MXServer] [CID-UI-993] BMXAA6719I - USER = (WILSON) SPID =
(137) app (WOTRACK) object (WORKORDER) : select * from workorder where (woclass in (select
value from synonymdomain where domainid = 'WOCLASS' and maxvalue in ('WORKORDER', 'WOACTIVITY'))
and historyflag = 0 and istask = 0 and siteid = 'BEDFORD')
06 Jun 2012 16:12:38:546 [INFO] [MXServer] [CID-UI-993] BMXAA6719I - USER = (WILSON) SPID =
(149) app (WOTRACK) object (WORKORDER) : select * from workorder where (workorderid = 202)
06 Jun 2012 16:12:38:582 [INFO] [MXServer] [CID-UI-993] BMXAA6719I - USER = (WILSON) SPID =
(27) app (WOTRACK) object (WORKORDER) : select * from workorder where (workorderid = 202)
06 Jun 2012 16:12:38:717 [INFO] [MXServer] [CID-UI-993] BMXAA6719I - USER = (WILSON) SPID =
(20) app (WOTRACK) object (WORKORDER) : select count(*) from workorder where
(woclass in (select value from synonymdomain where domainid = 'WOCLASS
' and maxvalue in ('WORKORDER', 'WOACTIVITY')) and historyflag = 0 and istask = 0 and siteid
= 'BEDFORD')
06 Jun 2012 16:12:38:998 [INFO] [MXServer] [CID-UI-993] Correlated data: BEGIN UIsessionId:3
Event:loadapp AppName:autoscript UserId:wilson UIClientIP:127:0:0:1 ElapsedTime:638 ms END

06 Jun 2012 16:12:44:589 [INFO] [MXServer] [CID-UI-994] Correlation started.
06 Jun 2012 16:12:44:597 [INFO] [MXServer] [CID-UIASYNC-995] Correlation started.
06 Jun 2012 16:12:44:634 [INFO] [MXServer] [CID-UIASYNC-995] BMXAA6719I - USER = (WILSON)
SPID = (149) app (WOTRACK) object (WORKORDER) : select * from workorder where ((woclass in
(select value from synonymdomain where domainid = 'WOCLASS' and maxvalue in ('WORKORDER',
'WOACTIVITY')) and historyflag = 0 and istask = 0 and siteid = 'BEDFORD')) and ((status like
'%WAPPR%'))
06 Jun 2012 16:12:44:641 [INFO] [MXServer] [CID-UIASYNC-995] Correlated data:
BEGIN UIsessionId:3 AppName:wotrack UserId:wilson UIClientIP:127:0:0:1 ElapsedTime:44 ms END
```

- The first log statement in the fragment displays a field `[CID-UI-993]` that is the component that is correlated in this example.
- CID is the correlation ID, followed by the component that is being correlated, and the numeric value that is applied to all the correlated statements output for the particular correlation.
- The `[CID-UI-993]` field groups a set of correlated log statements that are started by a UI request.
- A correlated set of log statements is marked by the Correlation started and Correlation data statements. The first set of correlated log statements begins with `[CID-UI-993]correlation started` and ends with `[CID-UI-993]Correlated data:BEGIN` the specific component information `END`.
- The second set of correlate log statements indicate that the next set of correlated log statements is being output.
- When a UI request is correlated, sql commands that run in response to user interaction are placed in the same group of correlated log statements as the UI request.
- In the second correlated statement for correlation `[CID-UI-993]`, the sql command is associated with the WORKORDER table.
- If multiple sql statements run in response to the UI request the statements are output to the same group of correlated log statements.
- The final log statement for correlation `[CID-UI-993]` begins with `Correlation data` and provides information about the user session that started the output of correlated log statement.
- The additional information includes:
 1. The UI session Identifier `3`.
 2. The UI event `loadapp`.
 3. The application that started the UI event `autoscript`.
 4. The user that started the event `wilson`.
 5. The IP address from where the UI request was received `UIClientIP`.
- In the final log statement for correlation `[CID-UI-993]`, the `ElapsedTime` information specifies the time that is spent by the application server to process the UI request.

Configuring custom log messages to help resolve bugs

To identify the section of a log file that contains statements or messages that are relevant to product use, problem creation, or a debugging activity, you can configure custom log messages. You specify start and end messages that are included in the log file. You can review the statements or messages that are shown in between the custom log start and end messages in the log file to help you trace a scenario or resolve an issue.

Before you begin

If you want to change any details of the custom messages that display in a log file, such as the prefix or message text, open the Database Configuration application. Select the Messages action. Filter for the `begincustomlog` or `endcustomlog` message, modify the message, and save the record.

About this task

Log files that are tagged with start and end messages can help product support organizations to more easily trace application actions and isolate potential issues.

Procedure

1. In the Logging application click **Configure Custom Log Messages** on the toolbar.
2. In the **Configure Custom Log Messages** window, specify any comments that you want included in the start and end sections of the log file.
3. Take note of the error message numbers for the start and end messages so that you can search for them in the log file later.
4. To inject the Start message into the log file to trace a scenario, click **Start Writing to the Log File**.
5. Perform the actions.
6. To inject the End message to stop writing to the log file, click **Stop Writing to the Log File**.
The log information that is captured between the start message and the end message can be reviewed.
7. Navigate to the location where the log file is saved.
8. Open the log file in a text editor and search for the start and end messages.
9. Review the statements and messages that are shown between the two messages to trace the scenario or resolve the issue.

Enabling thread logs

In the System Configuration application, you can enable thread logs to track actions made by specified users in Maximo® Manage, such as in the user interface.

Procedure

1. In the Logging application, select the **Configure Custom Logging** action. On the **Thread Logger** tab, create a row in the **Thread Loggers** section.
2. Select a context value so that actions that are performed in that area of Maximo Manage are tracked in the thread log. For example, you can select **UI** to track actions that are performed in the user interface.
3. Specify the name of the user whose actions are logged and select the **Is Enabled?** check box.
4. In the **Thread Logger Details** section, specify the type of log for the type of actions that are logged, such as SQL actions.
5. In the **Thread Logger Details** section, specify the level to indicate how much information is retrieved by the logger. The following table explains each of the levels:

Level	Description
INFO	Retrieves general information about completed actions.
DEBUG	Retrieves detailed information about completed actions. This level is the default level.

Scenario: Interpreting log file statements to resolve errors

Marco, a system administrator, wants to isolate and resolve an error that occurs when someone tries to save a work order. Marco can troubleshoot the problem by setting the Work Order Tracking root logger to **DEBUG** and the SQL root logger to **INFO**.

Replicating the error

In the Work Order Tracking application, Marco creates a work order and associates multiple tasks with the work order. Each task is arranged in sequence. When Marco tries to save the work order, the error `BMXAA5395E Task 20 is causing a loop condition by connecting back to task 10` is shown. The work order cannot be saved. If Marco enables the Work Order Tracking application logger and the SQL logger, he can view detailed information to determine the cause of the error.

Enabling loggers

In the Logging application, Marco searches for the **WOTRACK** root logger and sets the log level to **DEBUG**. Then, Marco searches for the **SQL** root logger and the **WORKORDER** child logger, and sets the log level for both loggers to **INFO**. Marco associates an appender with each logger.

Creating the log file statements

Marco attempts to save the work order again, but encounters the same error. Because Marco enabled the loggers, a detailed log file statement is produced. The cause of the error can be isolated by interpreting the log file statement.

Interpreting the log file statement

The log file statement shows a path that lists a sequence of successor tasks.

```
21 May 2012 11:37:03:927 [DEBUG] [MXServer] [] Task Successors
```

Task 40 is represented in the log file with the identifier T1088.

```
21 May 2012 11:37:03:929 [DEBUG] [MXServer] [] Task -> T1088 Successors -> []
```

Task 30 is represented in the log file with the identifier T1087.

```
21 May 2012 11:37:03:929 [DEBUG] [MXServer] [] Task -> T1087 Successors -> []
```

Task 20 is represented in the log file with the identifier T1086.

```
21 May 2012 11:37:03:930 [DEBUG] [MXServer] [] Task -> T1086 Successors -> [T1085, T1088]
```

Task 10 is represented in the log file with the identifier T1085.

```
21 May 2012 11:37:03:930 [DEBUG] [MXServer] [] Task -> T1085 Successors -> [T1086, T1087]
```

Task 50, represented in the log file statement with the identifier T1089, has successors Tasks 10 (T1085), 20 (T1086) and 30 (T1087).

```
21 May 2012 11:37:03:931 [DEBUG] [MXServer] [] Task -> T1089 Successors -> [T1085, T1086, T1087]
```

Each path for a sequence of tasks in the Work Order Tracking application is validated. Each path is called a branch. For each branch, the application determines whether any of the tasks in the branch points back to itself somewhere in the branch. This condition is called a loop.

After the list of tasks is created, each branch is validated starting at Task 50 (T1089).

```
21 May 2012 11:37:03:931 [DEBUG] [MXServer] [] Beginning from a new starting point [T1089]
```

```
21 May 2012 11:37:03:931 [DEBUG] [MXServer] [] Start validating branch:T1089
```

```
- - -
21 May 2012 11:37:03:932 [DEBUG] [MXServer] [] T1089
```

Tasks 10 (T1085), 20 (T1086), and 30 (T1087) are all checked for loops.

```
21 May 2012 11:37:03:932 [DEBUG] [MXServer] [] T1085
21 May 2012 11:37:03:932 [DEBUG] [MXServer] [] T1086
```

Debug statements are output for successors Task 10 (T1085) and Task 20 (T1086). Task 30 (T1087) does not have a corresponding debug statement, which indicates that the error was encountered when Task 20 (T1086) was being validating.

```
21 May 2012 11:37:03:932 [DEBUG] [MXServer] []
Task 20 is causing a loop condition by connecting back to task:10.
```

The following diagram shows the validation process for the branch that is associated with Task 50. The error message indicates that the loop is created by Task 20. Task 20 is invalid because it is listed as a successor to Task 10 twice in the path definition.

A successor = comes after a task

Viewing Maximo Manage Logs

View the IBM® Maximo® Manage logs for Server, Maxinst and Update database, User sync, Workspace operator, and Build logs from the Red Hat® OpenShift® console.

Procedure

1. Go to your Red Hat OpenShift console.
2. Go to Workload > Pods menu.
3. Select log type.
 - Maximo Manage Server logs.Server logs are written to the standard output.

- Select your Maximo Manage project.
 - Check your Liberty server pods.
 - Select the server pod to view log.
 - cron
 - mea
 - report
 - ui
 - all
 - Click Liberty server pod.
 - Select the Logs tab to view the log for the selected server.
- You can also configure IBM Maximo Application Suite (MAS) supported log configuration by Red Hat OpenShift. For example, Elasticsearch, Fluentd, and Kibana dashboard (EFK) can be configured for logging. The logs automatically flow to the EFK stack.

Aggregated Maximo Manage logs can be retrieved from the EFK stack.

<https://docs.openshift.com/container-platform/4.6/logging/cluster-logging-deploying.html>

You can also push the logs to any S3 compatible object storage by following these steps.

- Set up S3 credentials.
 - Create the following four environment variables in your Maximo Manage deployment:
 - LOG_BUCKETNAME
 - LOG_S3ACCESSKEY
 - LOG_S3ENDPOINTURL
 For example, <https://s3.us.cloud.object.storage.appdomain.cloud>
 - LOG_S3SECRETKEY
- Create a log request (POST) by using any HTTP Rest Client. For example, the Postman tool.

Request URL: <http://manageserver:7001/maximo/oslc/service/logging?action=wsmethd:submitUploadRequest>

 - Replace the Maximo Manage server in the URL to your Maximo Manage server host or IP address.
 - A record is created in the Maximo Manage table (LOGREQUEST)
- Use the S3 browser to view the logs by using your S3 credentials.
- Each Maximo Manage server handles the latest log request. It compresses the log files in the liberty log directory and uploads it in Cloud Object Storage.
- The logs can be downloaded from the Liberty server. It is saved in the directory that is set for the system property "server.output.dir".
 - For example, `/opt/was/libert/wip/usr/servers/default/`
 - A record is created in the Maximo Manage table (LOGREQUESTDET)
 - The Maximo Manage table records will be removed by crontask (LOGREQUESTCLEANUP) after the logs are posted to the object storage. The crontask needs to be activated manually. It runs one time every day.
- **Maxinst and update database logs**

The maxinst and update database logs can be retrieved from the maxinst pod.

 - Select the maxinst pod for your project.
 - Go to the Terminal tab and `cd /opt/IBM/SMP/maximo/tools/log/` to view logs.

You can also view the log from the Logs tab.
- **User sync logs**

The User sync logs can be accessed from the user sync pod.

 - Click the user sync pod and select Logs tab.
- **Maximo Manage Workspace operator logs**

The Maximo Manage Workspace operator log can be accessed from the Maximo Manage workspace pod.

 - In the Maximo Manage Workspace pod, select Logs tab.
- **Build logs**

The Build log can be accessed from the Maximo Manage build pods.

 - In the Maximo Manage build pod, select Logs tab.

What to do next

You can install OpenShift Logging by deploying the OpenShift Elasticsearch and Red Hat OpenShift Logging Operators. For more information, see [Installing OpenShift Logging](#).

Managing bulletin boards

You use bulletin boards to post messages about critical problems and incidents, and to broadcast information throughout an organization. You can also view communication logs from service desk agents and their users, and communications that are generated by workflow processes and escalations.

- [Bulletin board overview](#)

You can create messages about critical problems and incidents that you can broadcast throughout an organization. Recipients can view bulletin board messages from the navigation bar of an application or from the Start Center.

- [Working with bulletin boards](#)

Using the Bulletin Board application, you can create bulletin board messages, specify the audience for the messages, and perform other tasks.

Bulletin board overview

You can create messages about critical problems and incidents that you can broadcast throughout an organization. Recipients can view bulletin board messages from the navigation bar of an application or from the Start Center.

- [Communication logs for bulletin board messages](#)

You can view a communication log for bulletin board message in the Bulletin Board application. Communication logs are available in several applications.

Communication logs for bulletin board messages

You can view a communication log for bulletin board message in the Bulletin Board application. Communication logs are available in several applications.

The log contains communications about outbound messages that were sent between service desk users and agents. You also view communications that were generated by escalations and workflows if the related communication template specifies that these messages are stored in logs.

Working with bulletin boards

Using the Bulletin Board application, you can create bulletin board messages, specify the audience for the messages, and perform other tasks.

- [Viewing bulletin board messages](#)
You can use the bulletin board to create, view, and post messages related to critical problems and incidents, and to broadcast company-wide information. Creating and posting messages on the bulletin board minimizes the creation and duplication of tickets.
- [Creating bulletin board messages](#)
You can create messages to communicate to users about critical problems and incidents, and to broadcast information throughout the organization.
- [Specifying audiences for bulletin board messages](#)
You can specify the audience that can view a bulletin board message. You can limit the audience by organization, by site, or by person group. If you do not specify an audience, any user can view the message.
- [Changing the status of bulletin board messages](#)
You can change the status of a bulletin board message to control the content of what is posted to the bulletin board. The status of a bulletin board message can be draft, approved, or rejected.
- [Copying bulletin board messages](#)
You can copy an existing bulletin board message. Once you copy a message, you can use the same information that is in the original message. You can also change the values in the message that you copied and save it as a new message.
- [Viewing communication logs for bulletin board messages](#)
You can view outbound bulletin board messages and any attachments that were sent between users and service desk agents.
- [Viewing the history of bulletin board messages](#)
Each time you change the status of a bulletin board message, the change is stored in a history transaction. You can view this read-only status history of a bulletin board message.
- [Deleting expired bulletin board messages](#)
By default, expired bulletin board messages are not deleted. If you do not need to keep expired messages, you can change your settings so when expired the messages are deleted.

Viewing bulletin board messages

You can use the bulletin board to create, view, and post messages related to critical problems and incidents, and to broadcast company-wide information. Creating and posting messages on the bulletin board minimizes the creation and duplication of tickets.

Before you begin

You must be granted access to the Bulletin Board application before you can create and post messages.

About this task

Messages can be routed to all users, or just selected organizations, sites, or person groups. You can view only those bulletin board messages for which you have been selected as an audience. If the composer of the message has not selected a specific audience, any user who logs in to the system can view the message. Located in the Navigation bar of all applications, the icon named Bulletins indicates whether you have unread bulletin board messages. The icon uses a numeric value to indicate the number of bulletin board messages that you can view. The icon also changes from red to green when a new message is posted.

Procedure

1. In the Navigation bar, the Bulletin Board area displays all the bulletin board messages. When you change the value in the Viewed field, you change which messages you see. By default, the value in the Viewed field is N, and the Bulletin Board area displays unread messages. To view either previously viewed

messages or all messages:

- Enter Y in the Viewed field to see previously viewed Bulletin Board messages.
 - Leave the Viewed field blank to see all messages (both previously viewed and unread bulletin board messages). The messages display, with the most recent message appearing at the top of the list. Each message displays the date and time when the message was posted to the Bulletin Board.
2. In the Bulletin Board window, click a message to display the details of the message.
 3. Click the message again to collapse the detailed view of the message.
 4. Click OK.

Creating bulletin board messages

You can create messages to communicate to users about critical problems and incidents, and to broadcast information throughout the organization.

Procedure

1. In the Bulletin Board application, click New Message.
2. Type an identifier, a subject for the message, a posting date, and an expiration date.
3. Type a message of up to 4,000 characters.
4. Optional: Limit the message to an audience by organization, by site, or by person group.
5. Save your changes.
6. In the Select Action menu, click Change Status and change the status of the message to approved.

Specifying audiences for bulletin board messages

You can specify the audience that can view a bulletin board message. You can limit the audience by organization, by site, or by person group. If you do not specify an audience, any user can view the message.

Procedure

1. In the Bulletin Board application, open the message for which you want to specify an audience.
2. Click a tab to specify an audience by organization, by site, or by person group.
3. On the tab, select one or more organizations, sites, or person groups and save your changes.

Changing the status of bulletin board messages

You can change the status of a bulletin board message to control the content of what is posted to the bulletin board. The status of a bulletin board message can be draft, approved, or rejected.

Procedure

1. In the Bulletin Board application, open the message for which you want to change the status.
2. Select the Change Status action.
3. In the Change Status window, select a status and click OK to save your changes.

Example

For example, you can create a bulletin board message with a status of draft, and then route the message to a supervisor. The supervisor reviews the message, and changes the status to approved. The message is then posted to the bulletin board.

Copying bulletin board messages

You can copy an existing bulletin board message. Once you copy a message, you can use the same information that is in the original message. You can also change the values in the message that you copied and save it as a new message.

Procedure

1. In the Bulletin Board application, open the message that you want to copy.
2. Select the Duplicate Message action.
3. Optional: In the new message, change the subject, the message, and the posting and expiration dates.
4. Save your changes.

Viewing communication logs for bulletin board messages

You can view outbound bulletin board messages and any attachments that were sent between users and service desk agents.

Procedure

1. In the Bulletin Board application, open the message for which you want to view the communication log.
2. Click the Communication Log tab. By default, you can view the messages in reverse chronological order according to the Date field.
3. Click View Details to view the details of a message.
The information in the communication log is read-only.

Viewing the history of bulletin board messages

Each time you change the status of a bulletin board message, the change is stored in a history transaction. You can view this read-only status history of a bulletin board message.

Procedure

1. In the Bulletin Board application, display the message whose status history you want to view.
2. Select the View History action.
3. View the status information and click OK.

Deleting expired bulletin board messages

By default, expired bulletin board messages are not deleted. If you do not need to keep expired messages, you can change your settings so when expired the messages are deleted.

About this task

To activate this setting, you must change the `mxe.crontask.deleteBB` system property and add parameters for the ESCBLTNEXP escalation.

Procedure

1. In the System Properties application, open the `mxe.crontask.deleteBB` system property.
2. Specify the global property value as 1, save the property, and refresh the session.
3. In the Escalations application, open the ESCBLTNEXP escalation.
4. Select the Activate/Deactivate Escalation action.
5. Specify values in the Elapsed Time Interval field and in the Interval Unit of Measure field for the EXPIREDATE elapsed time attribute.
6. In the Actions section, add the DELEXPMSG action.
7. Save the escalation.
8. Activate the escalation.

Working with sets

You use sets to create item sets and company sets that are shared across multiple organizations.

About this task

The following relationships apply to sets and organizations:

- You must create at least one item set and one company set before you can create any organization.
- You can create as many item sets and company sets as your business practices require.
- You must associate each organization with only one company set.
- You must associate each organization with only one item set.

You cannot delete an item or company set if the set is not empty or if the set is associated with an organization.

- [Creating item sets or company sets](#)
You create an item or company set to enable the sharing of item master and company master information between organizations.

Creating item sets or company sets

You create an item or company set to enable the sharing of item master and company master information between organizations.

Before you begin

In the Sets application, you view organizations that are associated with sets. Before you can view the organization, you must use the Organizations application to assign the set to at least one organization.

About this task

You can create an unlimited number of sets. Multiple organizations can use the same item set or company set.

Procedure

1. In the Sets application, click New Row.
2. Provide the name of the set. The name must be unique for all sets; an item set and a company set cannot have the same name.
3. Optional: Provide a description of the set.
4. Specify a value for the type.
5. Optional: If you specified COMPANY as the value for type, select the Automatically Add Companies to Company Master check box to automatically create a company master record. A company master record is then created whenever a user adds a company in the Companies application. If you do not select this check box, users must add companies in the Company Master application.
6. In the Default Item Status field, specify the status that you want new item master, service item, and tool records to have.
7. Click Save Sets.
After you save the record, the only fields that you can edit are the Sets Description field and, for a company set, the Automatically Add Companies to Company Master check box.

What to do next

After you create a set, you use the Organizations application to assign the set to an organization.

- [Changing item or company sets](#)
After you create an item or company set, you can change settings to suit your business needs.

Changing item or company sets

After you create an item or company set, you can change settings to suit your business needs.

Procedure

1. In the Sets application, click View Details for the set that you want to change.
2. Change one or more of the following settings:
 - Change the description.
 - For a company set, change the Automatically Add Companies to Company Master check box.
3. Save your changes.

Managing organizations

You can set up the organizations and sites that you use. You can set defaults for various options that are related to applications or groups of applications, such as Work Order Tracking, Inventory, Purchasing, Preventative Maintenance, Assets, and so on.

About this task

The following relationships apply to sets and organizations:

- You must create at least one item set and one company set before you can create an organization.
- You can create as many item sets and company sets as your business practices require.
- You must associate each organization with only one company set.
- You must associate each organization with only one item set.
- [Organizations overview](#)
You can set up multiple organizations and sites for your company. The divisions are determined by the types of operations that are performed at different locations, and what data can be shared among them. Different organizations and sites keep parts of their operations separate, while sharing others.
- [Working with organizations](#)

Organizations overview

You can set up multiple organizations and sites for your company. The divisions are determined by the types of operations that are performed at different locations, and what data can be shared among them. Different organizations and sites keep parts of their operations separate, while sharing others.

- [Application levels and data storage](#)
Application data is stored at different levels. The separation of data allows you to reuse as much data as possible across organizations and sites without breaching best practices in security and authorization.
- [Sites and organizations](#)
A site is a division within an organization that maintains certain data independently from other sites. When you create an organization, you create at least one site.
- [Item sets](#)
Item sets let multiple organizations within a company view and choose from a common set of items stocked in the storeroom. An organization can be associated with only one item set. However, multiple organizations can use the same item set.
- [Autonumbering](#)
When you set up autonumbering and a user creates a record, the record IDs or other specified fields increment by one.
- [ABC breakpoints and organizations](#)
ABC analysis helps you quickly identify which inventory items represent the greatest monetary investment for your company in terms of dollar value and rate of turnover. This analysis ensures that crucial inventory does not fall below minimum levels, and helps keep current balance figures for an item reconciled with the actual count.
- [Enablement of repair facilities](#)
To create work orders in a site that is different from the site of the asset on the work order, enable the repair facilities feature.
- [Customization options for applications](#)
There are many options and settings that you can customize for your applications in the Organizations application. They include work order options, inventory, purchasing, asset, and preventive maintenance (PM) options. You can access the options from the Select Action menu or the More Actions section of the side navigation menu.

Application levels and data storage

Application data is stored at different levels. The separation of data allows you to reuse as much data as possible across organizations and sites without breaching best practices in security and authorization.

The following are the four application levels:

Table 1. Application levels

Application levels	Description
System level	The data is available to all organizations and sites.
Set level	This level is a special category by which multiple organizations can share items and vendor company data. The system stores this data by default at the organization level.
Organization level	The data is available to only the specified organization and all sites within the organization.
Site level	The data is available to only the specified site.

The following examples illustrate how the level at which application data is stored affects how you use the system:

- The application level determines the level at which record IDs must be unique.
For example, Work Order Tracking is a site-level application; two different sites can both use the same work order number to identify two different work orders. Chart of Accounts is an organization-level application; two different organizations can use the same general ledger account number to specify different general ledger accounts.
- The application level affects some aspects of security.
For example, if a security group has access to one site for an organization-level application, then members of that group can access all of the application records for that organization.
- The application level affects some user default settings.
For example, if a site is used as a filter to display records, but the application is at the organization level, then a user can access all records for the organization that owns that site.

Sites and organizations

A site is a division within an organization that maintains certain data independently from other sites. When you create an organization, you create at least one site.

When you create a site, the values that you specify are used as defaults for that site. You can change the values as needed. You cannot delete a site and you cannot delete an organization after you add a site.

You can use sites to administer security, and to give users different rights at different sites.

Sites that belong to the same organization must use the same currency. They must also share the same options for work orders, assets, labor, and other types of data.

- [Activation and deactivation of organizations and sites](#)
The ability to activate and deactivate organizations and sites is dependent on the enterprise hierarchy. When you create an organization, you create at least one site. When you deactivate an organization, all sites within that organization become inactive. This ensures that the structure of your company is not compromised.

Activation and deactivation of organizations and sites

The ability to activate and deactivate organizations and sites is dependent on the enterprise hierarchy. When you create an organization, you create at least one site. When you deactivate an organization, all sites within that organization become inactive. This ensures that the structure of your company is not compromised.

When you deactivate an organization or site, users can no longer create records for that organization or site. A deactivated organization or site and all its information is not deleted. Records that reference a deactivated organization or site are not affected.

If a site and its organization are both deactivated and you activate the organization, the site is not automatically activated.

You can activate and deactivate an organization or a site on the Organization tab of the Organizations application.

Item sets

Item sets let multiple organizations within a company view and choose from a common set of items stocked in the storeroom. An organization can be associated with only one item set. However, multiple organizations can use the same item set.

You identify an item set with a unique name or number, and each item that belongs to the item set has a unique item number.

When you create an organization, you associate an item set to it. When you create an item, by default the item is placed into the item set associated with the organization for your default insert site.

Autonumbering

When you set up autonumbering and a user creates a record, the record IDs or other specified fields increment by one.

Many applications, such as Work Order Tracking, Purchase Requisition, Purchase Orders, and Invoices have autonumbering set up for their key fields such as record ID. You can change the default starting sequence. You can also add a prefix to an existing numbering sequence or add autonumbering to other fields. For applications that do not have autonumbering, you can set up autonumbering for the record ID field or other fields.

Applications store data at one of these levels: system, set, organization, and site. You use different actions to set up autonumbering for applications at each level. For a multisite implementation, you can have different autonumbering sequences for different organizations and sites. For example, Work Order Tracking is a site-level application. You can set up different autonumbering sequences for each site.

You specify the numbering scheme for autonumbering in the Organizations application. To implement the numbering scheme in the organization that you are autonumbering, use the Database Configuration application.

System-level autonumbering

You can specify autonumber seeds and prefixes for applications at the system level.

For example, Incidents is a system-level application. Incident IDs are unique at the system level. If you implement autonumbering for incident records with a seed of 1000, each new incident record increments by one. This increment occurs regardless of where the incident record is entered. If incident 1000 is inserted at site 1 in organization A, and the next incident record is inserted at site 3 in organization B, then the incident number at site 3 will be 1001.

Organization-level autonumbering

If you want all organizations to be part of the same numbering sequence, you can use the Organizations application to implement autonumber seeds and prefixes for organization-level applications.

For example, Calendars is an organization-level application. Calendar IDs are unique at the organization level. If you specify autonumbering for calendars in organization A with a seed of 1000, then each new calendar record increases by one in the organization, regardless of which site generates the calendar. If calendar 1000 is inserted at site 1, and the next calendar record is inserted at site 2, the calendar number at site 2 is 1001.

Site-level autonumbering

If you want all sites in the organization to be part of the same numbering sequence, you use the Organizations application to implement autonumber seeds and prefixes for site-level applications.

For example, Preventive Maintenance is a site-level application and preventive maintenance IDs are unique at the site level. However, you can implement an organization-level sequence. You can choose to have the autonumbering work in the following ways:

- All sites are part of the same sequence. You set the autonumbering for preventive maintenance records and the autonumbering works the same as with an organization-level application. If preventive maintenance 1000 is inserted at site 1, and the next preventive maintenance record is inserted at site 2, the preventive maintenance number at site 2 is 1001.
- You have three sites and you want one to have independent preventive maintenance autonumbering. You want sites 1 and 2 to be on the same autonumber sequence, but you want site 3 to be independent. You set preventive maintenance autonumbering to 1000. You then specify an independent autonumber sequence for site 3.
- You want all sites to have independent preventive maintenance autonumbering. You specify autonumbering for all sites, or you specify autonumbering for all sites except one. The exception is defined by whatever you specify in the Organization Level window.

Set-level autonumbering

In the Organizations application, you can specify autonumber seeds and prefixes for applications at the set level.

For example, Item Master is a set-level application, and item master IDs are unique at the set level. You implement autonumbering for item master records with a seed of 1000. Each new item master record increments by one, regardless of where the item master record is added. If item master 1000 is inserted at site 1 in organization A, and the next item master record is inserted at site 3 in organization B, then the item master number at site 3 is 1001.

ABC breakpoints and organizations

ABC analysis helps you quickly identify which inventory items represent the greatest monetary investment for your company in terms of dollar value and rate of turnover. This analysis ensures that crucial inventory does not fall below minimum levels, and helps keep current balance figures for an item reconciled with the actual count.

The ABC type value for an item is determined by running the Inventory ABC Analysis report. You can run this report from the Inventory application or module. This report multiplies the current year-to-date issued quantity by the last cost of the item. The report sorts the items in descending order of the calculated dollar value.

The types values for A, B, or C are set based on the percentages that you specify in the Organizations application. You can set an ABC type to indicate no category, and that type is excluded from the ABC analysis.

For example, you can use these parameters:

- Type A break point 30% (enter .30)
- Type B break point 30% (enter .30)
- Type C break point 40% (enter .40)

Using these values, the top 30% of items by cost is type A, the next 30% of items is type B, and the last 40% is type C.

The Inventory ABC Analysis report also changes the cycle count for the item, based on the ABC type and the cycle count. If the ABC type is set to N, the cycle count is not changed.

You set the cycle count to the number of days for each ABC type. For example, type A cycle counts can be 30 days, type B cycle counts 60 days, and type C cycle counts 90 days.

You can run the Inventory Cycle Count report to show each item that is due for a cycle count in the next month, together with its ABC type.

Enablement of repair facilities

To create work orders in a site that is different from the site of the asset on the work order, enable the repair facilities feature.

Enablement of repair facilities is useful for transportation assets and other moveable assets. Moveable assets are often serviced on the road, at a repair facility that does not belong to the home site of the asset.

Enablement of the feature means that a repair facility, a special type of location, can take ownership of work orders from multiple sites that are in the same organization. User security can then be configured to give permissions to view work orders in multiple sites if the work orders are owned by the repair facility. When you enable the feature, fields that are related to repair facilities are made visible in the Work Order Tracking application and other affected applications.

The Enable Repair Facilities check box is on the Other Organization Options window in the Organizations application.

If you enable the repair facilities feature, the Bypass Site Mismatch Warning Message check box on the Other Organization Options window becomes read/write. Select the check box to prevent the display of a warning message when a work order is created in a site that is different from the site of the asset on the work order.

Customization options for applications

There are many options and settings that you can customize for your applications in the Organizations application. They include work order options, inventory, purchasing, asset, and preventive maintenance (PM) options. You can access the options from the Select Action menu or the More Actions section of the side navigation menu.

Table 1. Customization options

Options	Description
Work orders	Defines and changes work types and work order types for classes of work orders.
Edit rules	Specifies the work order properties that can be changed for a given work order status. For example, you specify that an asset and a location can be edited when it is approved.
Actual start date for work orders	Specifies whether the actual start date is the date when the work order status is changed to initiate or changed to complete.
Default problem start time	Specifies whether the downtime starts when someone reports the problem or when the problem occurs. The default date and time are shown in the Start field in the Downtime Report window.
Site options	Specifies how to increment task numbering such as the starting number for the first task and the increment value for each task. Task numbering is used on the Plans tab in the Work Order Tracking application
Inventory defaults	Specifies default settings for inventory such as ABC breakpoints, cost and currency variances, and negative current and available balances.

Options	Description
Inventory reorders	Specifies whether an approved or unapproved purchase requisition or purchase order is created when a reorder request is generated. You can also specify the maximum number of reorder lines on a purchase order or purchase requisition.
Inventory costs	Specifies the default issue cost that applies when an item is issued from a selected site.
Transfer options	Specify whether a shipment record is required to transfer items.
Purchasing defaults	Specify default settings for the purchasing life cycle such as whether a PR must be approved before it is converted to a PO or contract. You can also specify if costs can be added to or modified for line items.
Purchase order labor	Specify whether a purchase order is required to approve internal labor.
Tax options	Specify the default tax general ledger accounts and tax codes to calculate the amount of tax that is due on a purchase requisition, request for quotation, purchase order, or invoice at the organization level. You can also specify the order in which tax codes are used.
Contract options	Specify contract options such as contract types, and the terms and properties that are associated with contract types.
Invoice options	Specify default settings for invoices such as whether to validate the financial period when you save an invoice. You can also copy the invoice date specified by the vendor to the General Ledger (G/L) posting date.
Asset options	Specify whether to record asset history when the status of a work order changes to complete or to closed.
Drilldown options	Specify how a drilldown opens for locations and assets. Specify that the drilldown top level starts at the top-level location or asset.
Preventive maintenance (PM) options	Specify general preventive maintenance (PM) options such as whether the priority entered on job plans is used to sequence PMs. You can also specify whether the frequency criteria on a PM is used to generate work orders. You can also provide the lead time in days between when an automatically generated work order is created and when the preventive maintenance is scheduled.
Safety plan options	Specify whether data for hazards is available with the work assets data in the Safety Plans application.
Labor options	Specify default settings for labor transactions such as the approval process for internal and external labor. You can also specify whether craft and labor can be different or must match when you report actuals.
Global ticket solutions options	Specify whether solutions for global tickets are automatically applied to related global tickets.
Service level agreement options	Specify how you want to match service level agreements (SLAs) to records for example, one or multiple SLAs. You can also specify the target dates to apply to a record.
Workflow options	Specify workflow processes for work orders, purchase requisitions, and purchase orders.
System settings	Specify general system settings such as the default start and end dates, and the format of names. You can also specify the character that represents the unspecified general ledger components in an account code.

- [Taxes for organizations](#)
You can specify default tax general ledger accounts and tax codes to calculate the amount of tax that is due on a purchase requisition, request for quotation, purchase order, or invoice. You can also specify the order in which tax codes are used in calculations.
- [Drilldown options](#)
Drill-down options specify how a Drilldown window opens. The drill-down options apply to applications in which both the Location field and the Asset field on a record are blank. The options also apply to the Open Drilldown action in the Assets application.

Taxes for organizations

You can specify default tax general ledger accounts and tax codes to calculate the amount of tax that is due on a purchase requisition, request for quotation, purchase order, or invoice. You can also specify the order in which tax codes are used in calculations.

A tax type can be, for example, a federal, state, or city sales tax. Another tax type might be a special tax for handling hazardous material.

A tax code represents a particular tax rate, such as MA for the Massachusetts sales tax of 5%. Therefore, one tax type might include tax codes for all state or provincial sales taxes.

The requirements of your financial system determine how you specify the tax types, and also how many tax types you use. In the Tax Options window of the Organizations application, the default number of tax types that you can view is five. If your financial requirements dictate additional tax types, you can use the Database Configuration application to specify up to 27 different tax types. Each tax type can have any number of tax codes.

If your financial system uses one, you can specify a general ledger account for paid and unpaid taxes.

Taxes paid
Taxes paid to vendors
Unpaid taxes
Taxes not yet paid to the government

Adding taxes to the cost of an item increases the stocked item average cost for that item. To avoid this increase, you can add the tax to issue on receipt items only. For items issued directly to a work order, general ledger account, location, or asset, the tax is only added to the cost of the individual item.

Drilldown options

Drill-down options specify how a Drilldown window opens. The drill-down options apply to applications in which both the Location field and the Asset field on a record are blank. The options also apply to the Open Drilldown action in the Assets application.

The standard drill-down function includes two options:

Top Level Starts at Top Level Location (Start at Top Location in Primary System)

The Drilldown window opens to the Location tab, and begins with the top-level location of the primary system. This option is useful for organizations with many asset records that use location hierarchies to organize these records.

Top Level Starts at Top Level Asset (Show All Assets without Parent)

The Drilldown window opens to the Asset tab. This option is useful when asset records are organized into a hierarchy with a few top-level asset records. If the organization has many top-level asset records, selecting this option might slow or hinder performance when you display the records.

If you enable the extended drill-down view that displays both assets and locations in a single hierarchy, the Drilldown window does not display tabs. For related information, see [Extended drill-down view for assets displays top-level system location when an asset is blank](#).

Working with organizations

You can set up the organizations and sites that you use. You can set defaults for various options that are related to applications or groups of applications, such as Work Order Tracking, Inventory, Purchasing, Preventative Maintenance, Assets, and so on.

- [Creating organizations](#)
In the Organizations application, you create the organizations to use with the system. Each organization can have multiple sites.
- [Clearing material reservations for work orders](#)
To customize organization properties specific for your business needs, you can specify when to clear the material reservation for a work order.
- [Specifying options for work orders and ticket owners](#)
In the Organizations application, you can determine the behavior of the Select Owner action in the Work Order Tracking application and in several service desk applications. You can specify whether there is a value in the Date field in these applications, and if the list of persons is filtered according to availability.
- [Setting purchasing options](#)
You can customize purchasing options for your specific business needs.
- [Specifying autonumbering for applications](#)
You can specify autonumber seeds and prefixes for applications at the system, organization, site, and set levels so that all sets in an organization use the same numbering sequence.
- [Displaying user messages](#)
You can specify when users are prompted by user interface (UI) messages to provide them with information.

Creating organizations

In the Organizations application, you create the organizations to use with the system. Each organization can have multiple sites.

Before you begin

You must create at least one organization and one site. Before you create the first organization, use the Currency Codes application to create at least one currency code. You cannot change the base currency after you save the record. Use the Sets application to create at least one item set and one company set. Use the Chart of Accounts application to create a general ledger account. Multiple organizations can use the same item set or company set.

About this task

Multiple organizations and sites can use the same database, while certain business procedures and information remain specific to the individual organizations and sites. After you save an organization record, you cannot edit the item or company set. After you add a site to the organization and save the record, you cannot edit base currency 1.

Procedure

1. In the Organizations application, click New Organization.
 2. Type a name for the organization.
 3. Specify base currency code 1 for your base currency.
 4. Optional: Specify base currency 2.
 5. Specify the item set and the company set that you want to associate with this organization.
 6. In the Default Item Status field, select the status that you want new item master, service item, and tool records to have.
 7. Click Save Organization.
- [Activating organizations](#)
When you create an organization, it is inactive by default. To allow users to interact with an organization, you must activate it.
 - [Deleting organizations](#)
As your business needs change, you can delete the organizations that you created.

Activating organizations

When you create an organization, it is inactive by default. To allow users to interact with an organization, you must activate it.

Before you begin

To activate an organization, you must first create the account in the Chart of Accounts application. This process includes creating general ledger component values and general ledger codes, and activating general ledger components.

About this task

You can activate any sites that are inactive.

Procedure

1. In the Organizations application, select the organization that you want to activate.
2. On the Organization tab, in the Clearing Account field, specify the account code that you created in the Chart of Accounts application.
3. Select the Active check box.

Deleting organizations

As your business needs change, you can delete the organizations that you created.

About this task

You can delete an organization only if it has no sites associated with it.

Procedure

1. On the List tab in the Organizations application, select the relevant organization.
2. Select the Delete Organization action.
3. Save your changes.

Clearing material reservations for work orders

To customize organization properties specific for your business needs, you can specify when to clear the material reservation for a work order.

Procedure

1. In the Organizations application, select an organization.
2. Select the Work Order Options>Other Organization Options action.
3. In the Other Organization Options window, specify whether to clear the material reservation when the work order status changes to either Complete or to Closed.
4. Click OK.

Specifying options for work orders and ticket owners

In the Organizations application, you can determine the behavior of the Select Owner action in the Work Order Tracking application and in several service desk applications. You can specify whether there is a value in the Date field in these applications, and if the list of persons is filtered according to availability.

Procedure

1. In the Organizations application, select the organization for which you want to specify ownership options.
2. Select the Ownership Assignment Options action.
3. In the Ownership Assignment Options window, select a site.
4. Select one of the following options.

Option	Description
Do not check Person Availability	In the Work Order Tracking application and relevant service desk applications, the Date field is blank and the list of persons is not filtered by availability.
Check Person Availability	In the Work Order Tracking application and relevant service desk applications, the Date field is populated. The list of persons is filtered by availability at that date, according to calendars.

5. Click OK.

Setting purchasing options

You can customize purchasing options for your specific business needs.

- [Associating properties with contracts for organizations](#)

You can associate properties with a contract.

- [Associating terms and conditions with contracts for organizations](#)

You can associate terms and conditions with a contract.

- [Specifying options for invoices](#)

You can specify the invoice date as the start of the financial period. The invoice date and the general ledger posting date are matched, because the general ledger posting date is replaced with the invoice date. You can also specify that financial period validation is performed each time an invoice is saved.

Associating properties with contracts for organizations

You can associate properties with a contract.

Procedure

1. In the Organizations application, select the relevant organization.
2. On the Organization tab, select the Purchasing Options > Contract Options action.
3. In the Contract Options window, select the contract type.
4. Click Associate Properties.
5. In the Associate Properties window, select a property to associate with the contract type.
6. Optional: Specify a default value for the property and specify whether the property can be edited.
7. Click OK.

Associating terms and conditions with contracts for organizations

You can associate terms and conditions with a contract.

Before you begin

The terms and conditions that you associate are derived from values in the Terms and Conditions application.

Procedure

1. In the Organizations application, select the relevant organization.
2. On the Organization tab, select the Purchasing Options > Contract Options action.
3. In the Contract Options window, select the contract type.
4. Click Associate Terms.
5. In the Associate Terms and Conditions window, click New Row.
6. In the Terms field, specify a value.
7. Click OK.

Specifying options for invoices

You can specify the invoice date as the start of the financial period. The invoice date and the general ledger posting date are matched, because the general ledger posting date is replaced with the invoice date. You can also specify that financial period validation is performed each time an invoice is saved.

About this task

If the value specified in the Invoice Date field is not a valid financial period, the value in the G/L Posting Date field is updated to the start date of the next open financial period.

For consignment invoices, you can specify the maximum number of lines that can be included on the invoice for the vendor that is replenishing the consignment items. When the default maximum number of lines specified is reached, a consignment invoice is automatically created.

Procedure

1. In the Organizations application, select the organization for which you want to set invoice options.
2. From the Select Action menu, select Purchasing Options > Invoice Options.
3. In the Invoice Options window, specify whether you want the G/L Posting Date field to be updated with the date in the Invoice Date field.
4. Specify whether you want the financial period validated each time an invoice is saved. Clear this option if you want the financial period validated when the invoice is approved.
5. For consignment types of invoices, specify the maximum number of lines that can be included on the invoice for a specific vendor. The default maximum number of lines is 40.
6. Click OK.

Specifying autonumbering for applications

You can specify autonumber seeds and prefixes for applications at the system, organization, site, and set levels so that all sets in an organization use the same numbering sequence.

About this task

To create an autonumber or to attach an autonumber to a field, use the Database Configuration application.

Procedure

1. In the Organizations application, select the organization for which you want to set up autonumbering.
 2. Select the System Level, Set Level, Organization Level, or Site Level action.
 3. Specify the values for the appropriate level:
 - For the system level, set level, and organization level, specify or change values for the seed.
 - For the site level, specify or change values for the autonumber name and seed.
 4. Optional: To have the autonumber preceded by a standard value, specify a value for prefix.
For example, **IN** (for incident) can precede the autonumber.
 5. Click OK.
- [Specifying autonumbering for special order items](#)
Special order items are not kept in stock in the inventory, therefore, they do not have inventory item numbers. You must order these items by description.

Specifying autonumbering for special order items

Special order items are not kept in stock in the inventory, therefore, they do not have inventory item numbers. You must order these items by description.

Procedure

1. In the Organizations application, select the organization for which you want to specify autonumbering.
2. Select the Purchasing Options > PO Options action.
3. In the PO Options window, select Allow the Generation of Special Order Items.
4. Click OK and save your changes.

Displaying user messages

You can specify when users are prompted by user interface (UI) messages to provide them with information.

About this task

For assets that are down, if downtime was already reported, the message does not appear. Duplicate problem messages are displayed by default for assets and locations.

Procedure

1. In the Organizations application, select the relevant organization.
2. Select the Work Order Options > Other Organization Options action.
3. Specify the details you want to display to users:
 - To display asset status information after a user completes or closes a work order, and when the asset status is still down, select the Display Downtime Report Prompt upon WO Completion for Asset in a 'Down' Status check box.
 - To display a warranty message when a user enters an asset under warranty on a work order, select the Display Warranty Status check box.
 - To display a duplicate problem message when a duplicate problem is reported on an asset or on a location, select the On Asset or On Location check boxes.
4. Click OK.

Managing calendars

You can create and change calendars for organizations and for sites. You can create calendars to define working times as well as shifts. A calendar can also specify non-working time, such as weekends, holidays, and shutdowns.

- [Calendars overview](#)
Calendars are shared entities that define the framework for shifts, holidays, and so on, for organizations. A calendar can also specify non-working time, such as weekends, holidays, and shutdowns.

- [Working with calendars](#)

You can create multiple calendars for an organization to manage shifts, working time, and non-working time.

Calendars overview

Calendars are shared entities that define the framework for shifts, holidays, and so on, for organizations. A calendar can also specify non-working time, such as weekends, holidays, and shutdowns.

- [Shift patterns for calendars](#)
A shift defines working time that is not specific to a date. You choose the working days, then you designate the start time and end time for work.
- [Exceptions to the standard calendar](#)
Information for individuals, such as vacation days, sick leave, personal time, and overtime, is not stored on the main calendar record.

Shift patterns for calendars

A shift defines working time that is not specific to a date. You choose the working days, then you designate the start time and end time for work.

Once a shift is defined, you can apply it to a calendar. You can then apply the calendar to person, location, asset, and other records to specify working time.

Most shift patterns use a seven day pattern. Most patterns start with Sunday, or are multiples of seven, such as 14 days or 21 days, with a Monday start day. In some companies, there are unique circumstances for which a five day or other pattern might be used. You can create shift definitions that do not reflect the typical working time at your company, but would be useful for special work situations.

You use the Define Pattern action to create shift patterns. The number of days in the pattern specifies the block of days that repeat. If you use a number that is not a multiple of 7, the pattern does not repeat on the same days of the week. For example, with a 15-day pattern of 10 days on and 5 days off, the second instance of the shift starts on a different day than the first.

Example 1: Creating a shift

You can create a shift called first, which has the following properties:

- Working days are Monday through Friday.
- Work starts at 7:00 a.m. and ends at 3:00 p.m.
- Work hours for the day total 8.

Example 2: Creating a rotating shift

You can create a 21-day rotating shift, called shift A. The shift details are as follows:

- Working days are Monday through Friday.
- Work hours for the day total 8.
- During week 1, work starts at 7:00 a.m. and ends at 3:00 p.m. The description is Day, and the Pattern Day value is D.
- During week 2, work starts at 3:00 p.m. and ends at 11:00 p.m. The description is Evening, and the Pattern Day value is E.
- During week 3, work starts at 11:00 p.m. and ends at 7:00 a.m. The description is Night, and the Pattern Day value is N.

Exceptions to the standard calendar

Information for individuals, such as vacation days, sick leave, personal time, and overtime, is not stored on the main calendar record.

You can use the following applications and icons to enter exceptions to the standard calendar:

People

Modify Person Availability

Assignment Manager

Modify Availability

The system combines the standard calendar assignments and the exceptions to determine the availability of a person for a given day, shift, and so on.

Working with calendars

You can create multiple calendars for an organization to manage shifts, working time, and non-working time.

- [Creating calendars](#)
You can create calendars to define working time with a start date and an end date, as well as shifts. A calendar can also specify non-working time, such as weekends, holidays, and shutdowns.
- [Specifying shifts in calendars](#)
To customize shifts for your business needs, you can define shifts and apply them to calendars.
- [Applying shifts to calendars](#)
In the Calendars application, you can specify the range of dates over which you want to apply shifts. You can apply the shifts to the entire period defined for the calendar or for a shorter period.

- [Specifying shift patterns in calendars](#)
To customize shift patterns for your business needs, you can specify the hours in a shift for each day in a pattern.
- [Specifying shift breaks in calendars](#)
To customize shifts for your business needs, you can specify shift breaks.
- [Copying calendars](#)
The easiest way to create a calendar that is like an existing one is to copy the existing one and change the copy as needed.
- [Deleting calendars](#)
If you are no longer using a calendar, you can delete it.
- [Establishing work periods](#)
You can create work periods for a given date and then customize the work period to suit your business needs. You can also modify work periods, and specify non-working time for work periods.

Creating calendars

You can create calendars to define working time with a start date and an end date, as well as shifts. A calendar can also specify non-working time, such as weekends, holidays, and shutdowns.

Before you begin

Your default insert site must be in the organization for which you want to create the calendar. To check and change your default insert site, use the Profile > Default Information link in the toolbar.

About this task

The calendars that you create are for the organization of your default insert site.

Procedure

1. In the Calendars application, click New Calendar.
2. Type a name for the calendar.
3. Optional: Type a description for the calendar.
4. Specify the dates on which you want the calendar to start and end.
5. Save your changes.

What to do next

You created a calendar without shifts, work periods, holidays, or other details. Use the Define/Apply Shifts action to add shifts and the Define/Apply Non-Working Time action to add holidays and other non-working time. Use the People application to change person availability and the Assignment Manager application to change availability. In the calendar header, you can change the calendar description, start date, and end date.

Specifying shifts in calendars

To customize shifts for your business needs, you can define shifts and apply them to calendars.

Procedure

1. In the Calendars application, select the calendar for which you want to define a new shift.
2. Select the Define/Apply Shifts action.
3. In the Define/Apply Shifts window, click New Row.
4. Type a name for the shift.
5. Optional: Type a description for the shift.
6. Specify the day on which you want the pattern to begin.
7. Type the number of days in the pattern.
For example, the typical weekly patterns are seven days long, but you might need a 10-day, 14-day, or other pattern.
8. Optional: Define a pattern and apply the shifts to the calendar.
9. Click OK.
The Define/Apply Shifts window opens with the details in the Shift Pattern table window.

Applying shifts to calendars

In the Calendars application, you can specify the range of dates over which you want to apply shifts. You can apply the shifts to the entire period defined for the calendar or for a shorter period.

Procedure

1. In the Calendars application, select the calendar for which you want to apply a shift.
2. Select the Define/Apply Shifts action.
3. In the Define/Apply Shifts window, click Apply Shift(s).
4. In the Apply Shifts with Range window, select one of the following ranges.

Option	Description
Entire Calendar	The start date and end dates reflect the dates specified for the calendar, but are read-only.
Selected Dates	The start date and end dates defined for the calendar are inserted. Change these dates, if necessary.

5. Click OK.

Specifying shift patterns in calendars

To customize shift patterns for your business needs, you can specify the hours in a shift for each day in a pattern.

Before you begin

After you create a shift, you can specify a shift pattern.

Procedure

1. In the Calendars application, select the calendar for which you want to apply a shift.
2. Select the Define/Apply Shifts action.
3. In the Define/Apply Shifts window, click Define Pattern.
4. For the first work day in the pattern, specify the time the work period on that day starts and ends.
When you move the cursor to the Work Hours field, the work hours are calculated as the interval between the two times.
5. Optional: Specify a different value for work hours.
6. Specify the start time and end time for the remaining work days. To copy the values from one day to the other days, click Fill Out Work Days Data.
7. Click OK.

Specifying shift breaks in calendars

To customize shifts for your business needs, you can specify shift breaks.

Before you begin

After you create a shift, specify a shift pattern. Then, set up shift breaks to reflect the actual availability of your labor and crews for each shift.

Procedure

1. In the Calendars application, select the calendar for which you want to apply a shift.
2. From the Actions menu, select Define/Apply Shifts.
3. In the Define/Apply Shifts window, ensure that shifts and shift patterns are defined for the calendar.
4. In the Shift table, select the shift that you want to define shift breaks for.
5. In the Shift Pattern table, select the shift pattern that you want to define shift breaks for.
6. In the Shift Breaks table, click New Row.
7. In the Break field, click Select Value and choose the kind of shift break that you want to create.
8. Specify the start time and end time for shift break.
9. From the Actions menu, select one of the following options.

Option	Description
Apply Breaks	Applies the shift break to all patterns in the shift. Labor and crew availability is not modified.
Clear Breaks	Clears all shift breaks from all patterns in the shift. Labor and crew availability is updated to reflect the changes.
Apply Work Breaks	Modifies the availability of all labor and crews that are assigned to the shift. Labor/crews appear unavailable during the specified shift break for every instance of the defined calendar/shift/pattern day.
Clear Work Breaks	Updates the availability of all labor and crews that are assigned to the shift. The shift breaks remain in place in the Calendar application, but modified availability records are cleared for all labor and crews assigned to the shift.

10. Click OK to close the Define/Apply Shifts window.

Copying calendars

The easiest way to create a calendar that is like an existing one is to copy the existing one and change the copy as needed.

Procedure

1. In the Calendars application, select the calendar that you want to copy.
2. Select the Duplicate Calendar action.

3. Type a name for the new calendar.
4. Optional: Type a description for the calendar. The default is the description on the calendar that you copied.
5. Save your changes.
When you save the new calendar, all shift and non-working time information is copied from the old calendar.

Deleting calendars

If you are no longer using a calendar, you can delete it.

About this task

You cannot delete a calendar if it is used on any of the following types of records:

- Asset
- Asset status
- Personal calendar
- Service level agreement
- Preventive maintenance
- Job plan
- Location
- Work order

Procedure

1. In the Calendars application, select the calendar that you want to delete. You can select only one calendar at a time for deletion.
2. Select the Delete Calendar action.
3. Click Yes.

Establishing work periods

You can create work periods for a given date and then customize the work period to suit your business needs. You can also modify work periods, and specify non-working time for work periods.

- [Creating work periods](#)
A work period represents a single shift applied to a specific date. You can create work periods for a given date and then customize the work period to suit your business needs.
- [Changing work periods](#)
A work period represents a single shift applied to a specific date. To customize work periods for your business needs, you can change work periods for a given date.
- [Specifying non-working time for work periods](#)
You can define non-working time, such as holidays and shut downs, or any other non-working time that you want to apply to a work period.

Creating work periods

A work period represents a single shift applied to a specific date. You can create work periods for a given date and then customize the work period to suit your business needs.

Procedure

1. In the Calendars application, select the calendar for which you want to create work periods.
2. Click the Work Periods tab.
All work periods for the entire calendar display, including all dates with defined work hours or defined non-working time.
3. Click New Row.
4. Specify values for work date, shift, start time, end time, and work hours.
5. Optional: Add a note.
6. Save your changes.

Changing work periods

A work period represents a single shift applied to a specific date. To customize work periods for your business needs, you can change work periods for a given date.

About this task

You cannot change a non-working time period. However, you can delete it.

You also can change work periods from the Calendar tab. On the date for which you want to change working time, click the hours value and make the necessary changes.

Procedure

1. In the Calendars application, select the calendar that you want to change.
2. Click the Work Periods tab.
All work periods for the entire calendar are displayed, including all dates with defined work hours or defined non-working time.
3. Find the row with the work period that you want to change.
4. Change the start time, end time, work hours, and notes.
5. Save your changes.

Example

If you have a corporate calendar, and you want to change the work period for a single shift for a single date because the company is closing early, you change the shift for that date.

Specifying non-working time for work periods

You can define non-working time, such as holidays and shut downs, or any other non-working time that you want to apply to a work period.

Procedure

1. In the Calendars application, select the calendar for which you want to define non-working time.
2. Select the Define/Apply Non-Working Time action.
3. In the Define/Apply Non-Working Time window, click New Row.
4. Optional: Type a description for the non-working time.
5. Specify a start date and end date. For non-working time that occurs on one day, the start date and the end date are the same.
6. Specify a value for type.
7. Click Apply.
8. Click OK.

Managing classifications

You can use classifications to simplify the task of managing and of retrieving historical data from other applications. You can use classifications to align with external standards, such as vendor standards and industry standards. You can also use classifications to define the escalation path for incidents.

- [Classifications overview](#)
Classifications identify and characterize similar objects. A building, a notebook computer, and a centrifugal pump are types of classifications. A classification can also describe an event, such as a broken window or a hard disk failure. You use the Classifications application to create classifications and to establish classification hierarchies.
- [Working with classifications](#)
You can create classifications, and specify details about the attributes of classifications. You can search classification structures and attributes that have associated values when you use any record type that can be classified. You can also define associations between actual configuration item (CI) classifications and authorized CI classifications.

Classifications overview

Classifications identify and characterize similar objects. A building, a notebook computer, and a centrifugal pump are types of classifications. A classification can also describe an event, such as a broken window or a hard disk failure. You use the Classifications application to create classifications and to establish classification hierarchies.

- [Classification paths and hierarchies](#)
You can develop a classification structure by joining two or more classifications into a hierarchy. In a classification hierarchy, the next level up is called the parent, and the next level down is called the child. Each child (which is also a classification) can become a parent and can have its own child levels. This pattern can continue indefinitely. The structure from the top-level parent to the child is called the classification path.
- [Generate Description option](#)
On the Classifications tab of the Classifications application, the Generate Description option and the Use Classification option provide varying results. The results depend on the option that you select.
- [Associations of records with classifications](#)
You can associate types of records, such as assets, items, or solutions, with specific classifications. You modify the Use With settings in the Classifications application to associate records with classifications.
- [Classification searches](#)
You can search classification structures and attributes that have associated values. You can search for values in records that you created for items, locations, configuration items, work orders, tickets, and so on.
- [Actual and authorized configuration item classifications](#)
You can define associations between actual configuration item (CI) classifications and authorized CI classifications.

- [Attributes of classifications](#)
You use attributes to define the characteristics of classifications. For example, for a classification of pump, you can have an attribute of horse power. For a classification path of PROBLEM\COMPUTER, you can have an attribute of memory size.
- [Classifications planning](#)
You create classifications to retrieve information later. Before you create a classification, determine the information that you want to retrieve. You can base your classification structure on how you group objects in your enterprise. You can also use classifications to define the escalation path for incidents.

Classification paths and hierarchies

You can develop a classification structure by joining two or more classifications into a hierarchy. In a classification hierarchy, the next level up is called the parent, and the next level down is called the child. Each child (which is also a classification) can become a parent and can have its own child levels. This pattern can continue indefinitely. The structure from the top-level parent to the child is called the classification path.

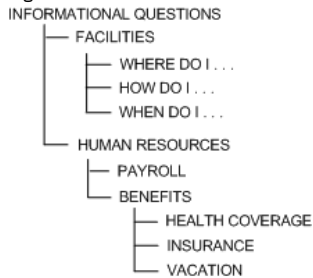

You can also use a numbering system in which a number describes the position of the classification in the classification structure. The number of digits describes the level in the hierarchy. Numbering systems are suitable only if they are not subject to change, because the identifier of the classification (PUMP, 30612456, ROTARY) cannot be changed. The identifier can be deleted only if it is not used in a classification hierarchy.

Example of a request for information

Someone calls the service desk to get information about the facilities. The service desk uses classifications to categorize the ticket as an informational request. The ticket is associated with the classification path INFORMATIONAL QUESTIONS \ FACILITIES \ WHERE DO I...

10 minutes later, the service desk receives a call about health coverage. The service desk can use the same classification structure to categorize both incidents. The following figure shows a classification structure that uses the example of a request for information.

Figure 1. Classification structure - example of a request for information

Example of a request for software installation

Someone contacts the service desk and requests a Microsoft Windows XP installation. A service request and change ticket are created. The ticket is associated with the classification path IT \ SOFTWARE \ INSTALLS \ WINDOWS XP Professional.

10 minutes later, the service desk receives a printer-related call. The service desk can use the same classification structure to classify the printer incident ticket as was used to categorize the earlier request.

The following figure shows a classification structure that uses the example of a request for software installation.

Figure 2. Classification structure - example of a request for software installation

Generate Description option

On the Classifications tab of the Classifications application, the Generate Description option and the Use Classification option provide varying results. The results depend on the option that you select.

The following table describes the results of using these options.

Option	Result
--------	--------

Option	Result
Select Generate Description only	The description that is provided in the Description field for the record, such as an asset record, that uses the classification is overwritten. The description is replaced with the attribute values that are entered in the Specifications tab of the record. Included in the description are the units of measure that are specified in the Attributes window of the Classifications tab. You can view generated descriptions in the application with which the record is associated, such as the Assets application.
Select both Generate Description and Use Classification	The description in the application with which the record is associated is overwritten with the identifier for the classification. The description is also overwritten with the values that are entered in the Specifications tab, and the units of measure that are specified in the Attributes window of the Classifications tab.

Associations of records with classifications

You can associate types of records, such as assets, items, or solutions, with specific classifications. You modify the Use With settings in the Classifications application to associate records with classifications.

The Select Value windows that display the classification can also be associated by the Use With settings.

You can tailor the attributes of a classification for each object that you want to use with it. You use the Attributes window to associate the attributes of classifications with specific objects.

Classification searches

You can search classification structures and attributes that have associated values. You can search for values in records that you created for items, locations, configuration items, work orders, tickets, and so on.

Example of a classification search

Your company created classifications for the following fields:

- Name
- Affected by (name)
- Asset
- Location
- Service Groups
- Service

When you create a service request record, you enter values in the Name field, and in the Asset field. You also enter values in the Location field, the Service Groups field, and the Service field. You can use the navigation tree in the Classification Search window to view the values that are associated with the classification structures and their attributes.

The classification hierarchy that is shown varies depending on the application or the field from which you access the window. The navigation tree shows classifications that can be used with a specific type of record.

Actual and authorized configuration item classifications

You can define associations between actual configuration item (CI) classifications and authorized CI classifications.

- [Actual configuration items](#)
An actual configuration item is an item that is loaded into the Actual Configuration Items application from the discovery engine using the IBM® Tivoli® Integration Composer. You can load configuration items into the database from a discovery engine or an asset management database. First load your configuration item data into the discovery engine using the bulk loader interface.
- [Authorized configuration items](#)
An authorized configuration item is an item that conforms to rules and relationships that you define in the Configuration Items application. These configuration items are items that you want to maintain under configuration management and change control.
- [Actual configuration item classifications and authorized configuration item classifications](#)
You use the Classifications application to define associations between actual configuration item (CI) classifications and authorized CI classifications. You can create an authorized CI from an actual CI record when you define these associations. You can include the number of attributes that you need for configuration management and change control.

Actual configuration items

An actual configuration item is an item that is loaded into the Actual Configuration Items application from the discovery engine using the IBM® Tivoli® Integration Composer. You can load configuration items into the database from a discovery engine or an asset management database. First load your configuration item data into the discovery engine using the bulk loader interface.

- [Actual configuration item details](#)

For configuration items that are based on actual configuration items, you can use the Configuration Items application to view detailed information that is in the Actual Configuration Items application.

Authorized configuration items

An authorized configuration item is an item that conforms to rules and relationships that you define in the Configuration Items application. These configuration items are items that you want to maintain under configuration management and change control.

When you create an authorized configuration item, it can be linked to an actual configuration item record. You can also create an authorized configuration item that is independent of any actual configuration item record, because not all configuration items need to work with the discovery engine. You can create a link between the authorized configuration item and the actual configuration item in the Configuration Items and Actual Configuration Items applications.

Actual configuration item classifications and authorized configuration item classifications

You use the Classifications application to define associations between actual configuration item (CI) classifications and authorized CI classifications. You can create an authorized CI from an actual CI record when you define these associations. You can include the number of attributes that you need for configuration management and change control.

You create an authorized classification hierarchy that maps to an actual classification hierarchy. You typically create partial mappings between the two classifications, rather than a complete mirror image. When creating an authorized CI from an actual CI you can create authorized configuration items. These items are created for the child classifications that have a containment relationship with the actual CI.

You use the discovery tool to discover actual configuration items in your environment. The number of actual configuration items that are discovered by the discovery tool is likely to be greater than the number of authorized configuration items for which you want to create records or to use. By mapping one hierarchy to another, you can limit the number of actual configuration items that you link to authorized configuration items. For example, an actual configuration item hierarchy has five levels. You can create authorized configuration item records for the top three levels of actual configuration items.

Attributes of classifications

You use attributes to define the characteristics of classifications. For example, for a classification of pump, you can have an attribute of horse power. For a classification path of PROBLEM\COMPUTER, you can have an attribute of memory size.

You can further define attributes by domain. A classification attribute can be tied to an ALN domain, to a numeric domain, or to a table domain. You can validate an attribute against the values in a particular database column by using a table domain.

You define domains using the Domains application.

- [Groupings of attributes](#)

You can group attributes into sections so that you can use the same attribute multiple times.

- [Apply Down Hierarchy option](#)

When you add an attribute to a classification, you can use the Apply Down Hierarchy option. When you check this box, the attribute that is assigned to that classification is added to the classifications that are below it in the hierarchy.

Groupings of attributes

You can group attributes into sections so that you can use the same attribute multiple times.

Example of an attribute grouping

For example, you define a pipe in the system as an asset. The pipe has the following characteristics:

- It is 80 feet (~25 m) long.
- It contains 10 sections of equivalent length.
- It has an interior diameter that narrows at one end of the pipe.

Because of the taper, the walls of the pipe must be thicker at the narrow end to withstand the higher pressure. Each section has a different average interior diameter and wall thickness. Therefore, the attribute is the interior diameter.

Related concepts

- [Apply Down Hierarchy option](#)

Apply Down Hierarchy option

When you add an attribute to a classification, you can use the Apply Down Hierarchy option. When you check this box, the attribute that is assigned to that classification is added to the classifications that are below it in the hierarchy.

The Inherited From field indicates that the attribute is associated with a classification that is higher up in the hierarchy. The Inherited From field displays the classification where an attribute originated.

Related concepts

- [Groupings of attributes](#)

Classifications planning

You create classifications to retrieve information later. Before you create a classification, determine the information that you want to retrieve. You can base your classification structure on how you group objects in your enterprise. You can also use classifications to define the escalation path for incidents.

- **[Types of records to be classified](#)**
You can use the Classifications application to store information about different types of records. You can classify application records and search for the records that you classified.
- **[Categories of items for reporting](#)**
You can organize your classification structures into categories or groups of items for reporting. You can create unlimited classification levels.
- **[Industry codes](#)**
You can apply industry codes when you create classifications. You can get a list of the codes that you frequently use in your enterprise, and apply them to your classifications.

Types of records to be classified

You can use the Classifications application to store information about different types of records. You can classify application records and search for the records that you classified.

You can classify the following types of records:

- Assets
- Items
- Locations
- Solutions
- Tickets (service requests, incidents, and problems)
- Work orders (activities, changes, and releases)

Categories of items for reporting

You can organize your classification structures into categories or groups of items for reporting. You can create unlimited classification levels.

You can organize information into top-level categories, such as the following categories:

- Information Technology assets
- Production assets
- Facility assets
- Fleet assets

You can work from the top-level categories into the more detailed levels. For example, fleet assets can contain 18-wheel trucks, and sales fleet cars.

Another example is to categorize the service desk call for a software installation differently than the service desk call for information. This type of categorization helps to determine how many customers complained about a software installation as opposed to how many calls were about health coverage.

Industry codes

You can apply industry codes when you create classifications. You can get a list of the codes that you frequently use in your enterprise, and apply them to your classifications.

Example of using an industry code

If your company does vehicle or code maintenance, you can use the vehicle maintenance industry standard codes. In the United States, most mechanics know that an oil change is code 42-3-2. You can use the same code when you create a classification for an oil change, or use the code that applies in your country.

Working with classifications

You can create classifications, and specify details about the attributes of classifications. You can search classification structures and attributes that have associated values when you use any record type that can be classified. You can also define associations between actual configuration item (CI) classifications and authorized CI classifications.

- [Creating classifications](#)
You classify information to categorize it logically, so that the information is easier to find. You can classify different types of records, such as location records, asset records, item records, and work order records.
- [Associating attributes with records](#)
You can specify detailed information about the attributes of a classification. You can enter attribute details about each record that you want to use with a classification.
- [Modifying classifications](#)
You can change classifications by modifying the information for the classification. You can also modify a classification by adding a classification to an existing classification to create a hierarchy for the top-level classification.
- [Searching for classifications from application records](#)
You can search classification structures and attributes with associated values when you use any record type that can be classified. Record types include assets, items, locations, configuration items, work orders, and tickets.
- [Defining associations between actual and authorized configuration item classifications](#)
You can define associations between actual configuration item (CI) classifications and authorized CI classifications. When you map associations, you create an authorized CI record from an actual CI record.
- [Adding units of measure](#)
You can specify or change the units of measure that you use when ordering and issuing items. Any units of measure that you add become available in the product for use with all items.
- [Configuring the signature option to enable classification images](#)
Signature options, which are defined in the Security Groups application, are used control access to functions in applications. By using signature options, you can grant access to specific groups of users. In the Classifications application, you can select images that represent asset classifications that are used.

Creating classifications

You classify information to categorize it logically, so that the information is easier to find. You can classify different types of records, such as location records, asset records, item records, and work order records.

About this task

To make a classification available for every organization and site, leave the Site and Organization fields blank.

Procedure

1. From the application toolbar of the Classifications application, click New Classification.
2. In the Classification field, specify a classification.
3. Specify the information for the new classification.
4. Optional: To specify the records that you want to use with the classification, click New Row in the Use With table and add one or more records.
5. To add child classifications, click New Row in the Children table.
6. Optional: To add attributes, insert rows and complete the fields in the Attributes table. For most of the fields, click Select Value to select from existing values. Alternatively, you can create values, as with the Classification field.
7. Click Save Classification.

Associating attributes with records

You can specify detailed information about the attributes of a classification. You can enter attribute details about each record that you want to use with a classification.

Procedure

1. From the Classifications application, click the Classifications tab.
2. In the Attributes section, click the Use with Object Detail icon on the row for the attribute whose details you want to enter.
3. In the Use With Object Detail window, specify details for the attribute.

Field or column name	Description
Use With Object	The record for which you enabled the classification.

Field or column name	Description
Sequence	The order in which you want the attribute to appear in the list of attributes on the Specifications tab of the related application. For example, the attribute capacity is one of three attributes of a classification that you enabled for the ASSET and WORKORDER records. In the Assets application, the attribute capacity can appear first in the list of attributes. In the Work Order Tracking application, the attribute capacity can appear third.
Mandatory	Makes the attribute a required field in the related application. For example, you can make it a required field in the Assets application, but not in the Work Order Tracking application.
Used in Description Generation	The description of the attribute appears in the description of the classification in the related application.
Used in Specifications	The attribute appears on the Specifications tab of the related application.

4. Optional: Specify a default value for the attribute:
 - a. In the row for the attribute, click View Details for the Use With Object name column.
 - b. In the Details area, specify a default value based on the data type of the attribute.
5. Click OK.

Modifying classifications

You can change classifications by modifying the information for the classification. You can also modify a classification by adding a classification to an existing classification to create a hierarchy for the top-level classification.

Procedure

1. From the Classifications application, click the Classifications tab.
2. Select the Add/Modify Properties > Classifications action.
3. To add a classification to an existing classification, perform the following steps:
 - a. Click New Row.
 - b. Type a unique classification name.
 - c. Type a description, an organization, and a site for the classification.
 - d. Repeat this process for each classification that you want to add.
4. To modify a classification:
 - a. Select the classification that you want to modify.
 - b. Modify the information for the classification.
5. Click OK.

- **Modifying attributes**

You use attributes to define the characteristics of classifications. You can modify the properties of attributes. You can then associate the attributes with classifications.

- **Adding attributes**

You can add attributes. You can then associate the attributes with classifications. You can use attributes with many record types, such as asset records, location records, and item records.

Modifying attributes

You use attributes to define the characteristics of classifications. You can modify the properties of attributes. You can then associate the attributes with classifications.

Procedure

1. From the Classifications application, click the Classifications tab.
2. On the Classifications tab, select the Add/Modify Properties > Attributes action.
3. From the Attributes area of the Classifications tab, find the attribute that you want to modify.
4. Edit the appropriate fields.
5. Repeat this process for each attribute that you want to modify, and click OK.

Adding attributes

You can add attributes. You can then associate the attributes with classifications. You can use attributes with many record types, such as asset records, location records, and item records.

Procedure

1. From the Classifications application, click the Classifications tab.
2. Select the Add/Modify Properties > Attributes action.

3. Add a row in the Attributes area, and specify the information for the new attribute.
4. Repeat this process for each attribute that you want to add, and click OK.

Searching for classifications from application records

You can search classification structures and attributes with associated values when you use any record type that can be classified. Record types include assets, items, locations, configuration items, work orders, and tickets.

Procedure

1. From the application associated with the type of record, click the Detail Menu button and choose Classification.
2. Select a classification category in the Classification Search tree, and drill down to find the record.
3. Select a record identifier in the window to return a value to the field.

Defining associations between actual and authorized configuration item classifications

You can define associations between actual configuration item (CI) classifications and authorized CI classifications. When you map associations, you create an authorized CI record from an actual CI record.

Before you begin

The classification must be at the top level of the hierarchy. You define the top level for a classification when you create the classification.

Additionally, in the Use With window, the applications must include configuration items.

About this task

For each actual CI classification hierarchy that you use to import actual configuration items, you can create one or more authorized classification hierarchies.

For each of the authorized CI hierarchies, you use the Manage CI Hierarchies window to map the links between authorized and actual classifications. Mapping includes the parent-child classification levels. At each level of the classification, you can also specify the relationships between source classifications and target classifications.

Procedure

1. From the List tab of the Classifications application, select the CI classification hierarchy that you want to manage.
2. Select the Manage CI Hierarchies action.
3. In the Actual CI Classification field in the Manage CI Hierarchies window, click Detail Menu and select Classify to select an actual classification.
4. In the Children window, select a row.
5. In the Actual CI Classification field, specify the actual CI classification that you want to associate with the authorized child classification.
6. Click Detail Menu and select Classify to select a classification.
7. In the Relationships window, specify the relationships that you want to define for the selected child classification. To add a relationship, perform the following steps:
 - a. Click New Row.
 - b. Specify the source and target classifications, the relationship, and other information.
 - c. Click Select Relation Rules to select from a list of relationship rules.
8. Optional: Repeat steps 4, 5, and 6 to map actual classifications to other child authorized classifications.
9. Click OK.

Results

After you map the classifications, you use them in the Actual Configuration Items application to create configuration items from actual configuration items. When you define mappings between authorized and actual configuration items, you can create many configuration item records at the same time. You link entire or partial hierarchies instead of individual configuration items. You create records for the child classifications and for the top-level classification.

Adding units of measure

You can specify or change the units of measure that you use when ordering and issuing items. Any units of measure that you add become available in the product for use with all items.

About this task

If the units of measure do not match when you receive or transfer an item into a storeroom, the product looks for a conversion ratio to determine the stocking balance. You associate the order and issue units to an item when you add the item to a storeroom. You can access the Add/Modify Units of Measure window from more than one application.

Procedure

1. From your application, display a record.
2. Select the Unit of Measure and Conversion > Add/Modify Units of Measure action.
3. Click New Row.
4. Specify a unit of measure.
5. Type an abbreviation for this unit of measure. If configured to do so, the product uses the abbreviations along with the classification of an asset to create descriptions for assets, locations, and items.
6. Type a description for this unit of measure.
7. Click New Row to specify additional units of measure.
8. Click OK.

Configuring the signature option to enable classification images

Signature options, which are defined in the Security Groups application, are used control access to functions in applications. By using signature options, you can grant access to specific groups of users. In the Classifications application, you can select images that represent asset classifications that are used.

Procedure

1. In the List tab of the Security Groups application, you select the group to be granted access to the relationship functions. For example, MAXEVERYONE for all Maximo® users.
2. In the Applications tab, on the Description column, click Classifications.
3. Scroll down to the third panel, listing Classifications application functions, select the Grant Access check box on the Add/Modify Image line, and Save.

Managing charts of accounts

You use the Chart of Accounts application to set up default general ledger accounts and resource codes for standard accounting functions.

- [Chart of accounts overview](#)
You can set up default general ledger accounts and resource codes for standard accounting functions. You create accounts and resource codes to correspond with accounts that you use in your external accounting system. You can also set up financial periods, and specify general validation options.
- [Working with chart of accounts](#)
You can set up default general ledger accounts and resource codes for standard accounting functions.

Chart of accounts overview

You can set up default general ledger accounts and resource codes for standard accounting functions. You create accounts and resource codes to correspond with accounts that you use in your external accounting system. You can also set up financial periods, and specify general validation options.

- [General ledger account codes](#)
You define values for the different components, and link together the component values to create general ledger account codes. You use the general ledger accounts for specific financial tracking purposes. You can also specify dates for general ledger accounts to be active or to expire.
- [Organizational default accounts for general ledgers](#)
In the Chart of Accounts application, you use organizational default accounts as holding accounts for financial considerations.
- [Merge of general ledger accounts](#)
When a general ledger account field is not uniquely specified, the general ledger components are merged. Generating work orders and other kinds of transactions requires choosing among component values. The product invokes a set of rules on how to handle them.
- [Resource codes for general ledgers](#)
A resource code typically consists of one component of the account code.
- [Inactive component values](#)
In the Chart of Accounts application, you can deactivate component values. Inactive components are not available to general ledger accounts that you add to records. General ledger accounts that use an inactive component become inactive also. You can also set component values to expire by a specific date, which renders them inactive.

General ledger account codes

You define values for the different components, and link together the component values to create general ledger account codes. You use the general ledger accounts for specific financial tracking purposes. You can also specify dates for general ledger accounts to be active or to expire.

A general ledger account code consists of several components (or segments), that are separated by delimiters, such as 6000-200-350. A component that has not been assigned a value is represented by placeholder characters, such as 6000-???-350.

You define the format of the account code in the following ways:

- You can define the number, length, and data type of components, whether the components are required, and any delimiter, in the Database Configuration application. The account structures defined in Database Configuration are the default, system-level structures.
- You can define the format of the account code to be specific to an organization. You can define the number, length, and data type of components, whether the components are required, and any delimiter, using the Chart of Accounts application.
- You can specify a default placeholder character in the Database Configuration application. You can specify an organization-specific placeholder character in the Organizations application.

You can specify the validation rules for the following component combinations for the general ledger account codes that users can use:

- A combination of existing components
- Only component combinations that are specified as general ledger accounts

You also can download account codes from your accounting system. A generic financial application programming interface and several product-specific application programming interfaces are provided. These application programming interfaces let the system interface with financial software, such as Oracle® and SAP®.

Organizational default accounts for general ledgers

In the Chart of Accounts application, you use organizational default accounts as holding accounts for financial considerations.

There are three organizational default accounts:

- Global rotating suspense account - You use rotating suspense accounts to hold the accumulated cost of repairs for rotating equipment.
- Global ticket account - You use the global ticket account when a ticket for a service request is created and no other account is available.
- Tool control account - You use the tool control account when a transaction involves a tool and no other account is available.

In the Chart of Accounts application, you use the Organization Default Accounts action to define default accounts.

Merge of general ledger accounts

When a general ledger account field is not uniquely specified, the general ledger components are merged. Generating work orders and other kinds of transactions requires choosing among component values. The product invokes a set of rules on how to handle them.

General ledger accounts are merged component by component. Defined components always supersede an undefined component. For example, if the first component of one account code is 6000 and the first component of the other account code is a placeholder (????), the merged first component is 6000.

When general ledger account codes merge, the result can be an unspecified account code. In this case, to complete the merge, complete one of the following actions:

- To use the merged account code, an authorized user must establish the account code in the Chart of Accounts application. The account code must be established before you can proceed with the transaction.
- If you do not use the merged account code, then ensure that the transaction is valid.

Resource codes for general ledgers

A resource code typically consists of one component of the account code.

There are three kinds of resource codes:

- Labor resource codes - General ledger account code components that track whether labor used in a transaction is internal labor or external labor.
- Tool resource codes - General ledger account code components that track whether a tool used in a transaction belongs to the enterprise (internal) or an external vendor.
- Inventory resource codes - General ledger account code components to attach to inventory items that are used in transactions.

Inactive component values

In the Chart of Accounts application, you can deactivate component values. Inactive components are not available to general ledger accounts that you add to records. General ledger accounts that use an inactive component become inactive also. You can also set component values to expire by a specific date, which renders them inactive.

When you deactivate a general ledger component value, no change is made to the general ledger accounts on existing records that use that value.

Example

A work order uses a cost center component with a value of 6250. You deactivate this cost center. The value is not available to use in new general ledger accounts. All general ledger accounts that use the cost center also become inactive. The existing work order still uses cost center 6250.

Working with chart of accounts

You can set up default general ledger accounts and resource codes for standard accounting functions.

- [Working with general ledger accounts](#)
You can change the configuration of general ledger account structures to be specific to your organization. You can create component codes and resource codes to correspond with accounts that you use in your external accounting system. You can also set up financial periods, and specify general validation options.
- [Creating general ledger component values](#)
You define valid component values for general ledger account codes. You use these values when you select a general ledger account code.
- [Changing general ledger account structures](#)
You can change the default component values for general ledger accounts to be specific to organizations within your enterprise. You might want organizations to have distinct general ledger account structures. For example, the lengths of the components might vary, and the components might be of different data types, depending on how the components are being used.
- [Updating databases for general ledger accounts](#)
After you change a default general ledger account or resource code, you can update the database for one organization at a time.
- [Setting up accounts](#)
You can set up organizational default accounts as holding accounts for financial considerations. You can also specify default general ledger accounts to be associated with company-related accounts, as well as external labor control accounts to be associated with general ledger accounts.
- [Specifying financial periods for general ledgers](#)
You can segment accounting periods by specifying the start date and close date of a financial period.
- [Specifying resource codes for general ledgers](#)
You can specify default values for different types of labor resources, tool resources, and inventory items. These codes are then used to determine accounting charges.
- [Specifying validation options](#)
You use validation options to specify how general ledger accounts are validated. General ledger accounts are validated when they are used in general ledger account fields.

Working with general ledger accounts

You can change the configuration of general ledger account structures to be specific to your organization. You can create component codes and resource codes to correspond with accounts that you use in your external accounting system. You can also set up financial periods, and specify general validation options.

- [Creating general ledger account codes](#)
You can use general ledger account codes to enable financial reporting. You specify the component values for general ledger accounts. You can also specify a date range for an account to be active. For example, you can specify that a general ledger account for a specific craft is active from 02/25/2010 through 02/25/2011, and expires on 02/26/2011.

Creating general ledger account codes

You can use general ledger account codes to enable financial reporting. You specify the component values for general ledger accounts. You can also specify a date range for an account to be active. For example, you can specify that a general ledger account for a specific craft is active from 02/25/2010 through 02/25/2011, and expires on 02/26/2011.

About this task

If the date set in the Expiration Date field is in the future, the general ledger account remains active until the specified date is reached. If no expiration date is specified, the general ledger account does not expire.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to create a general ledger account code.
2. Click New Row.
3. Specify the component values for the general ledger account value.
4. Click OK.
5. Optional: Change the long description.
If you change the descriptions for component values, the general ledger account description is not updated. Update the general ledger account description manually.
6. Optional: Specify the appropriate type code.
7. The default for the Active Date field is the date that the general ledger account is created. To activate the account at a different date, specify a future date.
The general ledger account remains inactive until the date specified is reached. The read-only Active check box shows as cleared to indicate that the account is not active.
8. If you want the general ledger account to expire by a specific date, specify a date in the Expiration Date field.
9. Save your changes.

Results

After you save your changes, you cannot edit the GL Account field.

- [Changing general ledger account codes](#)
After you create a general ledger account, you can change specific information. You might want to activate an account code or set the expiration date on an account code.
- [Deleting general ledger account codes](#)
As your business needs change, you can delete a general ledger account code at any time.

Changing general ledger account codes

After you create a general ledger account, you can change specific information. You might want to activate an account code or set the expiration date on an account code.

About this task

If the date set in the Expiration Date field is in the future, the general ledger account remains active until that date is reached. If no expiration date is specified, the general ledger account never expires.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to change the general ledger account code.
2. Click View Details for the code that you want to change.
3. Optional: Change the information in the GL Account Description field, the Type field, the Active Date field, and the Expiration Date field.
4. Save your changes.

Deleting general ledger account codes

As your business needs change, you can delete a general ledger account code at any time.

About this task

When you delete a general ledger account code, you cannot use the account code on new records. However, existing database records that used the deleted account code are not changed. Therefore, a deleted general ledger account code can still exist in previously created work orders, purchase orders, and so on.

Deleting general account codes can cause problems with the general accounting system that you integrate with the system.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to delete a general ledger account code.
2. Click Mark Row for Delete.
3. Save your changes.

Creating general ledger component values

You define valid component values for general ledger account codes. You use these values when you select a general ledger account code.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to create a general ledger component value.
 2. Select the GL Component Maintenance action.
 3. In the GL Component Maintenance window, select the component for which you want to create values.
 4. Click New Row.
 5. In the GL Component Value field, specify the value for the component.
The value that you specify must be in the format that was specified in the Database Configuration application. The value in Database Configuration is the default, system-level format.
 6. Type a description of the component value.
 7. Optional: To deactivate the component value, clear the Active check box.
 8. Click OK.
- [Changing component values in general ledger accounts](#)
To adapt to business changes, you can change the description of a general ledger component value. You can also activate and deactivate components that are used in general ledger accounts.
 - [Deleting general ledger component values](#)
To customize general ledger information for your business needs, you can delete a component value that is used in general ledger account codes.

Changing component values in general ledger accounts

To adapt to business changes, you can change the description of a general ledger component value. You can also activate and deactivate components that are used in general ledger accounts.

About this task

If you change the status of a component value to inactive, all general ledger accounts that use that component inherit that status. The Expiration Date field for the associated general ledger account on the main Chart of Accounts window is set to the current date and time. The Expiration Date field is set to the current date and time only if the field was previously set to a future date, or if the field was left blank. If the field was set to a date in the past, that value is restored.

When you reactivate an account component, you reactivate the general ledger accounts that use the component. Additionally, the Active Date field on the main Chart of Accounts window is set to the current date and time if the Active Date previously specified was in the future. If the Active Date field was set to a date in the past, that value is restored.

The Expiration Date field displays the expiration date that was previously specified if the date set is in the future. If the expiration date previously specified is in the past, that value is restored. If an expiration date was not specified, the Expiration Date field is left blank.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to change a component value.
2. Select the GL Component Maintenance action.
3. In the GL Component Maintenance window, click View Details for the component value that you want to change.
4. To change the component value, perform one of the following actions:
 - Change the description.
 - Change the active status of the component value in the Active check box. If you activate a component value that was previously deactivated, the Activate GL Accounts window displays. Click the Activate Accounts check box for the component that you are reactivating, then click OK.
 - Change additional information.
5. Click OK.

Deleting general ledger component values

To customize general ledger information for your business needs, you can delete a component value that is used in general ledger account codes.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to delete a general ledger component value.
2. Select the GL Component Maintenance action.
3. In the GL Component Maintenance window, click Mark Row for Delete for the component value that you want to delete.
4. Click OK.

Example

After you delete a general ledger component value, general ledger account codes in existing database records that use that value are not changed. For example, a work order uses a cost center value of 6500. If you delete 6500, the work order keeps this number as the cost center.

Changing general ledger account structures

You can change the default component values for general ledger accounts to be specific to organizations within your enterprise. You might want organizations to have distinct general ledger account structures. For example, the lengths of the components might vary, and the components might be of different data types, depending on how the components are being used.

About this task

The first time the Add/Modify Account Structure window displays, the default configuration defined for the general ledger account displays. You use the Database Configuration application to define the default configuration at the system level. The changes made to organization-specific account structures do not affect the configuration specified at the system level.

You can define one account structure specific to each organization. When the account structure is defined, you can modify the attributes. The modified account structure does not affect existing data.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to modify the general ledger account structure.
2. Select the Add/Modify Account Structure action.
3. In the Add/Modify Account Structure window, select the component for which you want to modify values.
4. In the Component field, specify the name of the component.

5. In the Length field, specify the length of the field. The length of the field cannot exceed the length defined at the system level.
6. In the Type field, specify the data type for the component. If the type defined at the system level is numeric, the type set at the organization level cannot be alphanumeric. If the type set at the system level is alphanumeric, the type set at the organization level can be numeric.
7. Optional: Click the Required check box if you want the component to be mandatory. If the value set at the system level is 1, the Required check box is read-only. If the value set at the system level is 0, this check box is modifiable for the organization.
8. Optional: Modify the Screen Delimiter to specify a different separator character between components.
9. Click OK.

Example

For example, you can create account structures for different organizations in separate geographic regions, as follows:

- Organization A is in Europe. Organization A has the account structure **xxx-xx-xxx** with component one and component two being required. Component two is of the alphanumeric type.
- Organization B is in North America. Organization B has the account structure **xxx-xxx-xx** with components one, two, and three being required. Component two is of the integer data type.

Updating databases for general ledger accounts

After you change a default general ledger account or resource code, you can update the database for one organization at a time.

Before you begin

When you update the database, ensure that no one is using the system. Historical records are not updated.

Procedure

1. In the Chart of Accounts application, select the organization whose database you want to update.
2. Select the Update Database action.
3. In the Update Database window, select one of the following updates:

Option	Description
Overwrite Blank Accounts Only	Use this option to overwrite blank GL Account fields
Overwrite Accounts With Old Defaults	Use this option to overwrite accounts that have not been updated since being inserted.
Overwrite All Accounts	Use this option to overwrite all relevant GL Account fields, including blank fields, with updated data.

4. Click OK.

Setting up accounts

You can set up organizational default accounts as holding accounts for financial considerations. You can also specify default general ledger accounts to be associated with company-related accounts, as well as external labor control accounts to be associated with general ledger accounts.

- [Setting up organization default accounts](#)
You use organizational default accounts as holding accounts for financial considerations.
- [Specifying company-related accounts for general ledgers](#)
For types of companies that use payment, you can specify default general ledger accounts for company-related accounts.
- [Specifying external labor control accounts for general ledgers](#)
You use external labor control accounts to set up default account codes for work performed by outside vendors.

Setting up organization default accounts

You use organizational default accounts as holding accounts for financial considerations.

About this task

You can set up the following global general ledger accounts:

Global Rotating Suspense Account

You use rotating suspense accounts to hold the accumulated cost of repairs for rotating equipment.

Global Ticket Account

You use the default account when a ticket for a service request is created and no other account is available.

Tool Control Account

You use the default account when a transaction involves a tool and no other account is available.

Procedure

1. Open the Chart of Accounts application.
2. In the Organizations table window, select the organization for which you want to define the accounts.
3. Select the Organization Default Accounts action.
4. In the Global Rotating Suspense Account field, click Select Value and choose an account.
5. In the Global Ticket Account field, click Select Value and choose an account.
6. In the Tool Control Account field, click Select Value and choose an account.
7. Click OK.

Specifying company-related accounts for general ledgers

For types of companies that use payment, you can specify default general ledger accounts for company-related accounts.

About this task

The accounts include accounts received but not invoiced, account payable suspense, and accounts payable control account. The accounts are based on company types that are specified in the Companies application.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to specify company-related accounts.
2. Select the Company Related Accounts action.
3. In the Company Related Accounts window, click New Row.
You can add a new row only if there is an enterprise type that has not yet been associated with general ledger accounts.
4. Specify a type, received but not invoiced account information, accounts payable suspense account information, and accounts payable control account information.
5. Click OK.

Specifying external labor control accounts for general ledgers

You use external labor control accounts to set up default account codes for work performed by outside vendors.

Procedure

1. In the Chart of Accounts applications, select the organization for which you want to specify an external labor control account.
2. Select the External Labor Control Accounts action.
3. In the External Labor Control Accounts window, click New Row. You can add a new row only if there is a vendor that has not yet been associated with a general ledger account.
4. Specify values for the vendor and control account.
5. Click OK.

Specifying financial periods for general ledgers

You can segment accounting periods by specifying the start date and close date of a financial period.

Before you begin

You must define at least one financial period.

About this task

The transactions must occur during an open, valid financial period. The requirements of the accounting system that you use determines the format of the financial period.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to define a financial period.
2. Select the Financial Periods action.
3. In the Financial Periods window, click New Row.
4. Enter the name or number for the period.
5. Specify start and end dates for the financial period:
If there is no financial period, the current date and time displays in the From field. If financial periods exist, the From field displays the date and time shown in the To field of the most recent period.
6. Optional: Specify a close date.
After this date, you cannot charge additional transactions to the accounting period.

Results

To prevent gaps and overlaps in time between contiguous periods, if you change the date of an existing period, the surrounding dates are reset. If you use financial periods, then a financial period stamp is added to all transactions when they are generated.

What to do next

You use the Actual Close Date field to close the financial period.

- [Closing financial periods](#)
You can close a specific financial period to ensure that no more transactions are entered in that period.

Closing financial periods

You can close a specific financial period to ensure that no more transactions are entered in that period.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to close a financial period.
2. Select the Financial Periods action.
3. In the Financial Periods window, specify the actual close date for the financial period that you want to close.
Your name is displayed in the Closed By field.

Results

After you close a financial period, financial transactions for that period are no longer accepted.

Specifying resource codes for general ledgers

You can specify default values for different types of labor resources, tool resources, and inventory items. These codes are then used to determine accounting charges.

Procedure

1. In the Chart of Accounts application, select the organization for which you want to define resource codes.
2. Select the Resource Codes action.
3. In the Resource Codes window, complete the information specific to the type of resource code that you are defining:

Option	Description
Labor resource codes	In the Internal field and External field, specify the labor resource code components.
Tool resource codes	In the Internal field and External field, specify the tool resource code components.
Inventory resource codes	a. Click New Row. b. Specify values for the commodity group. c. Optional: Specify a value for the inventory resource code component.

4. Click OK.

Specifying validation options

You use validation options to specify how general ledger accounts are validated. General ledger accounts are validated when they are used in general ledger account fields.

Before you begin

You specify the system-level, default format of general ledger account codes using the GL Account Configuration window in the Database Configuration application. You specify organization-specific general ledger account codes using the Add/Modify Account Structure option in the Chart of Accounts application.

Procedure

1. Open the Chart of Accounts application.
2. In the Organizations table window, select the organization for which you want to specify validation rules.
3. Select the Validation Options action.
4. Select or clear the appropriate check boxes in the following list:

Option	Description
--------	-------------

Option	Description
Deactivate GL Validations	If you deactivate general ledger validations, the entries in general ledger account fields are validated against values in the Chart of Accounts application. If you reactivate this setting, general ledger fields are not validated. You can enter values in general ledger fields, but cannot specify additional settings.
Validate GL Component Combinations	If you validate general ledger component combinations, only valid general ledger account entries are accepted. If you do not use this option, any combination of valid component values is accepted.
Validate Financial Periods	If you validate financial periods, checks are performed to ensure that a transaction occurs within an open, valid financial period. If you do not use this option, validations are not performed against defined financial periods.
Require Valid GL Account for All Transactions	If you require valid general ledger accounts for all transactions, transactions without a valid general ledger account are not allowed. Without this selection, valid general ledger debit and credit accounts must be present on all transactions.

5. Click OK.

Working with cost management

You use the Cost Management application to track the financial resources required to complete the project. You can also link work orders from a project in the Cost Management application to the Work Order Tracking application.

- [Creating cost management projects](#)

When you create a project in the Cost Management application you can assign work orders to that project in the Work Order Tracking application. You can then generate project cost information to track the financial resources required to complete the project.

Creating cost management projects

When you create a project in the Cost Management application you can assign work orders to that project in the Work Order Tracking application. You can then generate project cost information to track the financial resources required to complete the project.

About this task

After you assign the work order to a project or task, the project name appears in other applications in read-only format. To change the project or task to which the work order belongs, use the Work Order Tracking application.

Procedure

1. On the toolbar, click New Project and specify a project name.
2. Type a description for the project. By default, the application selects the Is Chargeable check box. This option allows you to charge costs to the project. If necessary, clear the Is Chargeable check box.
3. Specify a type for the project.
4. In the Parent Project field, assign the project to a parent project.
5. Optional: Type the Budget and Budget Line information.
6. In the Value field, specify the amount of money allocated for the project.
7. Specify the status of the project, the start date, and the end data for the project. By default, the system assigns an APPR status to the project.
8. In the Tasks table window, click New Row to add tasks to the project.
9. Click Save Project.

Managing currency codes

You can define and manage currencies that you can use in purchase orders, purchase requisitions, invoices, and so on.

- [Creating currency codes](#)

You create currency codes to define and manage currencies. A currency code record consists of a currency code, its description, and a setting specifying availability. All organizations can use currency codes.

Creating currency codes

You create currency codes to define and manage currencies. A currency code record consists of a currency code, its description, and a setting specifying availability. All organizations can use currency codes.

About this task

You cannot use a currency that is not active.

Procedure

1. In the Currency Codes application, click New Row.
2. In the Currency field, provide a code value to represent the currency.
For example, you use CND for the Canadian dollar.
3. Optional: Provide a description.
4. Optional: Deactivate the currency.
5. Click Save Currency.

- [Changing currency codes](#)

You change a currency code record to change the currency code description or to make the currency active or inactive.

Changing currency codes

You change a currency code record to change the currency code description or to make the currency active or inactive.

Procedure

1. In the Currency Codes application, find the currency code record that you want to change.
2. Activate or deactivate the currency.
3. Save your changes.

Setting system properties

You can set system properties that various components use to control how applications and other aspects of the product work.

A system property is a key-value pair that is used at the system level.

- [Global properties](#)
A global property applies to the entire system. The property applies to all the server instances that use a common database, including a clustered environment.
- [Options for system properties](#)
Every property defined in the System Properties application has options that you can manage.
- [Values for system properties](#)
You can modify the default values for system properties to tailor IBM® Maximo® Manage to your needs.
- [System properties that contain password information](#)
Several system properties contain password information. Therefore, if you change a password, you must update the associated property value.
- [Fetch stop limit memory errors](#)
A Java™ virtual memory heap out-of-memory error is caused by an operation that fetches and constructs too many objects into one Maximo business object (MBO) set. This type of error can disconnect all users from the server. You can use the mxe.db.fetch system properties to configure the fetch limit, which can help prevent out-of-memory errors.

Global properties

A global property applies to the entire system. The property applies to all the server instances that use a common database, including a clustered environment.

Global properties always have the following options selected by default, but you can clear the options:

- Online Changes Allowed - By default, you can change most properties by using the System Properties application.
- Live Refresh - By default, most properties allow a live refresh where a new value applied to a system property takes effect immediately.

Options for system properties

Every property defined in the System Properties application has options that you can manage.

Table 1. System property option

Property options	Description
File override	Specifies whether the property and its value are loaded from a file rather than from the database.
Online changes allowed	Specifies whether the System Properties application is used to change the value for the property. For example, the global property mxe.db.driver does not allow online changes.
Live refresh	Specifies whether the property value can take effect immediately after saving the value.
Encrypted	Specifies whether the property is stored in an encrypted manner in the underlying product database. The value is encrypted by using the standard encryption functions for the product. For example, the global property mxe.int.uddipassword is encrypted.

Property options	Description
Security level	Specifies the level of access to this property by various product components. Public The property and its value can be accessed through unauthenticated client sessions. Secure The property and its value can be accessed through authenticated client sessions. Private The property and its value can be accessed only with the business object framework of the system.
User defined	Specifies whether the property is created by a user or if the property is provided with the product.
Nulls allowed	Specifies whether the property can have null values. You can change this characteristic only for user-defined properties.
Data type	Specifies the type of value that can be provided for the property. The value can be an integer, alphanumeric, or a yes or no (YORN). For example, the global property mxe.allowLocalObjectsmxe.int.uddipassword is associated with the YORN data type. If you specify a value other than 1 or 0, an error message is displayed that indicates the value is invalid.
Domain	Specifies a domain that provides a list of values to which the property can be set. For example, the mxe.db.transaction_isolation global property is associated with the TRANSISO domain. Therefore, the values for the property must match a corresponding domain value.
Masked	Specifies whether the global and default values are hidden on the user interface.

Values for system properties

You can modify the default values for system properties to tailor IBM® Maximo® Manage to your needs.

You can specify values for system properties in the System Properties application.

You can also add custom properties for individual server bundles. Custom properties are useful when you want to handle processes for one bundle in one way and for another bundle in another way. For example, you might want the email address for the administrator of your reports server bundle to be different from the email address of the administrator for your user interface server bundle. You can specify server bundle properties when you deploy Manage.

If you add a new server bundle property, ensure that you also add the property to the System Properties application before you specify the property during deployment.

Restoring default values

In the System Properties application, you can restore the default values for system properties.

When you restore the system default values, the values are restored for the property names that you select. In effect, all user-defined values are removed and default values are restored.

To restore the system default values, click Restore Maximo Defaults.

System properties that contain password information

Several system properties contain password information. Therefore, if you change a password, you must update the associated property value.

When you change a password, you must update the values of the following system properties:

- mxe.adminPasswd
- mxe.adminusercredential
- mxe.b2b.password
- mxe.int.uddipassword
- mxe.report.bo.rptServerLogonPass
- mxe.system.regpassword

For example, if you change the administrative password, you must update the mxe.adminPasswd property.

Fetch stop limit memory errors

A Java™ virtual memory heap out-of-memory error is caused by an operation that fetches and constructs too many objects into one Maximo® business object (MBO) set. This type of error can disconnect all users from the server. You can use the mxe.db.fetch system properties to configure the fetch limit, which can help prevent out-of-memory errors.

You use the fetch stop limit properties to set an upper limit on the number of objects that are fetched from the database and constructed on the server into a single set. You can set different limits for different types of objects. When the upper limit is reached, an exception is thrown so that the process is stopped. You can then either reduce the number of objects by using filters or change the operation to prevent the database from fetching too many objects.

The fetch stop limit is enabled by default with a limit of 5000 for all objects. If the fetch stop limit is reached and the exception is thrown during a user interface operation, the error message is typically shown to the user. Depending on how the outer logic is implemented, this message might be wrapped by another message or not shown. However, the error is always logged on the server.

Scenarios where fetch stop limit errors occur

Large fetch counts that cause errors typically occur in two scenarios:

- When you apply an action to a large result set. The result set is retrieved without sufficient filtering. This error can occur when you mistakenly start a list page action or when a legitimate operation loads too many objects.
- Where an operation embedded in a user action retrieves a large set of objects and the data cannot be filtered.

Actions to take when fetch limit stop errors occur

Analyze the data and identify the operation that causes the error. You can try to correct the error by filtering the data or by splitting the target of the action into smaller batches. If the error cannot be corrected, the administrator must adjust the system in one or more of the following ways:

- Increase the fetch limit for the particular object if it is safe to use a higher limit. If you do not want other user operations to be capped by this high number, you can call the `MboSet.setLogLargFetchResultDisabled(true)` method on the MBO set.
- Correct the data to avoid processing such a large data set.
- Use discardable MBO sets to prevent all the objects from being fetched into memory.
- Move the operation into a cron task and schedule the cron task to run at a low-demand time or on another server.
- Modify the process so that it fetches fewer objects.

Automating routine tasks with automation scripts

You use automation scripts to implement object rules, attribute validations, workflow or escalation actions, and workflow and security condition logic for applications. Automation scripts can reduce the time that you spend on automating tasks because you do not need to recompile files or restart the server.

- **[Automation scripts](#)**
Automation scripts are small, targeted pieces of code that can extend the product. An automation script consists of a launch point, variables with corresponding binding values, and the source code. You use wizards to create the components of an automation script. You create scripts and launch points or you create a launch point and associate the launch point with an existing script.
- **[Creating automation scripts](#)**
You create automation scripts to automate routine application tasks. You can use the supplied wizards to create scripts and launch points with associated variables and bindings. You can also use the wizards to associate launch points with existing scripts.
- **[Example: Automating assigning service requests to service groups](#)**
The development team at a manufacturing facility is asked to implement a business rule into the production system. When a pipeline leaks in the facility an operator creates a service request to report the leak. The pipeline volume determines the service group that is assigned to the service request. The development team creates a script that assigns the service request to the appropriate service group. If the volume of the pipeline is greater than a specified limit, the team must also ensure that a work log is created.
- **[Example: Automating communication by using a custom role](#)**
The development team at a large maintenance organization must design a process that notifies people when quantities of certain parts are running low. Unexpected disruptions to the supply chain, for example due to adverse weather or industrial disputes, can affect the availability of parts for scheduled maintenance activities. With advance warning of shortages, work supervisors can reschedule non-essential work that requires these parts, conserving supplies and minimizing the effect on schedules.
- **[Launch points](#)**
A launch point is a complete script configuration. The configuration consists of the target application or context, the variables that are passed between the application and the script, and the body of the script.
- **[Examples of Maximo Business Rules \(MBR\) scripts](#)**
Several examples are provided to illustrate how to use Maximo® Business Rules (MBR) language in several common scripting scenarios.
- **[Variables in automation scripts](#)**
Variables determine how information is passed into or received from a script. You can configure the variables for the script in the wizards instead of declaring variables within the source code. By using variables, you reduce the complexity of the source code and make it easier to reuse the source code for different purposes.
- **[Gathering user input by using choice messages in automation scripts](#)**
A choice message gathers user input, which can then be used in the automation script. You can use choice messages in automation scripts to create an interactive user experience. For example, a message can say that a record does not exist and ask if the record should be created.
- **[Reusable library scripts in automation scripts](#)**
A library script is a reusable piece of programming logic that automation scripts can invoke from within the body of their code. Creating library scripts can save time and effort. Library scripts are stored in the database in the AUTOSCRIP table.
- **[Scheduling automation scripts to run as part of cron tasks](#)**
Cron tasks are jobs that run automatically on a fixed schedule on the application server. For example, the ESCALATION cron task processes escalations to ensure that critical tasks are processed on time. You can use several predefined cron tasks and you can also define new cron tasks. For new cron tasks, you must provide a Java™ class implementation that contains the business logic that is executed on a schedule.
- **[Adding scripts that run as asynchronous jobs](#)**
You can add scripts that can run as asynchronous jobs in the product. Use the asynchronous job framework to submit jobs that need to be run one time asynchronously, such as when you want to run something quickly in the background.
- **[Automation scripts for integration](#)**
You can use automation scripts to customize the processing transactions of integration messages by implementing object structure, publish channel, enterprise service, and invocation channel integration components.
- **[Debugging with automation scripts](#)**
You debug a script to remove any issues before you customize applications. Print statements can be placed in a script to capture the logs that are specific to

- a script. Log statements in the scripting framework are automatically sent to the autoscript logger.
- [Testing automation scripts](#)
It is possible to test automation scripts after you create them.
- [Error messages for users](#)
You can display error messages to users from inside a script. For example, you can display an error message for users to see in the Assets application when an asset number does not follow the rules for naming assets.
- [Creating scripts to manage attachments](#)
Maximo Manage can read or write attachments from any store that is registered with Maximo Application Suite.

Automation scripts

Automation scripts are small, targeted pieces of code that can extend the product. An automation script consists of a launch point, variables with corresponding binding values, and the source code. You use wizards to create the components of an automation script. You create scripts and launch points or you create a launch point and associate the launch point with an existing script. You can also create library scripts, which are reusable pieces of programming language that automation scripts can invoke from the body their code. Library scripts must be hosted on the same system.

Prerequisite skills

To extend the product business logic or automate tasks, you must have knowledge in the following areas:

- Scripting language syntax and operations
- Product configurations such as workflow processes, escalations, and actions
- Application data models and relationships

Experience with the Maximo® business object (MBO) API is an advantage although not a prerequisite.

Components of automation scripts

Launch points

A launch point defines the execution context for a script, for example when a business object is updated or a value is entered into a field. Five types of launch point are supported and the Automation Scripts application provides a separate wizard application for creating each type of launch point.

Variables and binding values

You can specify the variables that determine how information is passed into or received from a script in the wizard applications. Variables are not mandatory, but when you use variables it simplifies the amount of code to be written and is easier to reuse the code.

Source code

You can write source code in an external application and import it into the Automation Scripts application. Alternatively, you can enter code directly into the Source Code field in the wizard applications. The source code must be written in the languages that are supported by the following script engines:

- Nashorn JS
- Jython, version 2.7.2

Creating automation scripts

You create automation scripts to automate routine application tasks. You can use the supplied wizards to create scripts and launch points with associated variables and bindings. You can also use the wizards to associate launch points with existing scripts.

About this task

To automate tasks, you must have knowledge of the following areas :

- Scripting language syntax and operations
- Product configurations such as workflow processes, escalations, and actions
- Application data models and relationships

Experience with Maximo® business object (MBO) API is an advantage although not a prerequisite.

You use the same menu items for creating scripts and launch points as you do for creating a launch point to associate with an existing script. For example, you use the Create > Script with Object launch point action to create a script and an object launch point, or to associate an object launch point with an existing script.

In some automations, you must use the documented MBO APIs to automate a routine task. For example, when you automate a task that involves creating a record, you must use the documented MBO APIs for the record creation part of the automation.

Procedure

1. In the Automation Scripts application, select the type of launch point that you want to create.
2. Select whether to add a script or specify an existing script. If you add a script, you can code it in a source code field or you can import a script.
3. Create the launch point if you are using one, and then associate variables and bindings with the launch point.
4. Click Create to save the launch point, variables, and script code.

Example: Automating assigning service requests to service groups

The development team at a manufacturing facility is asked to implement a business rule into the production system. When a pipeline leaks in the facility an operator creates a service request to report the leak. The pipeline volume determines the service group that is assigned to the service request. The development team creates a script that assigns the service request to the appropriate service group. If the volume of the pipeline is greater than a specified limit, the team must also ensure that a work log is created.

About this task

The development team uses automation scripts to implement the business rule. In this procedure, steps 1 - 3 result in the script correctly assigning the service request to the service group. Step 4 involves creating a work log and so, requires Java™ or Maximo® Business Object (MBO) API invocations to be called.

Procedure

1. Create an action launch point and script.
2. Create an escalation.
3. Test the configuration.
4. Create the work log by using MBO APIs.

- [Example: Result of automating the assignment of service requests](#)

In a service request that is created to report a pipeline leak, an operator specifies the appropriate classification for the pipeline based on attributes such as diameter and length. When a business rule is implemented using automation scripts, if the volume of the pipeline is less than 1000 cubic feet, the service request is assigned to service group A. If the volume is greater than 1000 cubic feet, the service request is assigned to service group B and a work log entry is created.

- [Example: Assigning the service group to the service request](#)

You create a script to implement the business rule. You create an action launch point and associate the launch point with a script that identifies and correctly assigns the service group to the service request.

- [Example: Work log creation by using MBO APIs](#)

The scripting framework does not have any functions to create a work log. You must use the documented MBO APIs to create the work log.

Example: Result of automating the assignment of service requests

In a service request that is created to report a pipeline leak, an operator specifies the appropriate classification for the pipeline based on attributes such as diameter and length. When a business rule is implemented using automation scripts, if the volume of the pipeline is less than 1000 cubic feet, the service request is assigned to service group A. If the volume is greater than 1000 cubic feet, the service request is assigned to service group B and a work log entry is created.

The rule is implemented in an automation script. Upon implementation, an escalation definition created by the development team enables the script and its associated launch point.

By defining an escalation, the team ensures that service requests are automatically examined by the script. New service requests that meet the pipeline leakage criteria are automatically assigned to the appropriate service group.

When the development team create the automation script, the business rule is implemented with the following components:

- The escalation runs automatically and periodically in the application server.
- When the escalation finds service request records that match the criteria, an action starts.
- The action launch point is the entry point into the business rule implementation. The action starts the launch point.
- The script implements the business rule to identify and assign the correct service group. If required, a work log is generated.

The script code has two parts:

- The first part is written in the Jython scripting language and identifies the service group.
- The second part uses MBO API invocations to create a work log record and to set values. You can express business rules in the flow control constructs of the scripting language. However, certain tasks require Java™ or MBO API invocations to be called. Specifically, the creation of a new record from within the script requires the use of the Java MBO add() method.

Example: Assigning the service group to the service request

You create a script to implement the business rule. You create an action launch point and associate the launch point with a script that identifies and correctly assigns the service group to the service request.

- [Example: Creating the action launch point and script](#)

You use a wizard to create an action launch point with service request as the object. You can paste script code directly into the wizard.

- [Example: Creating the escalation](#)

You create an escalation that checks all new service requests for a classification of 'PIPE_LEAK'. When the escalation finds a service request with this classification, it calls an action. The result of the action is that a business rule is implemented. The service request is assigned to the correct service group and if required, a work log is created.

- [Example: Testing the configuration](#)

You test the solution to ensure that all new service requests that meet the criteria are assigned to the correct service group. You can therefore test that the business rule is being correctly implemented.

- [Example: Actions performed by the example script](#)

When the escalation runs the action, the action starts the script. The script determines which group the service request is assigned to.

Example: Creating the action launch point and script

You use a wizard to create an action launch point with service request as the object. You can paste script code directly into the wizard.

Procedure

1. In the automation scripts application, select the **Create_>Script** with **Action Launch Point** action.
2. Specify a launch point name and description.
 - a. Specify the object as **SR**.
 - b. Specify a name for the action.
For consistency, use the same name that you used for the launch point.
3. Enter a script name.
For consistency, use the same name that you used for the launch point.
 - a. Specify the script language as **Jython**.
 - b. Enter the variable names and binding values in Table 1.
 - c. For the **v_servicegroup** variable, select the **Suppress Access Control** check box.

Table 1. Variables, types, and bindings specified in the action launch point

Variable Name	Type	Binding
v_srclassif	IN	CLASSSTRUCTURE.CLASSIFICATIONID
v_sratrdiameter	IN	TICKETSPECCLASS[ASSETATTRID='DIAMETER'].NUMVALUE
v_sratrlen	IN	TICKETSPECCLASS[ASSETATTRID='LENGTH'].NUMVALUE
v_servicegroup	OUT	COMMODITYGROUP

4. In step 3 of the wizard, enter the following script code:

```
#Check if the SR is classified as a pipe leakage
if v_srclassif=='PIPE_LEAK':
    #Now calculate total volume of the pipe-formula is:3.14 * length * (diameter / 24) ^ 2
    volume = 3.14 * v_sratrlen * (v_sratrdiameter / 24)**2
    if volume < 1000:
        #If volume is less than 1000 cubic feet, just assign SR to GROUP A
        v_servicegroup = 'GROUP A'
    else:
        #If vol is greater than 1000 cubic ft, assign SR to GROUP B and create worklog
        v_servicegroup = 'GROUP B'
        # Now add the MBO API code to create a new record in the work log for the SR
        worklogset = mbo.getMboSet ('WORKLOG')
        worklog = worklogset.add()
        worklog.setValue('clientviewable',1)
        worklog.setValue('logtype','WORK')
        worklog.setValue('description','System initiated processing-work assigned to GROUP B')
```

5. To save the launch point, variables, and script code, click **Create**.

Example: Creating the escalation

You create an escalation that checks all new service requests for a classification of 'PIPE_LEAK'. When the escalation finds a service request with this classification, it calls an action. The result of the action is that a business rule is implemented. The service request is assigned to the correct service group and if required, a work log is created.

Procedure

1. In the Escalations application, create an escalation.
2. Specify a name for the escalation.
For consistency, use the same name you used for the launch point that you created in the previous task.
3. Specify **SR** as the business object the escalation applies to.
4. Specify the condition as **reportedpriority=1 and status='QUEUED' and commoditygroup is null**.
5. Specify the schedule as **1 minute**.
6. Create the escalation point.
7. In the Actions window, select the action you associated with the action launch point in the previous task.
8. Save the escalation.

Example: Testing the configuration

You test the solution to ensure that all new service requests that meet the criteria are assigned to the correct service group. You can therefore test that the business rule is being correctly implemented.

Procedure

1. In the Classifications application, create a classification named PIPE_LEAK.
 - a. Add an attribute called diameter with a numeric data type and specify inches as the unit of measure.
 - b. Add an attribute called length with a numeric data type and specify feet as the unit of measure.
 - c. In the Use with window, specify service requests.
2. In the Service Groups application, create two service groups named Group A and Group B.
3. In the Service Requests application, create a service request and specify the reported priority as 1 and the status as QUEUED.
 - a. In the Classify window, specify PIPE_LEAK as the classification.
 - b. Specify values for length and diameter. For example, length=720 feet and diameter=31 inches.
4. Activate the escalation that you created in the previous task.

Results

When the active escalation executes, the service request is assigned to the appropriate service group. By creating PIPE_LEAK service requests for pipes of different diameters and lengths, you can check that the correct service group is assigned. If the computed volume is greater than the specified limit, the work log is also generated against the service request.

Example: Actions performed by the example script

When the escalation runs the action, the action starts the script. The script determines which group the service request is assigned to.

The following script is used to automate the assignment of service requests to service groups:

```
#Check if the SR is classified as a pipe leakage
if v_srclassif=='PIPE_LEAK':
    #Now calculate total volume of the pipe-formula is:3.14 * length * (diameter / 24) ^ 2
    volume = 3.14 * v_srattrlen * (v_srattrdiameter / 24)**2
    if volume < 1000:
        #If volume is less than 1000 cubic feet, just assign SR to GROUP A
        v_servicegroup = 'GROUP A'
    else:
        #If vol is greater than 1000 cubic ft, assign SR to GROUP B and create worklog
        v_servicegroup = 'GROUP B'
        # Now add the MBO API code to create a new record in the work log for the SR
        worklogset = mbo.getMboSet ('WORKLOG')
        worklog = worklogset.add()
        worklog.setValue('clientviewable',1)
        worklog.setValue('logtype','WORK')
        worklog.setValue('description','System initiated processing-work assigned to GROUP B')
```

When the escalation runs, the script executes the following logic:

1. Checks if the service request has a classification of 'PIPE_LEAK'. Continues execution if a match is found.
2. Calculates the pipeline volume by using a formula and stores the result in a local variable.
3. If the volume is less than 1000 cubic feet, assigns the service request to 'GROUP A'.
4. If the volume is greater than 1000 cubic feet, assigns the service request to 'GROUP B'. Creates a work log to indicate that service request processing started.

The script indicates when the documented MBO APIs must be used. For calculations, you can define input variables to provide the data the script needs. The formula for calculating the pipeline volume is available on many public websites. In this example, the input variables `v_srclassif`, `v_srattrdiameter`, and `v_srattrlen` are used in the script. The input variables are based on the bindings in the SR, TICKETSPECCCLASS, and CLASSSTRUCTURE business objects.

Table 1. Variables that are used in the example script

Variable	Binding	How binding is resolved
<code>v_srclassif</code>	<code>CLASSSTRUCTURE.CLASSIFICATIONID</code>	The scripting framework traverses the CLASSSTRUCTURE relationship from the SR object to the CLASSSTRUCTURE object and retrieves the CLASSIFICATIONID value which is a string.
<code>srattrdiameter</code>	<code>TICKETSPECCCLASS[ASSETATTRID='DIAMETER'].NUMVALUE</code>	The scripting framework traverses the TICKETSPECCCLASS relationship from the SR object to the TICKETSPECCCLASS object and retrieves the value of the diameter attribute. To retrieve one attribute, the binding specifies a filter in square brackets [ASSETATTRID= 'DIAMETER'].
<code>v_srattrlen</code>	<code>TICKETSPECCCLASS[ASSETATTRID='LENGTH'].NUMVALUE</code>	The scripting framework retrieves a single value for the length attribute from the binding and filter.

When the volume of the pipe is calculated, the script checks if the value is greater or less than 1000 cubic feet. Based on the result of the *if* and *else* condition in the script, the output variable `v_servicegroup` is set to service group A or service group B. The script retrieves the value from the `v_servicegroup` variable and enters the value into the service request.

Example: Work log creation by using MBO APIs

The scripting framework does not have any functions to create a work log. You must use the documented MBO APIs to create the work log.

Many API invocations are used to create the work log. Because the script is running against the service request (SR) object, the scripting framework offers a handle to the service request object. The *mbo* keyword in the body of the script is used to retrieve the handle. Other related business objects can be accessed from the handle.

- The first API called is the `getMboSet` method on the SR business object. The API is called with the code: `worklogset = mbo.getMboSet ('WORKLOG')`. The `getMboSet` method accepts a parameter that represents a relationship from the current SR business object to the WORKLOG business object. The parameter is a relationship name defined in the data dictionary. The method returns a handle to a set that represents a container for the related object.
- The next API called is the `add` method. The API is called with the code: `worklog = worklogset.add()`. The `add` method returns a business object that can be initialized by setting values into the attributes of the object.
- The next API called is the `setValue` method on the business object. The API is called with the code: `worklog.setValue('clientviewable', 1')`. The `setValue` method sets the value of the attribute on the business object.
- Additional `setValue` methods are called to set the values of more attributes of the business object. The number of `setValue` invocations depends on the number of primary key and required attributes of the business object that is being created.

The data in the initialized business object is saved. You do not have to invoke a `save` method on the business object from within the script. The work log is now created if the volume of the pipeline is greater than 1000 cubic feet.

Example: Automating communication by using a custom role

The development team at a large maintenance organization must design a process that notifies people when quantities of certain parts are running low. Unexpected disruptions to the supply chain, for example due to adverse weather or industrial disputes, can affect the availability of parts for scheduled maintenance activities. With advance warning of shortages, work supervisors can reschedule non-essential work that requires these parts, conserving supplies and minimizing the effect on schedules.

About this task

The development team creates a custom role that identifies the users that are to receive notifications. An automation script constructs a mailing list of the email addresses from the person records that have been assigned the custom role and an escalation point specifies the quantity of an item that activates a notification. The escalation record uses a communication template to generate the communication that is sent to users.

Procedure

1. In the Roles application, create a custom role and name it, for example *MYTESTCUSTOMROLE*.
The name of the role that you create forms part of the name of the automation script you create to automate this process. The name must contain uppercase letters only.
2. In the Type field, select *Custom class* and, in the Value field, specify `com.ibm.tivoli.maximo.script.ScriptCustomRole`.
This file is a predefined Java™ class.
3. In the Communications Template application, compose a standard email and, in the Recipients tab, specify the custom role that you created in Step 1.
4. In the Escalations application, create an escalation to manage the communication flow:
 - a. Create an escalation point that specifies the minimum quantity of an item that causes a notification to be sent.
 - b. In the Notifications section, specify the role associated with the person group that you created in Step 3.
 - c. Activate the escalation.
5. In the Automation Scripts application, create a simple script based on any standard scripting language. The scripting language in this example is written in Python:
 - a. In the Script field, specify `MAXROLE.MYTESTCUSTOMROLE`.
The name must be a concatenation of MAXROLE followed by the name of the custom role that you created for this process and must contain uppercase letters only.
 - b. Either import a script that you created elsewhere or you can add the script directly into the record. You can use one of the following methods in your script:

Option	Description
<code>evalToPerson(ctx)</code>	Use this method if you want to select a person or a person group for this role. The <i>ctx</i> variable refers to an instance of the <code>com.ibm.tivoli.maximo.script.ScriptRoleContext</code> Java class. The script can call the <code>ctx.setPersonOrGroupMbo(pergroupmbo)</code> class to set the person or persongroup mbo to this <i>ctx</i> variable, where <i>pergroupmbo</i> is the reference to an existing persongroup mbo.
<code>evalToEmail(ctx)</code>	Use this method if you want to select a set of emails. The email addresses do not have to be associated with person records. As with the previous option, the <i>ctx</i> variable in the script is associated with an instance of <code>com.ibm.tivoli.maximo.script.ScriptRoleContext</code> Java class. You can use this <i>ctx</i> variable to set email addresses as shown in the following example: <pre>def evalToEmail (ctx): ctx.addEmailId("person1@example.com") ctx.addEmailId("person2@example.com")</pre>

6. Activate the script and save the record.

Launch points

A launch point is a complete script configuration. The configuration consists of the target application or context, the variables that are passed between the application and the script, and the body of the script.

You can create a script and associate a launch point to the script. Alternatively, you can create a launch point and associate it to variables and scripts. You can share a script among multiple launch points. Scripts and launch points can be promoted from development to production by using Migration Manager.

When a launch point is deactivated, the scripts associated with that launch point do not run. To debug an application, you can deactivate a launch point to test the behavior of the application without the script.

The status of the automation script does not affect how the scripting framework executes the script. A script in draft status is treated the same way as a script with a status of Active.

- [Script with an object launch point](#)
An object launch point associates a script with a business object and executes in response to a business object event. Events are associated with a specific context so that the script executes before or after the object is saved or after it is committed to the database. You can, optionally, associate an event with a condition and limit execution to circumstances where the condition is satisfied.
- [Script with an attribute launch point](#)
An attribute launch point associates a script with a specific field of a business object and an event occurring against that field, and executes only when a value is specified for that field.
- [Script with an action launch point](#)
An action launch point associates a script with an action and executes when the specified action occurs. Use the Actions application to configure the associated action.
- [Script with a custom condition launch point](#)
A custom condition launch point associates a script with a custom condition and executes when the condition is satisfied. Use the Conditional Expression Manager application to configure the associated condition.
- [Script without a launch point](#)
You can enter a script in the Automation Scripts application without associating it with a launch point. This approach is useful, for example, if you want to import a library of scripts that you intend to configure at a later stage.

Script with an object launch point

An object launch point associates a script with a business object and executes in response to a business object event. Events are associated with a specific context so that the script executes before or after the object is saved or after it is committed to the database. You can, optionally, associate an event with a condition and limit execution to circumstances where the condition is satisfied.

An object launch point can be based on any object in the database, and you must associate it with at least one of the following events:

Initialize value

Indicates whether the script is executed by the initialize event.

Validate application

Indicates whether the script is executed by the validate event.

Allow object creation

Indicates whether new Maximo® business objects (MBOs) can be created. For example, your business logic can state that when a purchase order is approved, new POLINE objects cannot be created. Only one launch point can be defined for the selected MBO and the Allow object creation event.

Allow object deletion

Indicates whether MBOs can be deleted. For example, your business logic can state that when a work order is approved, WOLINE objects cannot be deleted. Only one launch point can be defined for the selected MBO and the allow object deletion event.

Save

Indicates whether the script is executed by the save event. If you select the Save radio button, you must specify the context for the save in the Save section.

The save event can be executed in any of the following contexts:

Before save

The script is executed and sets values on the business object before the underlying transaction is saved. For example, you can apply a business rule that checks if a specific naming convention has been followed when a new record is being saved. If the naming convention rule has not been followed, the save activity is not allowed and the user receives an error message.

After save

The script is executed after the business object is saved but before the changes are committed. This event context enables you to incorporate a business rule and roll back processing on a transaction if necessary. For example, in an integration scenario, if a transaction update to an external system fails due to a connection issue, the initial transaction can be rolled back so that both databases remain synchronized.

After commit

The script is executed after a transaction has been committed to the database and cannot be rolled back. This event context is typically used to initiate additional actions immediately after the commit of a particular business object. For example, a script initiates sending email notifications when a work order is completed or sends an integration message to notify an external system when a purchase order is created.

In the Object Event Condition field, you can restrict activation of the script by specifying a condition that is related to the event. For example, to redirect a user to a new form when a user attempts to add a person whose language is not English. In this scenario, if the **langcode** attribute for the person is set to English, the script is not activated.

Example of an object launch point

When an asset record is created, the asset number must adhere to a naming convention. The asset number must be prefixed with the type of asset that the user is creating. For example, a Facilities asset must have an FT prefix. If the appropriate prefix is not specified, show an error message to indicate that the prefix is invalid. To implement the requirement, complete the following steps:

1. Define an object launch point on the ASSET business object.
2. Define the script that associates the prefix and associate the script with the object launch point:

```
def setError(prefix) :  
    global errorkey,errorgroup,params  
    errorkey='invalidassetprefix'
```

```

errorgroup='asset'
params=[prefix,assettype]

if assettype_internal=='FACILITIES' and not assetnum.startswith('FT'):
    setError('FT')
elif assettype_internal=='FLEET' and not assetnum.startswith('FL'):
    setError('FL')
elif assettype_internal=='IT' and not assetnum.startswith('IT'):
    setError('IT')
elif assettype_internal=='PRODUCTION' and not assetnum.startswith('PR'):
    setError('PR')

```

3. Test the object launch point and script, and activate or de-activate the launch point as required.

Script with an attribute launch point

An attribute launch point associates a script with a specific field of a business object and an event occurring against that field, and executes only when a value is specified for that field.

Similar to an object launch point, you associate an attribute launch point with a specific object in the database. However, in addition to an object, an attribute launch point must be associated with a specific attribute in that object. An attribute launch point is appropriate if you want to perform a routine every time an object attribute value is initialized, updated, or looked up by using a Lookup dialog box. For example, you can use an attribute launch point to get the account number for an existing customer.

You can associate an attribute launch point with the following events on a field:

Initialize access restriction

Sets the access level for the attribute's field. For example, you can change the access level for an attribute's field from read/write access to read-only access.

Initialize value

Sets the value for the attribute's field. For example, you can automatically enter the account number for an existing customer.

Validate

Checks whether the value in the attribute's field is valid. For example, you can check whether a telephone number is properly formatted or contains enough digits to constitute a valid number.

Retrieve list

Retrieves a list of valid values for the attribute's field. For example, in an invoice, you can set up the supplier field to return a list of approved vendors.

Run action

Runs an action that is based on the value that is in the attribute's field.

You use choice messages to gather and act on user responses. You can define choice messages in the Database Configuration application. You are able to use OK, Close, Cancel, Yes, and No buttons in choice messages. Then, in your automation script, you can create business logic to match the buttons in the choice message.

When you use a combination of buttons, ensure that you have a button for each of your options. For example, you do not want to use only the Yes and OK buttons because these options do not give the user the option to cancel or stop the process.

Example of an attribute launch point

You can define an attribute launch point that runs whenever a user completes the Purchase price field. You define the script that configures the fields and associates the script with the attribute launch point. For example, if the purchase price of an asset is more than \$100, the Vendor field is required. If the purchase price of an asset is less than \$100, the Vendor field is not required. For any purchase price, the replacement cost must be half the purchase price.

To implement this requirement, you complete the following steps:

1. Define an attribute launch point that is executed when a user moves out of the Purchase Price field.
2. Define the script that configures the fields and associate the script with the attribute launch point:

```

if purchaseprice > 200:
    errorgroup = "asset"
    errorkey="purchasepricemsg"
else:
    if purchaseprice >= 100:
        vend_required=True
    else:
        vend_required=False
    rc = purchaseprice/2

```

3. Test the attribute launch point and script and activate or de-activate the launch point as required.

Script with an action launch point

An action launch point associates a script with an action and executes when the specified action occurs. Use the Actions application to configure the associated action.

You can create actions to perform the following tasks:

- Start an application action
- Execute a custom class or specified executable program
- Set the value of a field on a record

To create a script with an action launch point, in the Automation Scripts application, select the **Create...Script with Action Launch Point** action. When you specify a name for the launch point, the value is copied to the Action field, but you can modify it. For example, you can specify the name of an existing action that you intend to use. If you create a new action name, you can use that name when you create the action in the Actions application. Specify the object that can launch this script.

Example of an action launch point

You can use an action launch point to automate tasks that are part of a workflow. When a service request record is worked on as part of a workflow process, the target contact and target start dates must be calculated. A work log entry must also be created for the service request.

To implement this requirement, you complete the following steps:

1. Define an action launch point on the service request object process.
2. Define the script that calculates the target contact and start dates, and generates the work log:

```
from java.util import Calendar

if status=='NEW' and reportedpriority==1 and assetnum is not None:
    cal=Calendar.getInstance()
    cal.add(Calendar.DATE, +1)
    targetcontactdate = cal.getTime()
    cal.add(Calendar.DATE,+1)
    targetstartdate=cal.getTime()

    worklogset = mbo.getMboSet ('WORKLOG')
    worklogentry = worklogset.add()
    worklogentry.setValue('clientviewable',1)
    worklogentry.setValue('logtype','WORK')
    worklogentry.setValue('description','System initiated processing')
```

3. Define the workflow process and associate the action that executes the action launch point with the workflow process. Validate, enable, and activate the workflow.
4. Test the workflow process, action launch point, and script and activate or de-activate the launch point as required.

Script with a custom condition launch point

A custom condition launch point associates a script with a custom condition and executes when the condition is satisfied. Use the Conditional Expression Manager application to configure the associated condition.

In the Conditional Expression Manager application, you can create conditional classes and expressions to restrict user access to fields, tabs, and other user interface controls. When you create a script with a custom condition launch point you specify the precise name of the condition that you create in the Conditional Expression Manager application.

Example of a custom condition launch point

You can use a custom condition launch point to restrict user access. For all users in a security group, for assets that have status of DECOMMISSIONED, the Assets application must not show the Spare Parts tab. You can define a custom condition launch point to evaluate the status of an asset record. You define the condition expression that starts the script and then define the signature option that controls access to the Spare Parts tab. You then associate the condition expression and signature option with the security group.

To implement this requirement, you complete the following steps:

1. Define a custom condition launch point.
 2. Define the script that evaluates the status of an asset record:
- ```
if(status=='DECOMMISSIONED') :
 evalresult=False
else:
 evalresult=True
```
3. Define the condition expression that invokes the script.
  4. Define the signature option that controls access to the Spare Parts tab.
  5. Associate the condition expression and signature option with the required security group.
  6. Test the complete configuration and activate or de-activate the launch point as required.

---

## Script without a launch point

You can enter a script in the Automation Scripts application without associating it with a launch point. This approach is useful, for example, if you want to import a library of scripts that you intend to configure at a later stage.

To create a script without associating it with a launch point, select **Create...Script**.

If you want to later associate the script with a launch point, you can create a script with a launch point and specify this script as the existing script to use.

Another example of an automation script that is not associated with a launch point is an automation script that runs as part of a cron task. You create the script in the Automation Scripts application. In the Cron Task Setup application, you reference the script-aware Java™ class in your cron task definition. Then, you can attach the automation script to the cron task.

---

## Examples of Maximo Business Rules (MBR) scripts

Several examples are provided to illustrate how to use Maximo® Business Rules (MBR) language in several common scripting scenarios.

- [Script for an object launch point to add an MBO to an MBOSet](#)
- [Script for an attribute launch point to manipulate dates](#)
- [Script without a launch point to set an attribute on a duplicate object](#)

---

### Example: Adding an MBO to an MBOSet

When a new asset is added with an asset type of GASENG, the record adds two meters to the meter MBOSet of the asset. The meters are O-PRESSUR and IN-PRESSUR.

Procedure

1. In the Automation Scripts application, create a script that has an object launch point.
2. Specify the launchpoint name and select the ASSET object.
3. In the Events section, select the Save event.
4. In the Save section, specify the context for the event and select Add and Before Save.
5. In the Script section, select the option to add a script and advance to the next page.
6. Specify a script name and set the log level to debug. Advance to the next page.
7. Paste the source code that follows into the Source Code field and click Create to add the script.

```
#my first MBR code for asset
setvar("isgaseng", (asettype == "GASENG" && countf("assetmeter")==0))
if(getvar("isgaseng"), invokescript(":createmeters"))

#my MBR function that will add the two meter MBOs to the asset MBO
:createmeters
newmbo("opressure", "assetmeter")
setvalue("opressure", "metername", "O-PRESSUR")
newmbo("inpressure", "assetmeter")
setvalue("inpressure", "metername", "IN-PRESSUR")
```

Analysis

This script contains two lines of main code and a function. The script is run when a user saves changes to an asset record. In the main code, the following logic is implemented:

1. Create a local variable and set the variable to **TRUE** if both of the following conditions are true:
  - The asset type is GASENG.
  - The meter MBOSet of the asset is empty.
2. Evaluate the local variable. If the local variable is **TRUE**, call a function to add MBOs to the meter MBOSet of the asset. In the createmeters function, the following logic is implemented:
  - a. Add an MBO to the meter MBOSet of the asset.
  - b. Set the name of the MBO to O-PRESSUR.
  - c. Add a second MBO to the meter MBOSet of the asset.
  - d. Set the name of the second MBO to IN-PRESSUR.

The script uses two internal variables, *asettype* and *assetmeter* to derive the asset type and the contents of the meter MBOSet of the asset.

Because this script runs when a user saves their changes, the application transaction framework saves and commits the newly created MBOs as part of the main transaction.

You can move the createmeters function code into a library script. For example, you can move the createmeters function code to a library script that is also called createmeters and then call the library script in the following statement:

```
if (getvar("isgaseng"), invokescript("createmeters"))
```

---

### Example: Manipulating dates

If an asset has a type of BUS, take the following actions:

- Set the end of life date to the installation date plus one year. If the asset does not have an installation date, set the end of life date to the current date plus one year.
- Make the priority attribute mandatory.

Procedure

1. In the Automation Scripts application, create a script that has an attribute launch point.
2. Specify the launch point name, and select the ASSET object and the ASSETTYPE attribute.
3. In the Events section, select the Validate event.
4. In the Script section, select the option for a new script and advance to the next page.
5. Specify a script name and set the log level to debug. Advance to the next page.
6. Paste the source code in the following section into the Source Code field and click Create to add the script.

```
if (asettype=="BUS", setvalue("estendoflife", nvl(installdate, now()) + duration(1,0,0,0,0,0))
if (asettype=="BUS", setrequired("priority", TRUE), setrequired("priority", FALSE))
```

## Analysis

This script is run when the asset type is modified. In the script, the following logic is implemented:

- If the asset has a type of BUS, set the end of life date:
  1. Evaluate the installation date of the asset.
  2. If the installation date is empty, set the end of life date to the current date plus one year.
  3. If the installation date is populated, set the end of life date to the installation date plus one year.
- If the asset has a type of BUS, make the priority attribute mandatory. If the asset does not have a type of BUS, make the priority attribute optional.

For both of these actions, the script checks to see whether the asset has a type of BUS, which is inefficient. You can improve the script by defining a function, moving both actions into the function, and calling the function if the asset has a type of BUS. The following code demonstrates this improvement:

```
if (assettype=="BUS", invokescript(":seteol"), setrequired("priority", FALSE))
:seteol
setvalue("estendoflife", nvl(installdate, now()) + duration(1, 0, 0, 0, 0))
setrequired("priority", TRUE)
```

The script uses the internal variables *assettype*, *estendoflife*, and *installdate* to derive the values of the type, end of life date, and install date of the asset.

## Example: Setting attributes on duplicate objects

When a work order is duplicated, copy the original work order number to a custom attribute in the duplicate work order.

### Procedure

1. In the Automation Scripts application, create a script that does not have a launch point.
2. Specify a script name of WORKORDER.DUPLICATE.
3. Specify MBR as the script language if it is not specified.
4. Paste the following source code into the Source Code field and click Create to add the script:

```
setvaluetombo("dupmbo", "copiedfrom", wonum)
```

## Analysis

The script name ensures that this script runs when a work order is duplicated. The script copies the original work order number into a custom attribute in the duplicate work order.

The script uses the internal variables *wonum*, *dupmbo*, and *copiedfrom* to derive the values of the original work order number, the duplicate work order number, and the custom attribute on the duplicate work order.

## Variables in automation scripts

Variables determine how information is passed into or received from a script. You can configure the variables for the script in the wizards instead of declaring variables within the source code. By using variables, you reduce the complexity of the source code and make it easier to reuse the source code for different purposes.

- [Launch point variables](#)  
When you create a launch point you can declare as many variables as required. After you create a script, you can add more variables or modify existing variables.
- [Implicit variables](#)  
Implicit variables are variables that you do not define. These variables are automatically provided by the framework. Some implicit variables are valid only when associated with a declared variable while others are not associated with any other variables.
- [Data retrieval by using variable bindings](#)  
You use variable bindings to retrieve values for the variables in the script. When variables are bound to business object attributes, the coding required in the script is simplified.

## Launch point variables

When you create a launch point you can declare as many variables as required. After you create a script, you can add more variables or modify existing variables.

When you declare a variable you must specify it as one of the following types:

### INPUT

Passes information into the script.

### OUTPUT

Passes information out from the script.

### INPUT/OUTPUT

Passes information into the script and returns information from the script.

The script can modify only the **INPUT** and **OUTPUT** type of variables. Modification of **IN** variables in the script has no impact outside the script.

When you create a script with an object launch point, you specify one or more events and the event context when the script is activated. If a script runs after the business object is saved, or after the business object is committed to the database, the only relevant variable type in the context is the **IN** variable type.

Variables have bindings that identify the source of the value for the variable. Variables can have a global binding value that is common to all launch points that are associated with the script. You can override the global binding value for specified launch points. The following table lists the binding types and values that you can use:

| Binding type     | Variable binding value                                                                                                                                                            |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ATTRIBUTE</b> | The name of an attribute of a business object that provides the value for the variable.                                                                                           |
| <b>MAXVAR</b>    | The name of a system control value that provides the value for the variable.                                                                                                      |
| <b>SYSPROP</b>   | The name of a system property that provides the value for the variable.                                                                                                           |
| <b>LITERAL</b>   | If you use a literal type of binding, you must specify the value for the variable in the Binding Value field. You must also specify the data type in the Literal Data Type field. |

## Implicit variables

Implicit variables are variables that you do not define. These variables are automatically provided by the framework. Some implicit variables are valid only when associated with a declared variable while others are not associated with any other variables.

In addition to implicit variables, a Maximo® business object (MBO) is also available to every script. You refer to the current business object by using the *mbo* reserved word.

Implicit variables that are not associated with another variable are set into the script and you can refer to these variables directly by name. For example, *app* or *mbo* are not associated with other variables.

The variables in the following table are not associated with any other variable in use:

Table 1. Implicit variables that are not associated with other variables

| Implicit variable     | Type    | Scope                                                                                                                                                                                                                                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>action</i>         | String  | Action launch point                                                                                                                                                                                                                                                                                            | Indicates the name of the action that is generated from the action launch point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>app</i>            | String  | All launch points                                                                                                                                                                                                                                                                                              | Indicates the name of the application that the script is running against. The <i>app</i> variable is passed to the script.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>domainid</i>       | String  | Use this variable only when the attribute launch point implements the retrieve list event.                                                                                                                                                                                                                     | Specifies the domain that is used to provide the list of values that are shown for the attribute launch point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>errorgroup</i>     | String  | All launch points                                                                                                                                                                                                                                                                                              | Selects the message group identifier that is defined in the Database Configuration application. The <i>errorgroup</i> variable is set in the script. Together with the <i>errorkey</i> variable, the <i>errorgroup</i> variable identifies an error message that is declared in the message repository.                                                                                                                                                                                                                                                                                   |
| <i>errorkey</i>       | String  | All launch points                                                                                                                                                                                                                                                                                              | Enables script authors to set an error message from the script into the business object. The script code selects the Message Key identifier that is defined in the Database Configuration application. The <i>errorkey</i> works with the <i>errorgroup</i> and the <i>params</i> implicit variables. The advantage of setting an error message from the messages repository is that translated messages are automatically picked up. The script code sets the error key that is configured in the Database Configuration application. The <i>errorkey</i> variable is set in the script. |
| <i>evalresult</i>     | Boolean | Condition launch point                                                                                                                                                                                                                                                                                         | Set in the script. Workflow condition evaluation and security conditions scripts return true or false values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>interactive</i>    | Boolean | All launch points                                                                                                                                                                                                                                                                                              | Indicates whether the script is running in an active user session or a non-user background session, such as integration transaction processing.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>launchPoint</i>    | String  | All launch points                                                                                                                                                                                                                                                                                              | Indicates the name of the launch point for which the script is run.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>listErrorGroup</i> | String  | Use this variable only when the attribute launch point implements the retrieve list event. Specify the <i>listErrorGroup</i> and <i>listErrorKey</i> variables together and use the messages facility in the Database Configuration application to select the message that is stored in the MAXMESSAGES table. | Identifies the group ID of the message that the user sees when the retrieve list event fails.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>listErrorKey</i>   | String  | Use this variable only when the attribute launch point implements the retrieve list event. Specify the <i>listErrorGroup</i> and <i>listErrorKey</i> variables together and use the messages facility in the Database Configuration application to select the message that is stored in the MAXMESSAGES table. | Identifies the key ID of the message that the user sees when the retrieve list event fails.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>listOrder</i>      | String  | Use this variable only when the attribute launch point implements the retrieve list event.                                                                                                                                                                                                                     | Set to any ORDER BY attribute names that are used to order the results of the retrieve list event.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>listWhere</i>      | String  | Use this variable only when the attribute launch point implements the retrieve list event.                                                                                                                                                                                                                     | Establishes which set of result data is displayed and which filter is set before the results are shown. Set the <i>listWhere</i> variable to a WHERE clause that uses the related MBO.                                                                                                                                                                                                                                                                                                                                                                                                    |

| Implicit variable     | Type                                         | Scope                                                                                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <i>mboSet</i>         | psdi.mbo.MboSet                              | Object launch points of Allow Create type                                                                                                                                   | References the MboSet that the new MBO will be added to.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>mboName</i>        | String                                       | All launch points                                                                                                                                                           | Indicates the name of the current MBO in the context of the script that is running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>mboValue</i>       | psdi.security.UserInfo                       | All attribute launch point events                                                                                                                                           | An instance of the MBO attribute for the attribute launch point.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>onAdd</i>          | Boolean                                      | All launch points. Ideally used with object launch points where the script applies to multiple event types such as add, update, and delete.                                 | Indicates whether the business object that the script is running against is being inserted or created. You can use the <i>onAdd</i> variable to perform conditional actions or validations that are based on the state of the MBO.                                                                                                                                                                                                                                                                                                                                                    |
| <i>onDelete</i>       | Boolean                                      | All launch points                                                                                                                                                           | Indicates whether the business object that the script is running against is being deleted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>onUpdate</i>       | Boolean                                      | All launch points                                                                                                                                                           | Indicates whether the business object that the script is running against is being updated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>params</i>         | String[]                                     | All launch points                                                                                                                                                           | Holds the final resolved parameters to be applied into the error message that is posted from the script. The <i>params</i> implicit variable is an array. A message that is declared in the messages repository might have parameters that are defined. The contents of the message are fully resolved only at run time in the context of the script code. The <i>params</i> variable is used with the <i>errorGroup</i> variable and the <i>errorKey</i> variable to prepare the error message that is posted from the script code. The <i>params</i> variable is set in the script. |
| <i>relationObject</i> | String                                       | Use this variable only when the attribute launch point implements the retrieve list event. Typically used with the <i>srcKeys</i> and <i>targetKeys</i> implicit variables. | Applies to the related MBO that is searched from the current MBO.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>relationWhere</i>  | String                                       | Use this variable only when the attribute launch point implements the retrieve list event. Typically used with the <i>srcKeys</i> and <i>targetKeys</i> implicit variables. | Establishes the criteria that is used to perform the retrieve list event. Set to a WHERE clause that queries the related MBO.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>scriptHome</i>     | psdi.mbo.Mbo                                 | Action launch point                                                                                                                                                         | References the MBO that is worked on. The preferred approach to implementing scripts is to use the <i>mbo</i> keyword in the script code.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>scriptName</i>     | String                                       | All launch points                                                                                                                                                           | Provides the name of the script that is running.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>service</i>        | com.ibm.tivoli.maximo.script.ScriptService   | All launch points                                                                                                                                                           | Added to a script by the scripting framework at run time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>srcKeys</i>        | String[]                                     | When the attribute launch point implements the retrieve list event                                                                                                          | Applies to the set of attribute names from the current MBO that is used to lookup a related record in another related or target MBO. For example, the set of attribute names from the current MBO might be used to look up that FAILURECODES field from the ASSET business object.                                                                                                                                                                                                                                                                                                    |
| <i>thisValue</i>      | MBO attribute for the attribute launch point | Use this variable as the init value and the init access restriction for attribute launch points                                                                             | Represents the current attribute. For example, <i>thisValue="abc"</i> sets the current value to abc.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>targetKeys</i>     | String[]                                     | When the attribute launch point implements the retrieve list event                                                                                                          | Applies to the set of attribute names in the target MBO that is looked up from the current MBO on which the attribute launch point is defined.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>user</i>           | String                                       | All launch points                                                                                                                                                           | Provides the user ID of the user who is logged in. The <i>user</i> variable is passed to the script and cannot be set in the code.                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>userInfo</i>       | psdi.security.UserInfo                       | All launch points                                                                                                                                                           | Provides the object for the current context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>wfInstance</i>     | psdi.workflow.WFInstance                     | Action launch point when the action is started from a workflow.                                                                                                             | Indicates the workflow instance from which the current action was started.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Some implicit variables are valid only when they are associated with a variable that you declare. You use these implicit variables by typing the variable that you declared, an underscore, and then the implicit variable. For example, if a variable called *siteid* is specified for a script, the line of code *siteid\_readonly=True* causes the associated *siteid* attribute of the business object to become read-only. This type of implicit variable is not available for variables that are bound to the MAXVAR, SYSPROP, or LITERAL binding types.

In the following table, *var* represents the name of the variable that you explicitly define in the Automation Scripts application. The implicit variable that is associated with the primary declared variable follows the underscore.

Table 2. Implicit variables that are used with a primary variable in automation scripts

| Implicit variable  | Type                                                           | Scope             | Description                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>var_hidden</i>  | Boolean                                                        | All launch points | Retrieves or sets the hidden flag for the business object attribute. The script can modify the <i>var_hidden</i> variable if the primary variable is of an OUT or INOUT type.                  |
| <i>var_initial</i> | The same type as the MBO attribute that the variable binds to. | All launch points | Provides the initial value for an attribute that is retrieved from the MBO. The <i>var_initial</i> variable is passed to the script. The script cannot modify the <i>var_initial</i> variable. |

| Implicit variable   | Type                                                           | Scope                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|----------------------------------------------------------------|------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>var_internal</i> | The same type as the MBO attribute that the variable binds to. | All launch points                                                            | Provides the internal value for an SYNONYMDOMAIN entry. If the primary variable is associated with a MBO attribute that is associated with a synonym domain, the <i>var_internal</i> implicit variable provides the corresponding internal value for the attribute. The <i>var_internal</i> variable is passed to the script. The script cannot modify the <i>var_internal</i> variable. |
| <i>var_modified</i> | Boolean                                                        | All launch points                                                            | Provides a flag that indicates whether the value for an attribute was modified. The <i>var_modified</i> variable is passed to the script. The script cannot modify the <i>var_modified</i> variable.                                                                                                                                                                                     |
| <i>var_previous</i> | The same type as the MBO attribute that the variable binds to. | Attribute launch points but only for the attribute that generated the event. | Provides the previous value for an attribute that is retrieved from the MBO. The <i>var_previous</i> variable is passed to the script. The script cannot modify the <i>var_previous</i> variable.                                                                                                                                                                                        |
| <i>var_readonly</i> | Boolean                                                        | All launch points                                                            | Retrieves or sets the read-only flag for a business object attribute. The script can modify <i>var_readonly</i> if the primary variable is of an OUT or INOUT type.                                                                                                                                                                                                                      |
| <i>var_required</i> | Boolean                                                        | All launch points                                                            | Retrieves or sets the required flag for a business object attribute. The script can modify <i>var_required</i> if the primary variable is of an OUT or INOUT type.                                                                                                                                                                                                                       |

- [Service.log\(\) method](#)

The `service.log()` method is used in a script to add log statements to a log file without buffering. Because there is no buffering, the `service.log()` method allows real-time logging.

## Service.log() method

The `service.log()` method is used in a script to add log statements to a log file without buffering. Because there is no buffering, the `service.log()` method allows real-time logging.

The `service` in the `service.log()` method is the script global variable that is added to a script by the scripting framework at run time.

To use the `service.log()` method in an object structure script, use the `ctx` input parameter. The `service` variable is passed to the function as the `ctx` input parameter. No `service` variable is passed from the script.

The following example is an object structure definition class script for the `overrideValues` callback:

```
{
 ctx.log(...);
}
```

## Data retrieval by using variable bindings

You use variable bindings to retrieve values for the variables in the script. When variables are bound to business object attributes, the coding required in the script is simplified.

- [Relationship notation and path](#)

A notation is the set of characters and symbols used to define an expression. An expression is a complete, usable binding definition in the context of scripting. An expression consists of a combination of business object name, relationship name, attribute name, and notations. The script uses the path defined by the expression to retrieve a value for variables that are associated with the launch point of the script.

- [Single value retrieval](#)

By using the relationships between business objects, you define a path for the script to retrieve a single value for a variable. The script retrieves the value from a business object attribute that is related to the primary business object.

- [Multiple value retrieval](#)

By using the relationships between business objects, you define a path for the script to retrieve multiple values for a variable. The script retrieves the values from a business object attribute that is related to the primary business object. You define the array of values by placing an asterisk after the required attribute.

- [Array notations as filters](#)

You use array notations to filter a set of data so that the script can retrieve a particular value or subset of values. You specify the required value or values by placing square brackets around the filter.

- [Example: Array notations in automation scripts](#)

When variables with relationship path bindings are resolved at run time, the scripting framework constructs and inserts a standard array object into the script code. The script code references the required array of values by the variable name you declared in the launch point configuration.

## Relationship notation and path

A notation is the set of characters and symbols used to define an expression. An expression is a complete, usable binding definition in the context of scripting. An expression consists of a combination of business object name, relationship name, attribute name, and notations. The script uses the path defined by the expression to retrieve a value for variables that are associated with the launch point of the script.

The binding for a variable that receives a value from a related business object uses the standard relationship notation. The relationship begins at the current business object and can traverse multiple relationships and business objects to reach the target business object. The relationship notation uses the format of

relationship name, a 'dot' separator, and the name of the target business object attribute. The binding for a variable against a related business object has the following format: **<relationship to related business object A>.<relationship to related object B>...<relationship to related object X>.<attribute of X>**.

---

## Single value retrieval

By using the relationships between business objects, you define a path for the script to retrieve a single value for a variable. The script retrieves the value from a business object attribute that is related to the primary business object.

---

### Example of an expression to retrieve a single value

If a script needs to retrieve the quantity declared on the distributed cost for the first PO line of a purchase order. The following relationship expression is used:

```
POLINE.POCOST.quantity
```

The expression is interpreted by the script in the following way:

- From the PO business object, traverse to POLINE business object by using the POLINE relationship and retrieve the first POLINE record.
- Traverse to the POCOST business object from the retrieved POLINE record by using the POCOST relationship and retrieve the first POCOST record.
- From the first POCOST record, retrieve the value of the 'quantity' attribute and set it into the launch point variable.

---

## Multiple value retrieval

By using the relationships between business objects, you define a path for the script to retrieve multiple values for a variable. The script retrieves the values from a business object attribute that is related to the primary business object. You define the array of values by placing an asterisk after the required attribute.

---

### Example of an expression to retrieve multiple values

In a script, the following expression retrieves all the quantity values declared on the distributed costs of a PO for all PO lines:

```
POLINE.POCOST.quantity*
```

The following relationship path uses a filter with a WHERE clause. The script retrieves an array of loaded cost values declared on the distributed costs of a PO for a subset of PO lines and PO costs:

```
POLINE[linecost>100].POCOST[percentage<100].loadedcost*
```

The following relationship path uses a filter with a condition. The script retrieves an array of loaded cost values declared on the distributed costs of a PO for a subset of PO lines and PO costs:

```
POLINE[linecost>100].POCOST[cond: PERCENTCOND].loadedcost*
```

---

## Array notations as filters

You use array notations to filter a set of data so that the script can retrieve a particular value or subset of values. You specify the required value or values by placing square brackets around the filter.

You can use filters to specify the value or values that the script must retrieve:

- Array index
- Filter with WHERE clause
- Filter with condition

---

### Array index

If multiple records exist for the same business object, you must specify the particular record for the script to retrieve. You specify the index of the record between the square brackets that represent an array.

---

### Example of an array index

A script must retrieve the quantity declared on the distributed costs of a purchase order for a single PO line. The relationship expression uses an array filter:

```
POLINE[3].POCOST[4].quantity
```

An array is indexed from 0 and the expression is interpreted by the script in the following way:

- From the PO business object, traverse to POLINE business object by using the 'POLINE' relationship and retrieve the fourth POLINE record.
- Traverse to the POCOST business object from the retrieved POLINE record by using the POCOST relationship and retrieve the fifth POCOST record.
- From the fifth POCOST record, retrieve the value of the quantity attribute and set the value into the launch point variable.

Retrieving values by using an array index uses business objects and sets of business objects already loaded into the memory by the business application. Using an array index is therefore *in memory* filtering.

## Filter with WHERE clause

If multiple records have the same business object, you specify the particular record or subset of records that the script must retrieve. You specify a WHERE clause between the square brackets that represent an array.

### Example of a filter with a WHERE clause

A script must retrieve the quantity declared on the distributed costs of a purchase order for a subset of PO lines. The relationship expression uses a filter:

```
POLINE[linecost>100].POCOST[percentage<100].quantity
```

The expression is interpreted by the script in the following way:

- From the PO business object, traverse to those POLINE business objects whose line cost is greater than 100.
- For each of the POLINE business objects, traverse only to the POCOST business objects whose percentage value is less than 100.
- Retrieve the quantity of the first POCOST record that has a percentage value of less than 100.

The WHERE clause is appended to the existing relationship WHERE clause that is pre defined in the data dictionary for the POLINE relationship. Retrieving values by using the WHERE clause filter retrieves data from the database. The values are accessed by the script by applying the complete WHERE clause to the target table or view that the business object represents. This type of filtering involves more processing than retrieving values by index or by condition.

## Filter with condition

If multiple records have the same business object, you specify the record or subset of records that the script must retrieve. You specify a condition between the square brackets that represent an array.

### Example of a filter with a condition

A script must retrieve a quantity declared on the distributed costs of a purchase order for a subset of PO lines. The relationship expression uses a filter:

```
POLINE[linecost>100].POCOST[cond: PERCENTCOND].quantity
```

The expression is interpreted by the script in the following way:

- From the PO business object, traverse to the POLINE business objects that have a line cost that is greater than 100.
- For each of the POLINE business objects, traverse only to the POCOST business objects that meet the condition defined by PERCENTCOND.
- Retrieve the quantity of the first POCOST record that meets the condition.

The condition PERCENTCOND is a condition expression configuration defined with Conditional Expression Manager. You define the configuration before using it in the relationship path. When specifying the condition in the relationship path, ensure that the condition is preceded by the keyword **cond** and the colon. Unlike a filter with a WHERE clause, retrieving values with the condition filter is done *in memory*.

## Example: Array notations in automation scripts

When variables with relationship path bindings are resolved at run time, the scripting framework constructs and inserts a standard array object into the script code. The script code references the required array of values by the variable name you declared in the launch point configuration.

### Example

Business logic needs to be implemented so that the total material cost that is associated with a work order is calculated. An object launch point is defined on the WORKORDER business object. You define a variable called *matcostarray* to represent the array of material costs. The binding for this variable uses a relationship path **MATUSETRANS.linecost\***. The relationship path traverses a pre defined relationship called MATUSETRANS. Traversing this relationship gives the script access to all of the MATUSETRANS business object records associated with the work order to retrieve all material costs. The variable is directly referenced in the script code:

```
if matcostarray is not None:
 if len(matcostarray)>0:
 for value in matcostarray:
 if value is not None and value !=0:
 totalmatcost += value
```

In the fragment of script code written with Jython, the following logic is implemented:

- Check whether the array object is valid.
- Check whether the array contains multiple elements.
- Loop through the array to retrieve each element.
- Sum the individual values into the local variable *totalmatcost*.

## Gathering user input by using choice messages in automation scripts

A choice message gathers user input, which can then be used in the automation script. You can use choice messages in automation scripts to create an interactive user experience. For example, a message can say that a record does not exist and ask if the record should be created.

You can define choice messages in the Database Configuration application. The buttons that you can use on a choice message are OK, Close, Cancel, Yes, and No. You can use curly brackets {} to insert variables into the choice message. For example, in the Labor text field, a user can enter the name of a person, but that person must have a person record. If a person record does not exist, the user receives the following error message: A person record does not exist for {0}. Would you like to create one?

You can use choice messages in automation scripts that are associated with action launch points, the Validate Value event for an attribute launch point or the Run Action event for an attribute launch point. Typically, an automation script that is associated with an attribute launch point presents a choice message to users. Such an automation script must contain code that triggers the display of a choice message, retrieves the user's choice, and performs the selected action for the user's choice.

When you write an automation script that uses a choice message, you first declare the functions that define the business logic that is necessary to process the user input. Then, you link the user input to the appropriate functions. Finally, you implement the business logic checks that are performed so that the user input is retrieved and applied to the dictionary to run the appropriate function.

One of the business logic checks that you can perform is to use the *interaction* implicit variable to check that the situation is interactive. This implicit variable takes a Boolean value of either true or false. If true, the script code is run in the context of an application user interface. If false, the script code is run from a backend service, from a component loading data through the integration framework, or from a cron task.

- **Example: Configuring choice messages**

A company requires that whenever the highest priority level is assigned to an asset, then an email is sent to the asset custodian. An automation script is created to send this email. The automation script uses a choice message to confirm that the email should be sent.

---

## Example: Configuring choice messages

A company requires that whenever the highest priority level is assigned to an asset, then an email is sent to the asset custodian. An automation script is created to send this email. The automation script uses a choice message to confirm that the email should be sent.

---

### About this task

The example launch point and automation script that implements a choice message, and its processing uses the Jython programming language.

---

### Procedure

1. In the Database Configuration application, select the Messages action and create a new message with the following values:

| Fields            | Values                                                                              |
|-------------------|-------------------------------------------------------------------------------------|
| Message Group     | asset                                                                               |
| Message Key       | assetpriorityemail                                                                  |
| Display Method    | MSGBOX                                                                              |
| Message ID Prefix | BMXZZ                                                                               |
| Message ID Suffix | W                                                                                   |
| Display ID        | 1                                                                                   |
| Value             | Asset custodian can be notified through email when priority {0} is set. Send email? |
| Buttons section   | Check Yes and No buttons.                                                           |

2. In the Automation Scripts application, create a script with an attribute launch point to run the Attribute Launch Point wizard.
3. In step 1 of the wizard, specify the launch point name, and select the ASSET object and the PRIORITY attribute.
4. In the Events section, choose the Run Action radio button.
5. In step 2 of the wizard, specify the script name and set the log level to debug.
6. In step 3 of the wizard, paste in the following source code and then click Create:

```
Business logic implementation if user selects Yes choice (clicks Yes button)
def yes ():
 service.log("Sending Email")

Business logic implementation if user selects No choice (clicks No button)
def no ():
 service.log("Not Sending Email")

Business logic to present the choice message initially
def dflt ():
 params=[str(priority)]
 service.log("Throw ERROR")
 # Use the service utility's yncerror() method to push the choice message
 service.yncerror("asset", "assetpriorityemail",params);

service.log ('$$$SAM$ - entering ASSETPRIORITYVAL')
Declare the user input choices and the corresponding functions implemented in this script
cases = {service.YNC_NULL:dflt, service.YNC_YES:yes, service.YNC_NO:no}

Make sure the choice message is presented only
#if the field validation was triggered from user interface
if interactive:
 if priority < 2:
 service.log ("About to do something")
 # Use the service utility's yncuserinput() method to trigger the entire interaction
```

```
User's response is stored in a local variable x
x = service.yncuserinput()
service.log("User input: "+str(x))
Process the user input using Jython's case statement
cases[x] ()
```

## What to do next

To test your script, in the Assets application, select a record and set the priority to 1. When a choice message appears, select a choice.

## Reusable library scripts in automation scripts

A library script is a reusable piece of programming logic that automation scripts can invoke from within the body of their code. Creating library scripts can save time and effort. Library scripts are stored in the database in the AUTOSCRIPt table.

An example of a basic script is multiplication. You can create a library script that is named MULTIPLY:

```
z=x*y
```

You can then create a script that uses the MULTIPLY library script and logs the result:

```
service.log("I want to multiply 2 numbers and log the result")
from java.util import HashMap
a=3
b=2
ctx = HashMap()
ctx.put("x",a)
ctx.put("y",b)
service.invokeScript("MULTIPLY",ctx)
service.log("the result is "+str(ctx.get("z")))
```

The implicit variable in the `service` line is used to invoke the MULTIPLY library script: `service.invokeScript("MULTIPLY",ctx)`. When the MULTIPLY library script is invoked, the variables that are required by the script are passed into the script, which is done by the `ctx` lines and argument.

When you use a library script in an automation script, you must then define a Java™ HashMap object, which is done in the example in the `ctx = HashMap()` line. You place the variable names and values into the HashMap object. You must know the required variables for the library script, their names, and their data types, which in the example is accomplished in the `ctx.put("x",a)` line and the `ctx.put("y",b)` line.

If you want to receive output from the library script, then you must also use the name of the response variable in the automation script. The example script uses the response variable in the `service.log("the result is "+str(ctx.get("z")))` line.

## Scheduling automation scripts to run as part of cron tasks

Cron tasks are jobs that run automatically on a fixed schedule on the application server. For example, the ESCALATION cron task processes escalations to ensure that critical tasks are processed on time. You can use several predefined cron tasks and you can also define new cron tasks. For new cron tasks, you must provide a Java™ class implementation that contains the business logic that is executed on a schedule.

Automation scripts support new cron tasks by providing the `com.ibm.tivoli.maximo.script.ScriptContask` Java class. By using this Java class reference in your cron task definition, you can attach an automation script that provides the business logic that is executed by the cron task.

- [Creating cron tasks that run automation scripts](#)  
When an automation script runs as part of a cron task, the automation script does not require a launch point. You reference the `com.ibm.tivoli.maximo.script.ScriptContask` Java class in your cron task definition, and then you can attach an automation script to the cron task.
- [Variables in automation scripts that run as cron tasks](#)  
You can use only variables of type IN because automation scripts that run as cron tasks are unassociated with Maximo® business objects. You can also use the implicit variables `scriptName`, `qName`, and `runAsUserInfo`.

## Creating cron tasks that run automation scripts

When an automation script runs as part of a cron task, the automation script does not require a launch point. You reference the `com.ibm.tivoli.maximo.script.ScriptContask` Java™ class in your cron task definition, and then you can attach an automation script to the cron task.

## About this task

Cron tasks are jobs that run automatically on a fixed schedule on the application server. For example, the ESCALATION cron task processes escalations to ensure that critical tasks are processed on time. You can use several predefined cron tasks and you can also define new cron tasks. For new cron tasks, you must provide a Java class implementation that contains the business logic that is executed on a schedule. By using this Java class reference in your cron task definition, you can attach an automation script that provides the business logic that is executed by the cron task.

## Procedure

1. In the Automation Scripts application, on the List tab, select the Create... Script action.
2. Specify a name, description, and log level for the script.
3. If the script requires variables, in the Variables section, add new rows to declare the variable and bindings.  
You cannot specify bindings to a Maximo® business object. You can specify only LITERAL, SYSPROP, and MAXVAR bindings.
4. Enter the source code of the automation script and click Create to save the automation script in the database.
5. In the Cron Task Setup application, create a new cron task definition.
6. In the Class field, enter `com.ibm.tivoli.maximo.script.ScriptCrontask`.
7. Create the cron task instance that runs the automation script.
  - a. In the Cron Task Instances section, add a row.
  - b. Specify the cron task instance name.
  - c. Set the schedule for when the cron task is run.
  - d. Select Run As User.  
The security authorizations that are granted to the specified user determines whether business logic that is related to Maximo business object can run in the script code.  
For example, a value cannot be set in a record unless the specified user has the security authorization to write values into that record.
8. In the Parameters tab, in the SCRIPTARG row, specify a value that represents an argument for the cron task.
9. In the SCRIPTNAME row, specify the name of the script that you created to run as part of the cron task.  
SCRIPTNAME is a mandatory parameter that must be populated. The script name that you specify is passed to the automation script in the form of the *scriptName* implicit variable.
10. In the Details section, select the Active check box to activate the cron task instance.
11. Save the record.

## Variables in automation scripts that run as cron tasks

You can use only variables of type IN because automation scripts that run as cron tasks are unassociated with Maximo® business objects. You can also use the implicit variables *scriptName*, *qName*, and *runAsUserInfo*.

The following limitations apply to using type IN variables with automation scripts that run as cron tasks:

- You can use variables with a literal binding to send parameters into an automation script that is run as a cron task.
- You can use variables with a System Property binding to send parameters.
- You can use variables with a MAXVAR binding with variables that are of SYSTEM MAXVAR. You cannot use MAXVAR variables at the site or organization level.

You can use the following implicit variables in automation scripts that run as cron tasks:

Table 1. Implicit variables

| Implicit variable    | Description                                                                                                                                       |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>scriptName</i>    | Name of the automation script that is run as a cron task.                                                                                         |
| <i>qName</i>         | Name of the cron task instance that is running the automation script as a cron task.                                                              |
| <i>runAsUserInfo</i> | Handle for the UserInfo Java™ object. You can use this object to get additional information about the user that is associated with the cron task. |

## Adding scripts that run as asynchronous jobs

You can add scripts that can run as asynchronous jobs in the product. Use the asynchronous job framework to submit jobs that need to be run one time asynchronously, such as when you want to run something quickly in the background.

## Procedure

1. In the Automation Scripts application, add a script to run the asynchronous job.  
The implicit variables *where*, *mboName*, and *userInfo* are available.
2. Specify other information as needed.
3. Register the script in the MAXASYNCJOB table by specifying the nonpersistent Manage business object (MBO), as shown in the following code sample.  
The MBO name is ASYNCSCRIPT and is the object that the job acts on. The job name is set by the script to be the same as the script name. The job name is used by the ScriptAsyncJobHandler and is registered with the new entry in the MAXASYNCJOB table to run the script.

```
MboSetRemote msr = get mboSet for ASYNCSCRIPT

((psdi.mbo.NonPersistentMboSet)msr).setup();

MboRemote mbo = msr.moveFirst();

mbo.setValue("autoscript", "TESTASYNC");

mbo.setValue("objectname", "PO");

((psdi.mbo.NonPersistentMboSet)msr).execute();
```

4. Activate the script.  
The scripted job is registered and is run one time by the asynchronous job framework.

---

## Example

For example, you can specify the job to fetch an MboSet by using the *userInfo* variable and the name of the MBO. Apply the WHERE clause and process the job for each MBO.

---

## Automation scripts for integration

You can use automation scripts to customize the processing transactions of integration messages by implementing object structure, publish channel, enterprise service, and invocation channel integration components.

---

## Debugging with automation scripts

You debug a script to remove any issues before you customize applications. Print statements can be placed in a script to capture the logs that are specific to a script. Log statements in the scripting framework are automatically sent to the autoscript logger.

- [Log statements in the application framework](#)  
The application framework generates logs on a debug level with information such as launch point name and application name.
  - [Print statements](#)  
Print statements can be placed in a script to capture logs specific to the script. The syntax of print statements depends on the language that is used to write the script.
  - [Finding debug files](#)  
If you have difficulty finding the debug file in the log file, associate the logger to an appender so that the debug file is easier to find.
- 

## Log statements in the application framework

The application framework generates logs on a debug level with information such as launch point name and application name.

Log statements in the application framework are automatically sent to the autoscript logger. To see the values passed by the script variable, set the autoscript logger to DEBUG, apply the logging settings, and run the script configuration. Variable values are output to the log file or system console.

The scripting framework generates logs on a debug level:

- The launch point name and script name that is executed.
  - The script execution time that is the time that has elapsed between the start and end of script execution.
  - The application name, logged in user name, Maximo® business object (MBO) name, and MBO unique ID values.
  - The variable values passed into the script based on variable bindings (variables that are sourced from MBO attribute, MAXVAR, system property or literal).
- 

## Print statements

Print statements can be placed in a script to capture logs specific to the script. The syntax of print statements depends on the language that is used to write the script.

The print statements are sent to the logger as ERROR, INFO, or DEBUG statements. The statement level depends on the level you have specified for the automation script you are using. For example, if you set the level of the automation script and autoscript logger to DEBUG, the print statements are written to the log file as DEBUG statements. If you set the autoscript logger to ERROR level, then the print statements inside the automation script are not written to the log file.

## Example of a Jython print statement

A print statement can be simple, such as `print "$$Entered automation script xyz"`. The print statement can also be an expression, such as `print "$$Automation script variable site value is:" + siteid`.

---

## Finding debug files

If you have difficulty finding the debug file in the log file, associate the logger to an appender so that the debug file is easier to find.

## Procedure

1. In the Logging application, select the autoscript logger.
2. Click the Manage Appenders icon.
3. Select the Rolling appender and specify the file name.

---

## Testing automation scripts

It is possible to test automation scripts after you create them.

### About this task

---

You can test the following types of automation scripts:

- Object launch point scripts
- Attribute launch point scripts
- Integration scripts
  - Object structure scripts
  - Publish channel scripts
  - Enterprise service scripts
  - Invocation channel scripts
- REST and other scripts

### Procedure

---

1. In the Automation Scripts application, create an automation script or select an existing script.
2. Click Test Script.
3. Specify a launch point if you want, and click Test. You can view the results in the Data and Process Log fields.

---

## Error messages for users

You can display error messages to users from inside a script. For example, you can display an error message for users to see in the Assets application when an asset number does not follow the rules for naming assets.

- [Error messages created with automation scripts](#)  
To post error messages, you set the predefined *errorgroup* implicit variable and the predefined *errorkey* implicit variable to the error message group and error key. You can also post error messages by using the `MXApplicationException` class in the API.
- [Displaying error messages](#)  
You can display error messages to users from within a script.

---

## Error messages created with automation scripts

To post error messages, you set the predefined *errorgroup* implicit variable and the predefined *errorkey* implicit variable to the error message group and error key. You can also post error messages by using the `MXApplicationException` class in the API.

---

### Example of sending an error message by using the `MXApplicationException` class

You can use the public `MXApplicationException` class and its constructor method. You pass in the message group ID, message key ID, and any parameters for the message into the constructor method `MXApplicationException`. You use the Python keyword `raise` before the `MXApplicationException` constructor method to send the error message to the user interface.

In the following script sample, the error to indicate that an invalid prefix on a new asset is used as an example:

```
from psdi.util import MXApplicationException
:
:
if<some condition>:
 params = [prefix, assettype]
 raise MXApplicationException('asset', 'invalidassetprefix', params)
```

---

### Example of sending an error message by using implicit variables

You can raise an error message from the script code by using the implicit variables that are available in the scripting framework. You set the *errorgroup* implicit variable to the error message group. You set the *errorkey* implicit variable to the error key. You set the *params* implicit variable to the prefix and object type, such as an asset.

When execution is complete, the scripting framework detects the error flag and the framework sends the corresponding exception for the error group and error key combination. After the error flags are set in the script, the script execution continues.

For example, you can require that when a new asset record is created in the Assets application, the asset number must adhere to a specific naming convention. You can create an error message to send to a user when the script detects that the asset number has the wrong prefix.

- If the asset type is FACILITIES, the asset number must be prefixed with FT.
- If the asset type is FLEET, the asset number must be prefixed with FL.
- If the asset type is IT, the asset number must be prefixed with IT.
- If the asset type is PRODUCTION, the asset number must be prefixed with PR.

When a new asset record is created and a user clicks Save, the script tests the asset number for a valid prefix. If the prefix is not found, the user receives an error message. The predefined message is picked up by the scripting framework and placed into the predefined variables.

*Prefix* and *assettype* are script variables in the following sample Jython code:

```
def setError(prefix):
 global errorkey, errorgroup, params
 errorkey=invalidassetprefix
 errorgroup=asset
 params=[prefix, assettype]

if atype_internal=='FACILITIES' and not anum.startswith('FT'):
 setError('FT')
elif atype_internal=='FLEET' and not anum.startswith('FL'):
 setError('FL')
elif atype_internal=='IT' and not anum.startswith('IT'):
 setError('IT')
elif atype_internal=='PRODUCTION' and not anum.startswith('PR'):
 setError('PR')
```

When the script code test of the asset number prefix fails, the code invokes a common function within the script. The script passes parameters for the function to use in the message. The common function sets the *errorgroup*, *errorkey*, and *params* implicit variables to the appropriate message that is defined in the Database Configuration application. The scripting framework recognizes that the implicit variables are used in the script, and after the script execution is finished, the scripting framework pushes the error message to the application user interface.

---

## Displaying error messages

You can display error messages to users from within a script.

### About this task

When you are declaring the message in the Database Configuration application, the message is identified by the combination of message group and message key. The message might also contain parameters that are resolved at run time.

---

### Procedure

1. In the Database Configuration application, declare a custom message.
2. In the body of the attribute launch point or the object launch point, place predefined variables that receive the message group and message key.
3. Run the script.

---

## Creating scripts to manage attachments

Maximo® Manage can read or write attachments from any store that is registered with Maximo Application Suite.

### About this task

Maximo Manage now has an interface that you can implement with Java™ or automation scripts. This interface accesses the store and reads, writes, or deletes documents from the store. For more information about interface methods and their descriptions, see [Interface methods](#).

---

### Procedure

1. Write a script to access the in-memory store.
2. Use the following commands in the script to manage attachments.

Create attachment

Use `createAttachment(ctx)` to create an attachment in the store, where *ctx* = *filename*. For example,  
`ctx.getFileName(ctx.getAttachmentName())`

Delete attachment

Use `deleteAttachment(ctx)` to delete the attachment from the store. Use `ctx.getFileName(ctx.getAttachmentName())` to get the file name and use it as a key to delete the file from the store before you can delete the attachment.

Validate attachment file type

Use `hasAttachment(ctx)` to validate the attachment file type from the file name and to check for duplicate file names. Use `ctx.getFileName(ctx.getAttachmentName())` to get the file name. Set the Boolean flag to true or false by using `ctx.setHasAttachment(Boolean)`. The framework checks the Boolean flag and if it is true, renames the file to avoid duplicates.

3. In the Automation Scripts application, import the script that you created.
  - a. From the More Actions menu, click Create...Script.
  - b. Set Allow Invoking Script Functions to on.  
Note: If you do not set Allow Invoking Script Functions to on, callbacks are not called by the framework.
  - c. Click Choose file to select the script that you created.
  - d. Click Import.
  - e. Click Create to save the script.

4. Optional: In System Properties, set the properties to register the new store that you create. The following example uses `custom:doclinks` as the path:

```
mxe.attachmentstorage=script:<script name in caps>
mxe.doclink.doctypes.defpath=custom:doclinks/default
mxe.doclink.doctypes.topLevelPaths=custom:doclinks
mxe.doclink.path01=custom:doclinks=http://<host>:<port>/maximo/oslc/attachstore
```

Note: The `path01` URL route `attachstore` is already provided in Maximo Application Suite, and it is sufficient to set only the host and port. Also, the `mxe.attachmentstorage` can be a Java class or a script. In this example, the script that is created implements the access to the attachment store.

- [Interface methods](#)  
Use interface methods to manage attachments.

## Interface methods

Use interface methods to manage attachments.

Table 1. Interface methods and descriptions

| Interface method                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>createAttachment(ctx)</code> | Called to create an attachment in the store. Code uses the <code>ctx</code> to get the file name. <ul style="list-style-type: none"><li>• <code>ctx.getAttachmentName</code> derives the full path-based file name</li><li>• <code>ctx.getFileName(..)</code> extracts the file name out of it.</li><li>• <code>ctx.getAttachmentData()</code> returns the attachment as a byte array.</li></ul>                                                                                                                                                                                                                       |
| <code>deleteAttachment(ctx)</code> | Called to delete the attachment from the store. Use the same methods as applicable for <code>createAttachment(ctx)</code> to obtain the file name and use it as a key to delete the file from the store.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <code>getAttachment(ctx)</code>    | Called to get the attachment. Two scenarios are possible, which the code must address: <ul style="list-style-type: none"><li>• The <code>ctx</code> has the doclinks mbo. Use it to get the file name to fetch <code>ctx.getFileName(ctx.getMbo().getString("urlname"))</code>.</li><li>• The <code>ctx</code> just has the URL name for the attachment. use <code>ctx.getFileName(ctx.getURLForAttachment())</code>.</li></ul> Leverage the file name to retrieve the attachment from the store and then set the attachment data as bytes into the <code>ctx</code> , that is, <code>ctx.setAttachmentData(..)</code> |
| <code>hasAttachment(ctx)</code>    | Called for validation the attachment file type from the file name and to check whether the file name is unique. Use the <code>ctx</code> to get the file name through <code>ctx.getFileName(ctx.getAttachmentName())</code> . Use this file name to check for duplicate names in the store. If a duplicate exists, rename the file in context to make it unique, and prefix it with the <code>mxe.doclink.doctypes.topLevelPaths</code> property value to create a qualified name.                                                                                                                                     |

## Managing building information model data

Building Information Modeling (BIM) is a process that manages the design and build phases of building construction projects. This process is used as part of the hand-over of the construction building from the contractors to the owners. It is during this process that you can import the data into Maximo® Manage so that you can manage your facility and view the data in 3D.

- [Building information modeling \(BIM\) in Maximo Manage](#)  
Building information modeling (BIM) is a 3D digital representation of a building and a set of process that use that representation for construction projects, such as buildings, roads, and bridges. This standard is used during the design and builds phases of construction and is also adopted for building operations.
- [Classifications for building information models](#)  
Classifications provide useful information about the role and function of an item for building information models. Before you import Construction-Operations Building information exchange (COBie) data, you can specify a classification type, such as OmniClass, UniFormat, or a custom classification, to associate attributes with items.
- [Configuring Maximo Manage for Building Information Models \(BIM\) applications](#)  
To import Construction-Operations Building information exchange (COBie) data and view building models, you must set up server directories, configure system properties, and create security groups in the applications for Building Information Models module in Maximo Manage.
- [Configuring building information model data](#)  
Before you import Construction-Operations Building information exchange (COBie) data into Maximo Manage, you define system settings, such as units of measure and currency codes and specify a classification type. You can also import classifications.
- [Configuring building information modeling \(BIM\) projects](#)  
Before you can import Construction-Operations Building information exchange (COBie) data into BIM projects, you define filters, map COBie attributes to existing Manage attributes that include custom attributes, create projects at a site level, and configure global settings for each site.
- [Importing model data into Maximo Manage](#)  
After you create a project for facilities, you can import COBie data by using validate, import, update, and merge sessions for the project.
- [Exporting data from Maximo Manage to Construction-Operations Building Information Exchange \(COBie\)](#)  
An export session extracts data from Maximo Manage and saves it in a .XLSX file in COBie format. The file is attached to the project and can be viewed and downloaded from the Attachments tab. You can export data at a later data that reflects any asset changes in Maximo Manage. This data is useful input into the design process for renovation or for a new build.
- [Commissioning buildings](#)  
The as-built state of the building is defined in the model during construction. After you import the as-built model data into the BIM Projects application, you can commission the building and begin the process of maintaining it. Commissioning a building creates a bulk status update for all objects that are related to the building and have the specified starting status.

- [Managing building models](#)  
After you import the building model data into Maximo Manage, you can view the data in the assets and locations and also view the import session details.
- [Attribute maps for COBie data](#)  
You can map attributes and extension columns in your COBie data to fields in Maximo business objects and to the attribute types in specifications in Maximo Manage.

---

## Building information modeling (BIM) in Maximo Manage

Building information modeling (BIM) is a 3D digital representation of a building and a set of process that use that representation for construction projects, such as buildings, roads, and bridges. This standard is used during the design and builds phases of construction and is also adopted for building operations.

The model that is created during a construction project describes the infrastructure and contents of a building. The data from the model is extracted into Construction-Operations Building information exchange (COBie) format and you can then import the data into the Building Information Modeling (BIM) Projects application in Maximo® Manage.

The model that is provided after construction is the as-built state of the building. Building owners who commission a building need the information in the model to be available in the BIM Projects application before facilities management begins. By using the BIM Projects application, you can collaborate and gather information throughout the design and building phase of a construction project and import the data before the building is completed.

After the data is imported, you can view a 3D visualization of the model in context with the imported data. This visualization can improve the efficiency of the maintenance work planning and execution process. You can export the as-maintained data to update the model for a renovation project.

You can search the Support knowledge base for technotes that are related to [troubleshooting BIM in Maximo Manage](#). If no information is available, the search returns no results.

- [Construction-Operations Building information exchange \(COBie\) standard data](#)  
The Construction-Operations Building information exchange (COBie) standard defines information for assets that are delivered as part of a facility construction project and is used to document the data for the building information modeling (BIM) process. You import COBie data files by using the BIM Projects application and manage the data as assets, locations, contacts, and job plan records in Maximo Manage.

---

## Construction-Operations Building information exchange (COBie) standard data

The Construction-Operations Building information exchange (COBie) standard defines information for assets that are delivered as part of a facility construction project and is used to document the data for the building information modeling (BIM) process. You import COBie data files by using the BIM Projects application and manage the data as assets, locations, contacts, and job plan records in Maximo® Manage.

COBie data, which is defined in .CVS or .XLS files, is a series of data fields that are organized in a spreadsheet with multiple worksheets. Each worksheet corresponds to a COBie table.

You can import data into Maximo Manage from the following COBie tables:

- Facility
- Floor
- Space
- Component
- Type
- System
- Zone
- Attribute
- Contact
- Document
- Job
- Tools in the Resources table
- Assembly

To ensure a successful import of COBie data, adhere to the following guidelines:

Adhere to the minimum table requirements.

The facilities and floor tables are required to import COBie data. Use the components table to collect the necessary data to support business processes.

Use unique model IDs.

All spaces and assets require a model ID. The model ID must uniquely identify the model element and must map to a property that is visible in the files in the viewer. This field is loaded from the COBie ExtIdentifier column. For an Autodesk model, the Revit GUID is used for the model ID. For an Industry Foundation Class (IFC) model, the IFC GUID is used for the model ID.

Use unique table IDs.

Each COBie table uses one or more columns for a unique ID. Tables that are referenced by other tables, such as the spaces table, must use a unique ID. If the COBie data was generated by using design tools, the tables might not have unique IDs.

Carefully define the space definitions.

The COBie specification requires that all components reference a space. Ensure that all spaces for every floor in the model, including external service areas, have a space definition. You can copy space definitions into linked models, and you can use the default floor or facility references for components.

Use standardized categorization carefully and consistently.

Use a single unified classification scheme consistently in all project contracts: OmniClass, Unifomat, or a user-defined scheme. The import utility compares the value for the Category attribute in the COBie data set to the values in the classification tables in the Maximo database. When a match is found, the Maximo Manage records that are created from the COBie data are assigned the matching classification. For OmniClass and Unifomat, the category value is processed to extract and normalize the number portion of the value before matching the classification.

Divide large files or large buildings into multiple files.

The import utility accepts multiple files, such as architectural, mechanical, electrical, and plumbing (MEP), and service model files, for input and reassembles them. In some COBie conversion tools, the size of models is limited. You can divide a large file into several smaller files and generate COBie data from each file. You can also use multiple files when the model consists of several linked files or when you have a large building that is divided into wings or sections.

Prevent the import of unnecessary attributes.

Some attributes are not required to use COBie data in Maximo Manage. Careful design and planning of your import can prevent the import of unnecessary attributes.

Spare parts are manifests, not actual inventory.

In Maximo Manage, the spares table from the COBie data is used to list the field-replaceable units for an asset. The spares table from the COBie data is not used as an actual inventory of spare parts in Maximo Manage.

---

## Classifications for building information models

Classifications provide useful information about the role and function of an item for building information models. Before you import Construction-Operations Building information exchange (COBie) data, you can specify a classification type, such as OmniClass, UniFormat, or a custom classification, to associate attributes with items.

COBie supports the classification of the Category field, which maps to a classification in Maximo® Manage. You can assign default classifications for each type of imported object. You can use automatically created classifications if they do not exist in Maximo Manage.

---

### OmniClass classifications

OmniClass is an industry-standard classification system in construction projects. The import utility that is used in Maximo Manage uses OmiClass classifications. OmniClass classifications are stored in a hierarchy table in .CSV, .XLS, or .XLXS formatted spreadsheet.

The required format for the table is the OmniClass Number followed by individual columns for level titles, such as the Level 1 Title column, up to a maximum of seven level titles. The format for the OmniClass number is *NN-NN NN NN*, for example, *11-11 00 00*.

The import utility can also use a flat file format that has one classification number per line and the entries in parent-child order. The import utility uses the OmniClass number structure to build the hierarchy.

---

## Specifications and attributes

You can map the COBie attributes to specifications in Maximo Manage. Using specifications, you can associate COBie data with assets, locations, and job plans. Classifications must be applied to records before specifications can be associated with the records.

Default classifications are defined for the project session types so that objects that are stored at the organization level still use the site level defaults for the project. The import utility requires that a classification must be compatible with the level of the associated Maximo business objects that the classification is used with. The following table shows the levels that are required for a standard import:

Table 1. Minimum classification levels

| Table           | Type                          | Minimum classification level |
|-----------------|-------------------------------|------------------------------|
| Asset           | Site                          | Site                         |
| Company contact | Organization                  | Organization                 |
| Job plan        | System, Site, or Organization | System, Organization or site |
| Location        | Site                          | Site                         |
| Person          | System                        | System                       |

---

## Configuring Maximo Manage for Building Information Models (BIM) applications

To import Construction-Operations Building information exchange (COBie) data and view building models, you must set up server directories, configure system properties, and create security groups in the applications for Building Information Models module in Maximo® Manage.

---

### Procedure

1. On your server, create directories to store the COBie import files, building model files, and attachments that are added when you import COBie data into Maximo Manage.

| Directory            | Description                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------|
| <b>C:/bim/import</b> | The directory where the COBie files that are imported are saved.                                |
| <b>C:/bim/models</b> | The directory where the building model files that are used by viewer implementations are saved. |
| <b>C:/bim/docs</b>   | The directory where documents that are imported with a building model are saved.                |

2. In the System Properties application, add the directories to the Global Value, the Current Value, and the Maximo Default fields of the following system properties:

| System Property   | Directory     |
|-------------------|---------------|
| bim.import.dir    | C:/bim/import |
| bim.model.dir     | C:/bim/models |
| bim.import.docdir | C:/bim/docs   |

3. In the Security Groups application, create the following security groups for BIM users:
- A security group for users who configure and import the COBie data, for example, **DESIGNER**.
  - A security group for users who configure Manage, for example, **FACILITIES**.
  - A security group for users who view the facilities and system information in the BIM applications, for example, **TECHNICIAN**.
4. On the Applications tab, grant signature options access for the applications to the user groups that you created

| Security Group                                                                                                                        | BIM Applications                                                                                                    |
|---------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| The security group for users who configure and import the COBie data, for example, <b>DESIGNER</b> .                                  | <ul style="list-style-type: none"><li>• BIM Projects</li><li>• Manage BIM Viewer</li></ul>                          |
| The security group for users who configure Manage, for example, <b>FACILITIES</b> .                                                   | <ul style="list-style-type: none"><li>• BIM Projects</li><li>• Manage BIM Viewer</li></ul>                          |
| The security group for users who view the facilities and system information in the BIM applications, for example, <b>TECHNICIAN</b> . | Access to 3D View tab in the Locations application, the Assets application, and the Work Order Tracking application |

• [Signature options for Building Information Models applications](#)

The signature options for the applications in the Building Information Models module control access to functions in the applications for specific groups of users. The signature options are defined in the Security Groups application.

## Signature options for Building Information Models applications

The signature options for the applications in the Building Information Models module control access to functions in the applications for specific groups of users. The signature options are defined in the Security Groups application.

### BIM Projects application

In the Security Group application, on the Applications tab, set the signature options to give users access to functions in the BIM Projects application.

| Signature option name | Signature option description          |
|-----------------------|---------------------------------------|
| BIM_CONFIG            | Configure Maximo® Data                |
| MDL_CONFIG            | Configure Model Data                  |
| BIM_FILTER            | Import Filters                        |
| BIM_MAP               | Map Attributes to Fields              |
| TYPE_MAP              | Map Attributes to Specifications      |
| OMNI_ADD              | Import OmniClass Classifications      |
| UNI_ADD               | Import Unifomat Classifications       |
| OMNI_HIST             | Classification Import History         |
| COMMISSION            | Commission Building                   |
| COMS_HIST             | Building Commissioning History        |
| BIM_ADVANCED_OPT      | Advanced Options tab in upload dialog |

### Manage BIM Viewer application

In the Security Group application, on the Applications tab, set the signature options to give users access to functions in the Manage BIM Viewer application.

| Signature option name | Signature option description                 |
|-----------------------|----------------------------------------------|
| DELETE                | Delete Building Model                        |
| INSERT                | New Building Model                           |
| READ                  | Read Access to Manage BIM Viewer application |
| SAVE                  | Save Building Model                          |

### Assets application

In the Security Group application, on the Applications tab, set the signature options to give users access to BIM functions in the Assets application.

| Signature option name | Signature option description                                                                          |
|-----------------------|-------------------------------------------------------------------------------------------------------|
| BIMVIEWER             | 3D View tab                                                                                           |
| BIMDATA               | Show BIM Data sections                                                                                |
| BIM_IMP               | View Building Model Import Sessions                                                                   |
| BIM_LOC               | Controls the visibility of the BIM Location hierarchy (Facility/Floor/Room) in the Assets application |

### Locations application

In the Security Group application, on the Applications tab, set the signature options to give users access to BIM functions in the Locations application.

| Signature option name | Signature option description        |
|-----------------------|-------------------------------------|
| BIMDATA               | Show BIM Data sections              |
| BIMVIEWER             | 3D View tab                         |
| BIM_ADDMOD            | Add/Edit Building Model             |
| BIM_IMP               | View Building Model Import Sessions |
| BIM_IAD               | Inspect Asset Details               |
| BIM_DS                | Display System Details              |
| BIM_US                | Update/Edit Systems                 |
| BIM_NS                | Create New System                   |

## Work Order Tracking application

In the Security Group application, on the Applications tab, set the signature options to give users access to BIM functions in the Work Order Tracking application.

| Signature option name | Signature option description |
|-----------------------|------------------------------|
| BIMVIEWER             | 3D View tab                  |

## Configuring building information model data

Before you import Construction-Operations Building information exchange (COBie) data into Maximo® Manage, you define system settings, such as units of measure and currency codes and specify a classification type. You can also import classifications.

- [Defining system settings for building information modeling \(BIM\) data in Maximo Manage](#)  
Before you can the import building information modeling (BIM) data, which is in the COBie file format, you can define units of measure, currency codes, and specify a classification type in Maximo Manage.
- [Importing OmniClass classifications](#)  
You can import OmniClass classifications to use with Maximo business objects. The import utility uses OmniClass classifications that are stored in a hierarchical table in a .CSV, .XLS, or .XLXS formatted spreadsheet.

## Defining system settings for building information modeling (BIM) data in Maximo Manage

Before you can the import building information modeling (BIM) data, which is in the COBie file format, you can define units of measure, currency codes, and specify a classification type in Maximo® Manage.

### About this task

Before you import COBie data, you must specify a classification type, such as OmniClass, UniFormat, or a custom classification, to associate attributes with items.

### Procedure

1. In the Currency Codes application, create currency codes to define and manage currencies.
2. In the Classifications application, define the units of measure for linear, area, and volume measurements by using the Add/Modify Properties > Units of Measure action.
3. To use custom classifications with the imported data, create classifications in the Classifications application.
4. To use the Omniclass classifications system with the imported data, import the Omniclass classifications tables.
5. To use the Unifomat classifications system with the imported data, import the Unifomat classifications tables.

## Importing OmniClass classifications

You can import OmniClass classifications to use with Maximo® business objects. The import utility uses OmniClass classifications that are stored in a hierarchical table in a .CSV, .XLS, or .XLXS formatted spreadsheet.

### Procedure

1. In the BIM Projects application, select the OmniClass Import action.
2. Optional: Specify an organization or a site.
3. Specify the parent classification. If this field is not specified, the OmniClass table name is created as a top-level classification in Maximo Manage.
4. Select the Maximo business objects that are used with the imported OmniClass classifications.
5. Click Import.

## Results

---

The import runs in the background. You can select the OmniClass Import History action to see the history of all import sessions.

---

## Configuring building information modeling (BIM) projects

Before you can import Construction-Operations Building information exchange (COBie) data into BIM projects, you define filters, map COBie attributes to existing Manage attributes that include custom attributes, create projects at a site level, and configure global settings for each site.

- **[Defining filters](#)**  
You can use filters to restrict the data that is imported during import, update, merge, and validate sessions. Filters are defined separately from projects at a system, organization, or site level, but can be applied to specific session types. A single filter can be used in any session, so you can create a library of reusable filters. By using filters, you can reduce memory usage of the import because filters are applied immediately when a row is read from an input file.
- **[Creating maps from COBie attributes to Maximo business objects specifications and fields](#)**  
By creating maps, you can map attributes and extension columns in your COBie data to fields in Maximo business objects and to the attribute types in specifications in Maximo Manage. Field maps are useful if your deployment is customized and has custom fields. Attribute maps for fields also reduce errors in the log files and rework when you validate and import data.
- **[Creating projects](#)**  
You can use a project to group import sessions for a single location, typically a building. All imported data uses the parent location that is defined for the project, which is a useful way of breaking a large project into subprojects such as wings, floors, or sections in a building.
- **[Creating system maps for COBie systems](#)**  
By creating system maps, you can map the data elements that are specified in a COBie system to an existing system in Maximo Manage instead of creating a new system.
- **[Configuring data for building models](#)**  
As a designer, you can configure how the COBie file is processed, how IDs are generated from the COBie data, and how attributes are used. Configuration is done at the site level for all projects in the site.
- **[Configuring data for Maximo Manage](#)**  
As a facilities manager, you can configure how data is saved in the records that are created during import in the Maximo database. For example, you can specify the classifications that are applied in Maximo Manage and the statuses that are applied to records. Configuration is done at the site level for all projects in the site.

---

## Defining filters

You can use filters to restrict the data that is imported during import, update, merge, and validate sessions. Filters are defined separately from projects at a system, organization, or site level, but can be applied to specific session types. A single filter can be used in any session, so you can create a library of reusable filters. By using filters, you can reduce memory usage of the import because filters are applied immediately when a row is read from an input file.

---

## About this task

Filters process references that are inherent in a single row of data. References are tested before the row is tested and if the referenced row is excluded, the row that is being tested is also excluded.

The following references are tested:

- Attribute references that use both sheet and row
- Document references that use both sheet and row
- Component references to a space
- Component references to a type
- Job reference to a type

Additional processing supports filtering by floor. Spaces that reference an excluded floor are excluded, and then references to the space are also excluded. Since the filter is applied immediately upon reading a row, references that are not resolved and referenced objects are not included in the filter. For example, if a space is excluded, the components that reference the space are excluded, but the attributes and documents that reference the components are not excluded. However, the attribute and documents are not imported because attributes and documents are imported as part of the object that they reference. A validate session reports unresolved references for these attributes and documents.

---

## Procedure

1. In the BIM Projects application, select the Import Filters action.
2. Add a row for the filter and specify a name.
3. Optional: Specify either an organization or a site to create the filter at that level. If you do not specify an organization or site, the filter is created at the system level.
4. Specify the filter type.
5. In the filter table, add the details about the filter.
  - a. Specify the COBie table that you want to filter.
  - b. In the Expression field, specify the value that you are filtering.
  - c. In the Expression Type field, specify how the filter is applied.
6. Save your changes.

---

## Creating maps from COBie attributes to Maximo business objects specifications and fields

By creating maps, you can map attributes and extension columns in your COBie data to fields in Maximo® business objects and to the attribute types in specifications in Maximo Manage. Field maps are useful if your deployment is customized and has custom fields. Attribute maps for fields also reduce errors in the log files and rework when you validate and import data.

### About this task

---

An attribute map can contain the following maps:

- A map that contains COBie attributes that are mapped to fields in a Maximo business object, such as the Asset object, which is useful for populating custom fields.
- A map that contains COBie attributes that are mapped to attribute types that are used in specifications in Maximo Manage.

Attribute maps are applied to project validate, import, update, and merge sessions, so that extra fields are not created unnecessarily with the values that are required in Maximo Manage. Attribute maps are also applied to export sessions, so you can use them to export a custom field in Maximo Manage to a COBie attribute.

### Procedure

---

1. To map a COBie attribute to a field in a Maximo business object, in the BIM Projects application, select Attributes Maps > Map Attributes to Fields.
2. Specify the COBie attributes and the fields that you need to map to in Maximo Manage.
3. To map a COBie attribute to a specification in Maximo Manage, in the BIM Projects application, select Attributes Maps > Map Attributes to Specifications.
4. Specify the Manage attribute types that are used to create specifications from COBie attributes.
5. Save your changes.

---

## Creating projects

You can use a project to group import sessions for a single location, typically a building. All imported data uses the parent location that is defined for the project, which is a useful way of breaking a large project into subprojects such as wings, floors, or sections in a building.

### About this task

---

When a project is saved, a document import directory is created in the directory that is specified in the bim.import.docdir system property. This directory must be available for file upload by using a method, such as FTP. Each site is a subdirectory, and each project is a subdirectory of its site. This directory is used for importing the documents that are specified on the COBie document tab.

### Procedure

---

1. In the BIM Projects application, add a project and specify its name.
2. Specify the parent location of the facility in the location hierarchy.
3. Specify the site, which is used for all site-level objects that are created for the project. The site can be different to the default site.
4. Optional: Attach documents to the project.

### What to do next

---

The parent location for the project is verified to ensure that it is a member of the primary system for its site. On the Mappings tab, you can add field and specification maps from the library. These maps apply to all sessions that are created for the project.

---

## Creating system maps for COBie systems

By creating system maps, you can map the data elements that are specified in a COBie system to an existing system in Maximo® Manage instead of creating a new system.

### About this task

---

A system map entry has the following elements:

Map from COBie system

The name of the system from the COBie model files.

Map to existing system in Maximo Manage

The name of the Manage system, which is to be updated with COBie data.

Connection location

A location that is a member of the selected Manage system.

When a system is mapped, a location is created by using either import generated IDs or an autokey that is based on configuration options that are specified in the Configure Model Data dialog box for the project. The location is assigned as a member of the system in Maximo Manage that is updated, and the parent location in that system is the connection location. The operating location that is associated with each component in the COBie system is added to the target system in Maximo Manage as a child of the location.

The system mapping table for a project can be populated with a list of all systems for a building model by selecting the Populate System Map option in a validate session for a project.

---

## Procedure

1. In the BIM Projects application, on the Mappings tab, in the System Map section, specify the COBie system that you need to map to in Maximo Manage.
2. Specify the system in Maximo Manage that the COBie system maps to.
3. If the system in Maximo Manage is not a network system, specify the connection location.
4. Save your changes.

---

## Configuring data for building models

As a designer, you can configure how the COBie file is processed, how IDs are generated from the COBie data, and how attributes are used. Configuration is done at the site level for all projects in the site.

---

### About this task

The configuration applies to the site of the currently active project.

---

## Procedure

1. In the BIM Projects application, open the project and select the Configure Import Data > Configure Model Data action.
2. On the COBie File tab, select the check boxes for how the COBie file is processed.
3. On the Generate ID tab, specify how IDs are created for attributes, facilities, floors, and spaces.
4. On the Attributes tab, specify how attributes are used.
5. Click OK.

---

## Configuring data for Maximo Manage

As a facilities manager, you can configure how data is saved in the records that are created during import in the Maximo® database. For example, you can specify the classifications that are applied in Maximo Manage and the statuses that are applied to records. Configuration is done at the site level for all projects in the site.

---

### About this task

The configuration applies to the site of the currently active project.

---

## Procedure

1. In the BIM Projects application, open the project and select the Configure Import Data > Configure Maximo Data action.
2. On the Classifications tab, specify the classifications that are applied to the records in the Maximo database if no other classification is found.
3. On the Import/Update Options tab, on the Record Creation subtab, specify the detail values that apply to each record that is created in the Maximo database during import.
4. On the Import Behavior subtab, specify the processing for contacts, warranties, bar codes, and attributes.
5. On the Import Status subtab, specify the statuses for location, job plan, asset, and facilities that apply to all records that are created during the import.
6. Click OK.

---

## Importing model data into Maximo Manage

After you create a project for facilities, you can import COBie data by using validate, import, update, and merge sessions for the project.

- **Validating data**  
Before you import data, you create a validation session to check the integrity of the Construction-Operations Building information exchange (COBie) file and to validate that the COBie data matches with items in the Maximo database, such as units of measure, attribute types, and classifications. You can view the validation messages on the Log Records tab.
- **Importing validated data**  
After you validate the data, you can import it into Maximo Manage by using the BIM Projects application.
- **Updating imported data**  
You can create an update session to update data that was imported to Maximo Manage to modify data that was imported before a building or complex asset was completed or if refurbishments to the building or complex asset are complete and the data need to be adjusted.
- **Merging design data with existing data**  
You can build the model for a building by merging COBie data with existing Maximo Manage data.

---

## Validating data

Before you import data, you create a validation session to check the integrity of the Construction-Operations Building information exchange (COBie) file and to validate that the COBie data matches with items in the Maximo® database, such as units of measure, attribute types, and classifications. You can view the validation messages on the Log Records tab.

### About this task

---

The following items are verified when the integrity of the COBie file is validated:

**Duplicate items**

Each item on a sheet is checked for uniqueness based on the identifying fields for that sheet. If multiple files are provided for validation, then the same item in different files is not reported as a duplicate. Duplicate items in different files are merged.

**Missing references**

Every space is checked for a reference to a floor, and every component is checked for a reference to a space.

**Missing row references**

Attribute and documents tabs are checked for a value in the Row column.

**Missing sheet references**

Attribute and documents tabs are checked to ensure that a value exists in the Sheet column.

**Mismatched values in a list**

A message is reported when two attributes that have the same name have different lists of valid values.

**Space lists**

Component references are checked for more than one space. The COBie specification allows a component to have a comma-separated list of space references, but the import session supports only a single parent for a component. The first space in the list is used.

**Uniqueness of asset IDs**

If you choose to use the floor tab, room tag, or bar code for the asset ID, these fields are checked for uniqueness.

**Unresolved references**

Every COBie reference to another COBie item is checked to ensure that the referenced item exists.

The following items are verified against the Maximo database:

**Categories**

All categories that are listed in the input files are verified as valid classifications that have a Use With value for the object type.

**Documents**

The sizes and types of the listed documents are checked to ensure that they do not exceed limits in Maximo Manage. The documents are also checked to ensure that their names do not duplicate names of existing attachments.

**ID fields**

The length of the generated IDs in the COBie file is checked to ensure that they do not exceed the maximum length for the specified fields in the Maximo database.

**Location values**

If one of the options for user-specified or structured location values is selected, the values are checked to ensure that they do not exceed the maximum length of the location field.

**Unit of measurement references**

All units that are specified in the import file are verified as existing in the Maximo database.

Select Log All Messages to see which records match data in the Maximo database and which records are added to Maximo Manage.

### Procedure

---

1. In the BIM Projects application, open the project and in the Project Sessions section, add a row.
2. Select Validate for the session type and click OK.
3. Select or add the COBie file that you want to validate and review the settings on the tabs.
4. To populate the system map on the Mappings tab with a list of all the systems that are defined in the COBie files, on the Options tab, select the Populate System Map option.
5. Click Validate.
6. View the results of the validation process on the Log Records tab.

### What to do next

---

After the validation is run, resolve any validate issues and repeat the process until the log file is clean. You must create a new session to repeat the validation or to run an import.

---

## Importing validated data

After you validate the data, you can import it into Maximo® Manage by using the BIM Projects application.

### About this task

---

You can apply a field or specification map to an import session to convert COBie attributes and COBie extension columns to fields in Maximo business objects and attribute types that are used in specifications. Maps are applied when fields are set in a newly created import object.

You can use filters to limit the data that is imported. Filters are applied immediately when a row is read, while attribute maps are applied later in the import process.

## Procedure

---

1. In the BIM Projects application, open the project and in the Project Sessions section, add a session.
2. Select Import for the session type and click OK.
3. On the Files tab, select the COBie files that you want to import.
4. Optional: On the Options tab, specify the specification or field map name.
5. Optional: Specify the default values for the import.
6. Optional: On the Filters tab, specify the filters to use for the import.
7. Optional: On the Advanced tab, modify the default configuration settings.
8. Click Import.

---

## Updating imported data

You can create an update session to update data that was imported to Maximo® Manage to modify data that was imported before a building or complex asset was completed or if refurbishments to the building or complex asset are complete and the data need to be adjusted.

## About this task

---

The selected location is automatically matched to the COBie facility record. Floors, spaces, and components use the following matching rules:

- For floors and spaces, the COBie name is matched to the description, and the value of the BIMUsage field is not used.
- For floors, spaces, and components, COBie records that specify an external identifier and do not match a model ID are matched to records in Maximo Manage that do not have model IDs.

The following update modes are used:

Update only field without values

When an existing record matches an update record, each field that can be updated is checked for a value. If a field does not have a value and the field in the update record has a value, the update value is added to the record.

Overwrite any existing data with updated data

If a record in the Maximo database matches a row in the update data, the associated COBie field that has a valid value is updated in the Maximo record.

Update objects when the updated data is newer than the current data

The value of the CHANGEDATE field in the Maximo database is compared to the COBie CreatedOn field. If both dates are valid, and the CreatedOn date is newer than the CHANGEDATE, then every COBie field that has a valid value is updated in the Maximo database.

## Procedure

---

1. In the BIM Projects application, open the project and in the Import Sessions section, add a row.
2. Specify the location that you are updating.
3. Select Update for the session type and click OK.
4. Select or add the COBie file that you want to use to update.
5. On the Options tab, select the update mode and any options for the update.
6. Optional: Specify the attribute map name.
7. Specify the default values for the update.
8. Optional: On the Filters tab, specify the filters to use for the update.
9. Optional: On the Advanced tab, modify the default configuration settings.
10. Click Update.

---

## Merging design data with existing data

You can build the model for a building by merging COBie data with existing Maximo® Manage data.

## Procedure

---

1. In the BIM Projects application, open the project and in the Project Sessions section, add a row.
2. Select Merge for the session type and click OK.
3. In the Merge with Existing Import field, select the location of the import.
4. Select or add the COBie file that you want to import.
5. Optional: On the Options tab, specify the attribute map name.
6. Specify the default values for the import.
7. Optional: On the Filters tab, specify the filters to use for the import.
8. Optional: On the Advanced tab, modify the default configuration settings.
9. Click Merge.

---

# Exporting data from Maximo Manage to Construction-Operations Building Information Exchange (COBie)

An export session extracts data from Maximo Manage and saves it in a .XLSX file in COBie format. The file is attached to the project and can be viewed and downloaded from the Attachments tab. You can export data at a later date that reflects any asset changes in Maximo Manage. This data is useful input into the design process for renovation or for a new build.

## About this task

---

The name of the exported .XLSX file is created by combining the site name, the prefix, and the session number. The export session checks the entire hierarchy by starting at the facility level.

The following options are used for the export ID:

### Import ID

Uses the model ID field for the COBie external identifier. You can select this option to synchronize data back to the import source, such as an IFC or Revit file.

### Maximo UID

Uses the Maximo database sequence number for the COBie external identifier. You can select this option when you import data that needs to use web services or other APIs. The Maximo business object that is the source of the export is used for the external object.

### IFC or UID

Uses both of the values in comma-separated format. The COBie standard does not specifically define this format. However, many other COBie fields do use a comma-separated list format.

### Changed After

Exports only the assets that changed after the selected date.

## Procedure

---

1. In the BIM Projects application, open the project and in the Import Sessions section, add a row.
2. Select Export for the session type and click OK.
3. Specify the facility that you want to export and the type of export ID to use.
4. Optional: Specify the attribute map name.
5. Optional: Specify whether to export attributes that do not contain a value.
6. Select the COBie tables that you want to export and click Export.

---

## Commissioning buildings

The as-built state of the building is defined in the model during construction. After you import the as-built model data into the BIM Projects application, you can commission the building and begin the process of maintaining it. Commissioning a building creates a bulk status update for all objects that are related to the building and have the specified starting status.

## About this task

---

Location and asset records have more fields that are only valid for some status changes. The tabs in the Commission Building window provide the following options for the commissioned building:

### Asset tab

Define the status of assets that are included and specify whether to remove references for active routes, safety plans, and update the status of child assets to the commissioned status.

### Location tab

Define the status of locations that are included and specify whether to remove references for all routes, safety plans, and job plans.

## Procedure

---

1. In the BIM Projects application, open the project and select the Commission Building action.
2. Specify the building that you want to commission.
3. Select the types of records to update.
4. On the tabs, define the options for the commissioned building.
5. Click Commission.

---

## Managing building models

After you import the building model data into Maximo® Manage, you can view the data in the assets and locations and also view the import session details.

You can also use a building model viewer to view a 3D version of the building. By using the 3D model, you can inspect assets and locations of the building, create work orders and service requests, and search for and create systems from the model. You can also view property data from the original model that includes form model elements that are not tracked in Maximo Manage.

- [Configuring the Building Information Modeling \(BIM\) viewer](#)

To view a 3D version of a building model, you can install a third-party building model viewer in Maximo Manage. You also can install multiple viewers, but only one viewer can be active at a time.

- [Associating building models with locations](#)

When COBie data is imported, the data in the COBie facility table is created as a location record in Maximo Manage. After the COBie data is imported, you can associate the location with the building model to view the 3D model in a BIM viewer.

- [Building models viewer](#)

When you install a building model viewer, you can associate the building model with the imported COBie data. You can then manage the assets, locations, and systems of the building and view the building model in 3D format.

---

## Configuring the Building Information Modeling (BIM) viewer

To view a 3D version of a building model, you can install a third-party building model viewer in Maximo® Manage. You also can install multiple viewers, but only one viewer can be active at a time.

---

### About this task

When the viewer is installed, you can view building models from the 3D View tab in the following applications:

- Manage BIM Viewer
- Assets
- Locations
- Work Order Tracking

If you install multiple viewers, you must specify the value of the active viewer in the **bim.viewer.active** property in the Systems Properties application. The list of values for each viewer that you install is added to the BIMVIEWERTYPE synonym domain. The default viewer value that is called vendor has no viewer functionality and is the active viewer when no other viewer is installed.

---

### Procedure

1. Install a third-party viewer.
2. In the System Properties application, specify the active viewer by changing the value of the viewer in the **bim.viewer.active** property to the value of the active viewer.

---

## Associating building models with locations

When COBie data is imported, the data in the COBie facility table is created as a location record in Maximo® Manage. After the COBie data is imported, you can associate the location with the building model to view the 3D model in a BIM viewer.

---

### Before you begin

Install a building information modeling (BIM) viewer.

---

### About this task

A single location can have more than one model associated with it, for example an architectural model and a mechanical, electrical and plumbing (MEP) model.

---

### Procedure

1. In the Manage BIM Viewer application, create a building model record by selecting the New Building Model action.
2. Specify the location for the building model.
3. Specify the model name or add the URL for the model.
4. Save the record.

---

### What to do next

Select the 3D View tab to view the 3D model.

---

## Building models viewer

When you install a building model viewer, you can associate the building model with the imported COBie data. You can then manage the assets, locations, and systems of the building and view the building model in 3D format.

In the Manage BIM Viewer application, you can associate a location with the building model to view the model in a BIM viewer.

In the Assets application, the Locations application, and the Work Order Tracking application, you can manage the assets, location, and systems of each building. If the current asset or location record has an associated model file, the building model is displayed in the viewer on the 3D View tab. You can then create work orders and service requests and search for and create systems from the model.

## Viewing import information

---

You can view import sessions for the parent facility from any location or asset that was created by the imported data, including project information and settings for the facility. To show the import sessions information for a selected asset or location record, select the View Building Model Import Sessions action in the Assets application or the Locations application.

## Inspecting asset details

---

To access the list of all assets that are associated with the location or child location, in the Locations application, select the Inspect Asset Details action. For example, selecting an operating location, such as an air handler, show the asset that is operating at that location. Selecting a space, such as a room, shows all assets that are associated with the space.

If a viewer is installed, you can select the Inspect Asset Details icon on the viewer toolbar. When the asset list is displayed in the viewer, the result set is highlighted on the model.

## Displaying system details

---

To display a list of all systems for a location, provide a tree view of the system, and access to attachments and classifications for systems, in the Locations application, select the Display System Details action.

If a viewer is installed, you can select the Display System Details icon on the viewer toolbar. When system details are displayed in a viewer, either all or a single member of the system is shown on the model.

## Attribute maps for COBie data

---

You can map attributes and extension columns in your COBie data to fields in Maximo® business objects and to the attribute types in specifications in Maximo Manage.

- **Contacts**  
The Contacts table in COBie can be mapped to the PERSON, COMPANIES, and COMPANY CONTACT in Maximo Manage. The import process tracks how a contact is referenced. If it is referenced in the COBie data in a createdBy field, the data can be stored in the PERSON object. Otherwise, the data is stored in the COMPANIES object.
- **Facility**  
The Facility table in COBie is mapped to the LOCATION Maximo business object. Additional values from the facility are stored in the import session.
- **Floor**  
The Floor table in COBie is mapped to the LOCATION Maximo business object. All location records that are created from floors in the COBie data use the facility location as their parent.
- **Space**  
The Space table in COBie is mapped to the LOCATION Maximo business object.
- **Component**  
A component in the COBie data is stored in a location record and an asset record in Maximo Manage. The asset record references the location record as its locations. The parent location is the space that is referenced by the component if it is valid. If the space is not valid, the parent location is either a floor, if one can be determined from attributes, or the facility.
- **Zone**  
The Zone table in COBie is mapped to the LOCSYSTEM Maximo business object. A location system record is created for each zone. The system is hierarchical and uses the facility location as the root of the system and each space as a child of the facility.
- **System**  
The Systems table in COBie is mapped to the LOCSYSTEM Maximo business object. A location system record is created for each zone. The system is hierarchical and uses the facility location as the root of the system. The operating location that is associated with each component is used as a child of the facility.
- **Job**  
The Job table in COBie is mapped to the JOBPLAN and JOBTASK Maximo business objects. If the job is preventative maintenance, a master preventive maintenance (PM) record is also created that has a reference to the job plan.
- **Attributes**  
The Attributes table in COBie is mapped to several tables in the Maximo database. First, the attributes are grouped by name to create attribute types. Then, the attribute values are added as specifications to the appropriate specification table.
- **Document**  
The Document table in COBie is mapped to the ATTACHMENT table in the Maximo database. Both DOCINFO and DOCLINK objects are created. If a single document is referenced more than once, then only a single DOCINFO object is created. Reference is validated by path and name during same import and by document checksum on matches from previous imports.
- **Resource**  
The Tool resources in COBie are mapped to the ItemTool Maximo business object. Only resources of type tool are imported.
- **Assembly**  
The Assembly table in COBie sets the parent field of the asset.

---

## Contacts

The Contacts table in COBie can be mapped to the PERSON, COMPANIES, and COMPANY CONTACT in Maximo® Manage. The import process tracks how a contact is referenced. If it is referenced in the COBie data in a createdBy field, the data can be stored in the PERSON object. Otherwise, the data is stored in the COMPANIES object.

## Person object

Table 1. Contacts table to PERSON object mapping

| COBie field        | Maximo field           | Changed by update session? |
|--------------------|------------------------|----------------------------|
| Email              | PERSONID/ PRIMARYEMAIL | Yes                        |
| CreatedBy          | Not Mapped             | No                         |
| CreatedOn          | Not Mapped             | No                         |
| Category           | CLASSSTRUCTUREID       | Yes                        |
| Company            | Not Mapped             | No                         |
| Phone              | PRIMARYPHONE           | Yes                        |
| ExternalSystem     | Not Mapped             | No                         |
| ExternalObject     | Not Mapped             | No                         |
| ExternalIdentifier | Not Mapped             | No                         |
| Department         | DEPARTMENT             | Yes                        |
| OrganizationCode   | Not Mapped             | No                         |

## Company and Company Contact objects

Contacts that are referenced from the type table are mapped to COMPANIES and COMPCONTACT. All contacts that share company are grouped as COMPCONTACT records under a single COMPANIES record. The first contact that is encountered is selected as the primary contact.

Table 2. Contacts table to COMPANIES and COMPCONTACT table mapping

| COBie field        | Maximo field      | Changed by update session? |
|--------------------|-------------------|----------------------------|
| Email              | EMAIL             | No                         |

| NetArea       | BIMNETAREA       | Yes                        |

## Component

A component in the COBie data is stored in a location record and an asset record in Maximo® Manage. The asset record references the location record as its locations. The parent location is the space that is referenced by the component if it is valid. If the space is not valid, the parent location is either a floor, if one can be determined from attributes, or the facility.

Table 1. Component table to LOCATION and ASSET object mapping

| COBie field       | Maximo field     | Changed by update session?                                                         |

| Description   | LONG_DESCRIPTION | The description can be updated but the operating location cannot be updated. |

## Job

The Job table in COBie is mapped to the JOBPLAN and JOBTASK Maximo® business objects. If the job is preventative maintenance, a master preventive maintenance (PM) record is also created that has a reference to the job plan.

JOBTASK records are created for each task that is defined for the Job.

## Attributes

The Attributes table in COBie is mapped to several tables in the Maximo® database. First, the attributes are grouped by name to create attribute types. Then, the attribute values are added as specifications to the appropriate specification table.

Attributes can be added to the following table types:

- Asset
- Item
- Job Plan
- Location

Table 1. Attributes table mapping

| COBie field   | Maximo field               | Changed by update session? |
|---------------|----------------------------|----------------------------|
| Name          | DESCRIPTION                | Yes                        |
| CreatedBy     | Not Mapped                 | No                         |

## Document

The Document table in COBie is mapped to the ATTACHMENT table in the Maximo® database. Both DOCINFO and DOCLINK objects are created. If a single document is referenced more than once, then only a single DOCINFO object is created. Reference is validated by path and name during same import and by document checksum on matches from previous imports.

Table 1. Document table to ATTACHMENT table mapping

| COBie field | Maximo field | Changed by update session? |
|-------------|--------------|----------------------------|
| Name        | DOCUMENT     | No                         |
| CreatedBy   | Not Mapped   | No                         |

- **[Predefined focal points and calculation rules](#)**  
The predefined focal points are provided and are based on assets, location, and general ledger accounts or components. Predefined calculation rules are also available and are based on estimated, committed, and actual costs.

## Budget monitoring

In the Budget Monitoring application, you can create budget records to monitor transactions in a financial period. Monitoring budget costs can help to ensure that projects or activities, such as work orders, are completed within an agreed budget and can improve estimation of the costs of future projects.

As an administrator, you can create budget records by configuring focal points and calculation rules. Focal points represent the item that you are monitoring in the budget record, such as assets, locations, or general ledger accounts or components. You create focal points, for example, to track costs on check type master preventive maintenance (PM) records for a specific model of an asset. You can configure calculation rules that are based on estimated, committed, and actual costs.

Users create transactions for work orders, purchase requisitions, purchase orders, receipts, invoices, and issues. The budget records then monitor these transactions and are used to create reports.

Budget reports provide a summarized and detailed view of costs by type, such as labor, tools, services, materials. Budget reports also provide a summarized and detailed view of costs by status such as estimated, committed, and actual costs, and compare them with related budgeted amounts.

## Configuring budget monitoring

In the Budget Monitoring application, you can create or modify focal points and calculation rules. Focal points and calculation rules are used to create budget records that monitor the planned, estimated, and actual costs of transactions.

### Procedure

1. In the Budget Monitoring application, select Manage Budget Focal Points from the menu.
2. Configure the attributes of the budget focal points.

| Option                                | Description                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------|
| To configure a predefined focal point | View and modify the predefined focal point attributes.                            |
| To create a focal point               | Add a new row, set the values for the object and attribute fields, and select OK. |

3. Select Manage Rules.
4. Create new rules or apply predefined rules.

| Option                    | Description                                                 |
|---------------------------|-------------------------------------------------------------|
| To create new rules       | Add a new row, select values for all fields, and select OK. |
| To apply predefined rules | Select Auto-Configuration.                                  |

### What to do next

You can create budgets that are based on the focal points and conditions that you configured.

## Creating budget records

In the Budget Monitoring application, you can create budget records to monitor transactions in a financial period. You create budget records to track estimated, committed, and actual costs of assets, locations, and general ledger accounts or components.

### Procedure

1. In the Budget Monitoring application, select New Budget.
2. Specify the financial period or year of the budget and the supervisor who approves the budget.
3. Add a new row and specify the focal points and conditions for the budget record.
4. To update the budget record with transactions, select Generate New Budget Lines from the menu.
5. Update the budgeted amount on each budget line and save the budget record.
6. Select Change Status from the menu and specify a value for the status.
7. Select Approve the Budget, and specify the approved status.

### What to do next

Periodically select Update Budget Lines to update the existing transactions for the budget record. The BUDGETUPD cron task is also available to run updates in the background.

## Predefined focal points and calculation rules

The predefined focal points are provided and are based on assets, location, and general ledger accounts or components. Predefined calculation rules are also available and are based on estimated, committed, and actual costs.

Table 1. Focal points

| Object          | Condition                                                     | Description                       |
|-----------------|---------------------------------------------------------------|-----------------------------------|
| ASSET           | None                                                          | Budget generation for assets      |
| CHARTOFACCOUNTS | None                                                          | Budget generation for GL accounts |
| GLCOMPONENTS    | BUDGL01, BUDGL02, BUDGL03, BUDGL04, BUDGL05, BUDGL06, BUDGL07 | Budget generation for segments    |
| LOCATIONS       | None                                                          | Budget generation for locations   |

Table 2. Calculation rules

| Object     | Condition  | Description                                             |
|------------|------------|---------------------------------------------------------|
| WPTOOL     | BUDMON75   | Canceled tools.                                         |
| WPTOOL     | BUDMON77   | Committed tools.                                        |
| WPTOOL     | BUDMON76   | Estimated tools.                                        |

## Removing personal information from records

To remove personal information from people records, you initially specify the information that you want to remove and then delete the information. In some cases, you can also remove personal information that is stored as a transactional reference.

- **[Removal of personal information](#)**

Personal information that is associated with an individual and is stored in person records provides personally identifiable information (PII) about that individual. When this information is no longer required, you can remove that information by specifying the information to be removed and then deleting the information in the People application.

- **[Deleting personal information](#)**

If personal information that is contained in a person record, such as a phone number or an email address, is no longer required, you can remove that information by deleting or replacing the data. Before you delete the data, you must specify the information that you want to remove and how that information is removed.

- **[Example: Deleting transactional references](#)**

In addition to deleting static personal information, you can also remove information that is stored as a transactional reference to a person. For example, personal information that is entered as free-form text in work orders or service requests rather than selected from a drop-down list. You can use advanced relationships to delete that personal information.

## Removal of personal information

Personal information that is associated with an individual and is stored in person records provides personally identifiable information (PII) about that individual. When this information is no longer required, you can remove that information by specifying the information to be removed and then deleting the information in the People application.

Object attributes can be used to store personal information about individuals in person records. By default, you can manage attributes that are related to the following objects to delete personally identifiable information:

- Person
  - Phone
  - Email

- SMS
- Labor
- MAXUSER

To manage an object attribute that is not listed by default, use the Domains application to add the object to the MAXPDOBJ domain. You use the Manage People Data action to specify the removal of personal information, and you use the Delete Person Data action to delete that information.

Typically, when you configure the removal of personal information, you specify a relationship that is based on the PERSONID attribute. Specifying the relationship to the PERSONID attribute ensures that the deleted information is limited to the selected person. If you specify a relationship that is not based on the PERSONID attribute, you risk deleting personal information for multiple people. Exercise caution, back up your database, and thoroughly test advanced relationships before you delete personal information.

Note: Deleted personal information cannot be recovered.

## Deleting personal information

If personal information that is contained in a person record, such as a phone number or an email address, is no longer required, you can remove that information by deleting or replacing the data. Before you delete the data, you must specify the information that you want to remove and how that information is removed.

### Before you begin

Back up your Manage database.

### About this task

How you remove the information depends on the type of data that needs to be removed. For fields that are required, you must randomize the field values. When you randomize a field, the attribute value is replaced with a random alphanumeric string. For non-required fields, you can randomize the field values, or you can clear the field values by using the NULL removal type. Use the DELROW removal type to delete multiple values from a field, for example, phone numbers, SMS addresses, and email addresses.

### Procedure

1. In the People application, select the Manage People Data action.
2. Specify the object attributes that you want to remove, specify removal types for each attribute, and specify relationships based on the PERSONID attribute. For example, to delete the email address from a record, specify the following information:

| Field               | Value              |
|---------------------|--------------------|
| <b>Object</b>       | EMAIL              |
| <b>Attribute</b>    | EMAILID            |
| <b>Relationship</b> | personid=:personid |
| <b>Removal Type</b> | DELROW             |

3. Click OK.
4. Select the person whose personal information you want to remove.
5. Select the Delete Person Data action.

### What to do next

The values for the specified attribute values are removed for the selected person. Verify that the data was removed.

## Example: Deleting transactional references

In addition to deleting static personal information, you can also remove information that is stored as a transactional reference to a person. For example, personal information that is entered as free-form text in work orders or service requests rather than selected from a drop-down list. You can use advanced relationships to delete that personal information.

### About this task

As an example, Louise, a location manager, wants to clean up personally identifiable information (PII) that is no longer necessary to store in the system. In addition to removing static people information, she wants to make sure that no PII remains as transactional references in some records. Users occasionally enter free-form text into some fields and you cannot easily find PII in those fields. Before she implements a stricter policy for users, Louise decides to remove the following personal information:

- Transactional references to the person in the Reported By field in the Service Requests application.
- Transactional references to all people in the On Behalf Of field for all open work orders at the AIR102 location in the Work Order Tracking application.

Since the objects for service requests and work orders are not default objects for removing PII, she must add these objects to the MAXPDOBJ domain before she can remove these transactional references in the People application.

Note: Exercise extreme caution when you use advanced relationships. Ensure that you test relationships thoroughly and back up your Manage database before you delete any personal information. When you delete personal information, the data is not recoverable.

## Procedure

1. Back up the Manage database.
2. In the Domains application, click Edit Detail for the MAXPDOBJ domain.
3. In the List Where Clause field, add the objects to the list that are in parentheses.  
For example, to remove attribute data from service requests and work orders, add 'SR','WORKORDER' to the list of objects that are in parentheses.
4. In the People application, select the Manage People Data action and insert a row.
5. Specify the attribute details for the data that you want to remove.

For example, to remove the transactional references to the person in the Reported By field in service requests, specify the following information:

| Field        | Value                |
|--------------|----------------------|
| Object       | SR                   |
| Attribute    | REPORTEDBY           |
| Relationship | reportedby=:personid |
| Removal Type | NULL                 |

To remove the transactional references to all people in the On Behalf Of field for all open work orders at the AIR102 location, specify the following information:

| Field        | Value                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Object       | WORKORDER                                                                                                                                                                                                                      |
| Attribute    | ONBEHALFOF                                                                                                                                                                                                                     |
| Relationship | location ='AIR102' AND Status in ('WAPPR','APPR','INPRG')<br>Note: The content in the On Behalf Of field is randomized for all people on all open work orders because the relationship is not based on the PERSONID attribute. |
| Removal Type | RANDOMIZE                                                                                                                                                                                                                      |

6. Click OK.
7. Select the person that has personal information that you want to delete or randomize.
8. Select the Delete Person Data action.

## Results

The values for the specified object attributes are deleted or randomized for the selected person or people.

## Customizing the application

If you make changes to Maximo® Manage, such as customized Java™ classes or database scripts, you can copy them to a customization archive. Then, you can apply the customizations to server bundles when you deploy Maximo Manage. This feature is useful for moving customizations from a test to a production environment and for upgrades.

- [Customization archive guidelines](#)  
The customization archive is a set of files that contain changes and customizations that you make to the application. Customizations can include changes such as Java classes, XML, database scripts, or additional application server files that you created in a development environment.
- [Adding customizations to the application](#)  
To customize Maximo Manage, create a customization archive that contains your changes, add the contents of the archive to a compressed file, and add the updated files to the application when you deploy it.
- [Configuring server bundle properties](#)  
To provide specific Maximo Manage system properties for your server bundles, you can add bundle-level properties when you deploy the application.
- [Configuring the application server](#)  
To customize IBM® WebSphere® Application Server Liberty, you can apply custom configurations when you activate Maximo Manage.
- [Configuring JVM options](#)  
Administrators can add Java virtual machine (JVM) configuration options to the IBM WebSphere Application Server Liberty application server on which a server bundle runs. For example, you can specify memory options to improve performance or specify logging options for the server bundle.
- [Retrieving the contents of an administrative image](#)  
After you configure Maximo Manage to send build images to an external registry, you can retrieve the administrative image and instantiate it in a Docker container. You can then review the contents of the container or use it as a development environment for customizations.

## Customization archive guidelines

The customization archive is a set of files that contain changes and customizations that you make to the application. Customizations can include changes such as Java™ classes, XML, database scripts, or additional application server files that you created in a development environment.

Some customizations might apply only to specific deployments. For example, ejb-jar.xml can be applied to a Maximo® Integration Framework cluster but not to others.

Use the following guidelines to create a customization archive:

Class files, such as Java customizations

Class files must be added to the appropriate directory in the customization archive so that they can be extracted to the existing code in the appropriate hierarchy. Class files can include the following types of customizations:

- MBO customizations
- Field validations

- Maximo Integration Framework customizations
- Other customer-specific code

#### Deployment descriptors

You can add deployment descriptors, such as web.xml, ejb-jar.xml, and webservices.xml files, that you changed to the customization archive. When the application is redeployed, the customized files override the files that are provided for the deployment. Use the following guidelines to create the structure of your customization archive.

- For server bundles with a bundle type of all, you can use the following directory structure:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximouiweb\webmodule\WEB-INFUI
deployment\web.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximo-x\webmodule\WEB-INFUI
deployment\web.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximo-x\webmodule\WEB-INFUI
deployment\web-guest.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximo-x\webmodule\WEB-INFUI
deployment\web.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maxrestweb\webmodule\WEB-INFUI
deployment\web.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\maximo-x\webmodule\WEB-INFUI
deployment\web.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\mboweb\webmodule\WEB-INFUI
deployment\web.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\meaweb\webmodule\WEB-INFUI
deployment\web.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-all\mboejb\ejbmodule\META-INF\ejb-jar.xml
```

- For server bundles with a bundle type of ui, you can use the following directory structure:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-ui\webmodule\WEB-INF\web.xml
```

- For server bundles with a bundle type of mea, you can use the following directory structure:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-mea\meaweb\webmodule\WEB-INF\web.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-mea\mboejb\ejbmodule\META-INF\ejb-jar.xml
```

- For server bundles with a bundle type of cron, you can use the following directory structure:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-cron\webmodule\WEB-INF\web.xml
```

- For server bundles with a bundle type of report, you can use the following directory structure:

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-report\webmodule\WEB-INF\web.xml
```

#### XSL customizations

If you have XSL customizations that were part of the Maximo EAR or WAR files in previous releases, you can include them in the customization archive. They are copied to the appropriate locations when the application is redeployed. For information about XSL customization, see the documentation for rule-based customization.

#### Database scripts

To add database scripts to the customization archive, you can create a a\_customer.xml file. The a\_customer.xml file incorporates system classes that have been customized. All modified class files and scripts must be referenced in the format shown in the following example.

In this example, the update utility runs the scripts representing each successive update version up to and including the referenced V600\_01 script. The altered <mboaset objectname> and <mbo object> entries indicate that the purchase order classes have been extended.

```
<?xml version="1.0" encoding="UTF-8"?>
<product>
 <name>Customer Product</name>
 <version>
 <major>6</major>
 <minor>0</minor>
 <patch>0</patch>
 <build>999</build>
 </version>
 <dbmaxvarname>DBCUST</dbmaxvarname>
 <dbscripts>cus</dbscripts>
 <dbversion>V600-01</dbversion>
 <lastdbversion>V520-20</lastdbversion>
 <extensions>
 <mboaset objectname='PO'>psdi.app.cust.POSet</mboaset>
 <mbo objectname='PO'> psdi.app.cust.PO</mbo>
 </extensions>
</product>
```

You can add the a\_customer.xml file to the customization archive. After deployment, the database update utility runs and applies your custom scripts.

#### Additional files for IBM® WebSphere® Application Server Liberty

You can customize WebSphere Application Server Liberty for a server bundle by adding directories and files to the customization archive for the bundle. To add files to WebSphere Application Server Liberty, create an additional-server-files directory in the root directory of your customization archive and add the files to that directory. If necessary, you can also create subdirectories in the additional-server-files directory for your files.

When you configure the server bundles for Maximo Manage for deployment, provide the URL and credentials for the customization archive. When the application is deployed, the files and directories that you added are extracted to the /managefiles/additional-server-files folder on the Liberty server.

For example, if you use an IBM MQ service for messaging, you can add a RAR file for your IBM MQ resource adapter to the additional-server-files directory. When Maximo Manage is deployed, the file is added to the Liberty server.

For tracking purposes, it is a good practice to apply versions your customization archives.

## Sample customization archive files

---

The following sample illustrates the kinds of files that you might want to include in your archive:

classes

```
applications\maximo\businessobjects\classes\cust\app\asset\Asset.class
applications\maximo\businessobjects\classes\cust\app\asset\AssetSet.class
applications\maximo\businessobjects\classes\cust\app\asset\FldAssetNewField.class
```

product XML

```
applications\maximo\properties\product\customer.xml
```

script

```
tools\maximo\en\cust\V7612_01.dbc
```

servlets

```
applications\maximo\commonweb\classes\com\ibm\tivoli\maximo\oslc\provider\MyPingServlet.class
```

deployment descriptors (web.xml)

```
deployment\was-liberty-default\config-deployment-descriptors\maximo-mea\meaweb\webmodule\WEB-INF\web.xml
deployment\was-liberty-default\config-deployment-descriptors\maximo-ui\meaui\webmodule\WEB-INF\web.xml
```

---

## Adding customizations to the application

To customize Maximo® Manage, create a customization archive that contains your changes, add the contents of the archive to a compressed file, and add the updated files to the application when you deploy it.

### Before you begin

---

Before you can add customizations to the application, you must create one or more archive files that contain your changes. Review the customization guidelines for details about the structure to use for the archive and the types of files that you can add. Then, complete the following tasks to create an archive:

1. Create a directory that has a structure that matches the /SMP/maximo folder structure that is used for Maximo Manage.
2. Add files that contain your customizations to the archive.
3. When the archive is complete, add the archive to a compressed file.
4. Put the compressed file in a location that is accessible to Maximo Manage.

If you use SSL and have a certificate that is not public, ensure that you provide the certificate details before you deploy the application.

### About this task

---

You can add a single or multiple customization archives through the Maximo Application Suite user interface when you configure Maximo Manage.

## Adding customizations by using the Maximo Application Suite user interface

---

You can add a single customization archive through the Maximo Application Suite user interface when you configure Maximo Manage. When you configure Maximo Manage, you can add customization archives through the Maximo Application Suite interface.

### About this task

Previously, only a single customization archive was available when you configured Maximo Manage. You can now add multiple customization archives when you configure Maximo Manage.

### Procedure

1. Log in to Maximo Application Suite as a system administrator.
2. To navigate to the application details page:
  - a. From the catalog, in the Applications tab, select the Manage tile.  
The application details page displays.
3. To navigate to the Manage Workspace details page :
  - a. Click the gear icon to go to the Suite Administration page.
  - b. Click the Workspaces tile to update a previous configuration.
  - c. In the Applications section, click the Manage tile.  
The Manage Workspace details page is displayed.
4. To edit the existing configuration:
  - a. Click Actions and select Update configuration.
  - b. In the Customization row on the Update Manage configuration window, click the Edit icon.
5. In the Customization section of the configuration window, click Add customization archive.

The row in the Customization archives table becomes editable.

- a. Specify a custom alias name in the Alias field or leave the default value.
- b. Specify the URL for the customization archive file in the File address field.

The following URL protocols are supported: HTTP, HTTPS, FTP, and FTPS.

Note: To include more customization archives, click Add customization archive **again**.

6. Optional: If you applied password security to the file or files, in the Credentials field, specify the user ID and password in the following format:

```
user=username password=password
```

7. After you complete all configurations, click Apply changes.

## Adding customizations manually to the custom resource

You can also add multiple customization archives to Maximo Manage, manually configure the custom resource for the Maximo Manage workspace.

### About this task

If you use both the customization and the customizationList properties, the archive that you add to the customization property is processed last. When you specify a customization list, ensure that you list the files in the order that you want to process them.

### Procedure

1. In the Red Hat® OpenShift® Container Platform console, in the Administration section, select Custom Resource Definitions.
2. In the CustomResourceDefinitions window, select the ManageWorkspace custom resource definition record.
3. In the CustomResourceDefinition details window, on the Instances tab, select the instance that you want to update.
4. On the YAML tab for the instance, in the Settings sub-section, under the Specs section, specify values for the secret name for the archive credentials, the archive name, and the archive URL for each customization archive that you want to add, as shown in the following example:

```
settings:
 customizationList:
 - customizationArchiveCredentials:
 secretName: customization-secret-name
 customizationArchiveName: archive2
 customizationArchiveUrl: >-
 https://url/path_to_customization_archive/CustomArchive.zip
 - customizationArchiveCredentials:
 secretName: customization-secret-name
 customizationArchiveName: archive1
 customizationArchiveUrl: >-
 https://url/path_to_customization_archive/CustomArchive.zip
```

- a. Create a secret:

```
user=username password=password

oc create secret generic <secret-name>
--namespace <manage-namespace-name>
--from-file credentials=<path-to-secret-file>
```

For example,

```
oc create secret generic Archivelsecret --namespace mas-test-manage --from-file credentials=/tmp/secretfile
```

5. Save the custom resource.

## Configuring server bundle properties

To provide specific Maximo® Manage system properties for your server bundles, you can add bundle-level properties when you deploy the application.

### About this task

Adding Manage properties to a server bundle is useful when you want to handle processes for one bundle in one way and for another bundle in another way. For example, you might want the email address for the administrator of your reports server bundle to be different from the email address of the administrator for your user interface server bundle.

You define Manage bundle level properties after deployment when you activate the application. To change the properties, you can update them and then redeploy the application.

If you add a bundle property, ensure that you add the property to the System Properties application before you deploy application.

### Procedure

1. Log in to Maximo Application Suite as a system administrator.
  2. From Suite administration, select Workspaces from the side navigation menu and then select the Manage tile.
  3. On the Manage workspace details page, click Actions and select Update configuration.
  4. In the Server bundles row on the Update Manage configuration window, click the Edit icon.
  5. In the Server bundles section of the deployment window, in the Additional properties column, click View.
- If no server bundles are added to the deployment, the View option is not displayed.

6. In the Bundle level properties section of the Additional server bundle properties window, click Add property.
7. Specify the name and value of the property or properties that you want to add.
8. Save your changes.
9. After you complete all configurations, select one of the following options:
  - If you are configuring a new deployment, click Activate.
  - If you are updating a deployment, click Apply changes.

## Configuring the application server

To customize IBM® WebSphere® Application Server Liberty, you can apply custom configurations when you activate Maximo® Manage.

### About this task

You can add custom server properties for the application server in XML format when you configure Maximo Manage. The customizations are applied when Maximo Manage is activated.

When you add application server customizations, ensure that your content conforms to the requirements for adding configuration to server XML files. The rules are provided in the WebSphere Application Server Liberty documentation.

The custom configurations are applied to the server-custom.xml that is used for the Maximo Manage pods and are included in the server.xml as additional configuration. Administrators can view the server-custom.xml file in the Red Hat® OpenShift® console on the Terminal tab for the pod. After deployment, the file is located in the /config/manage/serverxml directory.

### Procedure

1. Log in to Maximo Application Suite as a system administrator.
2. From Suite administration, select Workspaces from the side navigation menu and then select the Manage tile.
3. On the Manage workspace details page, click Actions and select Update configuration.
4. In the Server bundles section of the deployment window, in the Additional properties column for the server bundle that you want to configure, click View.
5. In the Route subdomain field of the Additional server bundle properties window, specify the subdomain for the server bundle that you want to configure.
6. In the Additional server config field, enter your custom server properties, as shown in the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<server description="new server">
 <logging traceSpecification="JMSApi=all:WAS.j2c=all"/>
 <variable name="wmqJmsClient.rar.location" value="{wlp.install.dir}/../wmq/wmq.jmsra.rar"/>
 <!--containerAuthData
id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_mas_man_configmap_server
_auth1" user="maximomif" password="xxxx"/-->
 <jmsConnectionFactory jndiName="jms/maximo/int/cf/intcf" connectionManagerRef="MIFJMS">
 <properties.wmqJms
 transportType="CLIENT"
 hostName="libertymanager-c553.qm.us-south.mq.appdomain.cloud"
 port="30216"
 channel="CLOUD.APP.SVRCONN"
 applicationName="maxliberty"
 userName="xxx"
 password="xxxxx"
 queueManager="LIBERTYMANAGER"/>
 </properties.wmqJms
 </jmsConnectionFactory>
 <connectionManager
id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_mas_man_configmap_server
_MIFJMS" maxPoolSize="20"/>
 <jmsQueue
id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_mas_man_configmap_server
_sqout" jndiName="jms/maximo/int/queues/sqout">
 <properties.wmqJms baseQueueName="sqout" baseQueueManagerName="LIBERTYMANAGER"/>
 </jmsQueue>
 <jmsQueue
id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_mas_man_configmap_server
_sqin" jndiName="jms/maximo/int/queues/sqin">
 <properties.wmqJms baseQueueName="sqin" baseQueueManagerName="LIBERTYMANAGER"/>
 </jmsQueue>
 <jmsQueue
id="home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_manage_deploy_t_mas_man_configmap_server
_jms/maximo/int/queues/cqin" jndiName="jms/maximo/int/queues/cqin">
 <properties.wmqJms baseQueueName="cqin" baseQueueManagerName="LIBERTYMANAGER"/>
 </jmsQueue>
```

7. Save your changes.
8. After you complete all your configuration changes, click Activate.

## Configuring JVM options

Administrators can add Java™ virtual machine (JVM) configuration options to the IBM® WebSphere® Application Server Liberty application server on which a server bundle runs. For example, you can specify memory options to improve performance or specify logging options for the server bundle.

## About this task

---

You can add JVM options when you specify additional configurations for a server bundle in the Maximo® Manage workspace.

## Procedure

---

1. Log in to Maximo Application Suite as a system administrator.
2. From Suite administration, select Workspace from the side navigation menu and then select the Manage tile.
3. On the Manage workspace details page, click Actions and select Update configuration.
4. In the Server bundles row on the Update Manage configuration window, click the Edit icon.
5. In the Server bundles section, set the System managed toggle switch to the off position.
6. In the Additional properties column for the server bundle, click View.  
If no server bundles are added to the deployment, the View option is not displayed.
7. In the Java virtual machine options section of the Additional server bundle properties window, enter the JVM options that you want to configure, as shown in the following example.  

```
-Xms4m\n-Xmx488m\n-XX:MaxPermSize=256m
```
8. Save your changes.
9. After you complete all configurations, select one of the following options:
  - If you are configuring a new deployment, click Activate.
  - If you are updating a deployment, click Apply changes.

---

## Retrieving the contents of an administrative image

After you configure Maximo® Manage to send build images to an external registry, you can retrieve the administrative image and instantiate it in a Docker container. You can then review the contents of the container or use it as a development environment for customizations.

## Before you begin

---

Before you can instantiate a Maximo Manage administrative image in a Docker container, you must complete the following tasks:

1. Install Docker Desktop on your local computer. For more information, see the [Docker Desktop](#) documentation.
2. Configure Maximo Manage to send image builds to an external registry. For more information, see [Storing images in an external registry](#).

## Procedure

---

1. Log in to the Docker image repository, as shown in the following example:  

```
docker login -u <username> -p <password> <your_docker_registry_server>
```
2. Pull the administrative image from the repository as shown in the following example:  

```
docker pull <your_docker_registry_server>/<image_folder>/<adminimagename:tag>
```
3. Run the **docker image** command and get a container shell.
  - a. Run the **docker image** command to get the image ID for the image that you pulled.
  - b. Run the following command:  

```
docker run -d <image id>
```
  - c. Use the **docker ps** command to get the container ID that is running the pulled image.
  - d. Run the following command:  

```
docker exec -it <container id> /bin/bash
```
4. Update the properties in the /opt/IBM/SMP/maximo/applications/maximo/properties maximo.properties file with the URL, user name, and password for your Maximo Manage database.

---

## Setting up a local Maximo Manage development environment

You can set up a local Maximo® Manage development environment to develop and test Maximo Manage Java™ code locally, without having to deploy development images on a remote Red Hat® OpenShift® cluster.

## Before you begin

---

You must have the following prerequisites before you begin:

- Access to a Red Hat OpenShift cluster with minimum Maximo Application Suite 8.9 and Maximo Manage 8.5.
- You must install Podman, which is the container engine for this project, on your system or local development environment. Podman is used to deploy and run a Maximo Manage image locally inside an Open Container Initiative (OCI) container, without Red Hat OpenShift and Maximo Application Suite.

- A build Docker file, which automates the process of building new Manage WebSphere® Application Server Liberty images. These images can then be deployed and run inside a Podman container. The multi-stage docker file contains commands to do the following tasks:
  - Add or replace Manage Java or JSP class files from the local file system to the MWLP image.
  - Configure the web deployment descriptors for local form authentication.
  - Build the EAR file.
  - Build the final MWLP image.
  - Set the necessary environment variables.

---

## About this task

The development environment is based on Maximo Manage images, specifically the Admin and ServerBundle images, which are downloaded from an Red Hat OpenShift internal image registry.

- [Installing Podman and exposing the default route](#)  
Install Podman on your development system to deploy and test the development images.
- [Preparing a development environment](#)  
Before building or deploying new development images, you must first download some images from the Red Hat OpenShift image registry, and tag and push them to a local Podman registry.

---

## Installing Podman and exposing the default route

Install Podman on your development system to deploy and test the development images.

---

## About this task

For more information on downloading and installing Podman, see [Podman Installation Instructions](#).

The development environment uses the Manage Admin and ServerBundle images as a base to build new development images. Therefore, these images must be downloaded from the Red Hat® OpenShift® cluster and tagged or pushed into the local Podman registry. However, before you can download the images, the Red Hat OpenShift internal image registry must be opened up for external access. You can open it up for external access by exposing a route to the internal registry. It is possible to expose custom routes, but it is enough to expose the default Route for this purpose. For more information on exposing routes, see [Exposing the registry](#).

---

## Procedure

1. From the Red Hat OpenShift command-line interface, use **oc patch** to patch the **imageregistry spec** by setting the defaultRoute to *true*.

```
oc patch
configs.imageregistry.operator.openshift.io/cluster --patch '{"spec":{"defaultRoute":true}}'
--type=merge
```
2. Get the login token from whoami and save it somewhere. It is necessary to download the images. The login token looks like **sha256~iqcyr4n41Q4Xc2tZTweRz2qvP9-\_utG8kXN9RmE2qTI**

```
oc whoami -t
```

---

## Results

The basic building blocks are now in place to start developing and creating development images.

---

## Preparing a development environment

Before building or deploying new development images, you must first download some images from the Red Hat® OpenShift® image registry, and tag and push them to a local Podman registry.

- [Pulling and tagging base images](#)  
The manage-admin and manage-bundle builds are used as base images to build new development images.
- [Building and deploying development images](#)  
Your local environment is ready for building and deploying Maximo Manage into a Podman container after you complete pulling and tagging base images.

---

## Pulling and tagging base images

The manage-admin and manage-bundle builds are used as base images to build new development images.

---

## About this task

Pulling and tagging base images is typically a one-time activity until you must have new base images.

---

## Procedure

1. Open a command-line shell like Windows Powershell or Mac Terminal and login to your Red Hat® OpenShift® cluster from Podman by using the following command.

```
podman login -u <username> -p <login token from whoami saved earlier> --tls-verify=false default-route-openshift-image-registry.<cluster hostname>
```

For example, `podman login -u kubeadmin -p sha256~06hW1xtAWvSqFP5WHXqTYDxyAAZtLQJAimXamEIHoOA --tls-verify=false default-route-openshift-image-registry.apps.sachttest.cp.fyre.ibm.com`

2. Pull the Manage admin base image first by using the **podman pull** command.

```
podman pull
default-route-openshift-image-registry.<cluster
hostname>/<namespace>/<image name>
--tls-verify=false
```

Note: "namespace" is the project namespace where Manage is installed on Red Hat OpenShift. The "admin image name" is the name of the admin image. It typically has the instance and workspace that is prefixed to -admin, delimited by a hyphen. For example, **sach-quick-sachdev-admin** where *sach-quick* is the instance name and *sachdev* is the workspace.

For example, `podman pull default-route-openshift-image-registry.apps.gushily.cp.fyre.ibm.com/mas-sach-quick-manage/sach-quick-sachdev-admin --tls-verify=false`

3. Pull the Manage Bundle image in the same way as the Manage Admin image, by using the **podman pull** command.

```
podman pull
default-route-openshift-image-registry.<cluster
hostname>/<namespace>/<image name>
--tls-verify=false
```

Note: "namespace" is the project namespace where Manage is installed on Red Hat OpenShift. The "bundle image name" is the name of the bundle image. It typically has the instance and workspace prefixed to -, delimited by a hyphen. For example, **sach-quick-sachdev-all** where *sach-quick* is the instance name and *sachdev* is the workspace. A specific server bundle contains the WebSphere® Application Server Liberty image with the Manage EAR file. This is the image that runs inside the Podman container and opens MXServer.

For example, `podman pull default-route-openshift-image-registry.apps.gushily.cp.fyre.ibm.com/mas-sach-quick-manage/sach-quick-sachdev-all --tls-verify=false`

4. Tag both the Admin and the Bundle images by using the **podman tag** command.

```
podman tag default-route-openshift-image-registry.<cluster
hostname>/<namespace>/<imagename>
<tag>
```

For example, `podman tag default-route-openshift-image-registry.apps.gushily.cp.fyre.ibm.com/mas-sach-quick-manage/sach-quick-sachdev-all manage-all-dev`

---

## Building and deploying development images

Your local environment is ready for building and deploying Maximo® Manage into a Podman container after you complete pulling and tagging base images.

---

### About this task

You can use a docker build file to build new development images.

The development flow and process can be described in the following way:

1. Make changes and add customizations, and so on, to Java class files.
2. Copy the class files by following the appropriate folder structure.
3. Build the new WLP development image by using the Docker build file. Download the [build](#) file.
4. Deploy the new development image into a new Podman container, which initiates the MXServer.
5. Access the Manage application by using the browser.

---

### Procedure

1. Before you build a new development image, you must update the Docker build file you downloaded. The following environment variables must be edited to reflect your database details.

```
ENV MXE_DB_URL='jdbc:db2://9.30.213.13:50000/bludb'
ENV MXE_DB_SCHEMAOWNER=maximo
ENV MXE_DB_DRIVER='com.ibm.db2.jcc.DB2Driver'
ENV MXE_SECURITY_OLD_CRYPTO_KEY=SzUwFenwARerIQCMotXkisoU
ENV MXE_SECURITY_CRYPTO_KEY=SzUwFenwARerIQCMotXkisoU
ENV MXE_DB_USER=maximo
ENV MXE_DB_PASSWORD=maximo
```

2. After you update the environment variables, use the following command to run the docker file relative to the `./manage-developer/Dockerfile` path.

```
podman build --build-arg BUNDLE=all --tag managedev:latest -f
./manage-developer/Dockerfile
```

Note: The server bundle type can be passed as a build arg. In this example, you are building the "all" wlp image. Depending on the bundle image type that was downloaded from the Red Hat® OpenShift® registry, the appropriate bundle image type arg must be passed. Valid bundle types are all, ui, cron, report and mea. Tag the new development image, for example, `--tag managedev:latest`.

3. When the build is complete, use the following command to see all the images inside the local image registry.

```
podman images
```

You can see at least three images, `manage-all-dev`, `manage-admin-dev`, and `managedev`.

4. After building the development image, you must deploy and run the image inside a Podman container. Run the following command to create a container and start a new process for the image.

```
podman run -dt --name maximo_dev -p 8080:80/tcp
localhost/managedev:latest
```

The -p option publishes the host and container TCP ports. The URL for the Manage application, in this example is <http://localhost:8080/maximo> or <http://localhost/maximo>. The --name flag assigns a name for the container. If this flag is not set, an arbitrary name is assigned.

5. To check if the maximo\_dev process is running, run the following command.

```
podman ps -a
```

You can see a container process named maximo\_dev listed for the managedev image.

6. Start the maximo\_dev container.

The development image is a Websphere Liberty Profile (WLP) image and deploys the Manage application into Liberty and starts MXServer. The following command starts the container in an interactive mode by passing the -i option. It is necessary to run the container in interactive mode so that MXserver can be up and running until the user stops it.

```
podman start -a -i maximo_dev
```

At this point, you can see MXServer starting and all the services, like BulletinBoard, Workorder, Scheduler, and others. When the server is up, you are able to access Manage from the browser.

Note: While testing, it was noticed that during server startup, sometimes the Podman container displays an out-of-memory exception. The reason for this is not yet known. However, recreating the machine typically resolves the issue. Also, adjusting the CPU and memory allocation during machine initialization might help in resolving the issue. The following commands are helpful:

```
podman machine stop
podman machine rm
podman machine init --cpus 2 --memory 2048 --disk-size 20
podman machine start
```

You can refer to a discussion thread to resolve the out-of-memory issue. For more information, see [How can I increase the number of CPUs?](#)

Note: Useful Podman commands:

```
podman machine start (or stop)
podman machine ls (status)
podman images
podman machine rm (removes the VM. Will lose local registry and everything else)
podman machine init (initializes and creates a new VM - start fresh)
podman ps -a
```

---

## Configuring the Help menu

You can add custom menu links to the Maximo® Manage Help menu from Maximo Manage version 8.5 onwards.

### Procedure

---

1. Open menus.xml from resources\presentations\system.
2. Search and check whether the menu ID MASHELP exists.  
If the MASHELP menu ID does not exist, create a new menu with the MASHELP ID.  
Note: The menu ID must be specified by using uppercase letters.
3. Define the custom menu links to appear in the Help menu.
4. Import the menus.xml file by using Application Designer.  
The following example menu entry defines two menu items to appear in the Help menu.

```
<menu
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_config_t_config_help_menu_MASHELP">

<menuitem event="loadlink"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_config_t_config_help_menu_esupportmam11"
label="Support1" link="http://www.ibm.com/support/docview.wss?uid=swg21418666&ibmprd=tivmx7"/>

<menuitem event="loadlink"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_config_t_config_help_menu_esupportmam22"
label="Support2" link="http://www.ibm.com"/>

</menu>
```

Note:

- Only links are supported.
- The event must be defined as loadlink.
- The link property must be defined with a valid link.

---

## Managing Maximo Mobile

Maximo® Mobile is a next-generation mobile application platform that allows users to securely access Maximo Manage functionality from a mobile device.

When Maximo Mobile is enabled, inspections are conducted through the Maximo Mobile user interface. Manage Inspection Forms are located on the Work Center. If Maximo Mobile is not enabled, inspections are conducted on the Work Center.

The Maximo Mobile app is available for download from Google Play and the Apple App Store. After a mobile user installs the app on their device and connects to the Maximo Application Suite server, role based apps that are mobile enabled are downloaded to the device, such as the Technician, Inspections, Service Request and other apps.

- [Introduction to Maximo Mobile](#)  
Maximo Application Suite customers who deployed and activated Maximo Manage can download the Maximo Mobile app from the Apple App Store or Google Play store.
- [Overview of Maximo Mobile authentication and data flow](#)  
You can use the Maximo Mobile application in online and offline scenarios. In an online scenario, the application is connected to Maximo Manage and uses the services and data that are provided. In an offline scenario, the application is not connected to Maximo Manage but continues to operate by using locally stored data.
- [Device requirements for Maximo Mobile](#)  
Device requirements include the operating system level, biometric authentication, and device sharing requirements.
- [Defining security privileges for Maximo Mobile role-based applications](#)  
Maximo Mobile role-based applications such as Technician and Inspections are hybrid applications. These applications can work in a browser, in connected mode or through the mobile application which also supports offline mode. Each mobile application can have one or more settings and object structures that control access to mobile data.
- [Installing the Maximo Mobile app on mobile devices](#)  
For Android or iOS devices, users install the IBM® Maximo Mobile app from Google Play or the Apple App Store.
- [Setting the URL of the Maximo Application Suite server in the Maximo Mobile app](#)  
To use the Maximo Mobile app with IBM Maximo Manage, the URL of your Maximo Application Suite server must be set in the app. The URL can be set manually by the mobile user or set centrally for each user by using a Mobile Device Management (MDM) application.
- [Configuring Map Manager](#)  
Configure Map Manager in an environment with Maximo Spatial Asset Management.
- [Creating a service address with map location](#)  
Create a service address that includes map location data.
- [Preloaded data on mobile devices](#)  
Instead of downloading individual records to initialize a Maximo Mobile application on mobile devices, you can download a compressed database that contains all supporting data.
- [Refreshing data](#)  
You can update the supporting data that is used by Maximo Mobile functions that are running on your mobile device.
- [Troubleshooting Maximo Mobile](#)  
You can identify and correct most errors by responding to the error messages that are displayed on your mobile device.
- [Configuring Maximo Mobile](#)  
After Maximo Manage is installed, the mobile apps are ready for use. Depending on your business needs, you can configure certain aspects of the apps.
- [Configuring and customizing applications with the Maximo Application Framework \(MAF\) Configuration application](#)
- [Anatomy of an application XML file](#)  
The app.xml file contains global elements and attributes that are defined at the beginning of the file.
- [Maximo Mobile Queries](#)  
Maximo Mobile uses queries to retrieve record data from the Maximo Manage server.
- [Adding an owner group reference on a work order](#)  
In the Maximo Mobile Technician application, a Create Work Order page is used by a technician to create a new work order. In some organizations, the technician might be responsible for assigning the ownership of the work order.
- [Maximo Mobile REST APIs](#)  
Maximo Mobile uses REST APIs to download data from Maximo Manage to a user's device.
- [Maximo Mobile application object structures, query information, and security authorization](#)  
Object structures, query information, and related security authorizations that are used in the Technician, Approvals, Inspections, and Service Request applications are listed here. Security authorization listed for applications that are installed using the same security group.

## Related concepts

- [What's new in Maximo Mobile](#)

## Introduction to Maximo Mobile

Maximo® Application Suite customers who deployed and activated Maximo Manage can download the Maximo Mobile app from the Apple App Store or Google Play store.

The functions in Maximo Mobile are also available in Maximo Manage. From the side navigation menu, click Work Orders > Role Based Applications or for inventory features, click Inventory > Role Based Applications.

## The navigator

The navigator is the home page of the app. From here, you can begin many of your key tasks for the day. If you have the correct permissions, you can even create records from the navigator. Tap the plus to create records such as work orders, service requests, and inspections. You can return to the navigator from any page in the app by tapping the navigator menu in the footer.

## Overview of functions

Note: Depending on your permissions, you might not see all the functions.

Table 1. Standard functions

Function	Description	Availability
Approvals	Approve, assign, and monitor work. This function is only visible to users who have the authority to approve work.	From Maximo Mobile version 8.3 and Maximo Application Suite version 8.6
Assets	See the details of all your assets, including their specifications and associated meters.	From version 8.9

Function	Description	Availability
Assets & Digital Twin	Access real-time data from operating assets to learn, diagnose, and take action.	Not available from version 8.10.
Defects	Create defects and use artificial intelligence to analyze photos to identify defects. The Defects function is only available to IBM® Maximo Civil Infrastructure customers.	From version 8.8
Help & Support	Learn more about how to use the app.	All releases
Inspections	Input results in predefined forms and easily review previous results. Create reports from the results of in progress and completed inspections by using the REP_INSPRESULTFORM object structure.	All releases
Inventory Counting	Use count books, ad hoc counts, and reconciliation to ensure valid inventory balances.	From version 8.8
Inventory Receiving	In the Inventory Receiving function, storeroom clerks can receive materials from purchase orders. As part of the receiving activity, the storeroom clerk can inspect and return items, and view or void receipts.	From version 8.10
Map	View the locations of your work on a map and plan your route. The map function requires IBM Maximo Spatial to be installed.	All releases
Materials & Tools	See a checklist of the materials and tools that you need to complete your work.	All releases
My Schedule	View detailed information about your work and complete work orders.	All releases
Service Request	Open a service request to report an issue.	From Maximo Mobile version 8.3 and Maximo Application Suite version 8.6
Settings	Specify your preferences for the app.	All releases

Table 2. Optional functions

Function	Description	Availability
Assist	Get AI insights to increase your fix rate and receive remote expert assistance.	All releases
Parts Identifier	Search for and identify industrial parts by using visual and text-based AI.	From Maximo Mobile version 8.2 and Maximo Application Suite version 8.5

Table 3. Map functions

Icon	Description	Availability
	Add or remove layers to see different information on the map.	All releases
	Save your GPS location.	From Maximo Mobile version 8.3 and Maximo Application Suite version 8.6
	Identify both visible and hidden features on the map.	From Maximo Mobile version 8.3 and Maximo Application Suite version 8.6
	Access more options.	From Maximo Mobile version 8.9
	Download the map for offline use.	From Maximo Mobile version 8.8
	Select a building and view the floor plans.	From Maximo Mobile version 8.9
	Search the map.	From Maximo Mobile version 8.9
	View related records.	From Maximo Mobile version 8.9

## Overview video

Check out the video to learn more about how a technician can complete a work order and an inspection:

## IBM Internet of Things Community

The [IBM Internet of Things Maximo community](#) provides additional information in the form of comprehensive application configuration examples, application upgrade guidance, and other developer resources.

## Related concepts

- [What's new in Maximo Mobile](#)

## Overview of Maximo Mobile authentication and data flow

You can use the Maximo® Mobile application in online and offline scenarios. In an online scenario, the application is connected to Maximo Manage and uses the services and data that are provided. In an offline scenario, the application is not connected to Maximo Manage but continues to operate by using locally stored data.

## Login and authentication

The first time that a user logs in to the Maximo Mobile application, they must have network connectivity, so they can connect to Maximo Application Suite. To log in to the Maximo Mobile application, the user must enter the credentials that they use in Maximo Application Suite. Using a single sign-on, the user is also authenticated with Maximo Manage, and the mobile apps that are on the Maximo Manage server are set up on the device. As part of the initial setup, a local JSON data store is created on the device. The data store is a repository for data that is downloaded from the Maximo Manage server. The data store is encrypted by using a unique key that is saved in the device's keystore. Each time a user opens the Maximo Mobile app, they are prompted for their device's security credentials so the application can access the local data store.

When a user authenticates to Maximo Application Suite, they are granted a token, which is used to authenticate all requests to the server. The token lasts for 12 hours after which the user is prompted to authenticate to Maximo Application Suite again. If the user does not authenticate successfully, they work offline until they authenticate to Maximo Application Suite again. A user can authenticate to Maximo Application Suite at any time by clicking the cloud icon from the application screen.

When you successfully use a biometric method to log in to a mobile device and you authenticate with the server through SSO, you have access to your own local database on the device that is used in offline mode. If another user uses biometrics to log in to the same mobile device, but they do not authenticate with the server, they are still able to access data as the last user to authenticate. If the second user was in offline mode, they would access the local database of the first user. The next time the device was used by the second user in online mode, they are given the option to switch users. If they accept, they can now access their own local database when in offline mode.

A user that has access to the device biometrics may access their own local DB after server authentication success. If user does not pass server authentication and he/she is a second user for the app that has access to the device biometrics, he/she would still be able to access as the last user that logged online if they were to access the application offline(they would use the last user's local DB). Then, if he/she logged online, there will be a popup message to let user confirm whether to switch user, if user confirmed, then the app would load current user's local DB. if not, the user would still access the application offline.

For information about Maximo Mobile security, see [Security and user management](#).

## Online and offline operations

When mobile users are online, Maximo Mobile apps interact with Maximo Manage and exchange data that is represented in JSON format. In Maximo Manage, requests are processed by an OSLC service provider, and a response is returned.

The data that is retrieved from Maximo Manage is automatically saved to the local data store on the device. The availability of locally stored data makes online data operations more efficient, and users can continue to work when a planned or unexpected disconnection occurs. While users are online, local data is automatically synchronized to maintain consistency with Maximo Manage. Users can also manually synchronize data.

When mobile users are offline, requests are processed on the device by using data that was retrieved during online operations. When connectivity is restored, local data is automatically synchronized. Mobile devices are considered offline when the following conditions are met:

- The device is in airplane mode.
- The network adapter of the device is disabled.
- Network bandwidth is low.
- The Maximo Manage is not reachable by the mobile device.
- The login session expires.

Some applications, like Assist and Parts Identifier, require the user to be online.

## Device requirements for Maximo Mobile

Device requirements include the operating system level, biometric authentication, and device sharing requirements.

To run Maximo® Mobile, a device must meet the following system requirements:

- Android version 11 or higher, iOS version 14.3 or higher, or Windows 10 version 10.0.17763.0 or better, or Windows 11 operating system installed.
- If the device is shared between users, the device sharing must be managed by the device operating system, and each user must have their own workspace and user profile. On iOS devices, to support device sharing, a mobile device management (MDM) solution must be installed on the device.
- Windows devices must include the WebView2 Runtime.
- Android devices must support AR Core if you intend to support the Assist application. Refer to [ARCore Supported devices](#) for more information.

Ensure that you have the latest version of Maximo Mobile applications available from public mobile app stores or, if you are using Windows, from the IBM portal.

## Defining security privileges for Maximo Mobile role-based applications

Maximo® Mobile role-based applications such as Technician and Inspections are hybrid applications. These applications can work in a browser, in connected mode or through the mobile application which also supports offline mode. Each mobile application can have one or more settings and object structures that control access to mobile data.

By default, role-based applications do not grant access during installation. Add access to existing security groups. The security for role based applications is made of three parts.

Table 1. Maximo Mobile application security components

Security component	Overview	Example
Object structure	Role-based applications can rely on Maximo Asset Management and multiple object structures to send data and updates. Role-based applications use OSLC/REST calls to exchange data with Maximo Asset Management. You define the level of access to an object structure from the Object Structure tab of the Maximo Asset Management Security groups application.	When you are editing an asset, the MXAPIVENDOR object can provide a list of vendor companies in the application. READ access is the minimum required to view the list of vendor companies in the role-based application.
Object security	Maximo Asset Management does not have an object level security itself. It grants access to object structures which does not ensure that a user has access to the Maximo Asset Management application that owns the object. In the Application security tab of the Maximo Asset Management Security groups application, you can control the level of access to the application and its associated objects.	Maximo Asset Management Companies application must have READ access at minimum to allow the MXAPIVENDOR to access the COMPANIES object.
Application option	Some role-based applications provide the ability to determine what the end user can do. These permissions are determined by the object structure associated with a role-based application. User permissions are defined in the Security options section accessed from the Object Structure tab of the Maximo Asset Management Security groups application.	The Technician role-based application uses the MXAPIWODETAIL object structure. When you select MXAPIWODETAIL from the Object Structure tab, you can control multiple end user features, like status changes, actual reporting and more.

Each application has a security group template. This template gives users the privileges that are needed by each role based application based on the security groups assigned to the user. You can use templates to grant all privileges needed by a role-based application. You can also use templates to view the options available to be configured. You can use the access the Manage/Apply security template option from the Applications tab of the Security Groups application. You can view the application and object structures required by the role-based application. You can grant everyone in a security group access to an application with the Apply Template option.

## Installing the Maximo Mobile app on mobile devices

For Android or iOS devices, users install the IBM® Maximo® Mobile app from Google Play or the Apple App Store.

If the Maximo Mobile app was installed previously for use with the Maximo Mobile Assist app for technicians, you must uninstall the app from each device and install it again.

- **[Configuring self-signed certificates for the Maximo Application Suite server on iOS devices](#)**  
A self-signed certificate can be installed on the Maximo Application Suite server for iOS devices. The certificate must be imported to each iOS device. This feature is intended for testing and development purposes and not intended for production use. Do not use self-signed certificates for production deployments as they can create a security vulnerability.
- **[Configuring self-signed certificates for Maximo Application Suite on Android devices](#)**  
A self-signed certificate can be installed on the Maximo Application Suite server for Android devices. The certificate must be imported on each Android device. This feature is intended for testing and development purposes and not intended for production use. Do not use self-signed certificates for production deployments as they can create a security vulnerability.
- **[Configuring self-signed certificates for the Maximo Mobile Windows application](#)**  
A self-signed certificate can be installed on the Maximo Application Suite server for the Maximo Mobile Windows application. This feature is intended for testing and development purposes and not intended for production use. Do not use self-signed certificates for production deployments as they can create a security vulnerability.

---

## Configuring self-signed certificates for the Maximo Application Suite server on iOS devices

A self-signed certificate can be installed on the Maximo® Application Suite server for iOS devices. The certificate must be imported to each iOS device. This feature is intended for testing and development purposes and not intended for production use. Do not use self-signed certificates for production deployments as they can create a security vulnerability.

### Procedure

---

1. Download the certificate file.
  - a. Access the Maximo Application Suite server page in your browser on a desktop computer. A message indicates that the connection is not private.
  - b. Find and save the certificate of the root certificate authority. On Safari, click to view the certificate, select the root certificate, and drag the file to a folder.
2. Install the certificate profile.
  - a. Use Airdrop to send the saved root certificate file to your iOS device.
  - b. Open the Device Settings page.
  - c. In the User details section of the device settings, click Profile Downloaded.
  - d. In the Install Profile page, click Install.
  - e. If you are prompted, enter the iOS device passcode. A certificate warning is displayed.
  - f. Click Install and click Install again if you are prompted.
  - g. On the Profile Installed page, click Done.
3. Trust the certificate.
  - a. On the device, go to Settings > General > About > Certificate Trust Settings. The installed root certificate is displayed in the Enable Full Trust for Root Certificates.
  - b. Turn on trust for the certificate that you installed and click Continue. The certificate is trusted and enabled and you can proceed to use the Technician and Inspections apps in the Maximo Mobile app.

---

## Configuring self-signed certificates for Maximo Application Suite on Android devices

A self-signed certificate can be installed on the Maximo® Application Suite server for Android devices. The certificate must be imported on each Android device. This feature is intended for testing and development purposes and not intended for production use. Do not use self-signed certificates for production deployments as they can create a security vulnerability.

### Procedure

---

1. Download the certificate file.
  - a. On a desktop computer, in a browser, access the Maximo Application Suite server page. A message indicates that the connection is not private.
  - b. Find and save the certificate of the root certificate authority.
  - c. Copy the certificate file to the Android device.
2. Install the certificate profile on the Android device.
  - a. Open Android settings and then select Encryption & credentials.
  - b. Select Install a certificate and then select CA certificate.
  - c. Select the certificate file that you downloaded.
  - d. After the installation process is complete, select Trusted credentials to ensure that the certificate was successfully installed.

---

## Configuring self-signed certificates for the Maximo Mobile Windows application

A self-signed certificate can be installed on the Maximo® Application Suite server for the Maximo Mobile Windows application. This feature is intended for testing and development purposes and not intended for production use. Do not use self-signed certificates for production deployments as they can create a security vulnerability.

## Procedure

1. Export the certificate in Google Chrome.
  - a. On a Windows system, start Google Chrome, and then open the URL for the Maximo Application Suite server.
  - b. In the address bar of the browser, click Not secure and then click Certificate is not valid.
  - c. In the certificate window, on the Certification Path tab, select the first certificate that is listed in the Certification path tree and then click View Certificate.
  - d. In the new Certificate window, on the Details tab, click Copy to File.
  - e. In the Certificate Export Wizard Welcome panel, click Next.
  - f. Select DER encoded binary X.509(.CER) and then click Next.
  - g. Specify an export file location and then click Next.
  - h. When the export process is complete, click Finish.
2. Import the certificate to the Trusted Root certificate authorities.
  - a. Right-click the exported certificate file and then select Install Certificate.
  - b. In the Certificate Import Wizard panel, select Local Machine and then click Next.
  - c. Select Place all certificates in the following store and then click Browse.
  - d. Select Trusted Root Certification Authorities and then click OK.
  - e. Click Next and then click Finish.

## Setting the URL of the Maximo Application Suite server in the Maximo Mobile app

To use the Maximo® Mobile app with IBM® Maximo Manage, the URL of your Maximo Application Suite server must be set in the app. The URL can be set manually by the mobile user or set centrally for each user by using a Mobile Device Management (MDM) application.

Maximo Mobile supports the standard approach to centrally configuring mobile applications that is defined by the [Appconfig](#) Community. When you load the Maximo Mobile Android app in an MDM application, the configurable settings are displayed, and you can set their values. For the Maximo Mobile iOS app, some MDM applications can load the configurable settings from an AppConfig.xml file. If your MDM application, can load the configuration setting from an AppConfig.xml file, create an appconfig.xml file and copy the following text to the file:

```
<managedAppConfiguration>
 <version>1</version>
 <bundleId>com.ibm.iot.maximo.mobile</bundleId>
 <dict>
 <string keyName="serverURL">
 </string>
 <boolean keyName="allowURLtoBeChanged">
 <defaultValue>
 <value>true</value>
 </defaultValue>
 </boolean>
 <boolean keyName="useSystemBrowserLogin">
 <defaultValue>
 <value>false</value>
 </defaultValue>
 </boolean>
 </dict>
 <presentation defaultLocale="en-US">
 <field keyName="serverURL" type="input">
 <label>
 <language value="en-US">Server URL</language>
 </label>
 <description>
 <language value="en-US"/>
 </description>
 </field>
 <field keyName="allowURLtoBeChanged" type="checkbox">
 <label>
 <language value="en-US">Allow URL to be changed?</language>
 </label>
 <description>
 <language value="en-US"/>
 </description>
 </field>
 <field keyName="useSystemBrowserLogin" type="checkbox">
 <label>
 <language value="en-US"> Use the system browser to log in?</language>
 </label>
 <description>
 <language value="en-US"/>
 </description>
 </field>
 </presentation>
</managedAppConfiguration>
```

For more information, see the documentation for your MDM application.

If your MDM application does not support the AppConfig.xml file, you can add the following settings and their values in your MDM application:

Table 1. AppConfig settings supported by Maximo Mobile

Setting	Type	Description
serverURL	String	The URL of the Maximo Application Suite server to which users connect.
allowURLtoBeChanged	Boolean	Allow the user to change the server URL in the Maximo Mobile application. The default value is <code>true</code> , which allows a user to change the URL in the app if, for example, they want to connect to a different server.
useSystemBrowserLogin	Boolean	The user logs in using the system browser instead of the embedded browser of the app. The default value is <code>false</code> . The user logs in using the system default browser when using the MDM application is used and <code>useSystemBrowserLogin</code> is set to <code>true</code> .

If you are not using an MDM application to manage your devices, you must send the URL of the Maximo Application Suite server to each Maximo Mobile user. Each user must then manually enter the URL of the server in the Maximo Mobile app.

After the URL of the server is set in the Maximo Mobile app, the Maximo Mobile applications, which are deployed on the Maximo Manage server, are set up on the device.

## Configuring Map Manager

Configure Map Manager in an environment with Maximo® Spatial Asset Management.

### Before you begin

Maximo Spatial Asset Management must be deployed in your environment before you can configure Map Manager.

### Procedure

- Log in as an administrator. Select your organization from the Organizations application.
- From the More Actions menu, select Service Address Options.
- Select the coordinate option X and Y and then click OK.
- Open the Map Manager application, select New Map Manager.
- Configure Map Manager general properties.
  - Enter a name and description.
  - Select a measurement unit from the Length and Distance Unit menu.
  - Select Maximo Spatial from the Map provider name menu.
  - Select Enable map?.
- Configure Map Manager map provider properties.
  - Set the geographic information system.
 

For example,

    - Geocode service URL:  
`https://geocode.arcgis.com/arcgis/rest/services/World/GeocodeServer`
    - Route service URL:  
`https://route.arcgis.com/arcgis/rest/services/World/Route/NAServer/Route_World`
  - Add one or more map services:
 

For example,

    - Name:  
`Basemap`
    - URL:  
`https://basemaps.arcgis.com/arcgis/rest/services/World_Basemap_v2/VectorTileServer`
    - Order:  
`100`
    - % Transparency:  
`0`
    - Visible:  
Selected
- Select the Services tab and add services.
  - From the Geocode Services section, add a new row.
 

For example,

    - Name:  
`GeoCodeServer`
    - URL:  
`https://geocode.arcgis.com/arcgis/rest/services/World/GeocodeServer`
    - From Geometry Service section, add the URL.  
`https://sampleserver6.arcgisonline.com/arcgis/rest/services/Utilities/Geometry/GeometryServer`
    - Click Save.
- Add a new site.
  - Select the Map Manager tab.
  - Click New Row and select a site.

- c. Click Map Initial Extent and then click OK.
  - d. Click Save.
9. Configure map tools.
- a. From the Common Actions menu, select Configure Map Tools.
  - b. Search for `Service Address`.
  - c. Click Enable All Map Tools for Selected Application.
  - d. Click OK.
- [Offline areas](#)  
You can create map areas to use when your mobile device is offline.
  - [Map toolbar functions](#)  
The map toolbar contains all the tools that you use to work with the map.

---

## Offline areas

You can create map areas to use when your mobile device is offline.

You can edit the local map data on your mobile device while it is offline. When connectivity is available, you can synchronize the data with the Maximo® Manage server.

- [Creating replicas and downloading to mobile devices](#)  
You can create a copy of map data for offline mobile devices.
- [Creating and downloading vector tile packages](#)  
You can create vector tile packages for offline mobile devices.

---

## Creating replicas and downloading to mobile devices

You can create a copy of map data for offline mobile devices.

---

### Procedure

1. Create and configure the map manager record.
  - a. In the Map Manager application, create a new record.
  - b. Choose Maximo Spatial for the map provider name, add a site, and then enable the MAF map component option.
  - c. Add and configure map services. Map service layers must be enabled for replicas.
  - d. Save the map manager record and then enable the Enable Map option.
  - e. Expand the site that you configured to display the Offline Area Extent section and then add a row.
  - f. Enter an area name and then click Preview.
  - g. Zoom in to select the area on the map that you want to replicate for offline use and then click OK.
  - h. For each Map Replica map service that is listed, click Create Replica.  
After the map replica is created, the Create Replica button is disabled, and Delete Replica button is enabled.
  - i. After the replica is created, click Create Offline Package.  
To download the replica to a device, an offline package must be created. An administrator can create an offline package at any time. This package contains all the replicas of that offline area.
  - j. After the offline package is created, the Package Ready? option is automatically selected which enables the package for download.
  - k. Select the Enable Preload? option to download the replica as preload data to mobile devices.
  - l. Select Configure Mobile Properties from the More Actions menu and then configure the following properties.
    - `pluss.replica.sync.daysToExpire`  
The number of days before an offline map expires. A 0 value indicates that the map never expires.
    - `pluss.replica.device.androidPath`  
The folder name that contains the unextracted VTPK file on the mobile device.
    - `pluss.replica.device.iosPath`  
The folder name that contains the unextracted VTPK file on the mobile device.
    - `pluss.replica.device.windowsPath`  
The folder name that contains the unextracted VTPK file on the mobile device.
  - m. Save the map manager record.
2. Download the offline replica to your mobile device.
  - a. On your mobile device, open the IBM® Maximo® Mobile application and log in.
  - b. Open the mobile application, for example, Technician or Inspections, and then open the map that includes the areas that were selected for the replica.
  - c. Click Offline Area and then click Replicas.
  - d. Select the replica that you want to download and then tap the download icon.
3. Delete the offline replica from your mobile device.
  - a. Open the IBM Maximo Mobile application from your mobile device and log in.
  - b. Open the mobile application, for example, Technician or Inspections, and then open the map that includes the areas that were selected for the replica.
  - c. Click Offline Area and then click Replicas.
  - d. Select the replica that you want and then click the trash icon to delete the replica.
4. Sync the offline replica on your mobile device.
  - a. Open the IBM Maximo Mobile application from your mobile device and log in.

- b. Open the mobile application, for example, Technician or Inspections, and then open the map that includes the areas that were selected for the replica.
- c. Click Offline Area and then click Replicas.
- d. Select the replica that you want and then click the sync icon to synchronize the replica with the server.

## Creating and downloading vector tile packages

You can create vector tile packages for offline mobile devices.

### Before you begin

You must have a .vtpk file available to upload to Maximo® Manage. This file that contains map vector tile data and graphic style resources. You can create a .vtpk file with the Package Toolset of the ArcGIS Data Management toolbox. See [Create Vector Tile Package \(Data Management\)](#) for more information.

### Procedure

1. Create the vector tile package.
  - a. In the Map Manager application, create a new record.
  - b. Choose Maximo Spatial for the map provider name, add a site, and then enable the MAF map component option.
  - c. Add and configure a basemap.
  - d. Save the map manager record and then enable the Enable Map option.
  - e. From the Common Actions menu, click Configure Tile Package .
  - f. In the Upload Offline Tile Packages window, expand the basemap row.
  - g. In the Specify VTPK file section, click Browse.
  - h. Select a .vtpk file from your local system and then click Open.
  - i. Click OK.  
The package file is uploaded to Maximo Manage.
2. Download the .vtpk file to your mobile device.
  - a. On your mobile device, open the IBM Maximo Mobile application and log in.
  - b. Open the Inspections application and then open the map that includes the areas that were selected for the .vtpk file.
  - c. Tap Offline Area and then tap Vector Tile Packages.
  - d. Select the map that you want and then tap the download icon to download the .vtpk file to your mobile device.

## Map toolbar functions

The map toolbar contains all the tools that you use to work with the map.

Table 1. Map toolbar functions

Tool	Icon	Function
Zoom to Previous Extent Tool		Focus on the previous map view.
Zoom to Next Extent Tool		Focus on the updated map view.
Zoom to Initial Extent Tool		Focus on the initial map view.
Zoom to Full Extent Tool		Focus on the entire map.
Basemaps		Dynamically apply basemaps to the current Spatial map. Default basemaps are provided with Maximo Spatial. These basemaps cannot be customized and must be used with Maximo Spatial maps only.
Add or edit a feature on the map		Can be used to edit or add new features to the map. New features are linked to the current record. You must grant users access to the current service layer from the security application to add or edit features with the edit tool.
Full Screen		Expands the map to full screen.
Geocoder		Configure a geocode service for a map manager to find a position on the map with location information. Configure a geocode service from the services tab of the map manager.
Identify		Use the identify tool to show layer data from a selected point on the map. The tolerance control defines the size of a radius that surrounds the selected point. Data from multiple points can be shown. You can add identified feature to the Results window. If the feature is linked to an application record, you can set the record that is associated with the feature as the current record.
Linear Visual Controller		Only available if you installed Maximo Linear.
Print and Export		Specify the URL of a print and export service server on the Services tab of a map to print a copy of the map or export it as a file.

Tool	Icon	Function
Query by Attributes		You create simple or complex attribute queries to identify features on the map and add data to the Results window.
Refresh		Refresh map data.
Results		Opens the Results window so you can view results of feature queries. You can update the map with results in the List tab, or update the List tab with results on the map by using the update functions. You can also merge the results from both sources into one set of results on the List tab and the Results window.
Selection		Opens the Selection Tools window. This window contains the different tools for selecting an area on the map and adding data to the Results window.
Sketch Tool		Draw figures and enter text on a map. When you are finished, you can save the sketch for the record. You can reload the saved sketch the next time you open the map.
Layers		Show all ArcGIS layers and related legend information.
Show Related Work Order		Displays the assets and locations related to a work order.
Find Location		Enter address information to find a location in the current extent of a map. When the address is located, a label is displayed on the map with the address details of the current record.

## Creating a service address with map location

Create a service address that includes map location data.

### Before you begin

Map manager must be configured with a map provider and map services.

### About this task

Service addresses can be associated to assets, locations and work orders. A map pin indicates the record location.

### Procedure

1. Log in as an administrator and open the Service address application.
2. Select New Service Address.
3. Enter a name, description, and site.
4. Select the Map tab.
5. Right-click on any area of the map and select Set record location.
6. Click Save.

## Preloaded data on mobile devices

Instead of downloading individual records to initialize a Maximo® Mobile application on mobile devices, you can download a compressed database that contains all supporting data.

### Overview

In previous releases, initializing a Maximo Mobile application for the first time on a mobile device might take an extended amount of time. Downloading applications and storing supporting data from the server to the mobile device took up most of the time that is spent during the onboarding process.

You can now download a per-populated SQLCipher database that contains all supporting data that is needed by the mobile applications. Each database is customized for a group and delivered as a compressed package to a mobile device.

This database is built on the server regularly by the MobileDbCronTask crontask. When applications are updated, the crontask updates the prepopulated database.

### Person groups

Maximo Mobile determines which prepopulated database to download based on assigned person groups. If a user belongs to more than one person group, then they are shown a list of available databases.

When you update a user profile, confirm that the user is a member of the intended group to ensure that they receive the correct database.

## Crontask configuration considerations

How often your data changes dictates how often the MobileDbCronTask is run. If your data changes daily, you might consider running the crontask weekly. If your organization establishes new users intermittently, you might consider configuring the crontask to run less frequently. Existing users can always refresh data in their mobile application to ensure that they have the latest information.

## Troubleshooting

---

If an error occurs during the creation of the SQLCipher database, the log file provides information about the object structure, query, and select statement that generated the error. Returned fields include USERID, SELECT, TABLENAME, SAVEDQUERY, OBJECTSTRUCTURE, and ERRORMESSAGE. The ERRORMESSAGE field contains the error message that is returned by the OSLC integration and the page that generated the error. The administrator receives an email about the crontask failure with log information.

In addition, the administrator can retrieve status information from the browser by opening `HTTPS://hostname:port/maximo/oslc/graphite/mobile/db?info=1&user=username`. The complete mobile ID record is displayed in JSON for the user who is specified in the user parameter. If no user is specified, information for the user who is logged in is displayed. If the info parameter is set to `all`, then all of the mobile ID records are returned as JSON.

You can download the entire database as a compressed file to examine its contents. For example, you might want to verify that all expected data is included. Retrieve the database file from the browser by opening `HTTPS://hostname:port/maximo/oslc/graphite/mobile/db?mobileDbId=mobiledbid`.

The *mobiledbid* value can be found in the Maximo Mobile logs by searching for MOBILEDBID.

- [Creating preloaded data for mobile devices](#)

You can create a preloaded database that contains all supporting data to save mobile application users time when they are onboarding.

## Related information

---

- [Maximo Mobile - How to setup preloaded database to improve lookup download performance?](#)

---

## Creating preloaded data for mobile devices

You can create a preloaded database that contains all supporting data to save mobile application users time when they are onboarding.

### About this task

---

Create a cron task that creates the preloaded database that includes the data for all lookup data sources that are defined in Maximo® Mobile applications.

### Procedure

---

1. Log in as an administrator and create a user.  
This user is the template user that is used by Maximo Mobile to create the preloaded database. The cron task queries that are used to retrieve the data to load in the database are sent by the template user.
2. Define a default insert site for the user.
3. Assign the user to any standard groups that are used by your organization.
4. Create a person group.
5. Assign the template user as the default user of the new person group.
6. Assign other users to the new person group, so they can receive the preloaded database that is associated with that group.
7. Open the Cron Task Setup application, search for the MobileDbGeneration cron task and then click to configure it.
8. Click New Row to create a new instance for the MobileDbGeneration cron task and then name it.
9. Specify the schedule for the cron task, mark it as active, and then enter the template user in the Run as User field.

### Results

---

Whenever the cron task runs, the preloaded database is created and stored in the Maximo database.

---

## Refreshing data

You can update the supporting data that is used by Maximo® Mobile functions that are running on your mobile device.

### About this task

---

The Maximo Mobile navigator consolidates transaction upload and data download tasks. You can refresh several types of data. Transaction data includes a transaction list to upload to the server. Configuration data includes user data and system configuration data. Functions data used to download a compressed file. Record data consists of function data that supports working in offline mode.

### Procedure

---

1. Open the Maximo Mobile navigator on your mobile device.
2. Refresh data with default updates.

- a. Open the Data update screen.
  - b. Tap the refresh icon.

Record data is refreshed according to the options that you selected from the Record data options screen.

All data is refreshed, including transactions, configurations, functions, and record data.
3. Refresh record data with custom updates.
  - a. Open the Data update screen.
  - b. Tap the Options icon.
  - c. Select the data that you want to update.

Choices include Supporting data, Map data, Work list data, and attachments. If Work list data is selected, attachments cannot also be selected. To enable the download of attachments, select the option from the Offline data screen from Settings.
4. Refresh with all updates of record data.
  - a. Open the Settings screen.
  - b. Select Full record update, and then tap Update all record data.

All record data is downloaded.

## Results

---

All functions are placed in a waiting status, and they cannot be accessed until the data download is completed.

## Troubleshooting Maximo Mobile

---

You can identify and correct most errors by responding to the error messages that are displayed on your mobile device.

- [Troubleshooting applications on Android](#)  
A debug version of Maximo Mobile for troubleshooting issues is available from IBM® Support.

## Troubleshooting applications on Android

---

A debug version of Maximo® Mobile for troubleshooting issues is available from IBM® Support.

### About this task

---

If you encounter issues while using Maximo Mobile, you can contact IBM Support to receive the debug version of Maximo Mobile.

## Procedure

---

1. Uninstall the release version of Maximo Mobile that you downloaded from the Google Play store.
2. On the mobile device, install the APK file for the debug application.
3. Verify that the Developer Options setting is ON.
4. Enable USB debugging in Settings > System > Advanced > Developer Options > USB debugging.
5. Connect the mobile device to your desktop by using a USB cable.
6. On the desktop, start the Chrome web browser and open the Web Inspector and Debugger tool.
7. Locate the mobile device and application.  
Application entries are named com.ibm.iot.maximo.mobile or com.ibm.iot.maximo.mobileeam.
8. Click Inspect.  
There are two inspectors available for an application. To inspect Network Requests, use Maximo Mobile Network/DB Inspector. To debug other issues or to inspect the DOM, use the default inspector.
9. Review the collected data.

## Results

---

You can review the collected data. You can use the debug version for up to 30 days. If you need to continue collecting data, you must reinstall the debug version of the application.

## Configuring Maximo Mobile

---

After Maximo® Manage is installed, the mobile apps are ready for use. Depending on your business needs, you can configure certain aspects of the apps.

- [Configuring default bar code formats](#)  
By default, the bar code reader in the Maximo Mobile applications tries to read all bar code formats. To reduce the number of formats that the bar code reader tries to read, you must specify one or more default formats that are used in your organization.
- [Configuring properties that affect mobile apps](#)  
In Maximo Manage, you can set system properties that affect the Maximo Mobile Technician and Inspections apps.
- [Push notifications](#)  
Push notifications are messages sent from the server to mobile devices when Maximo Mobile applications are being used.

- [Recording physical signatures](#)  
Maximo Mobile applications can be configured to require physical signatures for work orders based on their statuses. For example, before a work order is completed, the Technician application can prompt the user to sign the work order and then change its status to complete. This feature is not enabled by default.
- [Recording e-signature keys](#)  
Use e-signature keys on your mobile device to confirm that a change is complete and valid.
- [Configuring application links](#)  
You can configure an application to open from the field of another application. For example, you can open the Inspections application from a field in the Work Order Tracking application.
- [Enabling photo analysis by IBM Maximo Visual Inspection](#)  
To help inspectors detect defects during inspections, you can enable analysis of the photos that the inspector takes during the inspection. The analysis is completed by IBM® Maximo Visual Inspection.

## Configuring default bar code formats

By default, the bar code reader in the Maximo® Mobile applications tries to read all bar code formats. To reduce the number of formats that the bar code reader tries to read, you must specify one or more default formats that are used in your organization.

### Before you begin

Bar code scanning must be performed by using the camera on your mobile device. No other methods are supported. In addition to bar codes, QR codes are also supported.

### Procedure

1. Open the controller.js file for each app.
2. Locate the following line in the file:  
`'mxe.barcode.readers':  
['all_formats']`
3. Change the default value of the property, which is **all\_formats**, to the default formats that you want to use. If you want to specify multiple formats, use a comma separator, for example:  
`'mxe.barcode.readers':  
['code_128_reader', 'upc_reader']`  
The following bar code formats are supported:
  - code\_128\_reader
  - ean\_reader
  - ean\_8\_reader
  - code\_39\_reader
  - code\_39\_vin\_reader
  - codabar\_reader
  - upc\_reader
  - upc\_e\_reader
  - i2of5\_reader
  - 2of5\_reader
  - code\_93\_reader
4. Save the controller.js file.
5. Optional: In the Technician and Inspections apps, any button that scans bar codes tries to read all of the default bar code formats that you specified. In the app.xml for either app, you can override the default bar codes formats that an individual button in the app tries to read.
  - a. For each app, open the app.xml file.
  - b. Locate the line that contains the button that you want to configure, for example:  
`<barcode-button  
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_config_barcodebut  
ton1" on-scan="handleBarcodeScan" timeout="30"  
label="ScanBarcode"/>`
  - c. Add the readers property to the line and specify one or more bar code formats, for example:  
`<barcode-button  
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_config_barcodebut  
ton1" on-scan="handleBarcodeScan" timeout="30"  
label="ScanBarcode"> readers="[ 'ean_reader' ]"/>`
  - d. Save the app.xml file.
6. Build the apps and deploy them to the Maximo Manage server.

## Configuring properties that affect mobile apps

In Maximo® Manage, you can set system properties that affect the Maximo Mobile Technician and Inspections apps.

You configure system properties in the System Properties application in Maximo Manage. The following table describes the system properties that you can configure for mobile apps.

Table 1. System properties that affect mobile apps

Property	Description
----------	-------------

Property	Description
mxe.mobile.travel.radius	The radius from the user's GPS location to the work order over which travel time can be tracked. Depending on the user's region, the value is measured in kilometers or miles.
mxe.mobile.travel.prompt	Users can track travel time when the value in mxe.mobile.travel.radius is matched or exceeded. Set to 1 to enable.
mxe.mobile.travel.navigation	In the Maximo Mobile Technician and Inspections apps, when a user clicks Start travel, a map opens to help the user get to the location of the work. Set to 1 to enable.
mxe.mobile.navigation.ios	When you start a trip, a Maximo Mobile application opens a map service to help you navigate to your destination. Valid values for this property are <code>AppleMaps</code> , <code>GoogleMaps</code> , or <code>Waze</code> . This property requires the mxe.mobile.travel.navigation property to be enabled.  Longitude and latitude coordinates are reported. Information about x and y axes is not provided.  IOS devices default to using <code>AppleMaps</code> .
mxe.mobile.navigation.android	When you start a trip, a Maximo Mobile application opens a map service to help you navigate to your destination. Valid values for this property are <code>AppleMaps</code> , <code>GoogleMaps</code> , or <code>Waze</code> . This property requires the mxe.mobile.travel.navigation property to be enabled.  Longitude and latitude coordinates are reported. Information about x and y axes is not provided.  Android devices default to using <code>GoogleMaps</code> .
mxe.mobile.navigation.windows	When you start a trip, a Maximo Mobile application opens a map service to help you navigate to your destination. Valid values for this property are <code>AppleMaps</code> , <code>GoogleMaps</code> , or <code>Waze</code> . This property requires the mxe.mobile.travel.navigation property to be enabled.  Longitude and latitude coordinates are reported. Information about x and y axes is not provided.  Windows devices default to using <code>GoogleMaps</code> .
maximo.mobile.fetch.timeout	The time in milliseconds that the Maximo Mobile app waits for a response from the server and also the minimum time that the app stays offline if a response is not received. After the minimum time that the app stays offline expires, the app tries to connect to the server the next time that the mobile user sends a request to the server.
mxe.app.workorder.InspectionBatchRecord	Set to 1 to create batch records for inspections in the same work order, regardless of the hierarchy of the work order. This property is set to 1 by default.
mxe.app.workorder.StatusToCreateInspection	Defines the internal work order status where the inspection result is created.
mxe.app.inspection.UpdatePendingResults	Set to 1 to update pending inspection results with the newest active revision.
mxe.mobile.inspection.mobilefeatures	Enables features in Maximo Mobile that are not supported in Conduct an Inspection Work Center.
mxe.mobile.inspection.features.signature	Enables signature input on Inspections forms.
mxe.mobile.inspection.features.multiselect	Enable multi-select input on Inspections forms.
maximo.mobile.usetimer	Specifies whether Start work starts the timer. Set to 0 to change status only and not start the timer.
maximo.mobile.statusforphysicalsignature	The status that requires the user to provide a physical signature.
maximo.mobile ldap.isForm	This property is used by Maximo Mobile to detect what LDAP authentication method is used.
maximo.mobile.completestatus	The status that the work order changes to <code>Complete</code> when work is tapped in Maximo Mobile.
mxe.webclient.resetMobileSCCache	Reset the mobile start center cache. Resetting the cache might cause portlet loading issues.
maximo.mobile.allowmultipletimers	Determines whether multiple timers can be started at the same time. The default value is <code>true</code> . When set to <code>false</code> , the user can start one timer at a time in Maximo Mobile. Multiple work orders can still have In Progress status. This value applies only for transactions that are started by the user who is logged in to the mobile device.
maximo.mobile.attachments.bulkDownload.automatically	Automatically downloads files that are attached to a record every time transactional records such as work orders are downloaded or refreshed on a mobile device. You do not need to open each mobile application to download attachments. The default value is <code>true</code> .
maximo.mobile.attachments.bulkdownload.filesizelimit	The maximum file size for a file that can be downloaded in the bulk download process. Users can still download the file through the attachment page. The default value is 5120 KB.
maximo.mobile.attachments.bulkDownload.zipcount	The increment used to communicate progress of the bulk download of attachments. Progress count is displayed at the interval of the increment. For example, 10 of 100 is displayed, followed by 20 of 100. The default increment display value is 10.
maximo.mobile.attachments.bulkdownload.filetypes	Attachment file types available for bulk download. File types include jpg, png, mp4, pdf, doc, xls, and xlst. All file types are included by default.
maximo.mobile.ios.zipdownload.timeout	Dictates the timeout value in milliseconds for IOS native zip file downloads. IOS native zip file downloads include application files, the preloaded database package, and attachments.
mci.mvi.apikey	The API key of your Maximo Visual Inspection instance. This property is associated with the mxe.mobile.inspection.features.mviintegration property.

Property	Description
mci.mvi.apiUrl	The URL of your Maximo Visual Inspection instance. This property is associated with the mxm.mobile.inspection.features.mviintegration property.
mxm.mobile.inspection.features.mviintegration	Enables Maximo Visual Inspection photo analysis in Maximo Mobile.
maximo.mobile.esignatureenabled	Set to true to enable e-signatures to be used to confirm the status change of a work order in the Technician application.
maximo.mobile.wostat.usforesig	Set to a work order status that requires an e-signature. For example, COMP.
mxm.allownativeesig	Set to true to require a native key for Maximo Asset Management instead of user credentials. This property is required to enable e-signatures in Maximo Asset Management.

## Push notifications

Push notifications are messages sent from the server to mobile devices when Maximo® Mobile applications are being used.

Creating and implementing push notifications consists of several configuration steps.

- Configuring Apache Kafka or JMS queues.
- Configuring Maximo Manage notifications and subscribers.
- Generating and configuring an API Key for Maximo Application Suite.
- [Integrating Apache Kafka queues with Maximo Manage](#)  
Integrate Apache Kafka queues with Maximo Manage to implement notification messaging.
- [Integrating JMS queues with Maximo Manage](#)  
Integrate JMS queues with Maximo Manage to implement notification messaging.
- [Creating and configuring API keys for push notifications](#)  
Push notifications require API Keys.
- [Configuring Maximo Application Suite notifications](#)  
Configure a Maximo Application Suite notification and set user subscriptions.

## Integrating Apache Kafka queues with Maximo Manage

Integrate Apache Kafka queues with Maximo® Manage to implement notification messaging.

### Before you begin

This example assumes you already have a notification queue created in Kafka. For this example, the notification queue is named notfqueue.

### Procedure

1. Add a Kafka provider.
  - a. From Maximo Manage, open the External Systems application.
  - b. Add or select the external system and then select Add/Modify Message Providers to open the Message Hub Provider dialog box.
  - c. Set a name for your provider, KAFKA for example, and then set the properties required to connect to your Kafka server.

For more information, see [Specifying Kafka providers for message processing](#).
2. Add the Kafka queue to Maximo Manage.
  - a. From the External Systems application, select Add/Modify Queues.
  - b. Click the new row icon. For the Message Provider field, click the lookup icon and select the Kafka message provider that you specified.
  - c. For the Queue JNDI Name field, click the lookup icon and select the Kafka notification queue.  
For example, notfqueue.
  - d. Deselect Inbound.
  - e. Notification queues are sequential outbound.
  - f. Click OK.

For more information, see [Adding queues to external systems](#).
3. Create a Kafka cron task instance.
  - a. Open the Cron Task Setup application.
  - b. From the Cron Task field, search for Kafka.
  - c. Click the Kafka row to open the cron task.
  - d. From the Cron Task Instances list, click the new row icon to add an instance for the notification queue.
  - e. In the Details section, enter a Cron Task Instance Name.  
For example, kafkanotf.
  - f. Enter values for Schedule, Run as User, and other fields as required.
  - g. Enable the Active? option.
  - h. In the Parameters section, enter a name in the Value field of the TOPIC cron task parameter.  
For example, notfqueue.
  - i. Set the PARTITION parameter to 0.
  - j. Set the MESSAGEPROCESSOR parameter to com.ibm.tivoli.maximo.notification.NotificationMessageProcessor.

- k. Set the MESSAGEHUB parameter to the name of your message provider.  
For example, KAFKA.
  - l. Save the record.
- For more information, see [Configuration of the Kafka cron task](#).
4. Set the notification external system.
  - a. Open the External Systems application.
  - b. From the System field, search for NOTIFICATION.
  - c. Click the NOTIFICATION row to open the NOTIFICATION record.  
The NOTIFICATION system is the default system used for notifications. Use this system for all notification configuration. Do not create a new system to handle notifications.
  - d. If the Enable? option is enabled, deselect the option to disable it, and then save the record.
  - e. For the Outbound Sequential Queue field, click the lookup icon and select the Kafka notification queue.  
For example, notfqueue.
  - f. Enable the Enable? option, and then save the record.

---

## Integrating JMS queues with Maximo Manage

Integrate JMS queues with Maximo® Manage to implement notification messaging.

### Before you begin

---

This example assumes you have a **standalonejms** JMS server configured in the Maximo Manage environment with a notification queue named notf. For more information, see [Configuring JMS servers for Maximo Manage](#) and [Configuring Manage JMS Resources](#).

### Procedure

---

1. Create a JMS cron task instance.
  - a. Open the Cron Task Setup application.
  - b. From the Cron Task field, search for JMS.
  - c. Click the JMSSEQCONSUMER row to open the cron task.
  - d. From the Cron Task Instances list, click the new row icon to add an instance for the notification queue.
  - e. In the Details section, enter a Cron Task Instance Name.  
For example, jmsnotf.
  - f. Enter values for Schedule, Run as User, and other fields as required.
  - g. Enable the Active? option.
  - h. Set the QUEUENAME parameter to jms/maximo/int/queues/notf.
  - i. Set the MESSAGEPROCESSOR parameter to the name of your message provider.  
For example, com.ibm.tivoli.maximo.notification.NotificationMessageProcessor.
  - j. Save the record.
2. Set the notification external system.
  - a. Open the External Systems application.
  - b. From the System field, search for NOTIFICATION.
  - c. Click the NOTIFICATION row to open the NOTIFICATION record.
  - d. If the Enable? option is enabled, deselect the option to disable it, and then save the record.
  - e. For the Outbound Sequential Queue field, click the lookup icon and select the JMS notification queue.  
For example, jms/maximo/int/queues/notf.
  - f. Enable the Enable? option, and then save the record.

---

## Creating and configuring API keys for push notifications

Push notifications require API Keys.

### Procedure

---

1. Generate an API Key.
  - a. Open a browser and enter <https://c069b665-us-south.apigw.appdomain.cloud/auth/login>.
  - b. Click Sign in or up.
  - c. Log in to IBM with an IBMid.
  - d. Enter a name for the API Key and then click Generate API Key.
  - e. Copy the API Key value.
2. Configure the API Key in Maximo® Application Suite.
  - a. Log in to Maximo Application Suite.
  - b. Click the Administration icon and then click Configurations.
  - c. In the Users and identity section, click Push Notification.
  - d. Click Edit and enter the following values:

Bundle identifier:  
com.ibm.iot.maximo.mobile  
URL:

<https://c069b665.us-south.apigw.appdomain.cloud/pushnotification/sendPushNotification>

API Key

Enter the API Key value that you copied.

e. Click OK.

---

## Configuring Maximo Application Suite notifications

Configure a Maximo® Application Suite notification and set user subscriptions.

### About this task

---

In this example, you create a notification for the Technician application and add the user Smith to the Notification User Subscription. For more information, see [Creating notification events](#).

### Procedure

---

1. From Maximo Manage, open the Notifications application.
2. Click Create Notification from the Common Actions menu.
3. In the Event name field, enter `MXAPIWODETAIL`.

This value is the name of an API used by the Technician application.

4. Enter a description of the event.  
For example, type `Send emergency work order notification`.
5. Enter a condition for the Apply to Condition field.

For example, create a condition that sends a notification for work order approvals.

- a. For the Apply to Condition field, click the lookup icon and select Go To Conditional Expression Manager.
- b. From the Conditional Expression Manager application, click the new row icon.
- c. For the Condition field, enter `WOAPPR`.
- d. For the Type field, select `EXPRESSION`.
- e. For the Expression field, enter `:status='APPR'`.
- f. Select the Always Evaluate? option.
- g. Click Save Condition from the Common Actions menu.
- h. Click Return With Value.

For more information, see [Conditional Expression Manager](#).

6. In the Apply To Condition field, enter `WOAPPR`.
  7. In the Object Structure field, enter `MXAPIWODETAIL`.
  8. Create a notification message template.
    - a. Click Notification Message Template from the More Actions menu.
    - b. Click New Row.
    - c. In the Notification Template field, enter `WOAPPR` for the name for the notification template.
    - d. Select Message Text as the Notification Message Type and enter `Work order :wonum was approved.` for the message.
    - e. Click OK.
- For more information, see [Creating notification message templates](#).
9. For the Use With field, click the lookup icon and select `TECHMOBILE` to select the Technician application.
  10. For the Message Template field, click the lookup icon and select `WOAPPR` to select the work order approval message template.
  11. Select the On Update? option to trigger the event when the work order is approved.
  12. Select the Using AND option for Attribute Conditions.  
You can set other conditions as needed.

Apply to

Defines the objects affected by an event when it occurs. Use this attribute to filter the list of notification events for an object. This condition, if set, is combined with the event filter condition using an AND operator. These two conditions determine when the notification event occurs.

Event filter

The Event filter condition is combined with both the Attribute condition and the Apply to condition using an AND operator. Like the Apply to condition, the Event filter condition applies to the whole object.

Attribute condition

Attribute conditions can be combined with AND or OR operators. Use Attribute condition to track the state of the object attribute whether it has been modified or not. Optionally, you can also compare the attribute value.

All attribute conditions can be combined with an object operation, on Add, Update, or Delete, using an AND operator.

13. Click New Row from the Attributes list.
14. For the Modified Attribute field, click the lookup icon, select `WOPRIORITY`, and then set the Value field to `1`.
15. Save the record.
16. Configure notification recipients.
  - a. Click Notification User Subscriptions from the More Actions menu.
  - b. Click New Row.
  - c. In the Event For User field, select `SMITH`.  
As an alternative, you can configure the owner of the work order to receive the notification by entering `:OWNER`.
  - d. In the User Notification Type field, select `PUSHNOTIFICATION`.
  - e. Click OK.

For more information, see [Creating notification message templates](#).

## Recording physical signatures

Maximo® Mobile applications can be configured to require physical signatures for work orders based on their statuses. For example, before a work order is completed, the Technician application can prompt the user to sign the work order and then change its status to complete. This feature is not enabled by default.

### About this task

You can record and store images of signatures that are submitted from Maximo Mobile applications. Each signature is stored as an image and as part of an attachment object. The attachment description is automatically populated with the signature and the date and the time of the signature. A default name is also given to the image, which includes the status of the record it is associated with. After a signature is recorded, it can be retrieved from the attachment list of the signature's associated work order or item.

The signatures can be recorded in both connected and disconnected mode, but the signatures cannot be modified after they are recorded.

### Procedure

1. Log in to Maximo Manage and in the System Properties application, open the maximo.mobile.statusforphysicalsignature property.
2. Clear the Nulls Allowed checkbox.
3. Enter one or more status values in the Global Value field.  
For example, enter `APPR` or `COMP`.
4. Save the changes.
5. On a mobile device, open the Technician application and then open the details page for a work order.
6. Change the status of the work order to Approved.
7. Write your signature and click OK.  
The status of the work order is set to Approved.

## Recording e-signature keys

Use e-signature keys on your mobile device to confirm that a change is complete and valid.

### Before you begin

E-signature keys must be enabled in the Maximo® Manage system properties before you can use them. Enable the following system settings:

Table 1. Configuring e-signature system properties

Property	Summary
maximo.mobile.esignature enabled	Set to true to enable e-signatures to be used to confirm the status change of a work order in the Technician application.
maximo.mobile.wostatusforresig	Set to a work order status that requires an e-signature. For example, <code>COMP</code> .
mxe.allownativeesig	Set to true to require a native key for Maximo Asset Management instead of user credentials. This property is required to enable e-signatures in Maximo Asset Management.

### About this task

Maximo Manage e-signature keys capture and validate work order status changes on the My Schedule page in the Technician application. E-signature keys can also be used with applications that are duplicated from the Technician application.

When you change the status of a work order, and you enter an e-signature key on your mobile device, the work order status change transaction is sent to the Maximo Manage server. The e-signature verification request is sent to the Maximo Manage server after the status change transaction is completed. If you lose your connection to the Maximo Manage server before the e-signature key is sent, it is sent when you reconnect. Due to many factors, it might take an extended amount of time for the status change transaction to be completed.

When it is created, an e-signature key is stored both on the server and the mobile device. When you enter an e-signature key on your mobile device, the Technician application verifies it with the e-signature key that is stored on the Maximo Manage server. If you are using your device in either online or offline mode, the e-signature key is verified against the e-signature that is stored on your device. If your e-signature key is changed on the Maximo Manage server while you are logged in to the mobile device, you must log out and log back in to use the new e-signature key.

You can create an e-signature key from your mobile device during the Maximo Mobile onboarding process. If the Technician application is not installed on your device, you are still prompted for an e-signature if it is enabled on the Maximo Manage server. Alternatively, an e-signature key can be captured and stored on the server in the user profile. E-signature keys can be changed only on the Maximo Manage server.

If you log out of Maximo Mobile on your mobile device, then you are prompted for an e-signature key when you next log in. If you refresh data on the Data update page in Maximo Mobile, then you are prompted for an e-signature key.

IBM® Maximo Asset Management and IBM Maximo Application Suite both require e-signature keys to sign off on work order status changes. When you switch from Maximo Asset Management to IBM Maximo Application Suite, you must enable e-signature system properties and create an e-signature key in each user profile.

E-signatures keys are not supported in the web version of the Technician application.

Every object and attribute in Maximo Manage can be configured to require an e-signature key. The e-signature key is tracked by using the logintracking object, which validates the change and associates the user, date, time, the originator record, and the reason for the change.

## Procedure

---

1. As a new user, log in to the Technician application on a mobile device.
2. When prompted, set an e-signature key.
  - a. Enter your user ID.
  - b. Enter and verify a new e-signature key.  
E-signature keys must include at least one uppercase character, one lowercase character, a number, and a special character, such as !, @ #, or \$.
  - c. Tap Save.

---

## Configuring application links

You can configure an application to open from the field of another application. For example, you can open the Inspections application from a field in the Work Order Tracking application.

## Procedure

---

1. Log in to Maximo® Manage and open the Application Designer application.
2. Search for the application you want to modify.  
For example, search for `WOTRACK` to open the Work Order Tracking application.
3. Select a field in the application.  
For example, select the Inspection Result field of the Work Order Tracking application.
4. Open the Properties window for the field.
5. From the Go To Applications field, click the magnifying glass icon to open the application search window.
6. Search for a Mobile application.  
For example, `INSPECTION`.
7. Click the name of the application and then click OK.

## Results

---

You can now open the Inspection application from the Inspection Result field of the Work Order Tracking application.

---

## Enabling photo analysis by IBM Maximo Visual Inspection

To help inspectors detect defects during inspections, you can enable analysis of the photos that the inspector takes during the inspection. The analysis is completed by IBM® Maximo® Visual Inspection.

## Before you begin

---

If Maximo Civil Infrastructure is not installed, configure the object structures:

1. Log in to Maximo Manage as an administrator.
2. Go to System Configuration > Migration > Object Structures.
3. Open the MXAPIINSPECTIONRES object structure.
4. In the Source Objects for MXAPIINSPECTIONRES table, add a row.
5. In the Object field, select INSPECTIONIMAGEINFERENCE.
6. In the Parent Object field, select INSPFIELDRESULT.
7. In the Relationship field, select IMAGEINFERENCE.
8. Save your changes.

## About this task

---

This feature is only available to customers who have both Maximo Manage and Maximo Visual Inspection. If a suitable model for the inspection type does not exist, you must ask your Maximo Visual Inspection administrator to create the model.

## Procedure

---

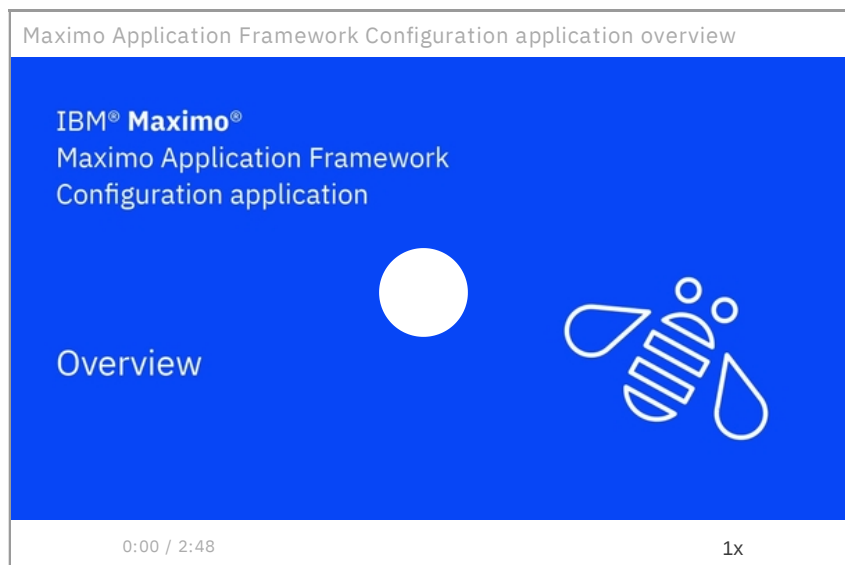

1. From the side navigation menu, click Planning > Manage Inspection Forms.
2. Create an inspection form or create a revision of an existing inspection.
3. Open the inspection form and add a question.
4. Complete the details of the question and from the Response Fields menu, select Media > File upload so that the inspector can upload the photo for analysis.
5. In the Model field, select the name of the model that you want Maximo Visual Inspection to use to analyze the photo.  
If you do not see the Model field, ask your system administrator to check the values in the required system properties.
6. Click Done.

## Results

During an inspection, an inspector can upload a photo and select Analyze photo. The inspector can continue the inspection while the photo is analyzed to detect anomalies. When the analysis is complete, the inspector can review and edit the results.

## Configuring and customizing applications with the Maximo Application Framework (MAF) Configuration application

You can use the MAF Configuration application to update applications that are built with the Maximo Application Framework. The MAF Configuration application supports IBM® Maximo® Mobile, IBM Maximo Health, and IBM Maximo Manage. Additionally, you can also configure non-mobile, role-based applications, such as Workflow Assignments.

The MAF Configuration application works through Docker container technology and Maximo Application Framework tools. Maximo Application Framework tools are used to create a configuration environment within a Docker image on your local system. You can download, modify, preview, and publish your configured IBM Maximo Manage applications with minimal setup.

- [Prerequisites](#)
- [Component reference](#)
- [Deprecated Maximo Application Framework components](#)  
Maximo Application Framework application components are sometimes deprecated and replaced.
- [Serviceability](#)
- [Removing Docker containers through the command line](#)  
Downloading Docker images and instantiating multiple containers can use significant disk space. Remove unneeded Docker containers periodically.
- [Command variable legend](#)
- [Configuration and customization summary](#)
- [Maximo Application Framework Configuration application deployment](#)
- [Maximo Application Framework Configuration application use](#)
- [Application upgrade](#)  
After you configure an application, create an upgrade plan for fix packs and upgrades.

## Prerequisites

Get your environment ready to deploy the Maximo Application Framework Configuration application.

- A minimum of 8 GB RAM on the development system (16 GB recommended).
- Docker Desktop (<https://docs.docker.com/desktop/>) or Docker Engine (<https://docs.docker.com/engine/>) installed on your development system. Docker engine can be installed natively on Linux® systems. For Windows, Docker must be installed on a Windows Subsystem for Linux (WSL) version 2 backend. For Mac OS, a Docker engine-supported operating system must be installed on VM. Ensure that your system meets all Docker requirements. Set the Memory Resources preference in Docker Desktop to 8 GB of memory.
- A working directory on your local system. The working directory is used to run Docker commands to start the Maximo Application Framework Configuration application. Make a note of the location of your working directory for future configuration efforts.
- Ensure that API Key is enabled on the Maximo® Manage application server. You must configure the mxe.oslc.webappurl system property with the name of your Maximo Asset Management or Maximo Manage server. For more information, see [API Keys](#) and [Setting system properties](#).
- If you are using Windows, you must have the Windows Subsystem for Linux (WSL) version 2 installed on your system.
- To configure the Maximo Application Framework Configuration application as an ODIC client for Maximo Application Suite, see [Manage OpenID client for Configuration Tool](#).

## Component reference

A Maximo® Manage component reference is available from the side panel of the application. This information describes the properties and XML code of Maximo Manage application components.

## Deprecated Maximo Application Framework components

Maximo Application Framework application components are sometimes deprecated and replaced.

- [container](#)

The Maximo Application Framework container component used to configure application layout is deprecated in Maximo® Application Suite v8.10. The box and border-layout components are now used for application layout. Refer to the [graphite component reference guide](#) for the latest information about Maximo Application Framework components and properties.

## container

The Maximo Application Framework container component used to configure application layout is deprecated in Maximo® Application Suite v8.10. The box and border-layout components are now used for application layout. Refer to the [graphite component reference guide](#) for the latest information about Maximo Application Framework components and properties.

Table 1. Layout component properties. Property information for migrating from the container component to the box component

container		box		Remarks
Property	Value	Property	Value	
layout	<ul style="list-style-type: none"><li>• vertical</li><li>• horizontal</li></ul>	direction	<ul style="list-style-type: none"><li>• column</li><li>• row</li></ul>	
align-self	<ul style="list-style-type: none"><li>• start</li><li>• end</li></ul>			The box component does not support the align-self property. Use the horizontal-align and vertical-align properties as an alternative.
hidden	<ul style="list-style-type: none"><li>• true</li><li>• false</li></ul>	hidden	<ul style="list-style-type: none"><li>• true</li><li>• false</li></ul>	
halign-items	<ul style="list-style-type: none"><li>• start</li><li>• center</li><li>• end</li><li>• between</li><li>• around</li><li>• evenly</li></ul>	horizontal-align	<ul style="list-style-type: none"><li>• start</li><li>• center</li><li>• end</li></ul>	
valign-items	<ul style="list-style-type: none"><li>• start</li><li>• center</li><li>• end</li><li>• between</li><li>• around</li><li>• evenly</li></ul>	vertical-align	<ul style="list-style-type: none"><li>• start</li><li>• center</li><li>• end</li></ul>	
min-width	<i>number#/%</i>	min-width	<i>number#/%</i>	min-width is a string and can be used with PX or %.
grow	<ul style="list-style-type: none"><li>• <i>number</i></li><li>• true</li><li>• false</li></ul>	children-sizes + fill-parent		
shrink	<ul style="list-style-type: none"><li>• <i>number</i></li><li>• true</li><li>• false</li></ul>			
padding	<ul style="list-style-type: none"><li>• internal</li><li>• internal-external</li><li>• external</li></ul>	<ul style="list-style-type: none"><li>• padding</li><li>• padding-top</li><li>• padding-bottom</li><li>• padding-left</li><li>• padding-right</li></ul>		The box component padding property applies the margin value. Applied in fraction of REM.
border	<ul style="list-style-type: none"><li>• true</li><li>• false</li></ul>	border	<ul style="list-style-type: none"><li>• true</li><li>• false</li></ul>

disable-auto-layout				
children-fill-parent-width	<ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>	fill-parent	<ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>	
display	<ul style="list-style-type: none"> <li>• flex</li> <li>• inline-flex</li> <li>• grid</li> </ul>			
overflow		children-hide-overflow	<ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>	
size		size	<i>number</i>	
		manage-children	<ul style="list-style-type: none"> <li>• true</li> <li>• false</li> </ul>	When set to true, children divide and equal the width of the parent. When set to false, children shrink to fit their width.

## Related information

- [IBM Maximo Application Framework Component Reference](#)

## Serviceability

The Maximo Application Framework Configuration application Docker image includes network tools that are commonly used to troubleshoot deployment issues. IBM Support can direct you to use tools such as **ping**, **tracpath**, **nano**, **ifconfig**, **netstat**, **traceroute**, and **dig** to collect information about your deployment to assist them in troubleshooting issues.

## Removing Docker containers through the command line

Downloading Docker images and instantiating multiple containers can use significant disk space. Remove unneeded Docker containers periodically.

To remove a Docker container from your system, complete the following steps.

1. List all Docker containers.

```
docker container ls -a
```

The output lists all running containers and their numeric IDs.

2. Stop the container.

```
docker container stop container_id
```

3. Remove the stopped container.

```
docker container rm container_id
```

Commands that use a *container\_id* value can typically accept a *container\_name* value instead. Refer to Docker documentation for more information..

## Command variable legend

These variables are used in examples.

Variable	Description
<code>\${maximo_workspace_directory}</code>	The working directory that you create on your local system.
<code>\${app_directory}</code>	The directory on your local system that contains application code when you download an application for configuring.
<code>\${maximo_app_name}</code>	The name of the Maximo® Mobile application that you are configuring. For example, Inspections or Technician.

*Configuration* refers to updates to the display data contained in application XML code. *Customization* refers to the creation of JavaScript code to support application functions. For example, you might configure an application by adding a field to an application page. If the field requires JavaScript to retrieve data, you would customize the application by creating JavaScript to support that field.

The diagram illustrates the architecture of the Maximo Mobile Apps ecosystem, showing the flow of configuration images and applications between various components:

- Docker.com**: The source of Docker images.
- Entitled Registry**: A repository for Configuration Images.
- Workstation**: A component that interacts with the Entitled Registry and the Maximo REST API. It contains a **Configuration Image** and **Docker**.
- Maximo REST API**: The interface for downloading and publishing apps. It contains a **Mobile Apps** section with **Technician** and **Inspection** app types, and a **Custom** app type.

The flow of data is as follows:

- Docker.com** provides Docker images to the **Workstation**.
- The **Entitled Registry** provides Configuration Images to the **Workstation**.
- The **Workstation** interacts with the **Maximo REST API** to **Download Apps** and **Publish Apps**.
- The **Workstation** contains a **Configuration Image** and **Docker**, which are used to run the **Configuration Application** and **Configuration Tools**.

1. Install Docker on your local development system.
2. Download the Maximo Application Framework Configuration application Docker image from the IBM Entitlement Registry.
3. Configure the [IBM Maximo application server application authorization settings](#).
4. Start the Maximo Application Framework Configuration application Docker container.
5. Log in to the Configuration application which requires an IBM Maximo Manage server and related credentials.
6. Select a Maximo Application Suite application to modify.
7. Modify the application.
8. Save your changes.
9. You can view changes to components with the component preview pane, or view the entire updated application locally by using the Preview function.  
Previewing an application rebuilds the application and starts a React server.
10. Publish the application to the IBM Maximo Manage server.

- [Environment configuration](#)
- [Downloading the Docker container image](#)
- [Running the Docker image](#)

1. Host your entire environment in a single VM. Your environment includes the IBM Maximo Manage application server, the Maximo Application Framework Configuration application, and your browser.
2. Host a IBM Maximo Manage server in a VM and host your Maximo Application Framework Configuration application and browser on your local system. Ensure that you can access the IBM Maximo Manage server VM from your local system.

Do not host the Maximo Application Framework Configuration application and your browser in one VM and deploy the IBM Maximo Manage server in a separate VM. This configuration causes performance issues.

Container network accessibility can cause access issues for the IBM Maximo Manage server if the following conditions occur:

- The Maximo Application Framework Configuration application Docker image is hosted in a VM.
- You cannot access the IBM Maximo Manage server during the configuration login.
- You can access the IBM Maximo Manage server from a browser that is hosted in the same VM.

Maintain separate workspaces for each version of IBM Maximo Manage deployed in your environment. For example, establish separate workspaces for version 8.7, 8.8 and 8.9.

---

## Downloading the Docker container image

The Maximo Application Framework Configuration application is provided in a Docker container image that is stored in the IBM® Entitled Registry. You need an entitlement key to download the container image.

1. Log in to the [My IBM container software library](#) by using the IBMid and password.
2. In the Entitlement keys section, click Get entitlement key.
3. Click Copy key.
4. Paste the key into an empty file. You need the key to deploy the Maximo Application Framework Configuration application with Docker.
5. Run the following command to log in to the IBM Entitled Registry. Replace the *entitlement\_key* variable with the key that you copied.

```
docker login cp.icr.io --username cp --password entitlement_key
```

6. Run the following command to download the Docker container image:

```
docker pull cp.icr.io/cp/manage/maf-tools:8.9
```

---

## Running the Docker image

After the image download is completed, you can run the Docker image to start the Maximo Application Framework Configuration application.

```
docker run -it --privileged -p 3001:3001 -p 3006:3006 -v maximo_workspace_directory:/graphite/.workspace -it cp.icr.io/cp/manage/maf-tools:8.8
```

Replace the *maximo\_workspace\_directory* variable with a working directory on your local system. Specify a port number with a value in the range 3000 - 3050. If you are using a Microsoft Windows system, you have to enable file sharing for your workspace directory.

If you run the Docker image by using a Windows system, you must include the *-e* parameter.

The following code is an example of the command with the parameter included.

```
docker run -it --privileged -p 3001:3001 -p 3006:3006 -v maximo_workspace_directory:/graphite/.workspace -it -e CHOKIDAR_USEPOLLING=true cp.icr.io/cp/manage/maf-tools:8.8
```

```
docker run -it --privileged -p 3001:3001 -p 3006:3006 -v maximo_workspace_directory:/graphite/.workspace -it -e CHOKIDAR_USEPOLLING=true cp.icr.io/cp/manage/maf-tools:8.9
```

You can use the *GRAPHITE\_RELEASE* parameter to reduce the size of the application package that you publish back to the Maximo® Manage server. Using this parameter can affect performance of the Maximo Application Framework Configuration application. To improve performance, you can increase the memory that is assigned to the Docker container.

The following code is an example of the command with the parameter included.

```
docker run -it --privileged --env GRAPHITE_RELEASE=1 -p 3001:3001 -p 3006:3006 -v maximo_workspace_directory:/graphite/.workspace -it cp.icr.io/cp/manage/maf-tools:8.8
```

```
docker run -it --privileged --env GRAPHITE_RELEASE=1 -p 3001:3001 -p 3006:3006 -v maximo_workspace_directory:/graphite/.workspace -it cp.icr.io/cp/manage/maf-tools:8.9
```

Maximo Manage requires a valid security certificate to retrieve and publish applications from the Maximo Application Framework Configuration application in production environments. In development or demonstration environments, you can use the *NODE\_TLS\_REJECT\_UNAUTHORIZED* parameter to bypass system checks for a valid security certificate.

The following code is an example of the command with the parameter included.

```
docker run -it --privileged --env NODE_TLS_REJECT_UNAUTHORIZED=0 -p 3001:3001 -p 3006:3006 -v maximo_workspace_directory:/graphite/.workspace -it cp.icr.io/cp/manage/maf-tools:8.8
```

```
docker run -it --privileged --env NODE_TLS_REJECT_UNAUTHORIZED=0 -p 3001:3001 -p 3006:3006 -v maximo_workspace_directory:/graphite/.workspace -it cp.icr.io/cp/manage/maf-tools:8.9
```

Do not forget to stop the Maximo Application Framework Configuration application Docker container when you are done with your work to free up system resources.

---

## Related information

- [Command variable legend](#)

---

# Maximo Application Framework Configuration application use

After the Maximo Application Framework Configuration application is installed, you can configure and customize IBM® Maximo® Mobile applications.

- [Authorizing with the Maximo Manage server](#)
- [Connect to the Maximo Manage server](#)
- [Modifying applications](#)
- [Duplicating applications](#)
- [Redownloading applications](#)
- [Deleting applications](#)

If you don't want to modify a default application, you can duplicate it, give it a new name, and then change the new application.

---

## Authorizing with the Maximo Manage server

1. Log in to Maximo® Manage
2. Open the Object Structures application and select the OSLCMAFAPPDATA object structure.
3. Select Configure Object Structure Security and then select Use Object Structure for Authorization Name.
4. Open the Security Group application and choose a security group or create a new group.
5. Grant the Maximo Application Framework Configuration application user group access to the OSLCMAFAPPDATA object structure.
6. Assign the user group to the user you want to authorize to use the Maximo Application Framework Configuration application.

Repeat this process for the MXAPIWPEDITSETTING object structure.

If you add an object structure in a Maximo data source to an existing or duplicated application, you need to grant access to that object structure.

---

## Connect to the Maximo Manage server

There are three ways to connect to the Maximo® Manage server from the Maximo Application Framework Configuration application.

1. Open a browser and go to <http://localhost:3001>.
2. From the Maximo Application Framework Configuration application log in screen, select an authentication method.
  - **API Key**  
API Key is the default authentication method. Enter the Maximo Asset Management or Maximo Manage server URL and the API Key value assigned to your user.
  - **Maximo Application Suite Token**  
Enter the URL for the Maximo Manage server and then select Login. You are re-directed to the Maximo Application Suite log in page. After you log into Maximo Application Suite, you are re-directed back to the Maximo Application Framework Configuration application.
  - **Maximo Asset Management Credentials**  
Enter the URL for the Maximo Asset Management server and then enter your user name and password.

---

## Modifying applications

After you log in to the Maximo Application Framework Configuration application, you can create or modify Maximo® Manage applications.

The Application list page displays the applications that you are authorized to run. Each application listed includes description information, the last time it was modified, and the current revision. Each application listed has an edit menu that you can use to duplicate the application, re-download it from the server, delete it, or view the history of each past revision of the application. Click the name of an application to open it in the Editor page.

The application XML code is available for editing in the XML editor. Select the file that you want to modify and edit it with the embedded XML editor.

Use the Navigator tree to locate specific components in the XML code. Select an entry to locate the component in the application XML file. For example, select the pages component to show all the pages that are defined in the application.

You can use the component search field to filter entries in the Navigator. For example, if you search for `dialog`, the Navigator displays only dialog components that are found in application pages. Alternatively, you can also search for a component ID. By default, searches return results that are like the term you entered. To search for an exact term, add an equals sign before the search entry. For example, `=id771`.

As an alternative to the XML editor, you can use the Properties editor to update component values in the XML file. Select a component from the Navigator or in the XML editor to view the properties for that component. Required properties are marked with an asterisk.

Property names must be declared using lowercase letters, for example, `item.somename`. Properties must always be declared and used in lowercase because the Maximo application server provides the data field in JSON as lowercase.

If your changes require custom JavaScript to implement, add code to the `AppCustomizations.js` file, and then reference it in the application XML code.

Do not publish an application immediately after you start editing the application. When you start editing an application, the local React preview server starts and can take a few minutes to complete the startup process. Errors can occur if you publish at the same time that the React server is starting. View the console for the

message that the preview server is available.

After an application is published, mobile devices can then download the new version of the application. If you edit application files outside of the Maximo Application Framework Configuration application, then you must ensure the integrity of those files. Use a virus or malware scanner before you publish the files to the Maximo application server.

When you open or re-download an application, the application is copied to the workspace directory that you specified in the Docker Run command. To facilitate the upgrade of your configured application to a new future version of the base application, you should create a backup of the files that you configure, for example, the app.xml file.

- [Application revisions](#)  
You can view the revision history of an application from the Maximo Application Framework Configuration application.
- [Application preview](#)  
You can preview changes that you make in an application before you publish it.

---

## Application revisions

You can view the revision history of an application from the Maximo Application Framework Configuration application.

You can view revision details for an application in the Application list. Click the Application's three dot menu and select History.

The revision history includes read-only information about any updates made to that application. Details include the publish date, the user that published it, the version of the application, and the status of each revision. A new revision is created whenever an application is published or when a new version of Maximo® Asset Management or Maximo Manage is deployed or patched.

---

## Application preview

You can preview changes that you make in an application before you publish it.

When you change the XML of an application, you can preview your changes in two ways.

---

## Canvas preview

After you change a component of the application in the XML editor, you can preview how it renders in the Canvas panel. The component is not functional in this preview, but it can help you evaluate its design. Not all application components are available to preview. Components such as pages and menus can be previewed, while datasources cannot. By default, when you select a component, the entire page that contains the component is displayed in the Canvas panel. You can choose to display only the component by selecting the option from the Canvas panel. You can also enable the ability to highlight the XML code for a component in the XML editor when you hover over a component in the canvas.

When you click components displayed in the Canvas panel, the XML code for that component is highlighted in the XML editor. The properties for the component are displayed in the Properties panel. The Navigator also opens to the entry for that component.

---

## Application preview

You can preview the entire application using the Preview button. When you preview the application, a React server starts and the application is loaded in a new browser tab. The application is functional, so you can test changes that you make before you publish the application.

---

## Duplicating applications

If you don't want to modify a default application, you can duplicate it, give it a new name, and then change the new application.

Custom or cloned applications cannot be used to circumvent licensing terms. You cannot use custom applications to grant users functions or access beyond your license agreement.

Select the application that you want to duplicate and then select Duplicate from the application menu.

Specify a name for the new application and provide a brief description.

When you duplicate a mobile application, the Mobile? option is not selected by default. The Mobile? option prevents the duplicated application from automatically being pushed to mobile devices.

When you duplicate an application, it inherits the security settings from the original application. You can change security settings for an application with the Security Groups application. For more information, see [Creating security groups](#).

---

## Editing applications

You can modify the description of any application from the application list by selecting the Edit action.

You can select the option to designate the duplicated application as a mobile application, making it available to mobile devices. The Mobile? option cannot be enabled for non-mobile applications.

---

## Redownloading applications

You can download the most recently published version of an application from the Maximo® Manage server anytime by selecting Redownload from the application menu.

When you redownload an application, any unpublished updates that you made to an application are discarded.

---

## Deleting applications

You can delete applications that you have created through the duplication process from the application menu. Default applications cannot be deleted.

---

## Application upgrade

After you configure an application, create an upgrade plan for fix packs and upgrades.

---

### Process

The Maximo Application Framework Configuration application allows you to configure a default Maximo Application Framework application, such as the Maximo® Mobile Technician application, which is named TECHMOBILE. You can also duplicate a default application, name it something like MYTECHMOBILE, and then configure that duplicated application. When you upgrade Maximo Mobile or Maximo Manage, or apply a fix pack, the default applications are automatically updated to new versions.

If you configured a default application, it is archived during an upgrade or after you apply a fix pack, and the new application becomes the active version of the application. Alternatively, if you configure a duplicate application, the application is not impacted by an upgrade or fix pack.

During the upgrade process you create a delta file. This file contains the differences between the default application and the configured application. You use this delta file to reapply your configuration values after you upgrade. Use version 8.9.2 or later of the Maximo Application Framework configuration application to apply delta changes.

Do not change component ID values in the application XML files of default Maximo Mobile applications. Before an upgrade, if you changed default Maximo Mobile applications, you can generate a delta file that contains your configuration changes. The delta file relies on the component IDs of the default applications to identify changes.

---

### Environments

It is beneficial to complete an upgrade in a test environment before you upgrade other environments. Features and functions that are included with a new release might prevent you from applying your existing configuration values without some modification. When you plan for an upgrade, ideally you would have three environments:

- An environment that includes your existing application. For example, version 8.8.
- An environment with the new default version of the application. For example, version 8.9.
- An environment with the new version of the application that includes your configuration changes.

Having these three environments can help you diagnose any configuration issues that result from the upgrade. Any changes included in a new version of Maximo Manage, such as automation scripts or domain configurations, can impact your configured application. This can limit your ability to test the new version of the application.

---

### Applications

Applications are stored as compressed files in the Maximo Manage database. The compressed file contains application XML files and related JavaScript files. When a new version of an application is deployed or if a fix pack is applied, a new row is created in the database table. That row contains the active version of the application. The previous application is disabled and is no longer available to use or configure.

---

### Workspace files

When you open an application in the Maximo Application Framework configuration application, the application is downloaded to a local workspace directory on your system. The workspace directory name includes information about the server and credentials that are used to download the application. In the workspace directory there are two subdirectories that are named after the application. For example, if you downloaded the Technician application, two directories, TECHMOBILE and TECHMOBILE\_backup, are created in your workspace. The backup folder contains the XML files of the application. These files can be used to generate a delta file, which can be used to migrate configuration information.

If you re-download an application using the Maximo Application Framework configuration application, the application XML files in the backup folder are updated to the last published version. An app.orig.xml file is created that contains the XML code for the original version of the application.

---

### File management

You manage multiple versions of configured application files to facilitate the upgrade. You can track versions of application files by using a hierarchy of folders.

```

/88to89 (Main folder)
 /88ORIG (Contains the original version 8.8 files before configuration changes.)
 /TECHMOBILE (Folder for each application to upgrade. Only modified files listed.)
 app.xml
 wo-card-group.xml
 /88CONF (Contains the configured version 8.8 files.)
 /88DIFF (Contains the version 8.8 delta files.)
 /89ORIG (Contains the original versions of the version 8.9 files before configuration changes.)
 /89CONF (Contains the upgraded files for version 8.9)

```

Two processes are used to migrate configuration information. The *diff* process compares the XML files that are located in the /88ORIG folder to the XML files located in the /88CONF folder. The differences are recorded in XML files and stored in the /88DIFF folder. The *apply* process applies any changes found in the diff file located in the /88DIFF folder to the version 8.9 base file located in the /88ORIG folder and writes the resulting file to the /88CONF folder.

- [Upgrade example](#)  
This example demonstrates how to configure an application and then upgrade it to the next version of Maximo Mobile.

## Upgrade example

This example demonstrates how to configure an application and then upgrade it to the next version of Maximo® Mobile.

This example references the Maximo Mobile Technician application, however, you can use these steps for duplicated applications.

- [Configuring an application](#)  
In this example, you add a Risk field to the Create work order page of the Technician application.
- [Creating a delta file](#)  
Create a delta file that contains application configuration changes made since the last time the application was published.
- [Applying the delta file](#)  
Apply configuration changes recorded in the delta file to the new version of the application. In this example, you merge configuration changes made to version 8.8 of the Technician application to the newer 8.9 version of the application.
- [Upgrading duplicated applications](#)  
There are deviations and additional steps to the upgrade process if you are upgrading a duplicated application.

## Configuring an application

In this example, you add a Risk field to the Create work order page of the Technician application.

### Procedure

1. Open the Maximo Application Framework configuration application and log in to a Maximo® Manage server.
2. Select TECHMOBILE from the list of applications.
3. From the XML editor, in the app.xml file, locate the Create work page.

```

<page
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application create
wo" title="Create work order" path="/createwo" comp-group-valid-chg="{page.state.cgvc=event}"
controller="WorkOrderCreateController">

```

4. Add a risk attribute after the wopriority attribute for the dsCreateWo datasource.

```

<maximo-datasource
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application dsCrea
teWo" object-structure="mxapiwodetail" where="wonum="0""
item-url="{app.device.isMaximoMobile ? 'nohref' : undefined}" auto-save="false">
 <schema
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application_w224k"
>
 <attribute name="workorderid" searchable="true" unique-
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application true"
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application_bj6qp"
/>
 <attribute name="wonum" searchable="true"
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application_n52n8"
/>
 <attribute name="description" max-length="100"
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application_y7g99"
/>
 <attribute name="description_longdescription"
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application_r8gpn"
/>
 <attribute name="wopriority"
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application_ye34g"
/>
 <attribute name="risk"
id=" home markdown jenkins workspace Transform in SSLPL8 cd com.ibm.mam.doc_mobile_t upgrading an application_re34g"
/>

```

5. Add the Risk field and display it under the Priority field.

```
<box direction="row" children-sizes="100" fill-parent="true" fill-child="true" padding-top=".5" padding-bottom=".5"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_upgrading_an_application_a5ezy"
>
<smart-input label="Priority" hide-step-buttons="true" placeholder="Enter {page.state.minPriority} to
{page.state.maxPriority}" value="{dsCreateWo.item.wopriority}" on-blur="validateFields" min="{
page.state.minPriority}" max="{page.state.maxPriority}"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_upgrading_an_application_j8265"
/>
</box>
<box children-sizes="100" direction="row" fill-child="true" fill-parent="true" padding-bottom=".5" padding-top=".5">
<smart-input hide-step-buttons="true" label="Risk" value="{dsCreateWo.item.risk}"/>
</box>
```

6. Save the application and then click Preview.
7. From the preview of the Technician application, open the Create work order page and confirm that the Risk field is displayed it under the Priority field.
8. Publish the configured application to the Maximo Manage server.

## Results

After you publish the configured application, a copy of the updated app.xml file is written to the TECHMOBILE/src workspace folder. A copy of the unmodified app.xml file is located in the TECHMOBILE\_backup/src folder.

## What to do next

The next step is to create a delta file by using these two files.

## Creating a delta file

Create a delta file that contains application configuration changes made since the last time the application was published.

## Before you begin

For this example, the following folder structure exists under the Users/myuser/Documents filepath.

```
/88to89
 /88ORIG
 /TECHMOBILE
 /88CONF
 /TECHMOBILE
 /88DIFF
 /TECHMOBILE
 /89ORIG
 /TECHMOBILE
 /89CONF
 /TECHMOBILE
```

The workspace folder used is /aconfig88/MaximoUser-Maximohost:port/TECHMOBILE.

## Procedure

1. Copy the /aconfig88/MaximoUser-Maximohost:port/TECHMOBILE/src/app.xml file to the /88to89/88CONF/TECHMOBILE folder.
2. Copy the TECHMOBILE application app.xml file to the 88to89/88ORIG/TECHMOBILE folder.
3. Generate the diff file.

```
docker run -it --privileged --entrypoint "/graphite/scripts/graphite-tools.js" --workdir /graphite/app
-v/Users/myuser/Documents/88to89:/graphite/app cp.icr.io/cp/manage/maf-tools:8.9.2 diff --original
88ORIG/TECHMOBILE/app.xml
--modified 88CONF/TECHMOBILE/app.xml --deltaOutput 88DIFF/TECHMOBILE/app.xml -d
```

The -d parameter is for debug mode. Debug mode produces the detailed output. Copy the diff command output from the console and save to a file. Refer to this output information to troubleshoot during testing.

The diff command generates a delta file with content similar to the following example.

```
<?xml version="1.0" encoding="UTF-8"?>
<updatescript version="">
 <app apptype="maf"
id="_home_markdown_jenkins_workspace_Transform_in_SSLPL8_cd_com.ibm.mam.doc_mobile_t_creating_a_delta_file_TECHMOBIL
E">
 <add before="xd5k8" container="w224k" control="attribute">
 <set property="id" value="jvvgb"/>
 <set property="name" value="risk"/>
 </add>
 <add before="dr9pg" container="gvvyv" control="box">
 <set property="children-sizes" value="100"/>
 <set property="direction" value="row"/>
 <set property="fill-child" value="true"/>
 <set property="fill-parent" value="true"/>
 <set property="id" value="ww34n"/>
```

```

 <set property="padding-bottom" value=".5"/>
 <set property="padding-top" value=".5"/>
 </add>
 <add container="ww34n" control="smart-input">
 <set property="hide-step-buttons" value="true"/>
 <set property="id" value="xb269"/>
 <set property="label" value="Risk"/>
 <set property="value" value="{dsCreateWo.item.risk}"/>
 </add>
</app>
</updatescript>

```

## Applying the delta file

Apply configuration changes recorded in the delta file to the new version of the application. In this example, you merge configuration changes made to version 8.8 of the Technician application to the newer 8.9 version of the application.

### Procedure

1. Open the Maximo Application Framework configuration application and log in to the Maximo® Manage server.
2. Select TECHMOBILE from the list of applications.
3. Copy the /aconfig89/MaximoUser-Maximohost:port/TECHMOBILE/src/app.xml file to the /88to89/89ORIG/TECHMOBILE folder.
4. Apply the delta file to create a version 8.9 Technician application that includes your version 8.8 configuration data.

```

docker run -it --privileged --entrypoint "/graphite/scripts/graphite-tools.js" --workdir /graphite/app
-v/Users/myuser/Documents/88to89:/graphite/app cp.icr.io/cp/manage/maf-tools:8.9.2 apply
--delta 88DIFF/TECHMOBILE/app.xml --input 89ORIG/TECHMOBILE/app.xml --output 89CONF/TECHMOBILE/app.xml -d

```

Copy the apply command output from the console and save to a file. Refer to this output information to troubleshoot during testing.

The apply command merges configuration changes to the version 8.9 Technician application. The apply command also generates output statements based on the configuration changes.

```

-- ADD: label (emnww) to e_bm6 before b7w3z
 set id to emnww
 set label to Inspection Summary:
 set wrap to true

```

```

-- REMOVE: y4_eq from rzvz4
-- RemoveNode: Removing: y4_eq

```

```

-- MODIFY: aw99_
-- clear slot

```

```

-- Warning: (techmobile) Cannot MOVE control (brq_e) to CONTAINER (jjwgb). NOT_FOUND_ERR: An attempt is made to
reference a node in a context where it does not exist.
.
.
.

```

```

-- MOVE: brq_e to CONTAINER (jjwgb) before bynje

```

The apply process attempts to resolve any warnings encountered earlier in the process. You might encounter an error related to a configuration change you made to an application component that was deprecated in the latest version of the application. In this case, you must reevaluate the change to determine if it is still needed. If the configuration change is required, you must re-implement it using a different component in the app.xml file.
